THE

PRACTICE OF PHARMACY

A TREATISE

ON THE MODES OF MAKING AND DISPENSING OFFICIAL, UNOFFICIAL, AND EXTEMPORANEOUS PREPARATIONS, WITH DESCRIPTIONS OF MEDICINAL SUBSTANCES, THEIR PROPERTIES, USES, AND DOSES

INTENDED AS

A HAND-BOOK FOR PHARMACISTS AND PHYSICIANS

AND

A TEXT-BOOK FOR STUDENTS

FIFTH EDITION

BY

JOSEPH P. REMINGTON, PH.M., PHAR.D., F.C.S.

CHAIRMAN OF THE COMMITTEE OF REVISION OF THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA; PROFESSOR OF THEORY AND PRACTICE OF PHARMACY, AND DIRECTOR OF THE PHARMACEUTICAL LABORATORY, IN THE PHILADELPHIA COLLEGE OF PHARMACY; PHARMACEUTICAL EDITOR OF THE UNITED STATES DISPENSATORY; HONORARY MEMBER OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, ETC.

ASSISTED BY

E. FULLERTON COOK, P.D.

ASSISTANT DIRECTOR OF THE PHARMACEUTICAL LABORATORY, AND INSTRUCTOR IN COMMERCIAL TRAINING IN THE PHILADELPHIA COLLEGE OF PHARMACY.

WITH OVER EIGHT HUNDRED ILLUSTRATIONS

PHILADELPHIA AND LONDON
J. B. LIPPINCOTT COMPANY
LONDON: 5 HENRIETTA STREET, COVENT GARDEN

Authority to use for comment the Pharmacopœia of the United States of America, Eighth Decennial Revision, in this volume, has been granted by the Board of Trustees of the United States Pharmacopœial Convention, which Board of Trustees is in no way responsible for the accuracy of any translation of the official weights and measures or for any statements as to strength of official preparations. Alternative quantities are put in square brackets [ ] and an asterisk (*) added to each official formula. The asterisk in the text of this volume has been used in accordance with the direction of the Board of Trustees. Authority to use the National Formulary in abstract has been granted by the American Pharmaceutical Association.

ELECTROTYPED AND PRINTED BY J. B. LIPPINCOTT COMPANY, PHILADELPHIA, U.S.A.

PREFACE TO THE FIFTH EDITION

THE enactment of Pure Food and Drug Laws by the National Government (1906) and by various States, having caused numerous changes in the United States Pharmacopœia (8th Rev.) has made a revision of this book necessary. In addition, the issue of the third edition of the National Formulary, which differs in some respects from the previous editions, and the fact that it was recognized legally, furnishes another reason for inserting an *abstract* (embodying the latest revisions and corrections) because the American Pharmaceutical Association forbids the publication by others, of the National Formulary *in full*. Since the issue of the Fourth edition of this book, the author has received many letters regretting the omission of the "questions" which were appended to each chapter in the Third edition; in order to supply this demand a revised list of "questions" will be found in this book on page 1369; these are intended to furnish the home student with a convenient means of revising his work and the suggestion is made that he should, after carefully reading a chapter, test his knowledge, by writing on paper the answers to the questions without looking at the text, and when through, comparing the answers with the text and marking his paper according to its deserts; another reason for their insertion is that they may furnish suggestions for State Boards of Pharmacy in framing Examination questions.

J. P. R.

PHILADELPHIA, October, 1907.

PREFACE TO THE FOURTH EDITION

THE publication of the Eighth Decennial Revision of the United States Pharmacopœia, the introduction of many new remedies, and the continued advance in pharmaceutical knowledge in recent years have rendered necessary a new edition of the Practice of Pharmacy.

Notwithstanding the efforts of the author to limit the number of pages by eliminating undesirable subjects, the pressing need of a comprehensive handbook which would serve as a daily companion for the busy pharmacist has necessitated an increase in the size of the book. As it is also a text-book, it is of paramount importance to present the subjects in proper sequence and introduce syllabi and tables which will enable the student to quickly grasp the outlines of the general subjects. The first edition of this work was published in October, 1885, and thus just twenty years have elapsed between the first and last editions. This period has been one of ceaseless activity in the pharmaceutical world, and the effort has been made by the author to keep pace with progressive pharmacy in at least a creditable measure.

This revision is marked by many changes and additions in matter and form and in typographical dress. The necessity for saving valuable space was the primary object in reducing the size of the illustrations wherever this could be done to advantage without sacrificing clearness of detail. This part of the work has been revised by the author's son, J. Percy Remington, B.S., P.D., most of the outline drawings having been made by him, and new cuts reproduced from these. This edition contains more than one hundred illustrations not in previous editions.

An improvement has been made in the arrangement of the official descriptions which now appear in small black-letter type throughout the work; the change will enable readers to find an official requirement more rapidly and easily than by the method used in previous editions of using lines and rules in tabular form.

Since the advent of the first edition of the Practice of Pharmacy the book has had an ever-widening field, and it has been deemed desirable to introduce in this edition preparations of the British Pharmacopœia when dissimilar from those official in the United States Pharmacopœia. Dismissed preparations of the previous Pharmacopœia, which still have considerable vogue, have also found a place.

The metric system of weights and measures has been given the preference in the working formulas, not only for the reason that it is the official method of indicating quantities, but because it is the simplest and best system in use. Unfortunately, the old-form quantities continue to be most largely employed in buying and selling drugs and in prescription work; hence, alternative formulas are appended to official preparations, as in previous revisions, and when used, an asterisk precedes the process, as explained in the special notice on the copyright page.

The old form quantities are not intended to be the equivalents of the metric quantities, and the two systems are not interchangeable; either "metric" or "old form" may be used, but in no case part of one and part of the other; different type distinguishes one from the other.

Part V, which is devoted to magistral or extemporaneous pharmacy, has been extensively enlarged by the addition of a new chapter on Incompatibility, the insertion of new illustrations of autograph prescriptions, and numerous new cuts of apparatus with descriptions. The condensed charts of inorganic chemical substances, vegetable official drugs, and animal substances have been thoroughly revised; these will be found very useful for students in preparing for examination, by enabling them to review the whole subject.

Part VI has been entirely remodelled, so as to permit an alphabetical arrangement of the many unofficial but largely used preparations and special formulas. These can now be quickly found by the busy pharmacist, black-letter titles being used.

Acknowledgments are tendered to Charles H. LaWall, Ph.M., for the revision of and additions to the chapter on Arithmetical Problems. The enlarged index has been prepared by J. Percy Remington, P.D. The tables in Part I and the black-letter official descriptions were compiled by Millicent S. Renshaw, P.D., who also assisted in the proof-reading of the entire work. The tables of Official and Unofficial Substances and preparations in the book were prepared by E. Fullerton Cook, P.D., who also gave valued assistance in every part of the revision. These services are hereby gratefully recognized, particularly as they were rendered immediately after the arduous labors upon the revision of the United States Pharmacopœia had been completed, and often during hours which should have been reasonably devoted to recreation.

In closing, the author desires to express his great appreciation of the reception of this work by his friends in many countries, and to venture the hope that the present edition adequately reflects the progress made in pharmaceutical practice since the last revision.

J. P. R.

Philadelphia, October, 1905.

PREFACE TO THE FIRST EDITION

THE rapid and substantial progress made in Pharmacy within the last decade has created a necessity for a work treating of the improved apparatus, the revised processes, and the recently introduced preparations of the age.

The vast advances made in theoretical and applied chemistry and physics have had much to do with the development of pharmaceutical science, and these have been reflected in all the revised editions of the Pharmacopœias which have been recently published. When the author was elected in 1874 to the chair of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy, the outlines of study which had been so carefully prepared for the classes by his eminent predecessors, Professor William Procter, Jr., and Professor Edward Parrish, were found to be not strictly in accord, either in their arrangement of the subjects or in their method of treatment. Desiring to preserve the distinctive characteristics of each, an effort was at once made to frame a system which should embody their valuable features, embrace new subjects, and still retain that harmony of plan and proper sequence which are absolutely essential to the success of any system.

The strictly alphabetical classification of subjects which is now universally adopted by pharmacopœias and dispensatories, although admirable in works of reference, presents an effectual stumbling-block to the acquisition of pharmaceutical knowledge through systematic study; the vast accumulation of facts collected under each head being arranged lexically, they necessarily have no connection with one another, and thus the saving of labor effected by considering similar groups together, and the value of the association of kindred subjects, are lost to the student. In the method of grouping the subjects which is herein adopted, the constant aim has been to arrange the latter in such a manner that the reader shall be gradually led from the consideration of elementary subjects to those which involve more advanced knowledge, whilst the groups themselves are so placed as to follow one another in a natural sequence.

The work is divided into six parts. Part I. is devoted to detailed descriptions of apparatus and definitions and comments on general pharmaceutical processes.

The Officinal Preparations alone are considered in Part II. Due weight and prominence are thus given to the Pharmacopœia, the National authority, which is now so thoroughly recognized.

In order to suit the convenience of pharmacists who prefer to *weigh* *solids* and *measure liquids*, the officinal formulas are expressed, in addition to parts by weight, in *avoirdupois weight* and *apothecaries' measure.* These equivalents are printed in **bold type**, near the margin, and arranged so as to fit them for quick and accurate reference.

Part III treats of Inorganic Chemical Substances. Precedence is of course given to officinal preparations in these. The descriptions, solubilities, and tests for identity and impurities of each substance are systematically tabulated under its proper title. It is confidently believed that by this method of arrangement the valuable descriptive features of the Pharmacopœia will be more prominently developed, ready reference facilitated, and close study of the details rendered easy. Each chemical operation is accompanied by equations, whilst the reaction is, in addition, explained in words.

The Carbon Compounds, or Organic Chemical Substances, are considered in Part IV. These are naturally grouped according to the physical and medical properties of their principal constituents, beginning with simple bodies like cellulin, gum, etc., and progressing to the most highly organized alkaloids, etc.

Part V is devoted to Extemporaneous Pharmacy. Care has been taken to treat of the practice which would be best adapted for the needs of the many pharmacists who conduct operations upon a moderate scale, rather than for those of the few who manage very large establishments. In this, as well as in other parts of the work, operations are illustrated which are conducted by manufacturing pharmacists.

Part VI contains a formulary of Pharmaceutical Preparations which have not been recognized by the Pharmacopœia. The recipes selected are chiefly those which have been heretofore rather difficult of access to most pharmacists, yet such as are likely to be in request. Many private formulas are embraced in the collection ; and such of the preparations of the old Pharmacopœias as have not been included in the new edition, but are still in use, have been inserted.

In conclusion, the author ventures to express the hope that the work will prove an efficient help to the pharmaceutical student as well as to the pharmacist and the physician. Although the labor has been mainly performed amidst the harassing cares of active professional duties, and perfection is known to be unattainable, no pains has been spared to discover and correct errors and omissions in the text. The author's warmest acknowledgments are tendered to Mr. A. B. Taylor, Mr. Joseph McCreery, and Mr. George M. Smith for their valuable assistance in revising the proof-sheets, and to the latter especially for his work on the index. The outline illustrations, by Mr. John Collins, were drawn either from the actual objects or from photographs taken by the author. J. P. R.

PRACTICE OF PHARMACY

INTRODUCTORY

THEORETICAL AND PRACTICAL PHARMACY

PHARMACY is the science which treats of medicinal substances. It comprehends not only a knowledge of medicine and the arts of preparing and dispensing them, but also their identification, selection, preservation, combination, and analysis.

The word Pharmacy is also used to designate the place where medicines are sold.

For convenience in study, Pharmacy may be divided into two great classes,—viz., *Theoretical Pharmacy* and *Practical Pharmacy.*

Theoretical Pharmacy.—Inasmuch as all Nature, animate and inanimate, has been laid under contribution to provide remedies for the alleviation of disease, it follows that those sciences which embrace a knowledge of substances obtained from the vegetable, mineral, and animal kingdoms, as well as those which treat of the laws governing them, are called upon to furnish important facts which form the basis of the science of Pharmacy.

Botany, the science of plants, *Mineralogy*, that of inorganic substances found in or on the earth, and *Zoology*, the science which treats of animals, are, however, less important than *Chemistry* and *Physics;* for upon these two Pharmacy is most dependent for its greatest development and its highest degree of usefulness.

Physics or *Natural Philosophy* is that branch of science which describes and explains the changes produced in bodies, by which their specific identity is not destroyed, while *Chemistry* treats of those changes which affect the specific identity of the bodies.

Materia Medica (medicinal materials) is a term applied to designate the substances which are used in the cure of diseases ; it is most intimately connected with *Pharmacognosy*, the science which treats of crude drugs, while the specific definition of Pharmacy limits the latter to the consideration of the preparations made from drugs.

In colleges of pharmacy, as well as in universities where pharmacy is a part of the instruction, it is usual to divide General Pharmacy into three departments,—Chemistry, Botany and Materia Medica, and Theory and Practice of Pharmacy.

Toxicology, the science of poisons, *Microscopy*, which requires the use of optical instruments called microscopes, and *Bacteriology*, a natural science which treats of micro-organisms, form valuable collateral and special subjects of study.

Practical Pharmacy is that branch of Pharmacy which treats of the operations, processes, and methods used in applying the principles of theoretical pharmacy. The practice of pharmacy will receive in this treatise much the greater share of attention ; separate text books on the sciences pertaining to the theory of pharmacy are now very accessible, and these may be referred to for specific and systematic information.

PHARMACOPŒIAS AND DISPENSATORIES

A *pharmacopœia*, in the modern acceptation of the word, is a book containing a list of medicinal substances, with descriptions, tests, and formulas for preparing the same, selected by some recognized authority. The necessity for legalized standards to define the character, establish the purity, and regulate the strength of medicines is recognized by all civilized nations; and although all of the nations of the globe have not yet formally adopted national standards, in nearly every case where this has not been done it will be found that the standards of some other country are in use. The most important pharmacopœias, with the dates of their latest issues, are as follows :

Official Pharmacopœias

Nation	Date of Issue	Title
1. United States	1905	Pharmacopœia of the United States of America Eighth Decennial Revision
Spanish Edition	1909	
2. Great Britain and Ireland	1898	British Pharmacopœia
and Colonies	1900	Indian and Colonial Addendum
3. Germany	1910	Arzneibuch für das Deutsche Reich (Pharmacopœa Germanica, editio V.)
4. France	1908	Codex Medicamentarius Gallicus (Pharmacopée Francaise)
5. Austria	1906	Pharmacopœa Austriaca.
6. Belgium	1906	Pharmacopœa Belgica
7. Chili	1886	Farmacopea Chilena
8. Croatia-Slavonia	1888	Pharmacopœa Croatico-Slavonica
9. Denmark	1907	Pharmacopœa Danica
10. Greece	1899	Ἑλληνικὴ Φαρμακοποιία
11. Hungary	1909	Pharmacopœa Hungarica
12. Italy	1909	Farmacopea ufficiale del Regno d'Italia
13. Japan	1906	Pharmacopœa Japonica
English Edition	1907	
14. Mexico	1896	Nueva Farmacopea Mexicana
15. Netherlands	1905	Pharmacopœa Nederlandica
16. Norway	1895	Pharmacopœa Norvegica
17. Portugal	1876	Pharmacopœa Portugueza
18. Roumania	1893	Pharmacopœa Romana
19. Russia	1910	Pharmacopœa Rossica
20. Servia	1908	Pharmakopœa Serbica
21. Spain	1905	Farmacopea oficial Español
22. Sweden	1908	Pharmacopœa Svecica (Svenska Farmakopén)
23. Switzerland	1907	Pharmacopoea Helvetica
24. Venezuela	1900	Farmacopea Venezolana

Notes on Official Pharmacopœias

1. In quoting this title, it is customary to abbreviate it to "U. S. P. (8th Rev.)." It is advisable to adhere to this form so as to preserve uniformity. The "eighth revision" means, of course, the same as "ninth edition." Formerly it was customary to use the year in which the Decennial Convention met, to designate the Pharmacopœias, thus "U. S. P. 1890 ;" much confusion resulted from this practice because it now requires three or four years to revise such an authority and hence the "U. S. P. 1890" would have been more appropriately termed the "U. S. P. 1893." In the last revision this was corrected by omitting a date upon the back of the book and using the words "Eighth Decennial Revision."
2. The Indian and Colonial Addendum to the British Pharmacopœia (1898) was published in 1900. This is intended especially to furnish an authority for the guidance of the colonies and distant parts of the British Empire.
3. The Swiss Pharmacopœia is published simultaneously in three languages,—German, French, and Italian.

The U. S. Pharmacopœia (Spanish Edition issued 1909) is now used in Cuba, Porto Rico and Philippine Islands. Since 1910 every drug store in Cuba is compelled by law to have a copy. Central and South American countries are now using the Spanish U. S. Pharmacopœia. In the West Indian Islands where French and Spanish is the principal language, the most generally used, unofficial work of reference is Dorvault's "L'Officine," an extensive commentary and supplement to the French Pharmacopœia, either in the French original, or in its Spanish translation and adaptation by Pontes.

Argentine Republic.—French and Spanish Pharmacopœias. Also (not official) Tratado de Farmacia y Farmacognosia. By Carlos Murray.
Bolivia.—French, Spanish, and Chilian Pharmacopœias.
Brazil.—French, Portuguese, and Spanish Pharmacopœias. Also (not official) Formulario ou Guia Medica, etc. By P. L. N. Chernovitz. Novo Formulario medico e pharmaceutico, ou Vademecum Medicum. By Th. J. H. Langgaard.
Central American States.—French, Spanish, and Mexican Pharmacopœias. Also, to some extent, the British and that of the United States.
China.—The native druggists and herbalists still regard as their chief authority the old Chinese Encyclopedia of natural history, entitled Pen-tsao-kang-mu, composed by Li-shi-chin between 1552 and 1578. The usual editions of this work are printed in 40 thin volumes, 8vo. Foreign pharmacists use the pharmacopœias of their respective countries. The British is most in use.
Cuba.—The United States Pharmacopœia (Spanish Edition) since 1910.
Ecuador.—French and Spanish, also several foreign pharmacopœias.
Haiti.—French and Spanish Pharmacopœias (chiefly).
Hawaiian Islands.—Chiefly the United States Pharmacopœia. To some extent, also, the British and the German.
Liberia.—The United States Pharmacopœia (chiefly).
Peru.—The French, Spanish, British, and United States Pharmacopœias.
Turkey.—The French Pharmacopœia.
Uruguay.—The French and Spanish Pharmacopœias. Occasionally, also, the British and that of the United States.
Venezuela.—The French and Spanish Pharmacopœias (chiefly). Also, occasionally, the British and that of the United States.

The official pharmacopœias are all issued under the authority of the respective governments, with the exception of the United States Pharmacopœia, which has, however, been accepted by the government and the individual States, through the National and State Pure Food and Drug Acts. Efforts are constantly being put forth to secure the adoption of an International Pharmacopœia. If these should prove successful, a great advance will be made in bringing about a uniformity in the strength of preparations; yet it may well be doubted whether such a work would be as generally useful as the pharmacopœias at present in use, which have been proved by long experience best adapted to the varying needs of the different nations. A practical plan of securing the chief advantages possessed by an International Pharmacopœia has been inaugurated by the establishment of the "International Conference for the Unification of Potent Remedies," which met in the City of Brussels in September, 1902. This body in the final *protocol* agreed upon standards of strengths for potent preparations which they expect the various pharmacopœias of the world to adopt. The United States Pharmacopœia (eighth revision) was the first national pharmacopœia to adopt some of these recommendations. In 1906, representatives from nineteen governments met at Brussels and with certain reservations formally signed the agreements drawn up in 1902 and also formulated details for further unification.

The Pharmacopœia of the United States, Eighth Decennial Revision, was prepared by a committee appointed by the National Convention of 1900 for revising the Pharmacopœia, which met in Washington, D. C., May 2, 1900. Sixty-two medical bodies and fifty-four incorporated pharmaceutical organizations sent delegates to this convention, which selected from those present twenty-six members, consisting of twenty-one pharmacists, chemists, and botanists (seven of which number hold medical degrees), and five physicians, who were designated the "Committee of Revision of the Pharmacopœia of the United States of America." At the Eighth Decennial Convention several important changes in the plan of the work were made, the business portion was separated from that of actual revision by creating a Board of Trustees whose duty is to make contracts, attend to the finances, and place the book on sale. The convention was incorporated, and it now carries on its work under a charter issued at Washington under the laws of the District of Columbia. The Committee of Revision, as soon after their election as possible, met, elected officers, and the Chairman organized the work of revision and appointed sub-committees to report upon the special parts of the work in the several departments. The reports were laid before the whole committee for action, and by vote they were then adopted, amended, or rejected. The Committee of Revision represent geographically various parts of the United States, and it is necessary to conduct the revision by mail communications, which are voluminous. The Board and Committee remain in office until the next decennial convention meeting, or until their successors are appointed. Permission to use the text of the Pharmacopœia is granted upon application to the Chairman of the Board of Trustees under certain regulations which are necessary to guard the copyright. As the U. S. Pharmacopœia will be largely quoted in this treatise, its plan and the outlines of its main features should be thoroughly understood at the outset.

Nearly one thousand substances (958), embracing crude drugs and preparations, have been deemed of sufficient importance to merit a place in the U. S. Pharmacopœia. On May 10, 1910, the United States Pharmacopœial Convention met in Washington to revise the Pharmacopœia. A radical change was made. A General Committee of Revision consisting of fifty members was elected by the Convention, they selected fifteen members to form the Executive Committee of Revision ; these fifteen to have immediate charge of the work. In this way it is believed that decisions may be arrived at more readily and the work facilitated.

Under the Food and Drug Acts, the United States Pharmacopœia is now the law of the land. Its standards are obligatory and violations are now punishable by fine or other penalty.

Nomenclature

The names of the various substances are indicated—1. By the OFFICIAL LATIN TITLE, which is always in the Latin language. 2. By the OFFICIAL ENGLISH TITLE. 3. By the SYNONYM. 4. By the BOTANICAL NAME (in the case of plants). 5. By the SYMBOLIC FORMULÆ (in the case of chemicals). Each of these names has a special use.

The following extracts from the Pharmacopœia are given in illustration:

CANTHARIS	[Official Latin title]	**CERATUM RESINÆ**
Cantharides	[Official English title]	**Rosin Cerate**
[Blistering Flies, Spanish Flies]	[Synonym in index]	[Basilicon Ointment]
POTASSII CHLORAS	[Official Latin title]	**CARUM**
Potassium Chlorate	[Official English title]	**Caraway**
$KClO_3 = 121.68$ [Symbolic formula]		The dried fruit of *Carum Carvi.* [Official definition, botanical name in Italics]

1. The Official Latin Title.—Example, **LIQUOR AMMONII ACETATIS.** The official Latin title is thoroughly distinctive, and is intended to be used in designating the drug or preparation where precision is required, as in writing prescriptions, in labelling store furniture, specimens, etc. Latin is selected for the official title because it is universally used and understood as the "language of science," and is not liable to change, as is the case with a living tongue. Although the official titles are usually abbreviated in practice,[1] the proper terminations and full titles should be known and observed carefully, and the habit of using the Latin abbreviations in English conversation strictly guarded against as not only inelegant, but vulgar.[2] A vast amount of careful consideration, extending over many years, has been expended in perfecting a system of pharmacopœial nomenclature which is at once "brief, simple, expressive, distinctive, and convenient." The following may be cited as models: Acacia, Camphora, Opium, Rheum, Sapo, etc., the full pharmacopœial definition of these titles being, respectively, *Acacia.* "A gummy exudation from *Acacia Senegal* Willdenow, and other species of *Acacia* (Fam. *Leguminosæ*)." *Camphora.* "The dextrogyrate modification of the saturated ketone [$C_9H_{16}CO$], obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier (Fam. *Lauraceæ*), and purified by sublimation." *Opium.* "The concrete, milky exudation obtained by incising the unripe capsules of *Papaver somniferum* Linné (Fam. *Papaveraceæ*), and yielding, in its normal, moist condition, not less than 9 percent. of crystallized morphine." *Rheum.* "The dried rhizome of *Rheum officinale* Baillon, *Rheum palmatum* Linné, and the var. *tanguticum* Maximowicz (Fam. *Polygonaceæ*), or probably other species of *Rheum* grown in China and Thibet, and deprived of most of the bark and carefully dried." *Sapo.* "Soap prepared from sodium hydroxide and olive oil." The *generic* or genus name (the first part of the botanical name) was generally chosen for the official Latin title, as, Pilocarpus, for "the leaflets of *Pilocarpus Jaborandi*" (botanical name). In the case of some old and very well known drugs, this rule could not be adopted without causing confusion, and the *specific* or species name (the second part of the botanical name) was retained, as Ipecacuanha, the official Latin title for "the dried root—of *Cephaelis Ipecacuanha.*" The official Latin title obviously cannot retain the simplicity of a single word where two parts of the same plant are official. Thus, for

---

[1] See table of abbreviations in chapter on Prescriptions.

[2] Example of what should be avoided in conversation: "I mixed the *Pulv. Pip. Nig.* with the *Pot. Carb.* and the *Muc. Trag.*, but could not form a mass."

example, the corm and seed of Colchicum must each be defined by affixing the Latin name of the particular part of the plant intended, as *Colchici Cormus* for Colchicum Corm, and *Colchici Semen* for Colchicum Seed ; nor can a single word be chosen for either official title where the specific names of two or more plants of the same genus differ. The generic name of the two official mints is Mentha, and to distinguish them it is necessary to use the full botanical name for each. Thus, the *Mentha Piperita* (Peppermint), *Mentha Viridis* (Spearmint).

There are a very few exceptions to the above principles of nomenclature, as in the case of *Pareira* and *Prunus virginiana*, derived, according to the most recent and reliable authorities, respectively from *Chondrodendron tomentosum* and *Prunus serotina*. These drugs are largely used, and the old names have become so well established that it would lead to confusing and possibly embarrassing mistakes to change them now. The Latin names are generally used in the singular number, although the definition of the drug distinctly indicates plurality ; for instance, *Galla* is the official name for *nutgalls*, as they are termed commercially, and is in the nominative singular (plural, *Gallæ*). The official definition indicates the singular, being "An excrescence on *Quercus infectoria*." *Anthemis* (nominative singular) is the official name for the flower heads of Chamomile. The reason assigned in the preface to the U. S. Pharmacopœia, 1850, for this apparent deviation, is that "the example of the Roman medical writers, particularly of Celsus, might be followed." In the case of compound medicines, such official titles were selected as would usually express the composition of the preparations as fully as possible, indicating the principal ingredients without sacrificing the important consideration of brevity and convenience in abbreviation, as Mistura Rhei et Sodæ, Mistura Cretæ, Pulvis Ipecacuanhæ et Opii, Tinctura Opii Camphorata, Tinctura Aloes et Myrrhæ. In some cases it is desirable to indicate in the title the medical properties or use of the preparation, as in Pilulæ Laxativæ Compositæ, Liquor Antisepticus. Where the number of important ingredients in a preparation is too great to admit of a selection, the participial adjective *compositus* (meaning compound) is added, the feminine (*composita*) or neuter (*compositum*) termination being used respectively where the noun is feminine or neuter, as Spirit*us* Juniperi Composit*us* (masc.), Tinctur*a* Lavandulæ Composit*a* (fem.), Extract*um* Colocynthidis Composit*um* (neut.).

2. **The Official English Title.**—Example, **Solution of Ammonium Acetate.** This name should be used when the drug or preparation is mentioned in ordinary conversation, in commercial transactions, in writing orders for supplies, and in all cases where the use of the Latin official title could be justly criticized as an ostentatious display of erudition. In the U. S. Pharmacopœia, 1880, a large number of English titles used in former Pharmacopœias were changed, the old vernacular names being either dropped altogether or inserted as synonyms. This advanced step was rendered necessary by the increase in articles used in the materia medica and by a desire for greater accuracy and better methods in nomenclature. The confusion which always exists in different localities concerning the common names of drugs is also avoided, as the anglicized Latin name is distinctive. The former English names *Irish Moss*, *Pipsissewa*, *Male Fern*, and *Yellow Jasmine*,

for instance, are replaced by *Chondrus*, *Chimaphila*, *Aspidium*, and *Gelsemium*.

On the other hand, some of the common English names were so fixed by usage that it was not deemed judicious to alter them ; besides, to have changed them would have often substituted a longer and less convenient word. The retention of the English names *Cloves*, *Elm*, *Hops*, and *Ginger* sufficiently illustrates this.

In the U. S. Pharmacopœia, 1890, a very important change was made in the English names of the chemical substances, the basylous or metallic component being given the first place ; for instance, *potassium citrate*, *ammonium bromide*, and *zinc sulphate*, replace the former names *citrate of potassium*, *bromide of ammonium*, and *sulphate of zinc*. This change required many alterations in nomenclature, but it was a necessary step for the Committee of Revision to make the names accord with the established usage of the best modern chemical writers. In the U. S. P. 1890 the salts of iron and mercury were for the first time differentiated by the use of the terms *ous* and *ic* respectively to designate lower and higher forms of the salts ; for example, ferr*ous* sulphate and ferr*ic* sulphate, mercur*ous* iodide and mercur*ic* iodide, replaced the names sulphate of iron and iodide of mercury ; the compounds of mercury, on account of the differences in dose existing among them, were further distinguished by the use of the adjectives "corrosive," "mild," "red," "yellow." For the scale salts of iron, which are of complex composition and not true chemical salts, notwithstanding the fact that the metallic component exists in them in the ferric state, the term "iron" was used in order to emphasize the fact of their defective chemical construction, for they are not definite double salts. These changes in nomenclature were retained in the Eighth Decennial Revision of the Pharmacopœia.

The Pharmacopœial names of chemical substances do not always represent their chemical composition. The enormous multiplication of synthetic remedies, and the length of the systematic names of these bodies, have compelled the use of shorter terms which are more conveniently employed in prescriptions and in commercial transactions. Thus, "metadihydroxybenzene" is a more cumbersome word than "resorcinol," "phenyldimethylpyrazolon" than "antipyrine." If we turn to unofficial substances, a better example is afforded by the use of "analgen," which is dignified by the systematic name of orthoethyloxyanamonobenzoylamidochinoline." In the U. S. P. (8th Rev.) it became necessary to introduce quite a number of synthetic remedies having long scientific names, and trade or proprietary names could not be used as titles in a standard book of this character, hence the long names had to be shortened, and "diethylsulphonedimethylmethane" became "sulphonmethane." The value of a long chemical name lies in the fact that the name indicates its composition, but some of the most useful modern remedies are very complex in their chemical composition, hence the inconvenience. The custom of abbreviating the official Latin titles in writing prescriptions is universal among physicians, and the new official names which are long, will not cause great inconvenience in practice. Thus "Hexamethylenamina" will undoubtedly be abbreviated to "hexa" or "hexameth."

3. **The Synonym.**—Example, [BASHAM'S MIXTURE.] In the Pharmacopœia the definition of the term synonym is restricted to an equivalent name in common use, which is usually antiquated and derived from an unscientific source, and which should really be abandoned, but which common custom and long usage demand shall not be entirely ignored. The synonyms should be rarely or never used, yet it is necessary for the student to be familiar with them in order to recognize their equivalent official Latin or English names when they are used by others. Common names, as snakeroot, dock, Indian hemp, balm, etc., have varying and often opposite meanings in different localities, and confusion and even loss of life have resulted from the unfortunate use of these common names. In the U. S. P. (8th Rev.) synonyms are placed in the index in small type under the official Latin titles; they are no longer to be found in the text as was the case in former editions of the Pharmacopœia.

4. **The Botanical Name.**—By this is meant the systematic name recognized by botanists for plants, which serves in pharmacopœial nomenclature as the basis of the official name. The botanical name usually consists of two Latin words, the first indicating the genus and the second the species to which the plant belongs. *Capsicum fastigiatum* is the botanical name for the particular variety of capsicum or Cayenne pepper which the Pharmacopœia designates. Here the generic or first name is chosen for the official title, and if no description followed the title it would be inferred that any part of any plant in the genus "Capsicum" could be officially used for making preparations; but the specific name, "fastigiatum," limits the use to this species, while the description which follows shows the *part* of the plant which must be employed: "the dried, ripe *fruit* of *Capsicum fastigiatum* Blume (Fam. *Solanaceæ*) deprived of its calyx." Now, Capsicum baccatum, Capsicum frutescens, Capsicum annuum, belonging to different species, are active members of the genus, but their claims are unrecognized, and the fruit from these species is not official. The specific name does not begin with a capital letter, except when it has been at some previous time itself a generic name, as in Rhamnus Frangula, or when it is derived from the name of a person, as in Garcinia Hanburii, or when the word is indeclinable, as in Theobroma Cacao, or when it is a combination of a noun and an adjective, as in Fagara Clava-Herculis. The name of the author follows the botanical name, as, *Capsicum fastigiatum* Blume, and after this the Family[1] to which the plant belongs is indicated in italics, and the whole enclosed in parentheses, as (Fam. *Solanaceæ*). The term Natural Order (Nat. Ord.) was replaced in the U. S. P. (8th Rev.) by the word Family (Fam.), to accord with modern usage among botanical authorities. It must be apparent that the botanical name need not be employed either in writing or speaking in ordinary pharmaceutical work; but its use is absolutely necessary in establishing the identity of any drug authorized by the Pharmacopœia, and hence it is important to know the botanical names.

5. **The Symbolic Formulæ.**—The adoption of certain arbitrary symbols[2] to represent chemical elements leads to a most convenient

---

[1] See index for chart of drugs arranged according to the Families.

[2] See index for table of elements, with symbols and atomic and molecular weights.

and useful application, whereby the composition of a chemical is expressed with the utmost brevity and exactness. Plumbi Iodidum and Lead Iodide are both much longer terms than "PbI_2," and not so definite. *Sodium Sulphite* does not always contain the same proportion of water of crystallization, and if the symbolic formula, $Na_2SO_3 + 7H_2O$, were not appended to the official title there might be some doubt about which sulphite was intended; the added $7H_2O$, however, accurately defines it. The *figures* which follow the symbolic formulæ indicate the *molecular weight* (the sum of the weight of the atoms) of the chemical. Thus, in $MgSO_4 + 7H_2O = 244.69$; the atomic weight of Magnesium, Mg, 24.18, is the first factor; this added to Sulphur, S, 31.83, makes 56.01; Oxygen, O, 15.88, multiplied by 4, gives 63.52; then Hydrogen having the atomic weight of 1 if multiplied by 2 and this by 7 gives 14, and seven times O, 15.88, is 111.16; then $56.01 + 63.52 + 14 + 111.16 = 244.69$, the molecular weight of magnesium sulphate.

The Official Definition.—In order to have no question arise as to the exact meaning of the official Latin title, or any other name by which an official substance is known, it is necessary to state explicitly in language that can be thoroughly understood what kind or variety of the substance should be used. In the case of drugs this has been already noticed (see page 29); for chemicals an illustration may be given in Guaiacol Carbonate, which is defined as "a guaiacol derivative $[(C_6H_4(OCH_3)O)_2.CO]$, obtained by the action of carbonylchloride upon sodium guaiacolate." Again Sevum Preparatum, Prepared Suet, is officially defined as "the internal fat of the abdomen of the sheep *Ovis aries* Linné, purified by melting and straining." This excludes beef suet and all other kinds, and states the method of purification.

The Purity Rubric.—This was introduced into the U. S. P. (8th Rev.) to limit the quantity of innocuous impurities in chemicals, by stating in terms of percentage the amount of pure substance that must be present. Thus, under Potassii Iodidum, Potassium Iodide, $KI = 164.76$, will be found the "purity rubric" as follows: "It should contain not less than 99 percent. of pure Potassium Iodide;" the caution to keep in well stoppered bottles is added. It might appear, at first sight, that chemicals should always contain 100 percent. of pure product, but practical experience shows that absolute purity is not attainable without the expenditure of much money, and the presence of minute quantities of impurities (provided that they are harmless) cannot affect the medicinal value of a chemical. Under the pharmacopœias formerly in use, prosecutions were often started, and penalties were imposed by the State authorities, because there was no purity rubric nor allowance for the absorption of moisture or the presence of traces of substances which were innocuous; the purity rubric remedies this defect by definitely stating the amount of permissible impurities.

The Official Description.—Immediately following the official definition of the substances there will be noticed in the Pharmacopœia, in smaller type, what has been termed the *official description;* this consists, usually, in drugs, of a concise statement of their physical characteristics, while in some cases tests of identity, with descriptions of the substances used as adulterants, are appended. In the chemicals the official definition is usually replaced by the symbolic formulæ, and these are followed immediately by the purity rubric and the official description, which is printed in smaller type, exactly as in the case of the drugs; to this description are usually added the solubilities, with the tests of identity and purity of the substance.

Assay Processes.—The assaying of drugs and preparations has become necessary in order to definitely fix their value as medicinal agents, and the U. S. P. (8th Rev.) has introduced many assays of alkaloidal drugs and their galenical preparations. This work requires skill, knowledge, and experience, and each process requires careful study. When alkaloidal drugs are to be assayed, the process which is usually followed consists of dissolving out the desired active principle, from a fluid preparation representing the drug, with the aid of certain solvents which are capable of extracting the desired constituents but which are not miscible with the liquid that is being assayed, and which may, therefore, be easily separated.

This immiscible solvent, after separation, is carefully treated to purify the substance which it has dissolved, and finally the quantity of the substance is determined by one of two methods: *gravimetric*, in which the solvent is evaporated carefully, the residue weighed, and the percentage present in the original drug calculated from this weight; or the process may be *volumetric*, in which case the amount of alkaloid dissolved is determined by its power to neutralize a standard acid volumetric solution, the amount of solution required being carefully noted, and the percentage of alkaloid calculated from the figure obtained. The method of assay is usually inserted near the end of the article. A number of chemical substances, volatile oils, animal products, etc., are also assayed, but for most chemicals it usually suffices to attach a *quantitative test*, which answers a similar purpose, and in which the strength may be determined by either a gravimetric or volumetric process without the elaborate preliminary treatment required in drug assays.

Doses.—An innovation was adopted in the U. S. P. (8th Rev.) by the insertion of the "Average dose" at the end of the greater number of the articles. The dose of a medicine can never be a fixed and unvarying quantity; the age and condition of the patient, the severity of the disease, the idiosyncrasy and tolerance for medicines, must all be reckoned with, and it would be a very unwise physician who disregarded these factors. For these reasons, an "average dose" was used in order to furnish a guide to pharmacists and physicians. The following quotation from the preface of the Pharmacopœia is appended:

"The Convention instructed the Committee 'to state the average approximate (but neither a minimum nor a maximum) dose for adults, . . . the metric system to be used, and the approximate equivalent in ordinary weights or measures inserted in parentheses,' and the Committee was further directed to make the following distinct declaration '*that neither this Convention nor the Committee of Revision created by it, intends to have these doses regarded as obligatory on the physician or as forbidding him to exceed them whenever in his judgment this seems advisable.*' "

The following examples, selected from the Pharmacopœia, are given in illustration:

OPIUM	[Official Latin title]	**SODII HYDROXIDUM**
Opium	[Official English title]	**Sodium Hydroxide**
The concrete, milky exudation obtained by incising the unripe capsules of *Papaver somniferum*, . . . and yielding . . . not less than 9 percent. of crystallized morphine, when assayed by the process given below.	[Official definition]	
	[Symbolic formula and Purity Rubric]	$NaOH = 39.76$ It should contain not less than 90 percent. of pure anhydrous Sodium Hydroxide. . . . It should be kept in well-stoppered bottles made of hard glass.
In irregular, flattened, more or less rounded masses, . . . internally dark brown, somewhat lustrous; odor strong, narcotic; taste bitter and characteristic.	[Official description]	Dry, white flakes, fused masses, or translucent or opaque white pencils, showing a crystalline fracture, odorless, and having a caustic taste. . . . Soluble in about 1 part of Water at 25° C. (77° F.). . . . The aqueous solution . . . should not respond to the Time-Limit Test for *heavy metals*.
Opium, in any condition to be valued . . . . . . **10.0 Gm.** **Ammonia Water . . 3.5 Gm.** **Alcohol,** etc.	[Assay]	
Introduce the Opium . . . into an Erlenmeyer flask, . . . add 100 Cc. of distilled water, . . . and agitate during three hours. . . . The difference, multiplied by 10, represents the percentage of crystallized morphine contained in the Opium.	[Quantitative Test]	Introduce about 1 Gm. of Sodium Hydroxide into a stoppered weighing bottle. . . . Dissolve this in about 50 Cc. of water, and titrate the solution with normal sulphuric acid V.S. . . . Multiply the number of Cc. of the normal sulphuric acid consumed, by 3.976, and divide this product by the weight of the Sodium Hydroxide taken; the quotient represents the percentage of Sodium Hydroxide present.
Average dose.— 0.100 Gm. = 100 milligrammes (1½ grains).	[Dose]	

The Preparations of the Pharmacopœia

Although these will be considered in detail in the body of this work, a few general remarks on them will be appropriate here. The "parts by weight" plan adopted by the U. S. Pharmacopœia, 1880, was dropped in the 1890 revision, and the "solids by weight, liquids by measure" principle accepted. This is more in accord with the methods used in English speaking countries. A great advance was made by the adoption of the metric system for expressing the quantities, which were thus also made definite. Every pharmacist should employ the metric system exclusively in making preparations; but on account of the revolutionary changes made necessary by the adoption of this system of weights and measures, corresponding quantities are given in the working formulas in this book, which are based on the old system of avoirdupois weight and apothecaries' measure. The latter will be found much less convenient than the metric quantities, especially if the operator has procured a set of metric weights and measures and has used them a few times.

The U. S. P. official text is printed in this book by authority from the Board of Trustees of the United States Pharmacopœial Convention, and the official processes are designated by an asterisk (*), printed before the name of the first ingredient, when alternative or "old form" quantities are given. The latter are enclosed in brackets in the text, and are printed in smaller type in the list of ingredients. The object of this arrangement is to indicate that the alternative or old form quantities are not used in the Pharmacopœia.

The old form quantities are not intended to be equivalents of the metric quantities and the two systems are not interchangeable; either "metric" or "old form" may be used, but in no case part of one and part of the other; different type distinguishes one from the other.

National Formulary

The Third Edition of this book was made a standard under the Pure Food and Drugs Act, June 30, 1906. It is the property of the American Pharmaceutical Association. Its origin dates from 1882 when Charles Rice, Ph. D., organized a Committee from New York and Brooklyn to frame a book of formulas for unofficial preparations. The New York and Brooklyn Formulary was subsequently enlarged and the joint Committee presented it to the American Pharmaceutical Association in 1885 as the nucleus for the construction of the National Formulary. The work has gone through three Editions and a fourth is in preparation. It is quoted in the national and state laws as of equal authority with the Pharmacopœia.

It is important to remember that if a drug or preparation is sold under or by a name recognized in the U. S. Pharmacopœia or National Formulary it must not differ from the standard of strength, quality or purity determined by the tests laid down in either of these books official at the time of investigation. A drug or preparation is not deemed to be adulterated if it differs from the official standards, provided such standards be plainly stated upon the bottle, box or container.

Dispensatories

A dispensatory is a commentary on a pharmacopœia. The U. S. Pharmacopœia describes the drugs and chemical substances of the materia medica, establishes the degree of purity of many of them, and defines the strength of the preparations. The dispensatories comment on the substances, giving their physical, medical, and pharmaceutical history, with their doses and uses. The number of substances noticed in the Pharmacopœia is limited. On the other hand, the dispensatories present information about those which are official in our own and other pharmacopœias, and those which are of occasional or rare use, in addition. There are at present two dispensatories which comment especially upon the materia medica and preparations of the U. S. Pharmacopœia,—the United States Dispensatory, which was first published in 1833, and the National Dispensatory, which was first issued in 1879. King's American Dispensatory, adopted by the National Eclectic Medical Association in 1879 as its standard authority, is especially designed for the use of Eclectic practitioners. The plans of these works are similar. The text of the Pharmacopœia is first inserted, and immediately following are appended the comments of the authors and editors. The arrangement of the subjects is strictly alphabetical, the United States Dispensatory dividing them, however, into two classes, distinguished by type of two sizes. The principal portion of the work, that in the larger type, is devoted to a commentary on the preparations of the United States and other Pharmacopœias; the unofficial and less important subjects are to be found in the second part. In the National Dispensatory the unofficial substances are considered either in the body of the book or under subdivisions as allied drugs. The possession of a reliable commentary upon the Pharmacopœia is a *necessity* which is fully realized by pharmacists. The United States Dispensatory is now preferred as a guide, and hence will be frequently quoted.

PART I

CHAPTER I

METROLOGY

Weight, Measure, and Specific Gravity

METROLOGY formerly and according to its strictest signification meant the science of measures, but its present definition includes the measure of the gravitating force of bodies, which always bears a direct ratio to their mass, and is commonly called *weight;* the determination of the bulk or extent of the body, its *measure;* and the relation which measure bears to weight when compared with a standard is known as *specific gravity.*

Weight

A knowledge of the systems of weights and measures in use must necessarily command the early attention of the student, and a short account of the origin of the present systems may be of service in fixing upon the mind the essential distinctions between them. The sense of the weight of a body cannot be conveyed intelligibly to the mind unless a means of comparison is chosen, and as weight is the measure of the gravitating force of a body, so this force is expressed as related to a standard of resistance, this being exactly that which would balance the body and keep it in equilibrium. Such standards are termed *weights.*

The standards which have been chosen by various nations are arbitrary, and instances are common where different standards are in use at the same time in the same country. Many of the ancient standards are clearly referable to parts of the human body, as nail, foot, span, pace, cubit (length of the forearm), orgyia (stretch of the arms). In the history of metrology three periods may be traced: 1. The *Ancient,* during which the old classical standards originated, and which terminated with the decline of the Roman Empire. 2. The *Mediæval,* extending to the sixteenth century. In this period the old standards were lost, but their names were preserved, and European nations adopted various independent standards. 3. The *Modern.* Since the seventeenth century the efforts of most enlightened nations have been directed toward greater accuracy and simplicity, and during the present century toward international uniformity.

In Great Britain, in the year 1266, the 51st act of the reign of Henry III. declares "that by the consent of the whole realm of England the measure of the King was made,—that is to say, that an English silver penny called the sterling, round and without clipping, shall weigh *thirty-two grains of wheat,* well dried and gathered out of the middle of the ear; and twenty pence (pennyweights) do make an ounce, and twelve ounces a pound, and eight pounds do make a gallon of wine, and eight wine gallons do make a bushel, which is the eighth of a quarter."

The sixteen-ounce pound (avoirdupois) was derived from a more ancient source, and was undoubtedly of Roman origin, and introduced at the time of the first civilization of the British island. The word "haberdepois," according to Gray, was, however, first used in English laws in 1303.

A statute of Edward I. (A.D. 1304) states "that every *pound* of money or of *medicines* is of *twenty shillings weight*, but the pound of all other things is *twenty-five shillings weight*. The *ounce* of *medicines* consists of *twenty pence*, and the *pound* contains *twelve* ounces (the Tower Pound), but in other things the pound contains *fifteen* ounces, in both cases the ounce weighing twenty pence."

These laws unfold the theory of the ancient weights and measures of Great Britain, and reveal the standard,—*i.e.*, a natural object, grains of wheat; a difference existed then between the troy and the avoirdupois pound, but the weights now in use are one-sixteenth heavier than those of Edward I., owing to the change made in the value of the coin by the sovereign subsequently; in addition to this, the true pennyweight standard was lost, and on the next revision of the weights and measures the present troy and avoirdupois standards were adopted. The old Tower or troy ounce and the avoirdupois ounce were intended to have the same weight, but after the revision it was found that the troy ounce was heavier than the avoirdupois ounce by forty-two and a half grains.

The subsequent adoption of troy weight by the London College of Physicians in 1618, on the recommendation of Sir Theodore Turquet de la Mayerne, who compiled their first Pharmacopœia, has entailed upon all apothecaries who are governed by British customs, to this day, the very great inconvenience of buying and selling medicines by one system of weights and compounding them by another.

In the next century efforts were made toward reforming the standards, and the Royal Society, in 1736, began the work, which ended in the preparation, under the direction of the House of Commons, by Mr. Bird, of the standard "yard" and standard "pound" troy in 1760. Copies of these have been made, no intentional deviation has been made since, and they are still the standards used most largely in the United States. In 1816, on account of the growing popularity of the French metrical system, and in view of the desirability of securing a standard which could easily be recovered in case of loss or destruction and which should be commensurable with a simple unit, steps were taken in England to secure these advantages. The labors of English scientists led to the adoption of the *Imperial* measures and standards, which were legalized January 1, 1826, and are now in general use in Great Britain.

In this system the *yard* is equivalent to 36 inches, and its length was determined by comparison with a pendulum beating seconds of mean time, in a vacuum, at the temperature of 62° F. at the level of the sea, in the latitude of London, which length was found to be 39.1393 inches. The *pound troy* (containing 5760 grains) was determined by comparison with a given measure of distilled water under certain conditions. Thus, a cubic inch of distilled water was weighed with brass weights in air at 62° F., the barometer at 30 inches, and it weighed 252.458 grains. The standard for measures of capacity (either dry or liquid) is the *gallon*, and this contains 10 pounds avoirdupois (each 7000 grains) of distilled water weighed in air at 62° F., the barometer standing at 30 inches, the *bushel* containing 8 such gallons. In 1819–20 efforts were made in the United States to secure uniformity in the standards which were in use by the several States. Finally, after a lengthy investigation, the Secretary of the Treasury, on June 14, 1836, was directed by Congress to furnish each State in the Union with a complete set of the revised standards, and thus we have the *troy pound* (5760 grains), the *avoirdupois pound* (7000 grains), and the *yard* (36 inches) all identical with the British standards; but the *gallon* is quite different, the old wine gallon of 231 cubic inches, containing 58372.2 grains of distilled water at its maximum density, weighed in air of the temperature of 62° F., the barometer standing at 30 inches, *being retained*, while the bushel contains 77.6274 pounds of water under the same conditions.[1]

In 1864 the use of the metric measures was legalized in Great Britain, but not made compulsory, and in 1866 the United States followed the same course.

By the United States law of July 28, 1866, all lengths, areas, and cubic measures are derived from the international meter equivalent to 39.37 inches. Since 1893 the United States Office of Standard Weights and Measures has been authorized to derive the yard from the meter, 1 yard equals $\frac{3600}{3937}$ meter, and the customary weights are referred to the kilogramme by Executive order approved April 5, 1893. All capacities are based on the equivalent 1 cubic decimeter equals 1 liter, the decimeter being equal to 3.937 inches. The gallon still remains at 231 cubic inches and the bushel contains 2150.42 cubic inches. The customary weights are derived from the international kilogramme based on the value that 1 avoirdupois pound = 453.5924277 grammes and that $\frac{5760}{7000}$ avoirdupois pound equals 1 troy pound.

Apothecaries' Weight (also called Troy Weight)

Pound		Troy Ounces		Drachms		Scruples		Grains
1	–	12	=	96	=	288	=	5760
		℥ 1	=	8	=	24	=	480
				ʒ 1	=	3	=	60
						℈ 1	=	gr. 20

The British Pharmacopœia, while giving alternative equivalents in the metric system, has adopted avoirdupois weight (termed Imperial weight) for expressing quantities which are to be weighed. Avoirdupois weight is also in general use in the United States for commercial purposes.

Avoirdupois Weight

Pound		Ounces		Grains
℔ 1	=	16	=	7000
		oz. 1	=	437.5

---

[1] Slight variations in these original equivalents are recommended by various investigators, and have been in use since Hassler made his report in 1832. (See Barnard on the Metric System, page 153.)

It will be observed that the troy ounce contains 42½ grains *more* than the avoirdupois ounce, while the troy pound contains 1240 grains *less* than the avoirdupois pound. Fortunately, one unit common to troy, or apothecaries', and avoirdupois weight has been saved,—namely, *the grain.* The abbreviations of the denominations of apothecaries' weight are represented by the signs ℥, ounce, ʒ, drachm, ℈, scruple, and gr. grain; these have long been in use, but are very likely to be mistaken for one another in rapid or careless writing. The abbreviations or signs for avoirdupois weight differ from those of troy weight, and care should be used not to confound them; they are lb., pound, oz., ounce, gr., grain.

Measures

Apothecaries' or Wine Measure, U.S.

Gallon		Pints		Fluidounces		Fluidrachms		Minims
Cong. 1	=	8	=	128	=	1024	=	61440
		O. 1	=	**16**	=	128	=	7680
				f℥ 1	=	8	=	480
						fʒ 1	=	♏ 60

Imperial Measure, Br.

(Adopted by the British Pharmacopœia)

Gallon		Pints		Fluidounces		Fluidrachms		Minims
C. 1	=	8	=	160	=	1280	=	76800
		O. 1	=	**20**	=	160	=	9600
				fl. oz. 1	=	8	=	480
						fl. dr. 1	=	min. 60

When the subject of the weights and measures in ordinary use is studied, the want of simplicity and close relation is clearly apparent. The pint of distilled water at 15.6° C. (60° F.) weighs 7291.2 grains, the fluidounce 455.7 grains, and at 25° C. (77° F.), the temperature adopted for taking specific gravities and solubilities by the U. S. P. (8th Rev.), the pint weighs 7273.3 grains and the fluidounce 454.6 grains, or, more accurately, 454.581 grains. We have thus three ounces in use of different values,—troy ounce, 480 grains; avoirdupois ounce, 437.5 grains; and fluidounce, 454.6 grains.

The U. S. gallon of water weighs 8.33 avoirdupois pounds, and the pint weighs 1.0416 avoirdupois pounds; the pound equals 0.9601 pints.

The Imperial measure differs from our wine measure principally in having twenty fluidounces in the pint instead of sixteen. A convenient relation exists, however, between measure and weight in the *Imperial gallon, which contains ten avoirdupois pounds of water* at 15.6° C. (60° F.).

The Imperial fluidounce contains the same number of grains as the avoirdupois ounce (437.5), which is 18.2 grains less than that of the U. S. fluidounce of water at the same temperature (455.7). Although this difference may be considered trifling in one fluidounce, it is not so when multiplied by four or eight, and this is one serious objection to the use of the English graduated measures in the United States, because they indicate Imperial fluidounces instead of U. S. fluidounces.

Approximate Measures

In apportioning doses for a patient, the practitioner is usually compelled to order the liquid medicine to be administered in certain quantities that have been established by custom, and estimated as follows:

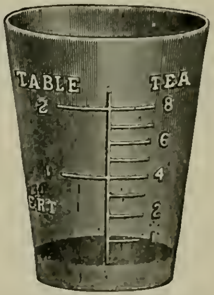
	Old form	Metric
A tumblerful	f℥viii	240 Cc.
A teacupful	f℥iv	120 Cc.
A wineglassful	f℥ii	60 Cc.
A tablespoonful	fʒiv	16 Cc.
A dessertspoonful	fʒii	8 Cc.
A teaspoonful	fʒi	4 Cc.

A drop, through a popular error, is considered to be 1 minim.[1]

The equivalents given above for the teaspoonful, dessertspoonful, and tablespoonful are authorized by the U. S. P. (8th Rev.).

In almost all cases the modern teacups, tablespoons, dessertspoons, and teaspoons, after careful tests by the author, were found to average 25 percent. greater capacity than the theoretical quantities given above, and the use of accurately graduated medicine glasses, which may be had now at a trifling cost, should be insisted upon (see Fig. 1).

FIG. 1



Graduated medicine glass

The Metric System.—This system, which originated with Prince de Talleyrand, Bishop of Autun, France, in 1790, seems destined to become universal, as it is now legally used by the majority of all civilized nations, and finds especial favor with scientists even in countries where its use is not compulsory. The starting-point was the *unit of length*, the **meter**, which is the $\frac{1}{40.000.000}$ part of the earth's circumference around the poles. From this, the *unit of capacity* was derived, the **liter**, which is the cube of $\frac{1}{10}$ part of a meter. The *unit of weight*, the **gramme**, was also derived from the meter, it being the weight of that quantity of distilled water, at its maximum density, 4° C. (39.2° F.), which will fill the cube of $\frac{1}{100}$ part of a meter.[2] The name Metrical System, it will thus be seen, is very appropriate, as *each unit is derived from the meter;* it is also known as the *Decimal System*, because in obtaining the multiples and subdivisions the number ten (*decem*) is used solely. The prefixes, which indicate *multiplication*, are of Greek derivation, and are usually spelled with a capital letter,—**Deka**, 10; **Hecto**, 100; **Kilo**, 1000; **Myria**, 10,000; while *division* of the units is expressed by Latin prefixes, the initial letters not being capitals,—**deci**, $\frac{1}{10}$; **centi**, $\frac{1}{100}$; **milli**, $\frac{1}{1000}$. The word Gild has been suggested as a useful mnemonic, thus:

G	I	L	D
reek	ncreases,	atin	ecreases

---

[1] See comparative table, page 73.

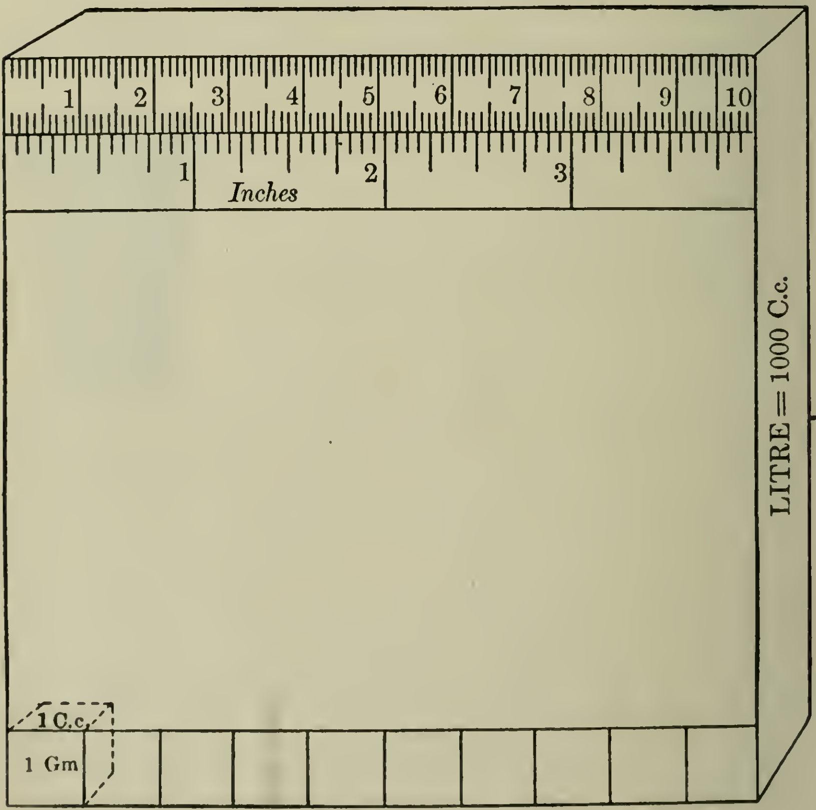
[2] The unit of surface measure, the *are*, being the square of ten meters, and the unit of solid measure, the *stere*, having the capacity of a cubic meter need not claim the attention of the practical pharmacist.

The following table gives a view of the system adapted to the use of the student :

	Abbreviation	Meter		Abbreviation	Liter		Abbreviation	Gramme
1 milli	meter, mm. =	.001	1 milli	liter, ml. =	.001	1 milli	gramme, mg. =	.001
1 centi	meter, cm. =	.01	1 centi	liter, cl. =	.01	1 centi	gramme, cg. =	.01
1 deci	meter, dm. =	.1	1 deci	liter, dl. =	.1	1 deci	gramme, dg. =	.1
	Meter, M.	**1.**		**Liter, L.**	**1.**		**Gramme, Gm.**	**1.**
1 Deka	meter, Dm. =	10.	1 Deka	liter, Dl. =	10.	1 Deka	gramme, Dg. =	10.
1 Hecto	meter, Hm. =	100.	1 Hecto	liter, Hl. =	100.	1 Hecto	gramme, Hg. =	100.
1 Kilo	meter, Km. =	1000.	1 Kilo	liter, Kl. =	1000.	1 Kilo	gramme, Kg. =	1000.
1 Myria	meter, Mm. =	10000.	1 Myria	liter, Ml. =	10000.	1 Myria	gramme, Mg. =	10000.

In pharmaceutical practice a number of the above measures are rarely or never used. Of the measures of length, the *millimeter* (mm.) and *centimeter* (cm.) are employed in the U. S. Pharmacopœia in the descriptions of drugs, accompanied by the equivalent measure in inches or its fractions, while in microscopy *micromillimeter* (mkm.), or preferably, micron (μ), signifying the thousandth part of a millimeter, is used. In measures of capacity, the term *milliliter* is generally replaced by *cubic centimeter* (Cc.) in chemical and pharmaceutical prac-

FIG. 2



Metric diagram

tice, while it and the liter are alone chosen as the most convenient units. In weight, the *milligramme*, *centigramme*, *gramme*, and *kilogramme* are selected; the latter being the commercial unit for larger quantities of drugs, and called *kilo.* This habit of appropriating only certain of the most convenient denominations for practical work has an analogy in the disuse of the theoretical terms of the system of United States coinage. Thus, the double eagle, eagle, and dime are ignored, while dollars and cents are preferred as units. The principal merits of the metric system are: 1. That every weight and measure bears a simple relation to the initial unit, the meter. 2. That every unit is multiplied or divided by the same number (*i.e.*, 10) to obtain the various denominations, and increase or decrease is expressed by simply moving the decimal point. 3. Its almost universal adoption makes it an international system.

Length.—*Meter.* Each side of the square (Fig. 2) measures 1 decimeter, one is graduated into tenths (*centimeters*); and these into tenths (*millimeters*); (the scale beneath shows the comparison with inches): 10 decimeters = 1 METER = 39.3700 in. (remember three threes, 3 ft., 3 in., 3 eighths).

Capacity.—*Liter.* A hollow cube having each side of the same size as the square would hold a LITER = 1000 Cc. = 2.1133 pints.

Weight.—*Gramme.* The weight of distilled water at 4° C. (39.2° F.) contained in a cube of the $\frac{1}{1000}$ of a liter is equal to a GRAMME = 15.432 grains, and measures 1 *cubic centimeter* (see Fig. 2).

The advantages of the metric system have become more and more apparent upon examination, and its simplicity, brevity, and adaptability to everyday needs are now universally conceded. The progress which it had made in this country up to 1890 fully warranted its exclusive adoption in the U. S. Pharmacopœia; hence definite quantities were given and metric weights and measures alone employed. The necessity for knowing thoroughly the denominations of all the systems in present use is one of the evils common to the age in which we live, and it must ever be a source of regret that when the young Republic, more than a century ago, abolished the complex system of coinage and adopted the decimal system, it did not go a step farther and adopt the same principle in weights and measures.

The chief disadvantage of the metric system is one which inheres to the decimal principle of arithmetic,—namely, that the number ten cannot be divided more than once without producing a fraction, as, 10, 5, 2.5, 1.25, 0.625. The practice of dividing five into the three parts of 2, 2, and 1 partly compensates for this defect, and metric weights are constructed on this principle. The use of the metric weights and measures in the text of the U. S. Pharmacopœia makes it necessary for every pharmacist to become familiar with them, and therefore an easy method of remembering their relations to one another and their equivalents in other systems is desirable. The following equivalents are derived from those established by Congress for use in legal proceedings, or are based upon the trustworthy determinations of Captain Clarke and Prof. Miller, while the accompanying rules, which show the methods of using the equivalents, are preferred, for scientific determinations, on account of giving more accurate results. When very fine calculations are unnecessary, it will be found that the tables of equivalents given on pages 46 to 54 will prove sufficiently accurate for most pharmaceutical work.

To convert metric weights or measures into those in ordinary use :

Rule.—**Multiply the metric quantities by the corresponding equivalent.**

Ex.—The equivalent of *one meter* is 39.370+ inches, and five meters would be 196.85 inches : 39.370 × 5 = 196.85. To convert

Meters	into	*inches,*	multiply by	39.370
Centimeters	“	*inches,*	“	0.3937
Millimeters	“	*inches,*	“	0.03937

As *one liter*, or 1000 *Cc.*, is equal to 33.8149+ fluidounces, or 35.235 Imperial fluidounces, to convert

Liters	into	*fluidounces,*	multiply by	33.815
Cubic centimeters	“	*fluidounces,*	“	0.0338
Liters	“	*pints,*	“	2.113
Liters	“	*Imperial pints,*	“	1.7617
Liters	“	*Imperial gallons,*	“	0.2202
Cubic centimeters	“	*Imperial fluidounces,*	“	0.0352

As *one gramme* is equal to 15.432+ grains, or 0.03527 avoirdupois ounce, or 0.03215 troy ounce, to convert

Grammes	into	*grains,*	multiply by	15.432
Centigrammes	“	*grains,*	“	0.15432
Milligrammes	“	*grains,*	“	0.01543
Kilogrammes	“	*avoirdupois ounces,*	“	35.2739
Grammes	“	*avoirdupois ounces,*	“	0.03527
Kilogrammes	“	*avoirdupois pounds,*	“	2.2046
Kilogrammes	“	*troy ounces,*	“	32.1507
Grammes	“	*troy ounces,*	“	0.03215

To convert the weights and measures in ordinary use into metric weights and measures :

Rule.—**Multiply the quantities by the corresponding metric equivalent.**

As *one inch* is equal to 0.0254 meter, *one fluidounce* to 29.572+ cubic centimeters, *one Imperial fluidounce* to 28.3807 cubic centimeters, *one* grain to 0.0648 gramme, *one avoirdupois ounce* to 28.3495 grammes, and *one troy ounce* to 31.1035 grammes, to convert

Inches	into	*meters,*	multiply by	0.0254
Inches	“	*centimeters,*	“	2.5399
Inches	“	*millimeters,*	“	25.3997
Pints	“	*liters,*	“	0.4731
Fluidounces	“	*cubic centimeters*	“	29.572
Imperial pints	“	*liters,*	“	0.5676
Imperial gallons	“	*liters,*	“	4.5409
Imperial fluidounces	“	*cubic centimeters,*	“	28.3807
Grains	“	*grammes,*	“	0.0648
Grains	“	*centigrammes,*	“	6.4799
Grains	“	*milligrammes,*	“	64.799
Avoirdupois ounces	“	*kilogrammes,*	“	0.02835

Avoirdupois ounces	into	*grammes,*	multiply by	28.3495
Avoirdupois pounds	"	*kilogrammes,*	"	0.4536
Troy ounces	"	*kilogrammes,*	"	0.0311
Troy ounces	"	*grammes,*	"	31.1035

It will be observed that there is a slight difference in the smaller quantities, increasing in the larger, between the equivalents in the following tables and those above given. This is owing to the fact that the temperature used as a basis for the metric units is 4° C., instead of 15.6° C., the usual temperature in practice, and the equivalents in the old form weights and measures in the table must correspond. The column upon the left of the page gives the weight in grains from one hundred pounds down; the difference in value from the next column is due to the variation in temperature standards; the fluidounce equivalent at 15.6° C. (60° F.) is 455.7 grains; the fluidounce at 25° C. (77° F.) weighs 454.6 grains; the fluidounce at 4° C. (39.2° F.) in vacuo weighs 456.392 grains. For practical work in pharmacy the discrepancy is too trivial to give serious annoyance.

Orthography, Pronunciation, and Reading

Orthography.—There are two methods of orthography of the metric units in use in the United States; in one of these, the original French, the units are spelled metr*e*, litr*e*, gram*me*; in the other, proposed by the American Metric Bureau, the units are spelled met*er*, lit*er*, gram. It would not be appropriate in a treatise of this kind to discuss the merits of either plan, but it is unfortunate that in the U. S. Pharmacopœia of 1890 the question was not settled, the French gram*me* having been retained and met*er* and lit*er* adopted, and the same rule has been followed in the 8th Revision of the Pharmacopœia. While the original orthography is used in the British Pharmacopœia, and is preferred by the author, the custom has now become established in the United States, and it is therefore followed in this work; some minor changes are desirable,—*i.e.*, *deca*, which is changed to *deka*, because *deca* could easily be mistaken for *deci*. In pharmacy particularly, *gramme* is to be preferred to *gram*, because in writing gram it could easily be mistaken for grain, particularly if the *i* in grain were not dotted.

Pronunciation.—Meter is pronounced mee′ter, liter lee′ter, gramme gram, not, as sometimes heard, gram′me; centimeter should be pronounced sen′tee-mee-ter, not son′tee-mee-ter. The latter faulty pronunciation is quite common, and is due to confounding the French pronunciation with the English. Either son-tee-mā′tr (French) or sen′tee-mee-ter (English) would be correct, but to use half of the French and half of the English is obviously improper, and, as the metric system is now anglicized, the simple English pronunciation is less stilted and more appropriate.

Reading.—Some difficulty is usually experienced by those unfamiliar with the metric system in reading the quantities. In the linear measures in Pharmacy, centimeters and millimeters are almost exclusively used; now, 0.05 M. would not be read five hundredths of a meter, but 5 centimeters (5 cm.); if the millimeter column contains a unit, as in 0.055 M., it is read fifty-five millimeters (55 mm.), in preference to fifty-five thousandths of a meter; or it is sometimes read five centimeters and five millimeters.

Fractions of a millimeter must be read decimally, as, 0.0555 m., fifty-five and five-tenths millimeters. In measures of capacity, cubic centimeters are exclusively used; if the quantity is less than a liter, the terms half liter, quarter liter, deciliter, centiliter, milliliter are replaced by 500 Cc., 250 Cc., 100 Cc., 10 Cc., 1 Cc.; in aqueous liquids the cubic centimeter is considered equivalent to a gramme. In weight, when the quantity is relatively large, and in commercial transactions, the kilogramme is abbreviated to kilo, pronounced kil′o; when less than a kilogramme, and not less than a gramme, the quantity is read with the gramme for the unit; 2000 Gm. would be read two kilos, and 543 Gm. would be read five hundred and forty-three grammes, while 2543 Gm. is usually read two kilos and five hundred and forty-three grammes, although twenty-five hundred and forty-three grammes is sometimes preferred. For quantities below the gramme, decigrammes are not used, but centigrammes and milligrammes are regarded as the most convenient units; they are read in the same way as centimeters and millimeters.

Weighing and Measuring

Among the first operations that the student is called upon to perform are the very important ones of *weighing* and *measuring.* The former process requires the use of the *balance,* or, as more frequently, but less preferably, termed, *scales.* As the successful performance of many of the processes noticed in this work depends upon a thorough knowledge of the principles of the balance, it has been selected as one of the first subjects for consideration, for this instrument in some form or other is relied upon to secure accurate quantities of the substances employed in the various operations of pharmacy.

The balance may be defined as an instrument for determining the relative weights of substances, and should be *correctly constructed, skilfully used,* and *carefully protected from injury,* if accurate results are expected.

Construction of the Balance.—For systematic consideration pharmaceutical balances may be classified as follows: 1. *Single beam, equal arms.* 2. *Single beam, unequal arms.* 3. *Double beam, unequal arms.* 4. *Compound lever balances.* 5. *Torsion balances.*

1. Single Beam, Equal Arm Balances.—The instrument which, notwithstanding many attempts to supplant it, still maintains its supremacy is the *single beam, equal arm balance,* which may be described as consisting of a metallic lever or beam, divided into two equal arms at the centre by a knife edge, upon which it is supported. At exactly equal distances from this point of support, and situated in the same plane, are placed the end knife edges; these suspend the pans which carry the substances to be weighed. A good balance should possess the following requirements:

1. *When the beam is in a horizontal position, the centre of gravity should be slightly below the point of support, or central knife edge, and perpendicular to it.*

The relative sensibility of the balance depends upon the fulfilment of this principle, which may be roughly illustrated by forcing a pin through the centre of an oblong piece of pasteboard; if the edge of the pasteboard is touched slightly it does not oscillate at all, but revolves around the centre to a degree corresponding to the impulse representing equilibrium; if the pin be removed and inserted a very short distance above the centre, and the edge of the pasteboard touched as before, it will oscillate slowly, corresponding to a sensitive beam, the point of support being slightly above the centre of gravity; if the pin be again removed and inserted far above the centre, and the same impulse imparted to the edge, it will oscillate quickly, illustrating stable equilibrium and a beam which comes to rest quickly and is not sensitive. A more elaborate method of illustration is furnished by the use of a beam with a movable fulcrum (see Fig. 3), when the relative position of the knife edge may be made to show, beginning at the top, 1, stable equilibrium; 2, in the centre, equilibrium; and, 3, when the lowest point is reached, unstable equilibrium, and then the slightest impulse upsets the beam.

2. *The end knife edges must be at exactly equal distances from the central knife edge; they must all be in the same plane, and the edges absolutely parallel to each other.*

It is very apparent that the conditions of a good prescription balance cannot be satisfied if there is inequality in the length of the arms of the beam. In Fig. 4 the distance from the central knife edge to the one on the left must be exactly the same as the distance from the central knife edge to the one on the right, otherwise unequal weights would be required to establish equilibrium, or the excess of weight of the longer arm must be subtracted at every weighing, or weighing by substitution resorted to, all manifestly impracticable. If the central knife edge be placed either above or below a line drawn so that it connects the end knife edges, the loading of the pans will either cause the beam to cease oscillating, or diminish the sensibility in proportion to the load. If the knife edges are not parallel, the weight of a body would not be constant upon every part of the pan, but would be greater if placed near the edge on one side, and correspondingly less at a point directly opposite.

Fig. 3

Illustration of equilibrium

Fig. 4

Position of knife edges

3. *The beam should be inflexible, but as light in weight as possible, and the knife edges in fine balances should bear upon agate planes.*

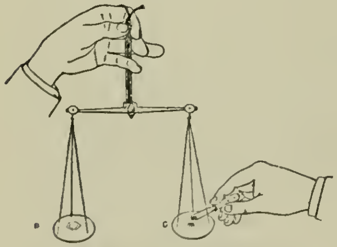
Rigidity of the beam is necessary, because any serious deflection caused by a loading of the pans would lower the end knife edges, and thus accuracy in weighing would be impossible. The beam should not be heavier than necessary, because its sensibility (particularly when light weights were placed upon the pans) would be thereby lessened, and to diminish friction arising from the rusting of the steel knife edges which constantly increases with the age and use of a balance, the bearings of the knife edges should be agate planes. Formerly this condition could not be practically carried out, except in expensive balances, owing to the cost of polished agate; but since the introduction of automatic machines for grinding and polishing this very hard substance, the cost has been so reduced that not only the bearings, but the knife edges themselves, are now made of agate and used upon fine prescription balances, and it is practical economy to employ exclusively those so mounted.

The Tests of a Balance.—Having stated the essential points in the construction of the balance, the tests, which should always be applied before accepting a balance, will now be described. The prescription balance, being one of the most delicate and important of the instruments in use by the pharmacist, is selected for illustration. 1. A perfectly level counter or table is secured, the balance is placed in position, the beam elevated so that it is free to oscillate, and when the oscillations have ceased, the smallest weight to which the balance is sensitive is placed upon the right hand pan,—it should at once respond to the weight; this tests its sensibility with unloaded pans. 2. Both pans are now loaded with the full weight that the balance is designed to carry, and then the smallest weight is placed upon the right hand pan,—the oscillation, although slower than in the first test, ought to be as decided ; this shows its sensibility when loaded. 3. The pans should now be loaded to half the capacity of the balance, and equilibrium perfected by adding, if necessary, a piece of tin foil. The weights on the right hand pan must now be exchanged for those on the left hand pan, and *vice versa ;* if equilibrium is still maintained, *the arms of the beam are equal.* 4. The pans should be moderately loaded and balanced, and one of the larger weights shifted in different positions upon the edge of one of the pans, and any variation in equilibrium carefully noted. This variation, as previously mentioned, indicates a want of parallelism in the knife edges.

Forms of Single Beam, Equal Arm Balances.—There are good reasons for believing that this kind of balance has a very ancient origin ; and at the present time it is used more frequently than any other.

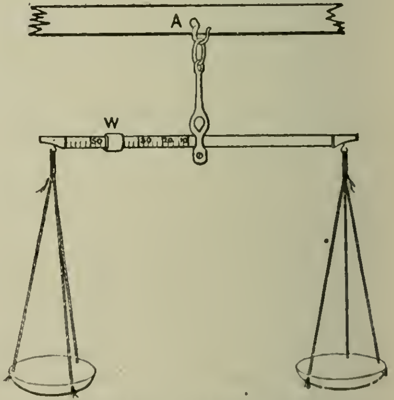
Hand Scales.—The commonest form in which this principle is utilized in pharmacy is seen in the cheap hand scales now fast passing out of use ; in the better qualities the beam is of steel, and the knife edges are enclosed so as to protect them from injury. In those usually seen the beam is of brass, with a steel central knife edge, having a perforation in each end of the beam for the insertion of two wire hooks, to which are attached silken cords for supporting the pans. The manner of holding these scales is shown in Fig. 5. They are now most largely employed in America by physicians and pharmacists having a very limited use for a balance. The silken tassel is held in the left hand, and care should always be taken *to see that the beam oscillates freely and properly* before the weight is placed upon the left hand pan, as the hooks frequently become entangled in the cords and the adjustment is lost. The requisite quantity of the substance to be weighed is placed upon the right hand pan, preferably with a spatula.

FIG. 5



Manner of holding scales

FIG. 6



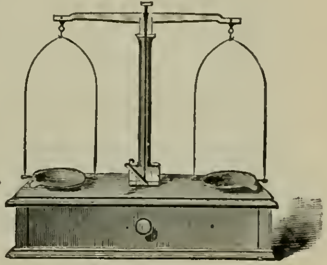
Hand scale with sliding weight

Alkaloids and very poisonous substances should never be weighed upon ordinary hand prescription scales, except when, by previous actual test at the time, they have been shown to be sensitive and accurate ; for, although this form has been in use many years, as now found in commerce they are the most unreliable of all kinds of prescription balances, and, notwithstanding their merits of cheapness and portability, in the end they may prove (through some serious error) an expensive investment. In Fig. 6 is shown an improved form of hand scale in which a sliding weight is used; this may be suspended on a hook at the proper height as shown in the cut.

Prescription Balances.—The advantage of substituting a rigid metallic column for the usually unsteady human arm, as a support to the beam, would seem to be apparent at a glance, for, in addition to the increased stability which is gained, both hands are left free to perform the weighing; more time can usually be devoted to secure equilibrium, and the oscillations can be more readily noticed.

A cheap prescription balance, an improved form of Troemner's "army prescription scale," is shown in Fig. 7; the beam, column, supports, pans, etc., are of lacquered brass, the knife edges of steel, while the drawer beneath is large enough to hold conveniently all the parts; this is a very useful feature where a balance is not in constant use, enabling the operator to set the balance at will, or keep it in the drawer protected from dust and corrosion. It may be made sensitive to the $\frac{1}{24}$ of a grain; but it soon loses this degree of delicacy, because of the rusting of the steel bearings and knife edges. With careful handling, and by protecting it from the atmosphere by covering with a glass shade, or glass case, it will remain in good order for years, and is vastly superior to the hand prescription scales.

Fig. 7



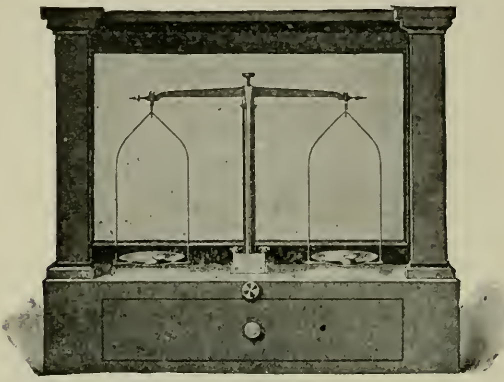
Army prescription scale

A pharmacist who desires to make use of all the modern improvements and secure the best practical results, should have, for *economy's* sake, *two* prescription balances,—one for delicate weighings and the other for ordinary work. These need not have the most fashionable and costly *cases*, but the workmanship of the balance itself cannot be too fine, if by it are secured the absolute essentials of accuracy, sensibility, and durability.

In addition to the theoretical requirements before noted, the finest prescription balances now made by Troemner are provided with solid nickel or solid silver pans and gold plated beams with adjusting screws on the ends to quickly restore equilibrium (see Fig. 8). As the pans are subjected to more wear and tear than any other part of the balance, it is economical to use *solid* rather than *plated* pans, for, as they have to be cleaned repeatedly, constant friction wears off the plating, and the additional cost for replating soon absorbs the difference in price. To secure the best results, when a showy appearance is not desired, a dead black finish to the column is preferable, as the labor of polishing, with the danger to the adjustment that it involves, is dispensed with. If the supports and pans are of solid silver or nickel, and the knife edges and the bearings of agate, a prescription balance is furnished which is durable and really cheap, because it will remain for a long time fully equal to the most exacting demands.

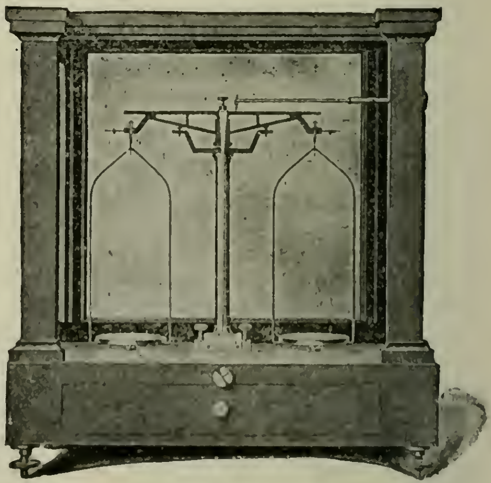
Analytical Balances.—The growing importance of analytical work, in connection with the quantitative tests introduced into the last revision of the U. S. Pharmacopœia, renders the possession of an analytical balance by the pharmacist very desirable. Formerly these delicate objects of mechanical skill were exclusively imported, but for thirty years American manufacturers have devoted unremitting effort to excelling in this fine work, with gratifying success. Fig. 9 shows a Troemner analytical balance of recent pattern. The open, metallic beam is light and rigid, the bearings and knives are of agate, and the bows are wide; the pans will each carry 100 grammes and the balance is sensible to $\frac{1}{4}$ milligramme. The ends of the stirrups are provided with hooks to suspend a body in taking its specific gravity, and a contrivance for arresting the motion of the beam and pans, together with one for elevating the beam entirely from contact with the agate planes when not in use, is provided. This balance is specially constructed for students' use and is not expensive.

Fig. 8



Fine prescription balance

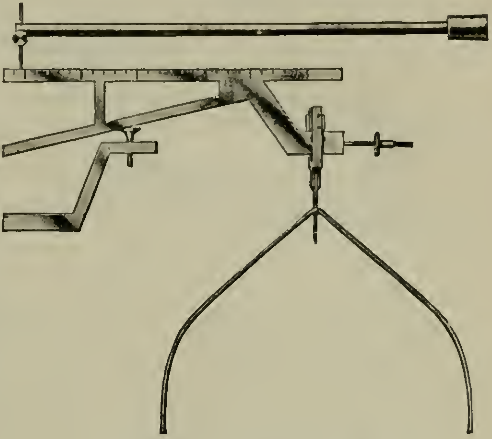
Fig. 9



Analytical balance

Fig. 10 shows an enlarged view of the end of the beam with the beam locked. The right arm of the beam is graduated so that each division represents one-fourth of a milligramme; an aluminum wire rider is pushed along the arm by a sliding rod to any point upon the graduated beam to indicate these fractions. An index needle traverses an ivory scale fixed on the base of the column, and the most delicate oscillations may be thus measured by the needle. If, for instance, *one-tenth of a grain* on one of the pans deflects the needle *ten* divisions on the scale, each one of these divisions would then represent one-tenth of the weight on the pan, or one-hundredth of a grain. With practice, the use of this means of weighing very minute quantities can be brought to great perfection.

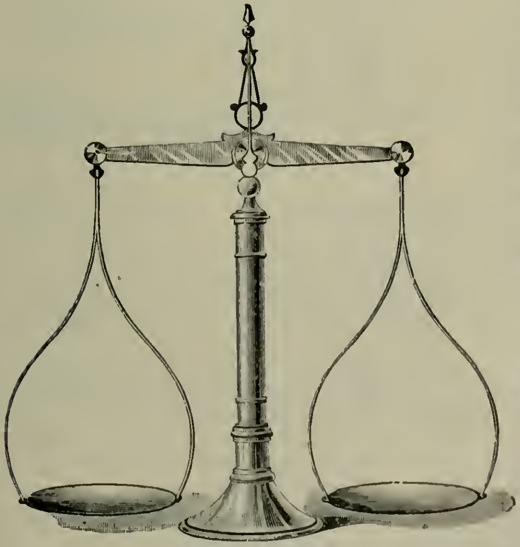
Fig. 10



Enlarged view of the end of beam

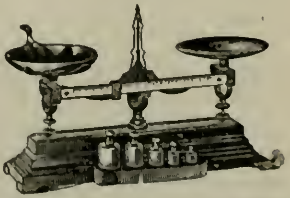
Counter Scales.— For counter and dispensing purposes, the single beam, equal arm principle was formerly exclusively used (see Fig. 11). These scales were usually made of polished brass, and answered most purposes if kept in good order, but were objectionable because the pan supports were frequently obstructive, as they only permitted the weighing of bodies having a limited surface, and the excessive amount of polished brass work about them required the expenditure of considerable labor to keep them bright, without any corresponding advantage. The form in which the pans are placed above the beam, thus getting rid of obstructive pan supports, is now greatly preferred (see Fig. 17). In these the objection to the polished brass is met by enclosing the working parts in a case; the copper or brass pan alone needs polishing. A very convenient form of dispensing scale for smaller weights, made by Troemner, is shown in Fig. 12. This beam is provided with a parallel, graduated, nickel plated bar, upon which a poise slides backward and forward; this is particularly useful for weighing small quantities of liquids. The tare of the bottle is easily taken by the use of the

Fig. 11



Old style counter scales

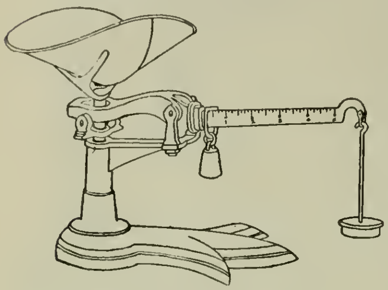
Fig. 12



Scale with graduated parallel beam and sliding weight sliding poise; the beam is graduated so that apothecaries' or metric weight may be used, and a projecting shelf attached to the base forms a convenient receptacle for the weights.

2. Forms of Single Beam, Unequal Arm Balances.—The principle upon which these very practical weighing machines are founded is best shown by referring to Fairbank's druggists' scale (see Fig. 13), and quoting the law in physics, "*The power is to the weight or resistance in the inverse ratio of the length of the arms of the lever.*" The inequality in the length of the arms of this beam permits of the convenient use of one movable weight upon the graduated longer arm of the beam, and thus dispensing with the use of small weights, which are liable to be lost; the scoop, which is useful in weighing bulky drugs, is sometimes replaced by a flat, circular disk when bottles, etc., are to be weighed.

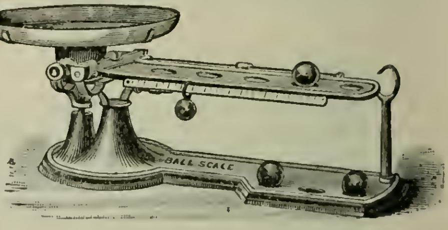
FIG. 13



Fairbank's druggists' scale

Troemner furnishes a convenient scale for pharmacists' use. It is termed the "Ball scale" (see Fig. 14). The beam is flat and perforated with five holes, which are about four inches apart; an iron ball is placed in one of these holes when a substance is to be weighed; the distance from the fulcrum of course determines the weight. It will weigh from $\frac{1}{4}$ oz. av. up to 16 pounds, and is furnished with an extra "sliding poise," to use in taring or balancing bottles when liquids are to be weighed. The purchaser of this scale need not buy a set of avoirdupois weights.

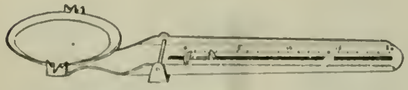
FIG. 14



Ball scale

A very simple vest pocket prescription scale is made by Shepard & Dudley, of New York; it is on the unequal arm principle, and is shown *half size* in Fig. 15. The principal parts are made in three pieces; the pan is detachable, the pan support being suspended on the short rod attached to the base; the graduated beam is more than double the length of the pan support; a slot runs nearly the length of this beam, and a sliding weight is pushed along in the slot. The scale is very cheap, and is intended for country physicians, who are often compelled to weigh medicines at the bedside of the patient.

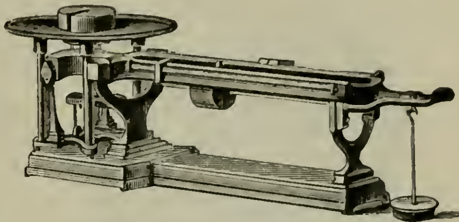
FIG. 15



Vest pocket prescription scale

3. Double Beam, Unequal Arm Balances.—It is preferable to have a double beam scale for constant use in the laboratory, and the most convenient form is upon the same principle as Fairbank's druggists' scale (Fig. 15), having, however, two parallel beams. This scale is particularly adapted for weighing liquids, the weight on the outside beam being used to tare the bottle or jar, while the other weight is left free so that it can be adjusted at once to the weight of the liquid desired. These are now to be had with the scale graduated into grammes, and are very useful in making preparations by the metric system, no loose weights being required when moderate quantities are to be weighed. (See Fig. 16.)

FIG. 16

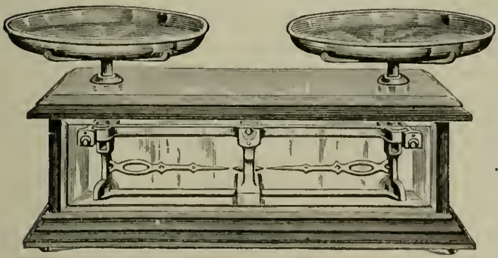


Troemner's scale for weighing liquids

4. **Compound Lever Balances.**—The principal of the compound lever was first applied in the construction of balances by Robervahl, of Paris, about A.D. 1660. It has only been recently adopted for delicate weighings in compounding prescriptions, although the general utility of counter and platform scales constructed upon this plan has long been recognized. The principal objection to them, when compared with equal beam balances, consists in the multiplicity of points of suspension, thus necessarily increasing friction and the liability to disarrangement; but their general convenience, and some recent improvements in their construction, have brought them into favor. The principle of the Robervahl compound lever balance, with the arrangement of the levers, is shown in Troemner's glass box scale in Fig. 17.

One of the practical advantages possessed by this form of balance is the small amount of polished metal to keep in order, and, as the working parts are enclosed in a tight box of glass, wood, or marble, dust and corrosive vapors are largely excluded; as they are made to occupy as little space as possible, the pans are conveniently low and unobstructed.

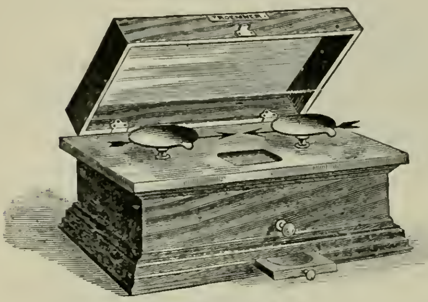
FIG. 17



Counter scales in "glass box"

Box prescription scales, on the compound lever principle, have come into extensive use, and they are the most convenient scales for weighing moderately small quantities (see Fig. 18). Although sensitive to $\frac{1}{30}$ of a grain when new, they do not retain this delicacy long. Their strongest recommendation is the ease with which they may be cleaned and kept in order; the only polished metal liable to be affected by corrosive vapors is found in the pans, and these are of solid nickel; the marble or plate glass top has a countersunk basin to keep weights in, and a hinged glass cover effectually excludes dust and vapors when the balance is not in use. If a pharmacist has a delicate, equal beam balance for weighing alkaloids and powerful poisons (see Fig. 8), and a box prescription scale for weighing ordinary quantities, he is well equipped for compounding prescriptions.

Fig. 18

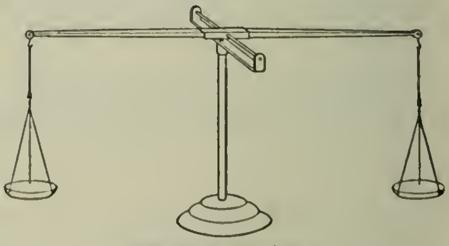


Box prescription scales

By far the most extensive application of the compound lever and unequal arm principles has been made in the universally known platform scales, which are manufactured largely by Fairbank and others; these are employed in weighing comparatively large quantities, and are most useful in the laboratory and warehouse. In these a platform or table is suspended by four short legs upon the ends of four levers, which are joined to a central nearly horizontal lever, which in turn is connected with a perpendicular iron rod attached to the graduated bar, suspended so that one of the arms is much longer than the other. This combination of levers is so nicely adjusted that one hundred pounds placed upon the platform may be balanced by a one pound weight placed upon the end of the graduated bar.

Torsion Balances.—A simple illustration of the principle of torsion is afforded by tying a stout piece of cord to a firm support and inserting a lead pencil in the middle of the cord between the strands, at right angles to it. If the free end of the cord is tightly stretched, and the effort is made to turn the lead pencil over, it will be at once noticed that resistance is offered, and if the pencil is released, it at once flies back to its original position.

Fig. 19



Ritchie torsion balance

Torsion is the term applied to this method of twisting. The principle of supporting the beam of a balance upon a tightly stretched wire, with the view of doing away with knife edges and diminishing friction, has occupied the attention of inventors for years. One of the earliest and simplest forms in which this principle was used was that devised by Ritchie, shown in Fig. 19. A very light beam is supported exactly in the middle (at its centre of gravity) upon a wire stretched upon a horizontal bar, having its ends slightly turned up; to these the ends of the wire are fastened, the beam is firmly secured to the wire, and when it is caused to oscillate the wire is twisted according to the extent of the force applied. This balance was very delicate and impracticable, because the torsional resistance was not overcome; this had to be neutralized before the wire could be used solely as a means of supporting the beam. In 1882 Prof. Roeder and Dr. Springer contrived an ingenious torsion balance which gave promise of valuable results. Two illustrations of this original balance are shown on page 54 of the first edition of the "Practice of Pharmacy." Recent improvements have greatly increased its efficiency; the most important difficulty in applying the principle—that of torsional resistance—was overcome by the device of placing a weight just above the centre of gravity, torsional resistance having the tendency to keep the beam in a horizontal position, while the elevation of a weight above the centre of gravity, by its tendency to produce unstable equilibrium (see page 56), exercises an opposite effect—that of inclining the beam to be top heavy, and therefore to tip on either side. If now the weight be made adjustable, by mounting it upon a perpendicular screw, so that it can be raised or lowered, it is possible to arrange these opposite forces so that one exactly neutralizes the other. In this manner sensitiveness is obtained.

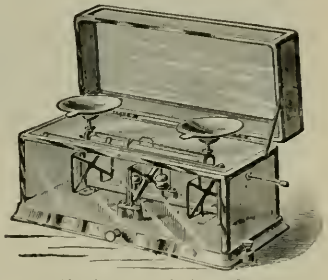
Fig. 20

Frame

Fig. 21

Frame with wire

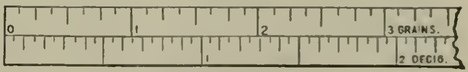
Fig. 22



Torsion prescription balance

In the torsion prescription balance (see Fig. 22) two beams are used, supported upon three frames, each of the latter having a flattened metallic band stretched tightly over its edge. Fig. 20 shows one of these frames, and Fig. 21 shows a frame with the wire stretched upon it. The form of the prescription balance is that of the box scale, enclosed in a glass case; a rider beam graduated upon the upper edge from $\frac{1}{8}$ of a grain to 8 grains and on its lower edge from 0.5 centigramme to 5 decigrammes (see Fig. 23) furnishes a very convenient means of weighing minute quantities without having to use the small weights. The single ball elevated over the central point of support has in the later patterns been replaced by two smaller weights, one on either side of the central frame. These serve the same purpose as the single weight, and do not have the objection that the latter has, of sometimes interfering with the convenient use of the scales when large pieces of paper are placed upon the scale pans to receive a substance to be weighed (see Fig. 24). A base upon which the torsion balance may be placed, containing a drawer, is very convenient for holding weights, powder papers, etc.

Fig. 23

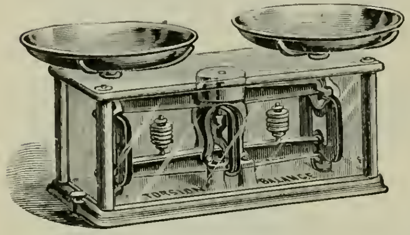


Part of the rider beam

The torsion principle has also been applied to analytical balances with short arms and scales designed to carry heavier loads, as well as counter scales constructed upon the compound lever principle; balances with unequal beams and those having sliding weights upon graduated beams are now manufactured in many different patterns.

Care of the Balance.—The necessity for protecting the delicate mechanism of a balance is frequently overlooked, notwithstanding the possibility of having a fine apparatus irretrievably ruined by want of care in using or cleaning it or in protecting it while at rest. The position chosen for the balance or scales should be upon a level and firm counter, desk, or table, where it will be subjected to little risk of injury from dampness, dust, or corrosive vapors, and where the knife edges will not be liable to become blunted by the jarring produced by heavy mortar practice or other vibration.

FIG. 24



Torsion counter scale

In the finer class of balances protection is afforded by enclosing them in glass cases having sash doors in the front or at the side, and providing against injury from vibration by the use of a lever for elevating or locking the beam, so that the knife edges are not in contact with any surface whatever. To prevent injury from jarring while the balance is in use, by a weight falling on the pan, or other accident, the finest balances are provided with pan supports, which break the fall and serve the additional purpose of quickly arresting the beam, thus saving time while weighing.

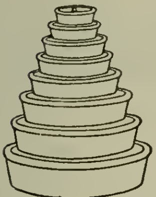
Substances which act on metals, like iodine, corrosive sublimate, etc., and those which are adhesive, like the extracts, should not be weighed directly upon the scale pans, but upon the glass pans which are furnished by the manufacturers, or, if these are not at hand, upon highly glazed paper, care being taken to balance the papers before weighing the substance. In cleaning the scales, great care should be exercised; polishing powders should be used sparingly; a portion is very apt to find its way into crevices and elude detection until an attempt is made to adjust the scales, when the increased weight of one of the sides of the beam leads to its discovery. Frequent cleaning with soft leather is generally sufficient to keep a balance in good order; but if through neglect it becomes necessary to use more active measures, some simple polishing powder for the silver and brass work, with soapsuds for nickel plate, and simple brushing for the lacquered brass, is all that is necessary.

Metallic Weights used in Pharmacy

The weights used by the pharmacist are a very important part of his outfit, and care in their selection and examination is necessary. Economy of the cheese paring order is particularly to be avoided, as the use of cheap, inaccurate weights must lead ultimately to serious consequences. Prescription weights are sometimes seen so worn that the characters on their faces have disappeared, and, *per contra*, weights are to be found with bits of hardened extract and dirt obscuring their characters. A set of standard weights should be kept on hand, so that at least once a year the weights in daily use can be tested

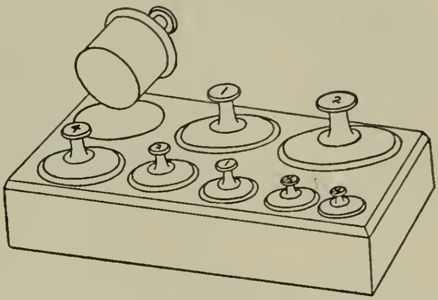
Common avoirdupois weights are usually made of iron, and are of the flat, circular form (see Fig. 25), japanned to prevent rusting; these form a pyramidal pile, and range from half an ounce to four pounds; they may be adjusted by adding to or diminishing the amount of lead which is hammered into a depression in the base of each. These weights are sometimes made of brass in this form, and sometimes of zinc; the latter, however, are brittle and unserviceable. When used for dispensing purposes, the cylindrical weights, known technically as "block weights," are preferable. If the block is made of two kinds of wood glued together, so as to avoid shrinkage, they are very desirable, particularly if each cylindrical hole in the block has been made large enough to hold easily each weight. The advantages of block weights are, that the gaps left by missing weights are readily noticed, and the greater surface of the weight is protected from the action of corrosive vapors when not in use. When the weights are nickel plated, a more imposing appearance is produced by arranging them on an ebonized block in recesses. The disadvantage of this form is that the surfaces are not protected from oxidation, and they need cleaning more frequently. J. M. Maris & Co., of Philadelphia, supply brass avoirdupois weights having a shoulder near the top, these fit into circular openings in a hollow cast iron frame (see Fig. 26), and by this expedient the annoyance common to ordinary blocks, caused by the shrinkage of the wood, is avoided.

Fig. 25



Common avoirdupois weights

Fig. 26



Avoirdupois weights in metal frame

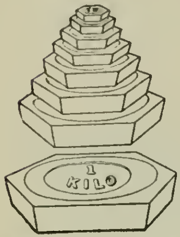
Troy weights may be had either as "block weights" or "cup weights;" the latter are to be preferred, particularly if the block avoirdupois weights have already been procured, for they are then easily distinguished from each other. The cup troy weights range from a quarter of an ounce to thirty two ounces, and have many conveniences (see Fig. 27). When the outside weight is separated, it will be found to have the exact weight of all the rest; if one of the weights is missing, its absence is at once noticed in the incomplete nest; and their compact form is a great recommendation. Weights cannot well be made to occupy less space, while all the inside weights are protected from abrasion and corrosion.

Fig. 27

Cup troy weights

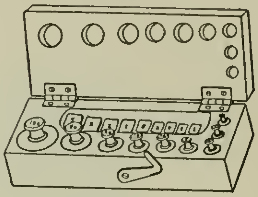
Metric weights may be procured of iron (japanned) for coarse weighing, when they are preferably hexagonal and flat in shape, to distinguish them from the ordinary round avoirdupois weights (see Fig. 28). The most useful for the pharmacist's purposes are undoubtedly the brass weights. Those made by Becker, and contained in a solid block, ranging from one centigramme to one hectogramme, as shown in Fig. 29, are very reliable and convenient.

FIG. 28



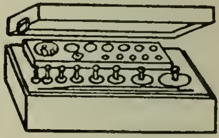
Metric weights (iron)

FIG. 29



Metric weights (block)

FIG. 30

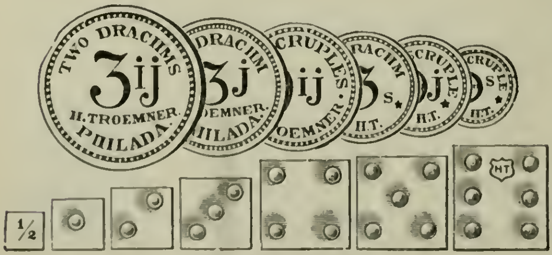


Metric weights (analytical)

For prescription purposes, a very inexpensive yet accurate set is made by Troemner, by which as high as forty grammes may be weighed by using all the brass weights, while ample provision is made for weighing the fractional parts of a gramme.

For analytical purposes, metric weights are almost exclusively used; in the most complete sets the highest weight is one kilogramme, the lowest one-tenth of a milligramme; three riders for use on the graduated scale beam are provided. The weights, from one gramme upward are of brass, finely lacquered; the smaller weights are made of squares of platinum foil, curved so as to permit of being easily handled with the forceps.

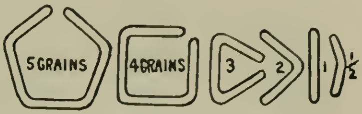
FIG. 31



Prescription weights

Prescription weights.—Too much care can hardly be exercised in the selection of weights to be used in compounding prescriptions. The cost of accurate weights is trifling, yet the market is flooded with weights which are disgracefully inaccurate, and it is greatly to be regretted that the latter find a ready sale. The round, flat, brass "drachm" weights, which have the denomination stamped distinctly on their face in raised characters, are most largely used (see Fig. 31). These range from ten grains to one hundred and twenty grains in weight. The old fashioned square brass "drachm" weights are rapidly passing out of use. The brass foil grain weights are usually inaccurate, and should not be employed, because of their liability to corrosion. Undoubtedly the best grain weights are the aluminum wire weights. These are more easily and quickly distinguished from one another than any other form, and there is less likelihood of dangerous mistakes than from the flat weights, where the denomination is stamped upon the face, often faintly, and is liable to be obliterated by constant use or corrosive contact. The number of sides in the wire weights at once gives the denomination (see Fig. 32). There is such a difference in the shape of these weights, and they are so simply handled practically, that they should be invariably used. The aluminum grain weights, cut out of aluminum plates, are to be preferred to the flat, brass grain weights, because less liable to corrosive action. They are usually more accurately adjusted ; the corners of the weights are clipped, and each weight is pressed into a curved form, so that it may be easily picked up (see Fig. 33).

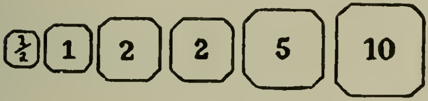
Fig. 32



Aluminum wire weights

Measuring Liquids.—Tinned iron measures nearly cylindrical in shape, but slightly wider at the bottom, are generally used for measuring liquids when the quantity is over a pint. A set of these measures usually consists of four (gallon, half-gallon, quart, and pint). Those made of tinned iron, or of the enamelled sheet iron called agate or marbleized, are greatly inferior to those made of *tinned copper.* Tinned iron measures soon become rusty ; and although a protection is afforded if enamelled, particles of the enamel become chipped off, and the exposed iron soon contaminates the liquids measured in them. Tinned copper measures cost more at first, but they are more economical, because more durable. Care must be taken to protect them from blows which will cause dents, as these may be serious enough to detract from the accuracy of the measures. Fig. 34 shows a copper gallon measure of the usual form. Cylindrical metric measures having a diameter just half their height, of tinned copper or brass, in sets of ten, including dekaliter, half-dekaliter, double liter, liter, half-liter, double deciliter, deciliter, half-deciliter, double centiliter, and centiliter are obtainable. An excellent measure for the laboratory, particularly where liquids are to be carried any distance, is shown in Fig. 35. It was designed by Dr. E. R. Squibb, and has the merit of being less liable to error in measuring than those of ordinary shape, because of the contracted surface at the top.

Fig. 33



Aluminum grain weights

Fig. 34

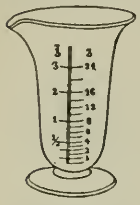
Tinned copper gallon measure

Fig. 35

Laboratory measure

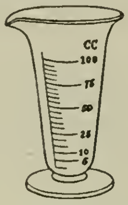
Glass measures are preferred for relatively small quantities of liquids, for, although always subject to loss by fracture, they can be more accurately adjusted to indicate the measure. On account of the transparency of glass, the level of the liquid at any height may be seen through the measure, while porcelain or metallic measures have to be full, or nearly so, to be used.

FIG. 36



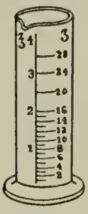
Tumbler-shaped graduate

FIG. 37



Metric graduate

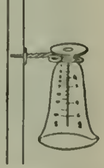
FIG. 38



Cylindrical graduate

Glass graduated measures are almost exclusively used for quantities of one pint or less, and these are of two forms,—*conical* and *cylindrical.* The conical graduate is preferred in practical work because of the greater ease with which it can be cleansed, but cylindrical measures are likely to be more accurate because of their smaller diameter. Thus, if a conical graduated measure has at the f℥ 3 mark a diameter of 3 inches (see Figs. 36 and 37), and the cylindrical graduate (see Fig. 38) a diameter at the same mark of 1 inch, it follows that a trifling error in reading off in the cylindrical graduate, either slightly above or below the line, would be increased if similarly made in the conical graduate by exactly the number of times that the surface of the liquid in the conical graduate exceeds that in the cylindrical graduate at the given point. Formerly it was usual to use exclusively glass measures which had been graduated by hand; but, owing to the large quantities of imperfect graduates found in the market, moulded measures came into use. These, while deficient in the attractive brilliancy of surface characteristic of blown glass, have the substantial merit of greater accuracy. Hodgson's moulded graduated measures were the first to appear, and were largely used for a while, but they have been supplanted by Hobb's graduated measures. In Hodgson's measure the graduations are upon the outside surface of the glass, and their accuracy largely depends upon whether the plunger, which forces the melted glass into the mould, is driven down to exactly the standard depth to secure the proper thickness of glass to indicate the correct capacity. This practical point could not always be attained, owing to the wear of the mould, and occasionally the measures were imperfect. In Hobb's graduated measures this difficulty is overcome by *graduating the plunger*, and when this is done it makes no difference about the thickness of the glass, because if the plunger is correctly graduated, if the proper allowance has been made for contraction in cooling, and if a correct impression can be made upon the inside of the glass, the measure itself must be accurate, and the same result can be indefinitely repeated. An objection arises, however, to this form of graduate in measuring thick or dark colored liquids, for then the graduations upon the inside are often completely obscured. This is sometimes remedied by correspondingly marking them upon the outside with an engraver's wheel. The introduction of the moulded graduates has had the natural effect of improving the accuracy of the blown, hand graduated measures, and it is now unusual to see a measure like one formerly in the possession of the author, which registered 25 percent. too much when filled to the highest graduation. If the custom of returning to the

FIG. 39



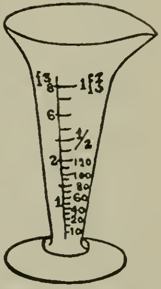
Graduate hook

maker all graduates which prove inaccurate were universal, it would soon be impossible to find an inaccurate one. As it is, reliable graduates can always be had by paying a fair price for them.

Fig. 39 shows a simple method of supporting a graduate after cleaning it. A brass hook is screwed into an upright, preferably over the sink; the prongs are so adjusted that they easily catch the graduate base.

An improvement has been made recently by graduating measures *doubly;* upon one side metric measures are marked, and upon the other ordinary fluid measures, and in addition they sometimes have two lips opposite to each other, for pouring either to the right or left, or for permitting the use of either scale. The testing of the graduation of a glass measure is effected most accurately by placing it upon a perfectly level surface and then pouring into it the proper weight of distilled water at the temperature of 25° C. (77° F.); the fluidounce, weighing 454.6 grains, is preferably taken as the basis. A sufficiently accurate and more ready method is to measure into the graduate from a standard burette or pipette 30 Cc. of water for a fluidounce (29.57 Cc. is the exact equivalent). The extension of the graduating mark into a circle which passes entirely around the graduate is an improvement which obviates the necessity of placing the graduate upon a level place, as the corresponding mark upon the opposite side may be seen through the glass, and the graduate easily levelled even when held in the hand. For measuring smaller quantities of liquids graduated glass tubes of much less diameter should be used, and minim pipettes are more accurate, cleanly, and convenient than the conical minim graduates which are often used, and which possess several radical faults. By referring to Fig. 40 it will be seen that the graduations on the minim measure are necessarily in the narrowest and lowest portion of a comparatively tall measure. Now, if it is desired to measure ten minims of a volatile oil, to add to a pill mass, the surface which the oil must traverse when this measure is inverted over the mortar is so great that probably 20 percent. of the oil will be left adhering to the measure. In those instances of liquid preparations where the smaller liquid is miscible with the larger quantity of diluting liquid, the minim graduate may be rinsed and this loss recovered, but inconveniences are largely overcome and greater accuracy secured by the use of the minim pipette suggested by Dr. E. R. Squibb (see Fig. 41). This in its simplest form consists of a glass tube of small caliber, with its lower extremity somewhat contracted, and having minim graduations upon its side. The pipette is used by dipping the contracted end into the liquid to be measured, and upon applying suction by the mouth at the opposite end the liquid is drawn into the pipette; the moistened tip of the right forefinger is now tightly applied to the upper end of the tube to regulate the flow of the liquid, and a sufficient quantity is allowed

Fig. 40



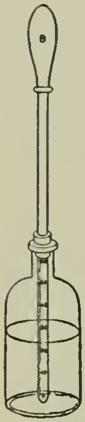
Minim measure

Fig. 41

Minim pipette

to flow out by slightly raising the finger until the height of the liquid corresponds to the measure desired; pressure with the forefinger at once stops the flow, and the accurately measured quantity can be transferred to the bottle, mortar, or graduate by raising the finger and allowing the liquid to flow out. These pipettes may be had of four different capacities, holding 15, 20, 30, and 60 minims, and a reference to the cut will show that a sufficient length of tube above the graduations is left to secure the operator from any risk of getting a poisonous liquid into the mouth, except through extraordinary carelessness. One of the best methods of keeping the pipette ready for use is to have it pass through a perforated cork which fits into a half-pint bottle containing alcohol or water (see Fig. 42), the liquid being renewed when it ceases to be clean. A rubber unperforated tube nipple, inserted on the top of the pipette, has also been suggested to obviate the necessity of using suction with the mouth; it is used by first pushing it down over the top of the pipette until it will go no farther, then compressing the bulb and inserting the tip of the pipette into the fluid, when upon gradually relieving the pressure on the bulb the pipette commences to fill, and if not filled to the mark desired the bulb is pushed upward gently until the end is attained. In the use of tubes or glass measures of small diameter, it will be noticed that two distinct lines are visible on the surface of the liquid. This is due to the capillary attraction of the glass, which causes the edge of the liquid to creep up the sides, and the surface becomes concave and a *meniscus* is formed; the lowest point of the lower zone is usually selected by analytical chemists as the reading point, but it is manifest that a line drawn between the upper and lower zones slightly below the middle would give the most correct reading. Fortunately, the occasions are very rare in pharmaceutical operations where a difference in the method of reading need cause concern.

FIG. 42



Minim pipette with bottle

In administering small quantities of liquids the very convenient *drop* is almost always used. The impression that a drop is equivalent to a minim, and that sixty drops of any fluid are equivalent to a fluidrachm, is widespread. This impression doubtless arose from the fact that sixty ordinary drops of *water* are about equal to a fluidrachm; but many circumstances cause variations in the relative size of drops. Thick viscous liquids, like the mucilages and the syrups, necessarily produce large drops, because the drop adheres to the surface of the glass so long as its weight does not overcome its power of adhesion, while bromine and chloroform, heavy, mobile liquids, having very little adhesion to the dropping surface, produce very small drops, only one-fifth the size of the drop of syrup of acacia. The shape and surface of the vessel from which the liquid is dropped also have an influence in determining the size of the drop. The greater the extent of surface for the drop to adhere to, the larger, proportionally, will be the drop. In order that this subject should have an investigation of a rather wide range, the late Stephen L. Talbot, at the author's suggestion, constructed, after many laborious trials, the following table:

Table exhibiting the Number of Drops in a Fluidrachm of Different Liquids, with the Weight in Grains and Grammes

Specific Gravity

A knowledge of the subject of specific gravity is necessary to the pharmacist, to enable him to identify substances or to judge of their purity, while the physician frequently depends upon it as an aid in diagnosing certain diseases. *Specific gravity is the weight of one body compared with the weight of an equal bulk or volume of another body selected as the standard, both bodies having the same temperature.* In ascertaining the ordinary weight of a body it is simply compared with an arbitrary standard selected by governmental authority, while in determining specific gravity, the body, if solid or liquid, is compared with a standard which is universal,—*i.e.*, an equal bulk of pure water expressed as 1 and taken at a given temperature[1] and atmospheric pressure. In all the methods hereafter detailed, it must be borne in mind that the main object sought for *is the weight of a bulk or volume of water equal to that of the body of which we wish to take the specific gravity.* Archimedes proved experimentally that *a body immersed in a liquid lost as much weight as its own bulk of that liquid weighed;* hence is derived the general rule for taking specific gravity:

Rule.—Divide the weight of the body by the weight of water displaced (loss of weight in water); the quotient will be the specific gravity.

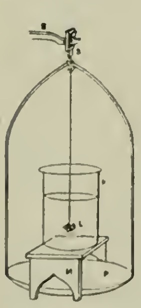
The taking of specific gravity will be considered as follows:

1. Solids insoluble in, but heavier than water.
2. Solids soluble in, but heavier than water.
3. Solids insoluble in, but lighter than water.
4. Solids soluble in, but lighter than water.

1. To take the specific gravity of a solid insoluble in, but heavier than water.

a. With the Balance.—It is customary to recommend a special balance for taking the specific gravity of solids, known technically as the hydrostatic balance; but a good prescription or analytical balance will answer perfectly for practical purposes. The substance, preferably in one piece, is first weighed accurately and the weight noted; a horse hair is then tied around it with a slip knot, and a tight loop at the other end is made, which is attached to the hook at the end of the scale beam; a small wooden bench made for the purpose, or extemporized by taking out the bottom and one of the sides of a small wooden or stiff pasteboard box, is now arranged over the scale pan so that it does not touch it or interfere with its free movement; upon this a small beaker or wide mouthed jar is placed, and two-thirds filled with pure water (see Fig. 43). The horse hair must be adjusted to such length that it will permit of the complete immersion of the substance in the water. Upon weighing the immersed substance, after freeing it from attached air bubbles, it will be at once noticed that it has lost weight, and all that remains to

Fig. 43



Taking the specific gravity of a solid

---

[1] The temperature directed in the U. S. P. (8th Rev.) is 25° C. (77° F.). When not specified, it is understood to mean 25° C. (77° F.); but in many investigations, particularly those conducted in Europe, the temperature selected is that of the maximum density of water, 4° C. (39.2° F.). For practical purposes the temperature adopted by the Pharmacopœia is most useful in the latitude of the United States.

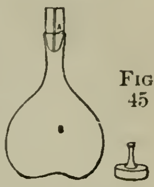
be done is to apply the rule,—divide the weight of the body by its loss of weight in water.

For example, 805.5 grains of copper lose by immersion in water 90 grains; then 805.5 divided by 90 gives 8.95, the specific gravity of the copper. See also Nicholson's hydrometer, page 84.

b. With the Specific Gravity Bottle.—This instrument in its most usual form is a bottle having an elongated, narrow neck, fitted with a ground glass stopper, and holding, when filled, exactly 1000 grains of pure water at a given temperature (see Fig. 44).[1] The reason for selecting 1000 grains for the contents is to avoid the necessity of making a calculation to obtain the specific gravity of a liquid.[2] To use the instrument for a solid substance, the previously weighed body is dropped into the bottle, which is then filled with water at the temperature of 25° C. (77° F.), the bottle carefully dried, and, after the counterpoise (the exact weight of the empty bottle, see Fig. 45) has been placed upon the opposite scale pan, it is weighed. To obtain the *loss of weight* in water of the substance, it is only necessary to deduct the weight of the contents of the bottle (*i.e.*, that of the water and the immersed body) from the weight of the body in air, plus that of the water which the bottle holds when full,—*i.e.*, 1000 grains; the rule is then to be applied,—divide the weight of the body by its loss of weight in water.

FIG. 44

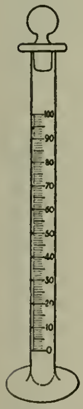
FIG. 45



1000 grain bottle with counterpoise

Example.—A piece of aluminum wire weighs 100 grains; when dropped into a 1000 grain bottle, and the bottle filled with water at the proper temperature, the weight of both is 1062 grains. As the bottle when filled with water alone held 1000 grains, and as the weight of the aluminum in air is 100 grains, both together weigh 1100 grains; hence 1100 grains, less 1062 grains, gives 38 grains, the loss of weight of the aluminum in water. *Apply the rule*, $\frac{100}{38} = 2.63$, sp. gr. The specific gravity of any insoluble powder, like calomel, litharge, etc., may be taken in exactly the same way, but care must be observed to agitate the powder with a small quantity of water in the bottle, before adding the rest, to cause the bubbles of air to escape.

FIG. 46



Graduated specific gravity tube

c. With the Graduated Tube.—A graduated tube is provided in which each space indicates a grain or a gramme (Cc.) of water (or better if graduated in smaller subdivisions); the zero mark should be somewhat above the bottom of the tube, as shown in Fig. 46. Now, if water be poured into the tube exactly up to the zero mark, and a weighed solid body dropped into it, the water will rise in the tube and indicate the weight of a bulk of water equal to that of the substance; this is equivalent to the loss in water. *Then apply the rule*,—divide the weight of the body by its loss of weight in water. It is evident that this method cannot be as accurate as either of those above mentioned, as small differences are more clearly indicated by a good balance than by tube reading.

---

[1] 50 Gramme Specific Gravity bottles are supplied by apparatus dealers for those who prefer metric bottles.

[2] See Specific Gravity of Liquids, page 77.

d. By immersing the Solid in a Transparent Liquid of the Same Density.—This method may be applied where the body is small, is not very heavy specifically, and is insoluble in the liquid. A heavy liquid is chosen, like solution of mercuric nitrate; the solid is found to float on the surface of the liquid, and water is added until the solid neither rises nor sinks, but swims indifferently. The specific gravity of the solid will of course be that of the liquid, which may be ascertained by the specific gravity bottle (see page 77).

2. To take the specific gravity of a solid soluble in, but heavier than water.

A liquid must be selected in which the solid is insoluble, like olive oil, almond oil, petroleum benzin, or oil of turpentine. The specific gravity of the oil having been ascertained, it is used just as if it were water, the object being to find out the loss of weight that the substance suffers when immersed in the oil; this having been obtained, a simple proportion must be made as follows: as the specific gravity of the oil is to the specific gravity of water, so is the loss of weight in the oil to the loss of weight in water. *Then apply the rule,*—divide the weight of the body by its loss of weight in water.

Example.—200 grains of citric acid lose by immersion in oil 115 grains; then, as

Sp. gr. of oil		Sp. gr. of water		Loss of weight in oil		Loss of weight in water	
0.920	:	1.000	: :	115	:	125	$\frac{200}{125}=1.6$, sp. gr. of citric acid.

It is obvious that either the balance, specific gravity bottle, or graduated tube can be used in this case; but it is possible in some cases to coat the soluble substance with varnish and treat it then as an insoluble substance, and thus avoid the use of an oily liquid. A pill of blue mass may be coated with shellac varnish, and then treated as an insoluble substance as in 1, *b*. The practical difficulty, however, is to secure a thin coating which shall be impervious to water.

3. To take the specific gravity of a solid insoluble in, but lighter than water.

The solution of this problem requires the aid of a heavy insoluble body, which is to be attached to the light body, so as to secure the immersion of both. It is plain that if the loss of weight in water of the heavy substance is deducted from the loss of weight in water of both the heavy and the light body, the result must give the loss of weight in water of the light body alone. *Then the rule must be applied,*—divide the weight of the body by its loss of weight in water.

Example.—A piece of paraffin weighs 174 grains, a piece of brass loses by immersion in water 6 grains; when the brass is attached to the paraffin, both together lose by immersion in water 206 grains; by deducting 6 grains (the loss in water of the brass) from 206 grains (the loss in water of both) the loss in water of the paraffin alone is found,—*i. e.*, 200 grains; then $\frac{174}{200}=0.870$, sp. gr. of paraffin. See also Nicholson's hydrometer, Fig. 57.

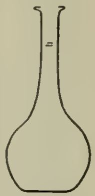
4. To take the specific gravity of a solid soluble in, but lighter than water.

The use of the specific gravity bottle is recommended in cases of this kind, and the process is the same as in 2. The selection of a suitable liquid lighter than the body, and in which it is insoluble, is, however, usually attended with difficulty. The proportion would be, as the specific gravity of the light liquid is to the specific gravity of water, so is the loss of weight in the light liquid to the loss of weight in water. *Then the rule must be applied,*—divide the weight of the body by the loss of weight in water.

Specific Gravity of Liquids

The *specific gravity bottle* (*pycnometer* or pyknometer) is the most accurate instrument for taking the specific gravity of liquids. Fig. 47 shows a practical form; it is used as follows. The liquid to be tested is first brought to the proper temperature, 4° C. (39.2° F.), 15.6° C. (60° F.), or 25° C. (77° F.), according to the standard selected for the bottle; the bottle is filled with the liquid to the mark on the neck, dried carefully, and weighed accurately, using the counterpoise on the opposite pan. If the 1000 grain or 100 gramme bottle has been used, the weight of the liquid at once indicates the specific gravity. Thus, the bottles would hold at 25° C. (77° F.) 1158 grains or 115.8 grammes of hydrochloric acid, 1246 grains or 124.6 grammes of glycerin, 716 grains or 71.6 grammes of ether, and 13535 grains or 1353.5 grammes of mercury, and the specific gravity of each would be respectively 1.158, 1.246, 0.716, and 13.535, thus directly showing the relation to the specific gravity of water, 1. To show the use of an ordinary prescription vial in this process, one containing about a fluidounce may be taken; if it holds 454.6 grains of pure water to a mark upon the neck it will be convenient, because it will at the same time give the weight of a fluidounce of the liquid. It is evident that a bottle holding any moderate quantity may be used in the same way.

Fig. 47



Specific gravity bottle

A fluidounce bottle at 25° C. (77° F.) would hold 526.4 grains of hydrochloric acid, 566.5 grains of glycerin, 325.5 grains of ether, and 6153.0 grains of mercury, and the specific gravity would be obtained by the following proportion:

Example.—As 454.6, the number of grains of pure water that the bottle holds, is to 1.000, the specific gravity of water, so is 526.4, the number of grains of hydrochloric acid that it holds, to 1.158, the specific gravity of hydrochloric acid. 454.6 : 1.000 : : 526.4 : 1.158.

In practice, it is simply necessary to divide the number of grains of liquid that the bottle holds by 454.6 and adjust the decimal point. The accuracy of these bottles depends entirely upon the care with which they are made and used, and it is better to scratch, with a file, two marks upon the neck of a long necked flask, one showing the upper edge of the meniscus and the other marking the lowest point (see Fig. 47). In filling, it is a good practice, after bringing the liquid to the proper temperature, to exceed slightly the quantity indicated by the mark on the neck, and then to make a small roll of filtering paper and neatly absorb the excess by inserting the roll in the neck so that it shall just touch the surface. The more expensive specific gravity bottles have an accurately fitted stopper made of thermometer tube, and hold exactly 100 grammes, or 1000 grains, when the bottle, including the capillary tube of the stopper, is entirely full (see Fig. 44). They are not so convenient as a correctly marked, narrow necked bottle (see Figs. 47 and 49), nor are they practically more accurate. They have to be filled to the brim and the stopper then inserted; this causes an overflow, and the necessary wiping and the natural warmth of the hands usually expand the liquid by raising the temperature, and prevent accurate results.

Fig. 49

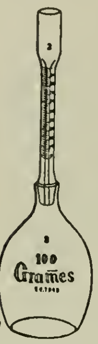


Fig. 48

Squibb's pycnometer with leaden collar

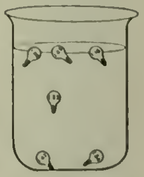
A more elaborate form of apparatus for taking specific gravity is needed for some purposes; for instance, where standards are required for the liquid preparations of the Pharmacopœia or in investigations where great accuracy is necessary. Dr. Squibb has devised the pycnometer shown in Fig. 49, which is admirably adapted for taking specific gravity with the objects above mentioned.

One of these bottles is shown in the illustration; the stopper is a tube lengthened out so that the central channel will permit the bottle to hold the volume of water at any temperature between 4° C. (39.2° F.) and 25° C. (77° F.), thus permitting any of the standards of temperature to be used, the tube being graduated to half-millimeters, and at the top it is enlarged so as to allow room for the expansion of light liquids and to permit the bottle to be loosely closed with a cork while adjusting the temperature, the cork being removed during the weighing. These bottles are all used in a bath of water containing ice when the lower standard temperatures are used; Fig. 48 shows a leaden collar to keep the bottle in position in the bath.

It is necessary to verify the marks of the contents of the bottles from time to time, as the glass flask contracts for a year or two after it has been made. The liquid that it is designed to test is weighed into the bottle, as in the ordinary cases of taking specific gravity; the bottle is loosely corked, loaded with the leaden collar, and set in a bath of water which has been brought to the desired temperature. When the liquid in the bottle has reached the same temperature (and this is indicated by the liquid in the tube remaining stationary, a careful watching of the rise or fall of the liquid in the graduated tube being necessary in order to determine this), the final adjustment is made and the bottle weighed.

Lovi's beads, or *specific gravity beads*, are sometimes used for taking the specific gravity of liquids; they are especially useful in cases where a boiling liquid is to be evaporated until it has a given specific gravity, and in mixing liquids of different densities. They are balloon shaped, hollow globes of glass, of different sizes and weights, having specific gravity figures scratched upon their sides. These figures indicate the specific gravity of a liquid in which the beads swim indifferently; they neither rise nor sink, when not disturbed at the given temperature, if the specific gravities of the bead and liquid are the same. The illustration, Fig. 50, shows their method of use, those heavier than the liquid sinking, those lighter floating,

Fig. 50

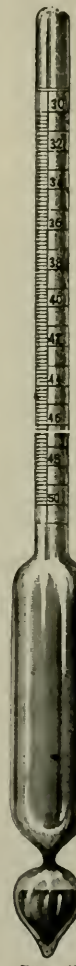


Lovi's beads

while the one supported indifferently (1.25) indicates the specific gravity of the liquid. Lovi's beads may be defined as hydrometers which indicate but one specific gravity.

Hydrometers

Fig. 51



Baumé's hydrometer

Hydrometers, sometimes called *areometers*, are floating instruments which are used to indicate the specific gravities of liquids by sinking to a depth corresponding to the densities of the liquids. Their principle of action was probably first made known by Archimedes, and depends upon the fact that when a solid body is placed in a liquid in which it is capable of floating, it sinks to a certain point, and this floating point is reached when the body has displaced a volume of liquid exactly equal to its own weight. Thus, if an hydrometer has a specific gravity exactly three-fourths that of water, it will sink in water until exactly three-fourths of its volume is immersed ; the same hydrometer would swim indifferently, like a Lovi's bead, in ether having the specific gravity of 0.750, for the obvious reason that the specific gravities of the solid and liquid are identical. Hydrometers may be divided into two classes for convenience of study : 1. Those in which the weight is constant, but the depth of immersion subject to change. 2. Those in which the depth of immersion is constant, but the weight subject to change. To the first class belong nearly all the hydrometers specially useful to pharmacists, and of these, two kinds are generally used, one for liquids heavier than water, the other for those lighter. They are known as Baumé's, Cartier's, Gay-Lussac's, Zanetti's, Twaddell's, but the best of all is the specific gravity scale hydrometer. To the second class belong the hydrometers which are intended to sink, by the addition of weights, to a given mark on the stem, and thus displace a constant volume, like Fahrenheit's, Nicholson's, Guyton de Morveau's, etc.

1. Hydrometers in which the weight is constant, but the depth of immersion subject to change.

Baumé's Hydrometers.—This form is treated first in detail because it was the first one of its class to come into general use, having been originally described by Baumé in his "Éléments de Pharmacie." Two instruments were used by Baumé, one termed *Pèse-Acide* or *Pèse-Sirop*, for liquids heavier than water, the other *Pèse-Esprit*, for liquids lighter than water. This hydrometer, as now made, consists of a glass tube loaded at the bottom with mercury or small shot, having a bulb blown in it just above the loaded end. (See Fig. 51.) A simple cylindrical tube, loaded so as to cause it to assume an upright position in a liquid, may be used as an hydrometer. The only advantage gained in expanding the lower portion into bulbs is one of convenience, that of increasing the volume of the hydrometer, and thus permitting the use of shorter instruments. The graduations upon the stem of Baumé's hydrometer are entirely arbitrary, and were made in the following manner :

For the hydrometer to be used for *liquids heavier than water*, sufficient mercury was added to the lower bulb to cause it to sink in water to a convenient point near the top of the stem ; this was marked 0. The instrument was then placed in a solution containing 15 percent. by weight of common salt, and the point at which it rested was marked 15. The space between these two points was divided into fifteen *equal* parts, and the scale below was extended by marking off similar spaces. *For liquids lighter than water,* the instrument was placed in a 10 percent. by weight solution of common salt, and loaded so that it floated at a point just above the bulb ; this was marked 0. The hydrometer was then transferred to water, the point at which it rested was marked 10, the space between was divided into ten equal parts, and the scale above was extended by marking off similar spaces. The illustrations, Figs. 52, 53, were drawn from Pile's hydrometers, and show the manner of graduating the Baumé scale for both hydrometers, and, in addition, the corresponding specific gravity figures. The Baumé hydrometer is rapidly going out of use, being replaced by an hydrometer having a graduated scale, in which the graduations represent the specific gravities.

Fig. 52

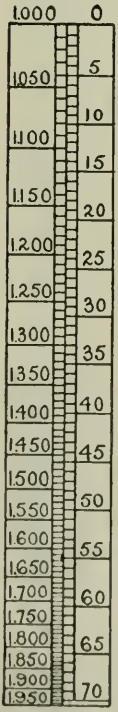


Fig. 53

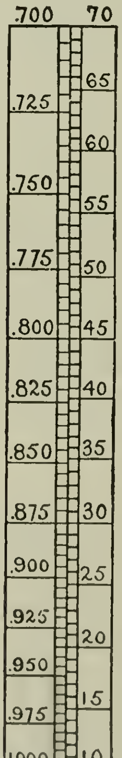


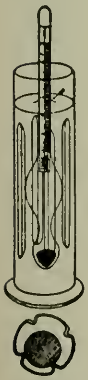
Scales of specific gravity hydrometer

The specific gravity scale hydrometer, which should be used exclusively, is more convenient and useful to the pharmacist. The graduations upon the stem are not arbitrarily chosen, but indicate at once the specific gravity of a liquid when floated in it. Two hydrometers are necessary, one for liquids heavier than water, and one for liquids lighter than water ; for special purposes it is often desirable to have five or six hydrometers, beginning with one for very light liquids and ending with one for very heavy liquids, and if the diameter of the stem is narrow the divisions in the scale are not so close together, and thus a more accurate reading of the graduations is possible and the delicacy of the hydrometer increased. It must be borne in mind, however, that the hydrometer cannot be as accurate an instrument for taking specific gravity as the specific gravity bottle. The adhesion of air bubbles when in use, the liability to variation in the diameter of the stem, the inaccuracies in the scale and the difficulties of adjusting it so as to give correct readings, and the want of uniformity among the makers in fixing the reading point, render it necessary for the pharmacist to verify each instrument and note its error before accepting it for practical use. In selecting an hydrometer with a specific gravity scale, it should be at once noticed whether the graduated spaces are equal. If they are, it is useless to attempt to verify it, as it cannot be accurate, for the degree of the immersion varies with the specific gravity of the liquid, and "equal differences of specific gravity cannot be indicated by equal spaces on the scale, but by the differences of the reciprocals of those specific gravities, or by proportionate quantities." In the illustration shown in Fig. 52, the arbitrary scale of Baumé, made up of equal spaces, is shown immediately in contact with a specific gravity scale. The spaces of the latter gradually increase in size from below upward, and the highest space is nearly four times the size of the lowest. The method of graduating this scale differs with different makers, but by the use of Clarke and Ackland's process it is possible to make a scale without using any other liquid than water if a correct table of reciprocals is employed (see Watts's Dictionary, vol. iii. p. 207). Before any hydrometer is accepted for use, it should be tested by floating it in water at the temperature indicated on the hydrometer, and, the specific gravity of several liquids having been ascertained carefully by the specific gravity bottle, the hydrometer should be floated in the same liquids, and any deviation carefully noted. An hydrometer which registers uniformly one or two points too low or too high need not be rejected, because the error can be added or subtracted each time and the constant error marked on the box for a memorandum; but if an error of any magnitude has to be added to one part of the scale, and another subtracted from another part, it is economy to reject the instrument at once. Hydrometers are usually floated in tall, cylindrical glass jars (see Fig. 54), and it is frequently necessary to cool the liquid by placing the jar in ice water after inserting a thermometer, and, after the temperature has been lowered to the desired degree, observing the point to which the hydrometer sinks in the liquid. It is to be regretted that there is no fixed rule for a reading point; some makers adjust their instruments so as to read from a reflection in the upper part of the meniscus, others (probably the majority) prefer to take the exact level of the liquid, disregarding the meniscus altogether; this may be easily done in all cases where the liquid is transparent, or nearly so, by holding the jar containing the hydrometer at first exactly on a level with the eye, and then glancing slightly below, when a line can be traced which will exactly join the divided surface of the liquid upon either side of the stem. In case of opaque liquids an allowance can be made for the meniscus. The pharmacist should choose one or the other method and adhere to his choice, so that his verification of his own hydrometer may not vary (see Fig. 55, in which the arrow shows the point to read). It is usually best to cool the liquid below the standard temperature adopted for the hydrometer, and then, after wiping the jar, the correct higher temperature may be gradually obtained by grasping the jar with the hands and passing them up and down to warm the liquid. An hydrometer having an elongated bulb with cylindrical sides, as shown in Fig. 56, is more likely to give a false indication if permitted to touch the sides of the

Fig. 54

Hydrometer jar

Fig. 55



Urinometer and jar (Squibb)

jar than one having an oval or globular bulb (see Fig. 55); the latter can touch the jar at only one point, and hence can move freely up and down, while the former may have one side touching the side of the jar for its entire length. To obviate this, Dr. Squibb suggests the use of a jar with four perpendicular indentations in it, and an hydrometer having an oval bulb (see Fig. 55). The points of contact between the urinometer bulb and the indentations in the jar are best shown in the transverse sectional view immediately below the cut of the urinometer.

FIG. 56

Alcoholmeter

The *urinometer* is one of the most useful special applications of the hydrometer; as its name indicates, it is used to take the specific gravity of urine; a special scale, which is easily understood, is sometimes used. The very delicate stem, which hardly permits of the use of specific gravity figures, is divided into sixty spaces, numbered from 0 to 60; by adding 1000 to each of these numbers, and pointing off three decimal places from the right, the true specific gravity is shown. In Dr. Squibb's urinometer the specific gravity is indicated without abbreviation, the number highest on the scale being 1.000, the lowest 1.060, the intervening figures being 1.010, 1.020, 1.030, 1.040, and 1.050.

The specific gravity of urine from healthy subjects ranges from 1.010 to 1.020; that from diabetic patients has a specific gravity varying from 1.030 to 1.060.

The *saccharometer* is intended to take the specific gravity of syrups. The scale is sometimes graduated so as to indicate the percentage of sugar in solution, rarely the actual specific gravity; usually Baumé's scale (*pèse-sirop*) is used. The *elæometer*, a very delicate instrument, is used to take the specific gravity of fixed oil. The *lactometer* is employed in detecting the adulteration of milk with water; it has a limited range, and the scale usually shows the points at which it floats in milk mixed with different proportions of water. Hydrometers are often made for taking the specific gravity of liquids, like petroleum benzin, ether, petroleum, vinegar, wine, beer, solutions of silver nitrate, sea water, etc.; probably the most useful to the pharmacist of all those having special applications is the one made for testing alcohol.

Alcoholmeters may be purchased which combine the thermometer with the hydrometer, as shown in Fig. 56, and the scale frequently has the percentage by volume of absolute alcohol marked opposite the corresponding specific gravity; when graduated so as to show the percentage by weight, they were formerly more useful, on account of the adoption of the principle of parts by weight in the U. S. Pharmacopœia of 1880, thus obviating the necessity of using an alcoholmetrical table or making a calculation.

Tralles's hydrometer is an alcoholmeter having a centesimal scale. It is used by the United States government in gauging spirits, and is in general use by distillers and others. Each division of the scale corresponds to a given percentage of pure alcohol by volume in the liquor. In the United States Dispensatory, 18th edition, page 1881, a table is given showing the value of Tralles's degrees in specific gravity and Baumé's degrees.

Cartier's hydrometer, largely used in France, is merely a modification of Baumé's *pèse-esprit*, or hydrometer for liquids lighter than water; the zero of the scale is the same as Baumé's (10°), but the degrees are not of the same value, 32° of Baumé's scale being equal to 30° Cartier. Dorvault gives the following approximate rule for conversion: Cartier's degrees may be converted into Baumé's by subtracting 10, multiplying the remainder by 0.08, and adding the product to Cartier's degree.

Baumé's degrees may be converted into Cartier's by subtracting 10, multiplying the remainder by 0.08, and subtracting the product from Baumé's degree.

Gay-Lussac's centesimal alcoholmeter has a scale divided into 100 unequal degrees. The zero corresponds to pure water at 15° C. (59° F.) and the 100 mark to absolute alcohol. The advantage of this method is that every intermediate degree expresses the percentage of pure alcohol by measure contained in the spirit. Thus, when the instrument stands at the 50 mark in an alcoholic liquid, it indicates that 100 measures of the liquid contain 50 of pure alcohol.

Sikes's hydrometer is used in Great Britain in the collection of the excise revenue. It is a brass instrument having a spherical bulb, with a weight at the bottom to make it float upright; the stem is divided into 20 parts, and every other division numbered, from 0 to 10. A series of nine weights are furnished with the instrument, numbered from 10 to 90; these are to be added to the weight at the bottom to cause the hydrometer to sink, so that a reading may be had on the graduated scale; this reading added to the number on the weight employed, gives a figure which indicates the strength of the spirit by referring to a table which accompanies the instrument.

Jones's hydrometer is similar to Sikes's, but by many is regarded as an improvement on it.

Dica's hydrometer belongs to the same class.

Twaddell's hydrometer is frequently employed in England, and technical works often quote the degrees of this scale. It is used for liquids heavier than water, and is graduated so that the number of the degree, multiplied by 5 and added to 1000, gives the specific gravity. Thus, 20° Twaddell indicates the specific gravity of 1100 or 1.100; 50° Twaddell, 1250 or 1.250.

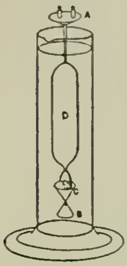
Beck's hydrometer is rarely used or referred to. In this scale 0 corresponds to the specific gravity 1.00, and 30 to that of 0.850; the scale is extended equally above and below 0. For tables, see Bayley's Chemist's Pocket Book, p. 178.

Zanetti's hydrometers have a scale which requires the addition of a cipher to the number of the degree to show the specific gravity.

2. Hydrometers in which the depth of the immersion is constant, but the weight subject to change.

Fahrenheit's hydrometer was one of the first instruments of this class to come into general use. Robert Boyle described, however, in 1675, his "New Essay Instrument," and Fahrenheit's hydrometer was very similar to it in principle; it had but a single mark on the stem, which was surmounted by a small scale pan; weights were placed in the pan to cause the hydrometer to sink to the mark. Now, as this mark indicated the point at which the instrument would float in water at a given temperature when certain weights were placed on the pan, it follows that when it was immersed in a liquid of different specific gravity the weights would have to be changed to float the instrument to the fixed mark; the ratio which this weight bore to the weight used for water gave the specific gravity.

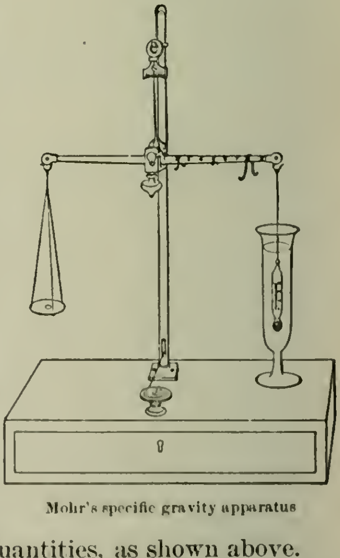
Fig. 57



Nicholson's hydrometer

Nicholson's hydrometer is similar in principle to Fahrenheit's, but is modified so that it can be used for taking the specific gravity of heavy or light solids. Fig. 57 is an illustration of one of the most convenient forms of the instrument; it is usually made of brass; there is a single mark on the stem and a scale pan on the summit. To the lower extremity of the hydrometer two conical cups are attached; their apexes are joined so as to resemble an hour glass; the lowest cone has several apertures at the top, to permit of the escape of air when the instrument is immersed. The weight of the hydrometer is usually so adjusted that a 1000 grain weight is needed on the scale pan to float it to the mark on the stem. Now, to take the specific gravity of a piece of zinc weighing less than 1000 grains, the 1000 grain weight is removed from the pan and the piece of zinc substituted for it, weights are added until the instrument floats at the mark on the stem, and it is found that an addition of 655 grains has been necessary. It is evident that the difference between 1000 and 655 gives the weight in air of the zinc, 345 grains. The zinc is now placed in the upper conical cup and weights are again placed upon the scale pan, and it is found that the zinc has lost in weight 50 grains by immersion in water; the specific gravity is obtained by applying the well known rule,—divide the weight of the body by the loss of weight in water: $\frac{345}{50} = 6.9$, sp. gr. of zinc. The lower cup is used for taking the specific gravity of bodies lighter than water, and is very convenient, the weight of the hydrometer keeping the light body submerged when the lower cup is placed over it. The specific gravity is obtained in the same manner as in the case of bodies heavier than water. One of the advantages of Nicholson's hydrometer is that it can be used in place of a balance for weighing small quantities, as shown above.

Fig. 58



Mohr's specific gravity apparatus

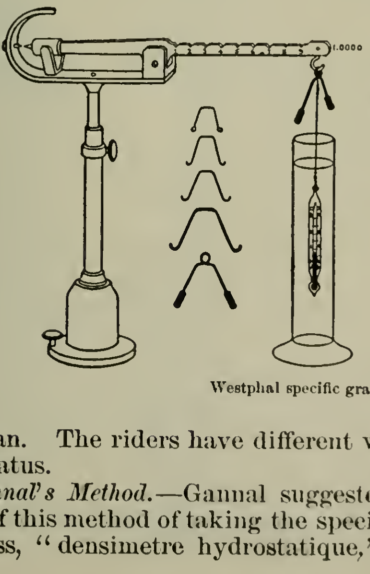
Methods of taking the Specific Gravity of Small Quantities of Liquids.

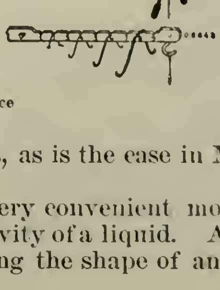
Mohr's Apparatus.—The illustration of this apparatus (see Fig. 58) represents an improved form, yet it is quite possible for a pharmacist to construct one for himself that will answer practical purposes. It will be noticed that one end of the beam is divided into ten equal spaces, and a small glass thermometer is suspended from the extremity by a slender platinum wire, while the opposite scale pan is so adjusted that it exactly counterbalances the thermometer. When the thermometer is immersed in pure water at 25° C. (77° F.), a brass wire weight is placed upon the hook at the end of the beam, and this restores the equilibrium. Now, it is apparent that if a lighter liquid, like alcohol at 25° C. (77 F.), is substituted for the water, the equilibrium cannot be maintained, and the thermometer will sink. The brass wire weight is then to be moved along the beam toward the central knife edge until the balance is nearly restored, and this point will be found at 8, which gives the first decimal figure; still further to approach the equilibrium, a wire weight, one-tenth the weight of the larger one, is pushed along the beam until it rests at the 2 mark, which gives the second decimal figure; while thoroughly to restore the balance the smallest weight (one-tenth of the second) is placed at 5, and thus the third decimal figure is obtained, and the specific gravity of the alcohol is shown to be 0.825. Specific gravities of liquids heavier than water are obtained in the same way, except that the large brass wire weight is left hanging on the hook at the end of the beam and additional weights are placed upon the beam until equilibrium is restored.

A prescription balance could be easily converted into a Mohr's apparatus, and the thermometer replaced by a glass stopper suspended by a horsehair. The thermometer in the improved form of apparatus merely serves to indicate the temperature and act as a convenient weight. In the home made apparatus especial care must be exercised in adjusting the wire hook weight so as exactly to immerse the stopper in water at the proper temperature.

Westphal Specific Gravity Balance.—This balance is more convenient than the Mohr's apparatus because a sliding weight (see Fig. 59) is used on the beam at the left, instead of ordinary weights in the pan. The riders have different weights, as is the case in Mohr's apparatus.

FIG. 59



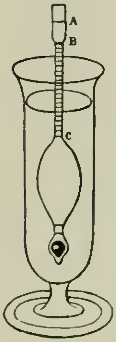


Westphal specific gravity balance

Gannal's Method.—Gannal suggested a very convenient modification of this method of taking the specific gravity of a liquid. A piece of glass, "densimetre hydrostatique," having the shape of an olive, has a volume of 10 cubic centimeters. This is suspended from the hook at the end of the beam of a balance by a horsehair (see Fig. 43), and weights are added to the opposite scale pan until the balance is restored ; it is then immersed in the liquid, and the metric weight required to restore the equilibrium gives the specific gravity without a calculation.

Specific Gravity Pipette.—Grauer recommends the use of a small pipette having a fine orifice at the lower end, and at the upper end a short piece of rubber tube closed by a pinchcock; a mark is scratched on the pipette to show a point to which a convenient weight of water rises (1 Gm.) ; enough of the liquid to be tested is drawn by the mouth through the tube to rise to the mark, and it is then closed ; the weight of the liquid indicates its specific gravity.

Fig. 60



Rousseau's densimeter

Rosseau's Densimeter.—This ingenious instrument is constructed upon the plan of an hydrometer (see Fig. 60). The stem from B to C is divided into 20 equal parts ; the cup shaped tube upon the summit of the stem holds exactly 1 cubic centimeter. When the densimeter is floated in water at the proper temperature, it sinks to the point C at the bottom of the stem ; when the cup is filled with water to the cubic centimeter mark, it causes the instrument to sink to the point B ; this space, B C, being then divided into 20 equal parts, it follows that each division corresponds to $\frac{1}{20}$ of a gramme, or 0.05 Gm. If one cubic centimeter of oil of rose were placed in the cup, it would sink the densimeter to 17.2 divisions of the scale ; then 17.2 × 0.05 = 0.860, the specific gravity of oil of rose.

Table giving the Specific Gravities of Official Substances arranged in the Order of their Densities at 25° C. (77° F.)

Official Name	Specific Gravity	Weight of one Fluidounce in grains
Benzinum	0.638–0.660	290.0–300.0
Æther	0.716–0.717	325.5–325.9

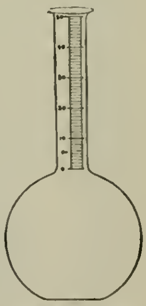
Iodum (17° C.; 62.6° F.)	4.948	
Hydrargyrum	13.535	6153.0

Specific Volume

Specific volume in pharmacy may be defined *as the volume of one body compared with the volume of an equal weight of another body selected as the standard, both bodies having the same temperature.* It is directly the opposite of specific gravity. The temperature chosen is usually 25° C. (77° F.). 1. *To obtain the specific volume of a liquid.*—**Rule,** Divide the volume of the given weight of the liquid by the volume of an equal weight of water, or divide the specific gravity of water (1.000) by the specific gravity of the liquid. Ex. 1403 Gm. of nitric acid measure 1000 Cc., and 1403 Gm. of water measure 1403 Cc.; then $\frac{1000}{1403} = 0.7127$, sp. vol. of nitric acid. 2. *To obtain the volume of a given weight of a liquid.*—**Rule,** Multiply the volume of an equal weight of water by the specific volume of the liquid. Ex. How many fl. oz. are there in 100 oz. av. of nitric acid? 100 oz. av. of water measure 96.21 fl. oz.; then $96.21 \times 0.7127 = 68.56+$ fl. oz. of nitric acid.

Very early in the tyro's experience the fact is recognized that pound bottles designed for different liquids vary in size, a pint bottle, for instance, of water (which may be regarded as a rough standard) holding about a pound avoirdupois; the same bottle, however, would only be four-fifths full if a pound of glycerin were poured into it, and two-thirds full if chloroform were used, while a pound of petroleum benzin would fill the pint bottle, and there would be almost enough to spare to fill another pint bottle. A bottle which would hold a pound of ether would hold two pounds of chloroform, and a pint bottle holding one pound of water holds fourteen pounds of mercury. These facts are, of course, capable of the explanation that the specific volumes of liquids lighter than water are greater than that of water, while those of liquids heavier than water are less. An instructive and useful bottle may be made by selecting a flask with a long and not very narrow neck (see Fig. 61), the bulb of which would hold about 100 Cc. of water at 4° C.; if the neck would hold about 50 Cc. of the same liquid at the same temperature, and a mark was made at the 100 Cc. point and the tube graduated from 100 Cc. to 150 Cc., it would follow that in order to find the specific volume of any lighter liquid within the capacity of the bottle, all that would be necessary would be to pour into the flask 100 Gm. of such liquid at the proper temperature and read off the point to which the liquid rises. A bottle to be used for heavy liquids would have the 100 Cc. mark at the top of the neck and the Cc. graduations below decrease in value. A bottle of limited range may be constructed having the 100 Cc. mark half way between the top of the bulb and the top of the neck. That specific volume is the antithesis of specific gravity is shown by the fact that in order to obtain the specific volume of a liquid the measure of a given weight of the liquid is divided by the measure of an equal weight of water, and (as has been shown heretofore) specific gravity is obtained by dividing the weight of a given measure of the liquid by the weight of an equal measure of water; therefore it follows that when the specific volume of a liquid is multiplied by its specific gravity the product must be 1, or the specific gravity of water.

FIG. 61



Specific volume bottle

Table of Weight and Volume Relations. U. S. P. (8th Rev.)

Specific gravity apparent 25° C. / 25° C.	Specific volume (volume of 1 kilogramme in liters)[1]	Weight of 1 U. S. gallon in pounds avoirdupois[2]	Weight of 100 fluidounces in ounces avoirdupois	Weight of 1 fluidounce in grains	Volume in U. ---

[1] Or of one gramme in cubic centimeters; strictly true only at 0° C. in vacuo.

[2] Multiply these figures by 2 for weight of one U. S. pint in ounces avoirdupois.

[3] Divide these figures by 2 for volume in pints of 100 ounces avoirdupois.

Table of Weight and Volume Relations—*Continued*

PRACTICAL PROBLEMS AND EXERCISES

(Chapter I.—Metrology)

Illustrating the Uses of Weights, Measures, Specific Gravity, and Specific Volume

(The answers to these questions will be found on page 1347)

1. If Dover's powder contains one grain of powdered ipecac, one grain of powdered opium, and eight grains of powdered sugar of milk, how much of each ingredient will be needed to make one pound (av.) ?
2. What is the percentage of each ingredient in Dover's powder?
3. Add the following together, giving the answer in grains: ℥iv, ℈ii, ʒvi, 2 oz.
4. Subtract ʒx from 10 oz.

5. How much postage would be required to send a book, weighing 4lb. 3 oz., to Brazil, the rate being one cent for each 2 oz. or fraction?

6. How many fluidounces are there in a wine gallon?

7. How many minims are there in a pint?

8. In an Imperial pint?

9. How many grains are there in 4 oz. of water?

10. In f℥iv?

11. In ℥iv?

12. How many wine gallons are there in 40 Imperial gallons?

13. How many avoirdupois pounds in 5 wine gallons of water?

14. How many fluidrachms in an Imperial half-pint of water?

15. A physician ordered, as an application to a burn, 4 tablespoonfuls of linseed oil to be mixed with a teacupful of lime water. What are the equivalent quantities in apothecaries' measure?

.16. A traveller was ordered by his physician to take with him on a journey enough of a quinine mixture to last five weeks, taking one teaspoonful three times a day for the first week, one twice a day for the second week, one once a day for the third week, one four times during the fourth week, and one twice during the fifth week. How many fluidounces of the mixture must the apothecary compound for him?

17. A physician wants a pharmacist to make him one fluidounce of a one percent. aqueous solution of cocaine hydrochloride. How will he do it?

18. How much quinine, strychnine, and ferric phosphate would be required to make a pint of elixir of iron, quinine, and strychnine phosphates, so that each teaspoonful of finished elixir should contain $\frac{1}{64}$ of a grain of strychnine, one grain of quinine, and two grains of ferric phosphate?

19. What would an Imperial gallon of rose water cost at the rate of 12 cents a pound (av.)?

20. A merchant offered to exchange 2 oz. of musk, valued at 4 cents per grain, for 20 Imperial gallons of orange flower water, valued at 17 cents per pound. How much would he gain or lose?

21. Express the following: 7.5 meters in millimeters. 22. 806.23 centimeters in meters. 23. Six meters and three decimeters. 24. Twelve meters, five decimeters, four centimeters, and three millimeters. 25. Twelve thousand five hundred and forty-three millimeters.

26. Write one meter and one millimeter.

27. Read 25 Dm.

28. Read 25 dm.

29. Is the equivalent number of centimeters usually read in practice instead of using the term decimeters?

30. Read 1.2 M.

31. How does this practice resemble that in daily use in relation to our decimal system of coinage? (See No. 30.)

32. Read 4263.678 M.

33. Add 816 cm., 732 dm., and 36 mm.

34. What is the difference in length between two roots, one being 5 cm. long, and the other 65 mm. long?

35. Divide 3784.128 M. by 8.

36. How many square millimeters are there in 5 square centimeters?

Note.—In square measure length is multiplied by width ($10 \times 10 = 100$), hence each denomination is increased or decreased by 100 instead of by 10; two decimal places are therefore required to express square measure.

37. Write eight sq. meters, thirty-six sq. decimeters.

38. Write eight sq. meters, thirty-six sq. decimeters, eight sq. centimeters.

39. Write three sq. M., three sq. dm., three sq. cm., three sq. mm.

40. Express in figures twenty sq. millimeters, twenty sq. centimeters, twenty sq. decimeters, twenty sq. meters.

41. Express in figures five hundred sq. meters, five hundred sq. decimeters, five hundred sq. millimeters.

42. How many cubic centimeters in a cubic meter?

Note.—In cubic measure length is multiplied by width and this by thickness, $10 \times 10 \times 10 = 1000$; so that three decimal places are required to express cubic measure.

43. Express in figures sixty-three cubic meters, sixty-three cubic decimeters, sixty-three cubic centimeters, sixty-three cubic millimeters.

44. How many cubic centimeters in a liter?

45. What metric measure of capacity corresponds with a cubic decimeter?

46. How many 100 Cc. bottles will be required to hold five liters of water?

47. A drug merchant having purchased a cubic meter of olive oil, sold from it at different times 100 liters, 87 liters, 375 Cc., 638 liters. How much had he left?

48. In making one kilo. of U. S. 1880 compound spirit of juniper, how many grammes of each ingredient would be required, the formula being as follows: Oil of juniper 10 parts, oil of caraway 1 part, oil of fennel 1 part, alcohol 3000 parts, water 1988 parts?

49. How many grains of each ingredient would be required to make one pound avoir.? (See No. 48.)

50. What percentage of an avoirdupois pound is a troy pound?

51. How much water must be added to a pint of solution of ferric chloride (containing 37.8 percent. of anhydrous salt, specific gravity 1.387) to make the solution contain 10 percent. of anhydrous salt?

52. How much of the above solution of ferric chloride and how much water must be used to make a pint of solution containing 20 percent.? (See No. 51.)

53. If moist opium containing 10½ percent. morphine loses 30 percent. of its weight by drying, how much morphine percent. will it contain when dry?

54. If one pint of a solution contain 704 grains, how much is there in each fluidrachm?

55. If one fluidrachm of a solution contain 3¼ grains, how much is there in 14½ fluidounces?

56. If 8 fluidounces contain 240 doses, how much in each dose?

57. How many doses of 12½ minims in 12½ fluidounces?

58. If 96 minims of water will dissolve 7⅞ grains of salt, how much will one pint dissolve?

59. How much will one pound avoirdupois dissolve? (See No. 58.)

60. How much will one pound troy dissolve? (See No. 58.)

61. If Liquor Acidi Arsenosi contains 37 grains of arsenic trioxide in 8 fluidounces, what fraction of a grain (exactly) is there in a fluidrachm?

62. If Liquor Ferri Citratis (U. S. P. 1890) (specific gravity 1.250) contains 35.5 percent. of anhydrous salt, how much of the anhydrous salt is contained in 1 pint?

63. How much in one fluidrachm? (See No. 62.)

64. If Liquor Ferri Nitratis (U. S. P. 1890) contains 6 percent. of anhydrous salt (specific gravity 1.050), how much of the salt is there in each fluidounce?

65. If Liquor Ferri Subsulphatis (specific gravity 1.548) contains 43.7 percent. of basic ferric sulphate, how much of the salt is contained in one pound avoirdupois?

66. How much in one pint? (See No. 65.)

67. How much in one fluidrachm? (See No. 65.)

68. How many minims would contain 10 grains? (See No. 65.)

69. Liquor Ferri Tersulphatis (specific gravity 1.432) contains 36 percent. of normal ferric sulphate How much in Oi?

70. If Liquor Acidi Arsenosi contains 74 grains of arsenic trioxide in Oi, what quantity of the liquid contains one grain?

71. How many pills of 235 mgm. can be made from a mass weighing 423 grammes?

72. How many cubic inches are there in one liter (1 liter = 2.1134 pints)?

73. What part of a liter is a pint (to four decimal places)?

74. How many Cc. in a cubic foot (1 Cc. being equal to 0.061028 cubic inches)?

75. How many Cc. in a quart (1. L. = 33.815 fl. oz.)?

76. How many pints in one cubic meter (1 deciliter being equal to 3.3815 fluidounces)?

77. How many fluidrachms in a liter?

78. How many grammes in one pound avoirdupois?

79. How many grammes in a quart of a liquid of specific gravity 1.45 (1 gramme = 15.432 grains)?

80. How many milligrammes in one pound troy?

81. How many centimeters in one yard (1 mm. = 0.03937 inch)?

82. What is the weight in grammes of 14 cubic centimeters of mercury, its specific gravity being 13.5?

83. What is the weight in grammes of 555 cubic centimeters of sulphuric acid of specific gravity 1.84?

83a. What is its weight in kilogrammes? (See No. 83.)

83*b*. What is its weight in milligrammes? (See No. 83.)

84. How many meters are there in a mile (1 meter = 39.37043 inches)?

85. How many inches in 1833 centimeters?

86. How many grains of compound extract of colocynth are required to make 144 compound cathartic pills (there being 65 grs. in 50 pills)?

87. How much jalap is contained in one pound avoirdupois of compound powder of jalap (the official process ordering 35 parts in 100)?

88. What percentage must be added to 400 minims to bring the measure up to one fluidounce?

89. If 32.4 grammes be divided into 144 pills, what is the weight of each pill in grains?

90. If 46.656 grammes be divided into 144 pills, what is the weight of each pill in grammes? What in grains?

91. How much valerian must be used to make 4 pints of tincture, so that each fluidrachm shall represent 10¼ grains?

92. If a Seidlitz powder is composed of 35 grains of tartaric acid, 120 grains sodium bicarbonate, and 40 grains Rochelle salt, how much Rochelle salt must be used to make enough Seidlitz mixture to put up one gross of boxes of Seidlitz powders, each box to contain ten doses?

93. How much sodium bicarbonate? (See No. 92.)

94. How much tartaric acid? (See No. 92.)

95. How many deciliters of oil (specific gravity 0.905) will a bottle hold which weighs, when full of water, 1050.5 Gm., the weight of the bottle being 610.5 Gm.?

96. If a body weighs 2.31 kilogrammes in air and 1.76 kilogrammes in water, what is its specific gravity?

97. A piece of lead weighs 148.392 pounds, and measures 12 inches long, 6 inches wide, and 5 inches thick (cu. in. water = 252.+ gr.). What is its specific gravity?

98. A piece of zinc weighs in air 77.88 grains, in water 65.88 grains. What is its specific gravity?

99. What is its specific volume? (See No. 98.)

100. What is the weight of a piece of iron measuring 50 cm. long, 6 cm. wide, and 2 cm. thick, its specific gravity being 7.8?

101. What is the length of a bar of iron 8 cm. wide, 5 cm. thick, its specific gravity being 7.8 and its weight 195 kilogrammes?

102. What is the weight of a piece of iron measuring 4 decimeters long by 1 decimeter wide and 7 centimeters thick (specific gravity 7.8)?

103. One pound av. of lead shot is put into a bottle, and it is then filled with water and found to weigh 25566 grains (the bottle when filled with water alone weighs 19174 gr.). What is the specific gravity of the lead shot?

104. What is the specific gravity of a substance of which 9.7 Cc. equal 40.74 Gm?

105. What is the specific gravity of a liquid of which one pound avoirdupois will measure one pint?

106. If 52.98 Cc. of a liquid weigh 1207 grains, what is its specific gravity, and what is the liquid (Oi = 473.18 Cc.)?

107. If 65.008 Cc. of a liquid weigh 1250 grains, what is its specific gravity, and what is the liquid?

108. What is the weight in grammes of one pint of glycerin (Oi = 473.18 Cc.)?

109. What is the weight in grammes of one fluidounce of glycerin?

110. What is the weight of Oi chloroform in grammes (specific gravity 1.476)?

111. What is the weight of one fluidounce of chloroform in grammes?

112. What part of a liter is a pint (to four decimal places)?

113. What part of a gallon is a fluidrachm?

114. What part of a gallon are 32 minims?

115. What part of one pound avoirdupois are 1¼ ounces troy?

116. What is the specific gravity of a piece of wood which weighs in air 177.45 grains? A piece of brass weighs 68.25 grains when immersed in water. The wood and brass together immersed in water weigh 35.7 grains.

117. A piece of wood (specific gravity = 1.6), when weighed in oil of turpentine (specific gravity = 0.87), loses 217.5 grains in weight. What is its weight? (Its loss in weight (in oil) divided by the specific gravity of the oil is equal to its loss of weight in water. This multiplied by its specific gravity gives its weight.)

118. A bottle full of water weighs 31 ounces avoirdupois; the same bottle filled with oil (specific gravity 0.91) weighs 29 ounces, 245 grains avoirdupois. How many avoirdupois ounces of water will the bottle hold? What is the weight of the bottle?

NOTE.—To find the capacity divide the difference between the two weights by the difference between the two specific gravities.

119. How many Cc. would the same bottle hold? (See No. 118.)

120. What is the weight of a piece of iron 25 inches long, 4 inches wide, and 2 inches thick, its specific gravity being 7.8 (cu. in. water = 252.509 gr.)?

121. What is the capacity in Cc. of a vessel which will hold 2 pounds avoirdupois of glycerin?

122. If one pound avoirdupois of lead, when weighed in water, loses 611 grains, what is its specific gravity?

123. A bar of iron, when immersed in water, loses 13 percent. of its weight. What is its specific gravity?

124. A piece of copper, when immersed, loses $\frac{1}{9}$ of its weight. What is its specific gravity?

125. A troyounce of silver, when weighed in water, weighs 434.72 grains. What is its specific gravity?

126. A druggist proposes exchanging 5 pints of phenol (specific gravity 1.065), valued at 40 cents per pound (avoirdupois), for 5 pints of glycerin (specific gravity 1.25), valued at 32 cents per pound. Does he gain or lose by the exchange, and how much?

To find the specific gravity of a liquid by immersing a solid in it: *Immerse in it a solid of known specific gravity and weight; carefully note its loss of weight when thus immersed; then use the proportion: As its weight in air is to its specific gravity, so is its loss of weight when immersed in the liquid to the specific gravity of that liquid.* If the weight of the solid is made the same number in grains as its specific gravity, its loss of weight, when immersed in the liquid, is equal to the specific gravity of the liquid.

127. A piece of iron weighs 1560 grains; its specific gravity is 7.8. When immersed in syrup it loses 262 grains weight. What is the specific gravity of the syrup?

128. A piece of aluminum weighing 256 grains, having the specific gravity 2.56, loses 82 grains when immersed in a liquid. What is the specific gravity of the liquid? What is the liquid?

129. What is the volume of a block of ice 12 feet long, 8 feet wide, and 2 feet thick? What is its weight, and how many cubic feet of water will it yield when melted, supposing that water upon freezing increases in volume $\frac{1}{15}$? (See No. 120.)

130. How many gallons and parts and how many pounds and parts of water will it take to fill a vessel 14 inches wide, 21 inches long, and 9 inches deep (cu. in. water = 252.509 gr.)?

131. What is the specific volume of mercury?

132. What is the specific volume of diluted sulphuric acid?

133. What is the specific volume of glycerin?

134. What is the specific volume of iodoform (specific gravity 4)?

135. How much (wine measure) will one pound (avoirdupois) tincture of chloride of iron measure (specific gravity = 1.005)?

136. If 65.1 Gm. of Rochelle salt be divided into seven powders, what would be the volume of water equal to the weight of one powder?

137. How much silver nitrate must be used to make 2 fluidounces of a 4 percent. solution of the nitrate? (See No. 17.)

138. A bottle when filled with syrup (specific gravity 1.31) contains 23.58 ounces (av.). How much nitric acid (specific gravity 1.42) will it contain?

139. A bottle when filled with syrup (specific gravity 1.31) weighs 36 ounces, 285 grains (av.), when filled with oil (specific gravity 0.9) it weighs 30 ounces, 219 grains. What is the weight of the bottle? Of the syrup? Of the oil? (See No. 118.)

140. A bottle when filled with syrup (specific gravity 1.31) weighs 34.96 ounces (av.), when filled with nitric acid (specific gravity 1.42) it weighs 36.72 ounces. What is the weight of the bottle, and how much water will it hold? (See No. 118.)

141. A bottle filled with water weighs 32 ounces (av.); when filled with chloroform (specific gravity 1.47) it weighs 39.755 ounces (av.); when filled with acid it weighs 34.64 ounces. What acid does it contain? (See No. 118.)

142. In a mixture of lard 2 pounds, wax 4 pounds, and spermaceti 1 pound, what is the percent. of each constituent in the whole amount?

143. How many grammes of each of the foregoing ingredients would be required to make one kilogramme of the mixture?

144. If I purchase 500 grammes of ether for 75 cents, and sell 4 fluidounces for 50 cents, what percent. profit do I make?

145. If a druggist's pound weight is 65 grains lighter than it should be, what percent. increase of profit does he make upon goods sold by it as compared with a correct weight?

146. What will be the value of 2405.365 grammes of opium at $13.50 per kilogramme?

147. How many fluidounces of creosote are required to fill 4 gross of 5 minim capsules?

148. How much of each ingredient will be required to make 60 grammes of compound morphine powder according to the following formula:

Morphine sulphate	1.5 Gm.
Camphor	32.0 Gm.
Glycyrrhiza	33.0 Gm.
Precipitated calcium carbonate	33.5 Gm.

149. What will be the value of 125 grammes of lactucarium at $12.50 per kilogramme?

150. How many ounces avoirdupois in one pound troy?

151. How many troy ounces in one pound avoirdupois?

152. How many pounds avoirdupois in one gallon of water?

153. How many pounds troy? (See No. 152.)

154. How many pounds avoirdupois in one gallon of honey (specific gravity 1.370)?

155. What percent. of an avoirdupois ounce is a grain?

156. What percent. of an avoirdupois pound is a grain?

157. What factor would you use in converting fluidounces into avoirdupois ounces?

158. What factor would you use in converting avoirdupois ounces into fluidounces?

159. If I sell two-fifths of an ounce of oil of rose for three-sevenths of the cost of the entire ounce, what percent. do I gain or lose?

160. From a one pound can of opium the following quantities have been removed: 3 ounces, 1¾ ounces, 1.64 ounces, 175 grains, 2 grammes. How much opium remains in the can?

161. How many fluidounces will be contained in a box 5 cm. long, 5 cm. wide, and 5 cm. deep?

162. If you received an order to spread a plaster 8 by 12 cm., what size in inches would you give?

163. A druggist orders a five inch funnel, but receives one measuring 12 cm. Is the one sent larger or smaller than the one desired, and how much?

164. If a pint of water weighs 7291.2 grains, how many grains of solid matter are present in a gallon of water containing 58 parts of solid matter in the million?

165. If a prescription calls for 75 pills each to contain 200 mgm. of quinine sulphate, how many grains of quinine sulphate would be required to make the whole number of pills?

166. If I pay $1.00 a kilogramme for a substance which I sell for 10 cents an ounce retail, what percent. profit do I make?

167. If 500 Cc. of official alcohol be mixed with 500 Cc. of water, and the contraction in volume amounts to 30 Cc., what will be the percent., by volume, of official alcohol in the resulting mixture?

168. What will be the cost of the mixture, per pint, with alcohol costing $2.40 per gallon. (See No. 167.)

169. How many Cc. of camphorated tincture of opium represent 1 gramme of morphine, if 1000 Cc. represent 4 grammes of powdered opium (12 percent.)?

170. If tincture of opium is found to contain 1.45 grammes of crystallized morphine in each 100 Cc., how much diluted alcohol must be added to each pint to reduce it to the official minimum strength (1.2 Gm. in 100 Cc.)?

171. How many Cc. of official minimum strength tincture of opium can be made from 123 grammes of granulated opium, assaying 13.25 percent. morphine? (See No. 170.)

172. If 10 avoirdupois pounds of a solution contain 8 avoirdupois ounces of sodium chloride, what is the percentage strength of the solution?

173. How much salt and how much water would be required to make 15 avoirdupois pounds of a 5 percent. solution?

174. If 3 grammes of potassium nitrate are dissolved in 27 grammes of water, what is the percentage strength of the solution?

175. If $\frac{1}{8}$ ounce of cocaine hydrochloride be dissolved in 1 fluidounce of water, what will be the percentage strength of the solution?

176. What will be the percentage strength of $\frac{1}{8}$ ounce troy if dissolved in the same amount of water?

177. How much corrosive sublimate must be used to make 1 pint of a 1-2000 solution?

178. How much must be used to make a liter of a 1-3000 solution?

179. If 1 troyounce of sodium chloride be dissolved in 1 pint of water, what is the percentage strength of the resulting solution?

180. Boric acid is souble in 18 parts of water. What is the percentage strength of a saturated solution?

181. What percent. of sugar is there in a syrup made by dissolving 1 avoirdupois pound of sugar in 1 pint of water?

182. What will be the percent. if 1 pound troy of sugar is used?

183. How much physostigmine salicylate will be required to make approximately 1 fluidounce of a 2 percent. solution?

184. Potassium iodide is soluble in about three-fourths of its own weight of water. What is the percentage strength of a saturated solution?

185. How many grammes of mercuric chloride will be required to make 100 Cc. of a solution, 10 Cc. of which when added to 990 Cc. of water will make a solution containing the equivalent of 1 gramme in 2000 Cc.?

186. If the specific gravity of acetone is 0.79, what will 2 fluidounces weigh in grammes?

187. What is the value of 4 pints of glycerin, specific gravity, approximately, 1.25, at 18 cents per pound avoirdupois?

188. Which is heavier and how much, 1 fluidounce of mercury, specific gravity, approximately, 13.50, or 1 pint oil of turpentine, specific gravity, approximately, 0.850?

189. What is the value of 5 avoirdupois pounds of spirit of nitrous ether, specific gravity 0.820, at 40 cents per pint?

190. What will be the cost of a gallon of extract of witchhazel, if the distillate costs 35 cents a gallon, and 12 percent., by volume, of alcohol, costing $2.75 a gallon, is added to it for preservation?

191. A formula calls for 246 grammes of nitric acid, specific gravity 1.414. On account of the corrosive nature of the acid it is advisable to measure it. How many Cc. will be required?

192. If 1 pint of syrup, specific gravity 1.313, be mixed with 500 Cc. of glycerin, specific gravity 1.246, how many troyounces will the mixture weigh?

193. What size bottle in fluidounces, approximately, will be required to hold 1 avoirdupois pound of ether?

194. Five hundred grammes of chloroform? (See No. 193.)

195. One troy pound of olive oil? (See No. 193.)

196. One avoirdupois pound of bromoform? (See No. 193.)

197. One avoirdupois pound of mercury? (See No. 193.)

198. How much salicylic acid, and how much monohydrated sodium carbonate would you use to make 240 grains of sodium salicylate, when, by referring to the saturation tables of the Pharmacopœia, it will be found that 100 parts of salicylic acid require 45.18 parts of monohydrated sodium carbonate to combine to form 115.97 parts of sodium salicylate?

199. How much of each will be required to make 100 grammes of the salt?

200. What will it cost to make a pound of sodium salicylate, if the salicylic acid costs 50 cents a pound, and the monohydrated sodium carbonate costs 15 cents a pound, allowing 10 cents for labor?

Alligation Applied to Pharmacy

(The answers to these questions will be found in the Appendix)

Rules for ascertaining the quantities of drugs of different percentages of strength, to be used in making a mixture of definite strength; also of liquids where no change of volume takes place when mixed.

Percentages

Rule.— *Write the percentages of the different ingredients in a horizontal row; connect with a line each percentage which is greater than that of the mixture sought with one that is less, and each one that is less than that of the mixture sought with one that is greater; then write the difference between the percentage of the mixture sought and that of each of the ingredients under the percentage of the other ingredient or ingredients with which it is connected by the line. The figures thus placed under each percentage will be found to indicate the proportionate parts (by weight) of each ingredient to be used.*

It is apparent that where there are more than two ingredients there will be an indefinite number of ratios. Either one of the ingredients of less strength than the mixture may vary, and therefore one or more of the other ingredients must vary correspondingly.

The same rules are applicable to liquids of different specific gravities (where no change of volume takes place when they are mixed), writing "specific gravities" in places of "percentages."[1]

Specific Gravities

Rule.— *Write the specific gravities of the different ingredients in a horizontal row; connect with a line each specific gravity which is greater than that of the mixture sought with one that is less, and each one that is less than that of the mixture sought with one that is greater; then write the difference between the specific gravity of the mixture sought and that of each of the ingredients under the specific gravity of the other ingredient or ingredients with which it is connected by the line. The figures thus placed under each specific gravity will be found to indicate the proportionate parts (by measure) of each ingredient to be used.*

1. In what proportion must two quantities of powdered opium, containing respectively 7 and 18 percent. of morphine, be mixed so that the mixture shall contain 16 percent.?

16		*Answer*	*Proof*
7	18	2 parts of 7 percent.	$2 \times 7 = 14$
2	9	9 parts of 18 percent.	$9 \times 18 = 162$
		11 parts	11)176
			16

2. In what proportions to yield a mixture of 12 percent.? (See No. 1.)

3. In what proportions may three quantities, containing respectively 7, 16, and 18 percent., be mixed so that the mixture shall contain 14 percent.?

14			*Answer*		
			6 parts of 7 percent.	=	42
7	16	18	7 parts of 16 percent.	=	112
2	7	7	7 parts of 18 percent.	=	126
4			20 parts		2.0)28.0
6					14

When there are three or more ingredients the proportion of these may be varied indefinitely, as will appear from the following:

In the preceding example suppose that only 1 part of that containing 16 percent., and the same number of parts containing 7 percent. as before be used, it will then require more than 7 parts of that containing 18 percent. to make the mixture contain 14 percent.

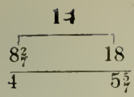
When the quantities of more than one ingredient are given, each quantity may be multiplied by its percentage and the sum of the products divided by the sum of the quantities; this will give the mean percentage of the quantities.

Thus 6 parts of 7 percent. } = 7 parts of $8\frac{2}{7}$ percent.
1 part of 16 percent. }

$6 \times 7 = 42$
$1 \times 16 = 16$
7)58
$8\frac{2}{7}$ percent.

---

[1] Of course, mixed liquids which contract may be allowed to stand until contraction ceases, and sufficient liquid can then be added to make up the intended measure.

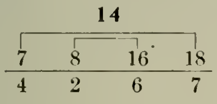


and it will require 4 parts of $8\frac{2}{7}$ percent. and $5\frac{5}{7}$ parts of 18 percent. to make a mixture containing 14 percent. Now if 4 parts of $8\frac{2}{7}$ percent. require $5\frac{5}{7}$ parts of 18 percent., then 7 parts of $8\frac{2}{7}$ percent. will require 10 parts of 18 percent., or 4 : $5\frac{5}{7}$: : 7 : 10; therefore the mixture will be—

6 parts of 7 percent. $6 \times 7 = 42$
1 part of 16 percent. $1 \times 16 = 16$
10 parts of 18 percent. $10 \times 18 = 180$
17)238(14
17
68
68

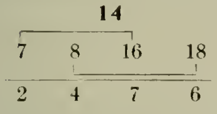
The different percentages may be connected in various ways, care being taken that in every case one larger than the required mixture shall be connected with one smaller, but every one must be connected with some other.

4. In what proportions may four quantities, containing respectively 7, 8, 16, and 18 percent., be mixed so that the mixture shall contain 14 percent.?



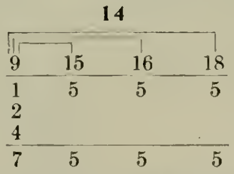
Answer
4 parts of 7 percent. = 28
2 parts of 8 percent. = 16
6 parts of 16 percent. = 96
7 parts of 18 percent. = 126
19 parts 19)266(14

Or,



Answer
2 parts of 7 percent. = 14
4 parts of 8 percent. = 32
7 parts of 16 percent. = 112
6 parts of 18 percent. = 108
19 parts 19)266(14

5. In what proportions may four quantities, containing respectively 9, 15, 16, and 18 percent., be mixed, so that the mixture shall contain 14 percent.?



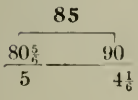
6. In what proportions may five quantities, containing respectively 7, 8, 9, 11, and 16 percent., be mixed, so that the mixture shall contain 12 percent.?

7. How much of each kind of scammony, containing respectively 77 percent., 83 percent., and 92 percent. of resin, may be used to make a mixture containing 85 percent.?

8. How much scammony of 90 percent. must be mixed with 7 ounces of 80 percent. and 5 ounces of 82 percent. to make the mixture contain 85 percent. of resin?

$$\left.\begin{array}{l} 7 \text{ oz.} \times 80 \text{ percent.} = 560 \\ 5 \text{ oz.} \times 82 \text{ percent.} = 410 \end{array}\right\} = 12 \text{ oz. of } 80\tfrac{5}{6} \text{ percent.}$$

12)970
$80\frac{5}{6}$



Then if 5 ounces of the mixture require $4\frac{1}{6}$ ounces of 90 percent., 12 ounces of mixture will require 10 ounces of 90 percent. 5 : $4\frac{1}{6}$: : 12 : 10

7 oz. × 80 percent. = 560
5 oz. × 82 percent. = 410
10 oz. × 90 percent. = 900
22 22) 1870(85
176
110
110

9. What quantities (by measure) of glycerin (specific gravity 1.246) and alcohol (specific gravity 0.816) must be mixed to have the specific gravity 1.000?

1.000

1.246 0.816

184 246

184 glycerin
246 alcohol
430

184 × 1.246 = 229.264
246 × 0.816 = 200.736
430.000

430 ÷ 430 = 1.000

10. What quantities (by measure) of glycerin (specific gravity 1.250) and diluted alcohol (specific gravity 0.928) must be mixed to have the specific gravity 1.000?

11. How much each of alcohol 94 percent. and 60 percent. must be used to make 100 ounces (by weight) of 80 percent.?

80

94 60

20 14

Or, 10 7

17 : 10 : : 100 : 58.82

100.00
58.82 of 94 percent.
41.18 of 60 percent.

When the quantity of one of the ingredients is given, to find the quantities of the other ingredients:

Proceed as before to find the ratios of the ingredients; then by proportion: As the ratio of that ingredient of which the quantity is given is to its quantity, so is the ratio of each ingredient to its quantity.

12. How much alcohol (specific gravity 0.820) and how much glycerin (specific gravity 1.25) must be mixed with 24 Cc. of syrup (specific gravity 1.31) to make 250 Cc. of mixture having the specific gravity 1.000 (no allowance for contraction)?

24

If 430 parts of mixture require 283 alcohol, how much will 226 require?

430 : 283 : : 226 : 148.7 ; then 226 — 148.7 = 77.3

148.7 Cc. alcohol, 77.3 Cc. glycerin, 24 Cc. syrup

When the quantity of more than one ingredient is given, each quantity may be multiplied by its specific gravity and the sum of the product divided by the sum of the quantities; this will give the mean specific gravity of the quantities.

13. In what proportions must 3 pints each of alcohol (specific gravity 0.935 and 0.865) be mixed with alcohol of specific gravity 0.820 so that the mixture shall have the specific gravity 0.835?

3 × 0.935 = 2805
3 × 0.865 = 2595
6 6)5400
900

3 pints of 0.935 and 3 pints of 0.865 are equal to 6 pints of 0.900 (mean specific gravity).

Then,

0.835

0.820 0.900

65 15

13 3

as 3 pints of specific gravity 0.900 are required to be mixed with 13 pints of 0.820 to make the specific gravity 0.835, so 6 pints will require twice 13 pints, or 26 pints of alcohol (specific gravity 0.820), to be added to 3 pints each of 0.865 and 0.935 to bring the whole to specific gravity 0.835.

14. How much opium containing 8 percent. of morphine must be mixed with 10 troy ounces of opium containing 17 percent. to make the mixture contain 12 percent.?

15. How much opium of 16 percent. must be mixed with 1 troy ounce of opium of 12 percent. to make the mixture 13 percent.?

16. How much scammony containing 92 percent. of resin must be mixed with 1 troy ounce of 75 percent. to make the mixture contain 85 percent. of resin?

17. How much alcohol of 35 percent. (by weight) will 1 quart of alcohol of 92.3 percent. (by weight) make on dilution with water?

18. How much opium of $16\frac{1}{2}$ percent. must be mixed with 4 ounces (10 percent.) and 5 ounces (11 percent.) to make the mixture 14 percent.?

19. How much opium of $15\frac{1}{2}$ percent. must be mixed with 3 ounces (9 percent.), $3\frac{1}{2}$ ounces (10 percent.), and $3\frac{1}{2}$ ounces (12 percent.) to make the mixture contain 14 percent.

When the quantity of the mixture and the percentages of the ingredients are given, to find the quantity of each of the ingredients:

Proceed as before to find the ratio of the ingredients, and then by proportion: As the whole amount of difference is to any one difference, so is the amount of the required mixture to the required amount of that particular difference.

20. An apothecary has opium of the following percentages of morphine,—viz.: 8, 11, 16, and 18. How much of each kind may be used to make 10 troy ounces of 12 percent.?

$$\begin{array}{cccc} & \mathbf{12} & & \\ 8 & 11 & 16 & 18 \\ \hline 4 & 6 & 4 & 1. \end{array} \qquad \begin{array}{rcl} 4 \times 8 & = & 32 \\ 6 \times 11 & = & 66 \\ 4 \times 16 & = & 64 \\ \underline{1} \times 18 & = & \underline{18} \\ 15 & & 15)180(12 \\ & & \underline{15} \\ & & 30 \\ & & \underline{30} \end{array}$$

15 : 4 : : 10 : to the required amount of 8 percent.

4 ounces = 1920 grains 15 : 1920 : : 10 : 1280 grains

If 4 parts correspond to 1280 grains, 6 parts will correspond to 1920 grains, 4 parts to 1280 grains, and 1 part to 320 grains; thus,

1280 grains,	8 percent.	15 : 1920 : : 10 : 1280
1920 grains,	11 percent.	15 : 2880 : : 10 : 1920
1280 grains,	16 percent.	15 : 480 : : 10 : 320
320 grains,	18 percent.	
4800 grains = 10 troy ounces.		

21. How many parts by weight of official alcohol (92.3 percent.) must be added to diluted alcohol (41.5 percent.) to make it the strength of 60 percent. by weight?

$$\begin{array}{cc} \multicolumn{2}{c}{\mathbf{60}} \\ 41.5 & 92.3 \\ \hline 32.3 & 18.5 \end{array} \qquad \begin{array}{lcccr} 32.3 \text{ parts}, & \times & 41.5 & = & 1340.45 \\ \underline{18.5} \text{ parts}, & \times & 92.3 & = & 1707.55 \\ 50.8 & & & & 3048.00 \end{array}$$

3048 ÷ 50.8 = 60

22. How much of each to make 1 pound (av.) of 60 percent.? (See No. 21.)

23. An apothecary has two kinds of opium, one $13\frac{1}{2}$ percent., the other 16 percent.; he desires to make 8 troy ounces of 14 percent. How much of the weaker kind must he use?

24. I have two qualities of cinchona, containing respectively $1\frac{3}{5}$ and $3\frac{7}{8}$ percent. of quinine. How much of each shall I take to make the mixture contain 2 percent.?

$$\begin{array}{cc} \multicolumn{2}{c}{\mathbf{2}} \\ 1\frac{3}{5} & 3\frac{7}{8} \\ \hline 1\frac{7}{8} & \frac{2}{5} \end{array} \qquad \begin{array}{lclr} 1\frac{7}{8} \text{ oz.} & = & 900 \text{ grains}, & 75 \\ \frac{2}{5} \text{ oz.} & = & 192 \text{ grains}, & 16 \end{array}$$

25. Two qualities contain $\frac{15}{16}$ of 1 percent. and $3\frac{1}{4}$ percent. respectively. How much of each shall I take to make the mixture contain 2 percent.?

26. Two qualities contain 1.235 percent. and 2.345 percent. respectively. How much of each shall I take to make the mixture contain 2 percent.?

27. Two qualities contain 1.676 percent. and 3.188 percent. respectively. How much of each shall I take to make the mixture contain 2 percent.?

28. Three qualities contain 0.840 percent., 1.848 percent., and 2.688 percent. respectively. How much of each shall I take to make the mixture contain 2 percent.?

29. Having the three qualities, as before (see No. 28), and having 5 ounces of the percentage 0.840, how much of the mixture will it yield?

If	43 parts are equal to 5 oz.,	0.840
	82 parts are equal to 9 oz., 256¾ grains,	2.688
	43 parts are equal to 5 oz.,	1.848
oz.	19 + 256¾ grains	

30. Having the three qualities, as before (see No. 28), with 5 ounces of the percentage 0.840, and wishing to make 32 ounces of the mixture, how much of each of the others must be used?

In this case proceed to find by previous rules how much of percentage 2.688 will be required to mix with the 5 ounces, 0.840, to make the mixture 2 percent.

This amount of mixture subtracted from 32 ounces will give the amount remaining to be made up of the other two percentages,—1.848 and 2.688.

2

0.840	2.688
0.688	1160
86	145

86 : 5 : : 145 : 8.4302

5.0000 oz.	of	0.840
8.4302 oz.	of	2.688
13.4302 oz.	of	2 percent.

Subtracting this from 32 ounces leaves 18.5698 ounces to be made up.

2

1.848	2.688
0.688	152
86	19

86
19
105 : 18.5698 oz. : : 86 : 15.2095 oz. of 1.848

Or, subtracting this from 18.5698 ounces gives 3.3603 of 2.688; adding 8.4302 gives the whole amount used of 2.688 percent. = 11.7905.

31. A solution of ferric sulphate is found to have the specific gravity 1.6520. How much water must be added to make it of the official strength (1.432)?

1.432

	1.6520	1.000
	0.4320	0.2200
Or,	43.20	22.00

43.20 fl. oz. of solution
22.00 fl. oz. of water

32. How much water must be added to 5 pints of solution of ferric sulphate (specific gravity 1.6520) to make it of the official strength?

33. A solution of ferric sulphate is found to have the specific gravity 1.412. How can it be made of the official strength?

The easiest method is to evaporate a portion of it until its specific gravity is considerably above the official strength (1.432), and then mix the proper quantities of the two solutions.

Suppose a portion of it has been evaporated until it has the specific gravity 1.448. How much of each solution must be taken to make 36 fluidounces of specific gravity 1.432?

1.432

	1.412	1.448
	16	20
Or,	4	5

$$\left.\begin{array}{l}\text{16 fl. oz. of 1.412}\\ \text{20 fl. oz. of 1.448}\end{array}\right\} = \text{36 fl. oz. of 1.432}$$

34. How much water must be added to 2 pounds of stronger ammonia water (28 percent.) to reduce it to ammonia water (10 percent.)?

10

28	0
10	18

10 : 18 :: 32 : 57.6 oz. water

35. How much water must be used to make 2 pounds of 10 percent. ammonia water?

36. How much official alcohol (U. S. P. 8th Rev.) (94.9 percent. by volume) must be added to 2 pints of alcohol of 76 percent. (vol.) to make it 81 percent. (vol.) (no allowance for contraction)?

37. How much official alcohol (U. S. P. 8th Rev.) (94.9 percent. by volume) must be added to 2 pints of 70 percent. (by volume) to make the mixture 85 percent. by weight, 87.8 by volume (no allowance for contraction)?

38. In what proportion must powdered nux vomica, assaying 1.03, 1.10, 1.32, and 1.28 percent. strychnine, be mixed in order to obtain a product containing 1.25 percent. strychnine?

39. If 1000 grammes of the mixture are desired, how much of each must be used? (See No. 38.)

40. How much water must be added to 100 Cc. of 92.5 percent. sulphuric acid (specific gravity 1.826) to make the official 10 percent. acid?

41. How much water will be required for 100 grammes of the acid? (See No. 40.)

42. If 1000 Cc. of the diluted acid (specific gravity 1.067) are desired, how many grammes of the strong acid will be required?

43. How much menstruum must be added to 500 Cc. of the fluidextract of coca, assaying 0.58 grammes of alkaloids to 100 Cc., to reduce it to the official strength of 0.50 grammes of alkaloids to 100 Cc.?

44. How many pints of 10 percent. ammonia water (specific gravity 0.958) can be made from 500 Cc. of 28 percent. ammonia water (specific gravity 0.897)?

45. How many pints of the weaker can be made from 500 grammes of the stronger? (See No. 44.)

46. How much milk sugar must be added to 125 grammes of extract of belladonna, assaying 1.48 percent. of alkaloids, to reduce it to the official strength of 1.40 percent.?

47. How much 36 percent. acetic acid can be made from 127 grammes of 99 percent. acetic acid?

48. How many fluidounces of water will be required to dilute 1 pound av. of a 12 percent. solution of potassium hydroxide so as to make it 5 percent.?

49. What will be the total weight of the product in grammes? (See No. 48.)

50. If a druggist has two lots of fluidextract of cinchona, assaying 3.52 and 4.84 grammes of ether-soluble alkaloids to each 100 Cc., how can he mix them so as to obtain a product of official strength (U. S. P. 8th Rev.)?

CHAPTER II

OPERATIONS REQUIRING THE USE OF HEAT

Generation of Heat

THE consideration of the theories which have been advanced from time to time to explain the phenomenon of heat, although very interesting and instructive, cannot be treated of in a work of this character, and the reader is therefore referred to any of the recent works on physics, which are everywhere accessible. The view which is now almost universally accepted is that known as the dynamical theory of heat, in which it is assumed that heat is produced by the constant motion of the particles composing the body, and that heat varies in quantity according as the body is *solid*, *liquid*, or *gaseous*.

It will be convenient to consider the various practical operations and appliances for generating heat under four heads:

1. Operations and forms of apparatus in which *solids* are used in developing heat.
2. Those in which *liquids* are used in developing heat.
3. Those in which *gases* are used in developing heat.
4. Those in which *electricity* is used in developing heat.

Operations and Forms of Apparatus in which Solids are used in developing Heat

Kinds of Fuel.—Under this head is included the very well known employment of solid fuel, as wood, charcoal, anthracite coal, bituminous coal, coke, etc.

Wood is seldom relied upon as fuel in pharmaceutical operations where a regular, well sustained heat is desired, yet from its wide distribution, ready inflammability, and comparative cheapness it is indispensable in kindling a fire. The large quantity of unconsumed carbon which is either lost in smoke or deposited upon vessels that are being heated constitutes the chief objection to its use.

Charcoal is more convenient, although more costly, than wood. It ignites easily, burns readily, and leaves but little residue. On account of its ready combustibility, it is well fitted for operations requiring a quick, strong heat.

Anthracite coal is probably the best form of solid fuel for general use, being the most economical. Its hard, dense structure renders it difficult to kindle, but where a long continued, strong heat is desired it is to be preferred.

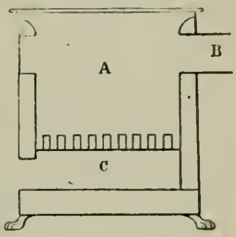
Bituminous or *semibituminous coal* affords a strong heat, but it is not equal to anthracite as fuel for pharmaceutical purposes. Unconsumed carbon is found in the smoke in large quantity, and this is apt to condense on the surfaces of kettles, vessels, etc., which are being heated, and the deposits of soot are uncleanly and often difficult to remove.

Coke, the residue obtained from the distillation of coal at gasworks, is an excellent fuel, and may be used either mixed with coal or by itself. It is more easily kindled than anthracite.

Pharmaceutical Furnaces, etc.—Much ingenuity has been used in the contrivance of various forms of furnaces, ranges, stoves, etc., to meet general or special applications, yet in all there are certain fundamental principles of construction which must be well understood if faults are to be avoided. The elements of a furnace are the *airflue, combustion chamber*, and *vent* or *chimney*, and the relative proportions of these must depend upon the special object sought in the construction of the furnace, and the character of the fuel that is to be used. Fig. 63 represents a sectional view of a pharmaceutical furnace,—C being the airflue, A the combustion chamber, and B the vent.

Coal being the principal solid fuel in use, it will be most appropriate to treat of those furnaces adapted for its combustion, and therefore the chemical constitution of coal and the theory of its combustion must be noticed. Hard anthracite, which is the best kind of coal for pharmaceutical furnaces, usually has a specific gravity of 1.550, and has been shown to consist of 94 percent. carbon, 0.40 percent. hydrogen, and 1.26 percent. oxygen; there are also apt to be present 2 percent. of water and about 2.3 percent. of incombustible impurities or ash, consisting of ferric oxide, silica, alumina, magnesia, lime, etc. The poorer grades of this kind of coal contain from 85 to 90 percent. of carbon. Anthracite may be distinguished from other varieties by its rich, glassy lustre, its peculiar conchoidal fracture, and its hard, dense structure. It burns freely, without black smoke, showing the absence of unconsumed carbon. Soft anthracite or *semi-bituminous* coal has a tendency, when broken into pieces, to assume the form of irregular cubes, and to crumble easily under pressure. It burns freely, but with the production of large quantities of black smoke. The heat produced by its combustion is very strong, and it is largely used in many parts of the United States.

FIG. 63

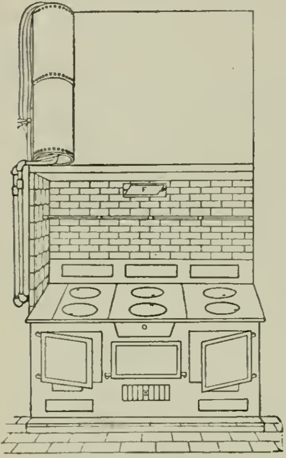


Pharmaceutical furnace, sectional view

The combustion or oxidation of coal requires the presence of a certain quantity of air in contact with the burning coal to furnish enough oxygen to combine properly with the carbon of the fuel. The result of the combination is carbon dioxide, CO_2, and carbon monoxide, CO, both of which are gases. It is very important to provide means of escape for these gaseous compounds, as they are both poisonous, and the former is a decided non-supporter of combustion. Theoretically, it has been calculated that one hundred and fifty cubic feet of air are necessary to consume perfectly one pound of coal in an ordinary furnace, but practically, because of the obstruction of the ashes, which prevents the thorough contact of the air with all parts of the glowing carbon, nearly double this amount is necessary.

Stoves and ranges are now so universally used that it would be needless to multiply illustrations of them. The proper selection of such as are suited to the special uses of the pharmacist must be left to individual decision, and will depend upon the space that can be spared and the character of the work that is to be done. One important feature should not be overlooked, however, in this connection,—*i.e.*, the addition of a boiler or waterback, whereby a constant supply of hot water can be had. Where stoves are used, this can generally be effected by having a circulating hot water boiler in a convenient corner, the pipes conveying the hot water being heated in the upper part of the combustion chamber of the stove. If sufficient space can be appropriated, a range is very useful, particularly if a sheet iron sliding door can be lowered over the front to enclose the space. Now, when a communicating flue, controlled by a damper, is made to enter the chimney from the top of this space, operations can be conducted here that would otherwise be impossible, noxious vapors being at once carried off by the flue. Fig. 64 represents an ordinary range which is well adapted for many pharmaceutical operations. The front has been removed, in order to show the construction more clearly. This front is of sheet iron, and is hinged to the shelf which supports the boiler; it extends half way over the top of the range, and when the damper is opened, the vapors arising from operations conducted on the top are carried up the chimney. The hot water boiler is connected by pipes with the cold water supply in such a manner that the cold water circulates through pipes which surround the combustion chamber, and, after becoming heated, ascends into the boiler.

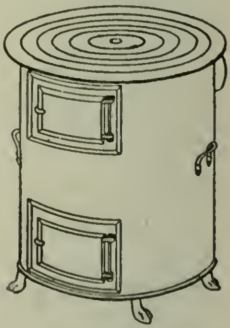
Fig. 64



Pharmaceutical range

Fig. 65 shows a durable pharmaceutical furnace made by Mershon's Sons, which has proved very useful in practical work. The body of the furnace is of wrought iron; it is lined with firebrick, and the top is composed of a series of rings, which permits of the use of various sized kettles, evaporating dishes, etc. It has two cast iron doors, the upper one being especially useful, as it permits the ready feeding of coal to the furnace while a kettle or dish is being heated, without disturbing the latter. Fig. 63 affords a sectional view of the same furnace, and it will be noticed that the combustion chamber, A, is sufficiently deep to contain a considerable body of ignited coal and permit the introduction of hot water pipes. The proportion of the airflue, C, is well arranged, while the vent, B, has sufficient capacity to serve all pharmaceutical purposes.

Fig. 65



Pharmaceutical furnace

The merits of this furnace are that the greater part of the heat rises and is available for heating the vessel placed on the rings, the heavy lining of firebrick preventing lateral radiation to a great extent, and, while it has all the advantages of a stationary furnace, its position can be changed repeatedly if desired, the relative proportion being so well adjusted that, while it is very sensitive to an increase or decrease of draught, a moderate heat may be as steadily maintained as the intensity of a strong fire.

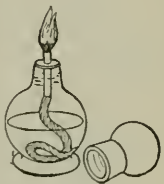
A drying closet can be adapted to this stove by which the waste heat may be utilized. This will be described in a chapter on Desiccation.

Operations and Forms of Apparatus in which Liquids are used in developing Heat

The liquids which are most used in pharmaceutical operations for heating are alcohol, methyl alcohol, petroleum, or coal oil, and petroleum benzin, or gasoline. All of these liquids contain carbon and hydrogen, while alcohol contains 34 percent. of oxygen in addition.

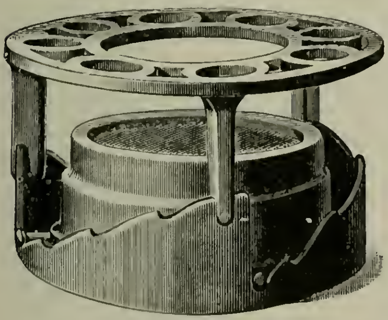
Alcohol burns with a blue flame, which does not deposit soot, and the heat produced is intense. It is in many respects the best liquid to use for generating heat in small operations, but the expense attending its use in this country is a serious objection. Refined *methyl alcohol* or *columbian spirit* has nearly all of the advantages of alcohol when used for burning in lamps, and it is much cheaper than ethyl alcohol. It should, however, never be used as a solvent in pharmaceutical preparations, as it is a dangerous liquid when taken internally, and too much caution cannot be exercised to guard against its improper use. In burning alcohol it is more economical to use a glass spirit lamp, which is provided with a ground glass cap (see Fig. 66), than an extemporaneous lamp made from an ordinary bottle. In the latter the loss by the evaporation of the alcohol from the wick, which is exposed when the lamp is not in use, is considerable. The older forms of alcohol lamps, such as Berzelius's, Mitchell's, etc., have almost gone out of use, being superseded by improved forms. Fig. 67 shows one of the simplest of these very convenient spirit lamps. Alcohol is poured upon the brass wire gauze, which sinks into and is absorbed by the asbestos, or mineral wool, with which the body of the brass lamp is filled ; a lighted match is now applied to the gauze, which retains sufficient spirit to ignite, and a strong heat is at once obtained, the large extent of surface of the gauze producing a solid blue flame. The great advantages of spirit lamps of this kind are that, all parts being of metal, accidents from breakage are avoided, while explosions cannot occur, as neither the alcohol nor its vapor is confined in a tight receptacle, and if the lamp is upset accidentally no spirit can be

FIG. 66



Spirit lamp

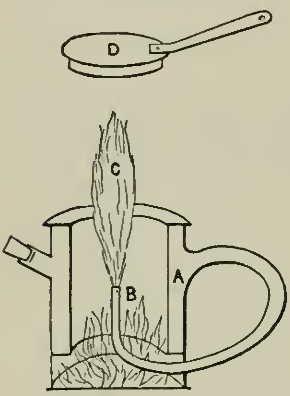
FIG. 67



Metal spirit lamp

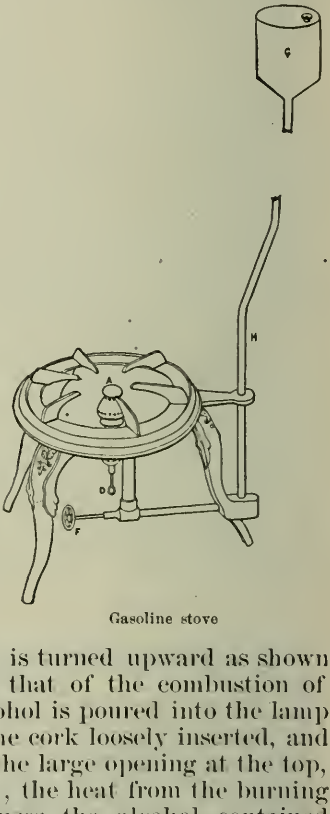
spilled, because it is absorbed by the asbestos. The lamp may be raised or lowered so as to increase or decrease the quantity of heat applied to the vessel. Many modifications of this simple contrivance have been introduced which are elaborate and useful.

Fig. 68



Russian blast lamp

Fig. 69

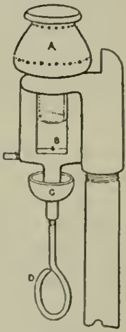


Gasoline stove

The so-called Russian blast lamp is one of the best contrivances for generating an intense heat. It is useful when glass tubes of large diameter are to be bent, or in crucible operations. A sectional illustration is seen in Fig. 68. It is made of sheet copper, and consists of a partially jacketed cylinder, A, with an opening on one side for introducing the alcohol, and on the opposite side a bent, tapering tube, B, which pierces the cylinder below the jacketed portion, and is turned upward as shown in the cut. The principle of action is that of the combustion of the *vapor* of the spirit. If sufficient alcohol is poured into the lamp through the side opening to half fill it, the cork loosely inserted, and half a fluidounce of alcohol poured into the large opening at the top, and then a lighted match dropped into it, the heat from the burning alcohol in the bottom of the lamp causes the alcohol contained between the jacketed sides to boil, and the vapor, having but one means of escape, rushes out by the tapering, bent tube, and at once ignites and produces a powerful upward blast. The flame, C, may be at once extinguished by putting the cover, D, over the central opening.

Petroleum benzin, or *gasoline*, is now used for heating purposes, and Fig. 69 shows one of the most convenient stoves for employing this cheap but very volatile hydrocarbon. The difficulties in the use of the very inflammable and often dangerous liquids of this class for heating have been here largely overcome. To avoid a smoky, luminous flame the *vapor is burned in contact with air*, while to prevent explosions the reservoir for the liquid is elevated and placed four or five feet away from the ignited vapor. Fig. 69 shows the stove, and Fig. 70 an enlarged view of the burner. The reservoir, G, is filled with gasoline, care being taken at the same time to see that the valve F is closed. When the burner is to be lighted, the valve F is opened slightly, and the valve D turned very carefully, so that a small quantity of gasoline shall flow from B over the sides and collect in the cup, C. When C is full, both valves, F and D, are turned off, and a lighted match applied to C. The burning gasoline will heat the burner, A, and when all of the liquid in C has been burned and the flame extinguished, the valve D is turned on slightly and a lighted match applied at A. The parts surrounding B being hot, the gasoline *is vaporized*, and passing upward through the burner, A, issues through the numerous circular openings and is ignited. The upward current of air caused by the heat mixes with the gasoline vapor and supplies the oxygen necessary to produce a perfectly blue and intensely hot flame, the size of which is regulated by the valves D and F. When fairly ignited, F is slightly opened, and D is used to control the flame by turning to the right or left.

Fig. 70



Gasoline stove burner

Although this stove is safe in careful hands, the volatile and very inflammable character of the hydrocarbon must be constantly borne in mind. In a large laboratory in the southern part of Philadelphia these burners were exclusively used, an elevated tank in the yard supplying the gasoline to the gaspipes, which are conveniently laid around the sides of the room and communicate with the burners on the tables.

Kerosene, or *coal oil*, is so widely known as a refined petroleum product used for illuminating and heating purposes that any extended notice of its properties in a practical work would be superfluous; as it is heavier in specific gravity and has a much higher flashing point[1] than gasoline, it is much safer for popular use. For many years the only kind of a coal oil stove available for druggists' use were wick-burners. In these, the oil is poured into a reservoir in the base of the stove; the upper part is surrounded with perforated tin, which admits air to the flame and acts as a protection; the wicks, which are flat and wide, have corresponding chimneys, by which the heat is conveyed to the vessel that is to be heated. The disadvantage common to all coal oil stoves using wicks is that the chimneys have to be high enough to secure perfect combustion and prevent smoking, and this removes the vessel that is to be heated so far from the flame that quick heating is almost impossible; in addi-

Fig. 71

Wickless blue flame coal oil stove

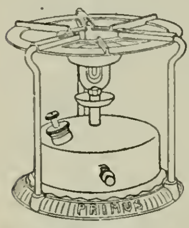
---

[1] By this term is meant the temperature at which coal oil begins to give off inflammable vapor which forms an explosive mixture with air. This temperature, fixed by the laws of different states, varies from 43.3° to 65.5° C., (110° to 150° F.).

tion to this, the wicks require constant attention, and imperfect combustion frequently results even when care is exercised.

The introduction of the "wickless blue flame oil stove" marked an era in practical methods of generating heat. Fig. 71 shows a good form. The stove must stand upon a level surface, for if it does not the coal oil will not flow properly. The cylindrical reservoirs on the side are supplied with an automatic feeder, whereby a uniform quantity of oil is furnished to the burner. The principle upon which this kind of a stove operates is that of *burning the vapor* of the oil (see gasoline stove, Fig. 69), and the control becomes an important factor. A lighting ring containing asbestos is first saturated with oil by turning one of the valves, and when a lighted match is applied sufficient heat is soon generated to cause the coal oil to burn with a blue flame without smoke or odor. Fig. 72 shows a smaller wickless coal oil stove which is very efficient.

Fig. 72



Wickless blue flame coal oil stove

Operations and Forms of Apparatus in which Gases are used in developing Heat

Gas.—The extensive employment of manufactured illuminating gas and the growing use of natural gas as sources of heat for pharmaceutical and other purposes render necessary a somewhat extended notice of gas in this connection. Illuminating gas was frequently called carburetted hydrogen, but it is really a mechanical mixture of various gases, some of which produce luminous flames and others do not; besides the hydrocarbon, CH_4 (carburetted hydrogen), which is the principal constituent, it contains condensible hydrocarbons, hydrogen, carbon dioxide, carbon monoxide, aqueous vapor, and traces of oxygen and nitrogen. Gas is usually produced by the destructive distillation of gas coal, while coal tar, gas liquor, and coke are the liquid and solid by-products, and these are now exceedingly useful as the sources of valuable manufactures in the arts. Gas which is fitted for illuminating purposes must have its composition modified by admixture with air before it is fit for heating purposes; this may be best illustrated by the examination of an ordinary fishtail gas flame. In Fig. 73 it will be noticed that three zones are visible,—the lower or dark central zone, which is not luminous and not at all hot, because the gas is not fairly ignited; A, the luminous zone, where the emission of light is due to the suspension of minute particles of incandescent carbon in the flame, caused by the incomplete combustion of the gas; and the outer non-luminous zone, or "mantle" which fringes the flame, and where the particles of carbon coming in direct contact with the air are entirely consumed, the commonly accepted theory being that the oxygen in the air unites chemically with the incandescent carbon particles, producing the invisible gases carbon monoxide and carbon dioxide.

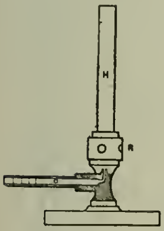
Fig. 73

Gas flame

Soon after gas came into use it was discovered that the properties which rendered it most valuable as an illuminator prevented its use as a source of heat, because of the deposition of the particles of soot from the luminous portion of the flame upon vessels that were to be heated. Dr. Duncan, of Edinburgh, showed that if gas properly mixed with air was made to enter at the bottom of a tall tinned iron cylinder, the upper end of which was covered with wire gauze, it would burn when ignited above the gauze with a blue, smokeless flame. The unnecessarily long cylinders (sometimes thirty inches) which were originally used were soon replaced by others of the length of five or six inches, for the sake of greater convenience. This discovery was at once utilized, and gas stoves and burners for various purposes came into use immediately.

Bunsen burners are more frequently used in simple operations than any other form (see Fig 74). The coal gas issues from a small orifice, O, near the base, passes up through a brass tube, H, four inches high, and is ignited at the top of this tube; four large circular openings surround the small orifice at the base, and these may be closed either wholly or in part by a perforated brass ring, R; this permits the regulation of the supply of air, which mixes with the gas as it ascends the tube, and a blue, smokeless, intensely hot flame may be produced; if the perforated ring is turned so that the air openings are closed, a luminous, smoky flame results. One of the objections to the ordinary Bunsen burner is that, after being used for a time under a low gas pressure, when the tube becomes hot the flame will sometimes recede and the gas become ignited at the lower orifice. This may usually be avoided by gradually turning the brass perforated ring, so as to admit less air to suit the diminished pressure. Morton corrected this receding of the flame by contracting the orifice of escape at the top to about two-thirds of the area of the tube. That the length of the perpendicular tube does not materially affect the smokeless character of the flame may be proved by the use of the convenient little burners shown in Figs. 76 and 77. These are made by the Buffalo Dental Manufacturing Company, and have proved very useful at the prescription counter. Bunsen burners with the tube arranged horizontally have grown in favor because they are less likely to be overturned, and if they have a broad base they will easily support a large vessel. Fletcher's radial burner (see Fig. 78) has the merit of having no loose parts, and, as the casting is well annealed, it is well adapted for

Fig. 74



Bunsen burner

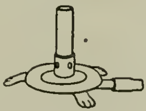
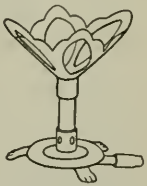
Fig. 76



Short burner

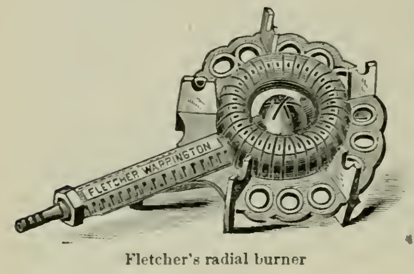
Fig. 77



Short burner with support

rough usage, the gas issuing from narrow slits cut radially in the raised circular burner; the flame is solid and non-luminous. No gauze is needed to distribute the heat. In Fig. 79 is shown a very compact and useful gas burner, well adapted for the dispensing counter, it is of the horizontal Bunsen type, and is furnished with an attachment for distributing the flame, and three short legs for supporting the vessel that is to be heated.

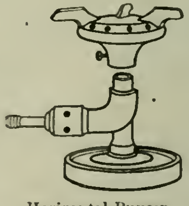
Fig. 78



Fletcher's radial burner

In many localities outside of cities and towns, gas made by vaporizing gasoline and mixing air with it is used for illuminating purposes. It is made by gas machines, as they are termed, the air pump, operated by weights and pulleys or by a water wheel, being usually located in the cellar of the residence or building, while the gasometer is buried underground at a safe distance. This gas is very satisfactory, but it has been only within a few years that it has been utilized for heating purposes. Special burners are required when this gas is used as an illuminant, and they require some adjustment at first to secure the proper proportion of air. Fig. 80 shows the Springfield laboratory burner, which gives a very hot, blue flame with this kind of gas, and it may also be used with ordinary gas. The milled head at the base of the burner is used to control the quantity of the gas passing through, while by revolving the burner itself upon the thread of the screw by which it is connected with the base, the quality of the gas is determined,—*i.e.*, the proper proportion of air is admitted.

Fig. 79



Horizontal Bunsen burner

Fig. 80

Springfield laboratory burner

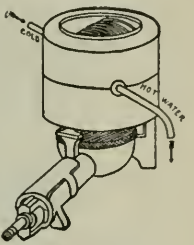
Fig. 81

Economy gas stove

Gas stoves are now made in such variety that it seems difficult to make a judicious selection for general pharmaceutical work. The error most frequently made is in the choice of those which are intended to produce only very high temperatures. It is very seldom that a heat of great intensity is desired in pharmaceutical operations. The chief points to be secured in a good gas stove are—1, a smokeless flame; 2, a strong, firm, indestructible frame that will easily support a large or small vessel and is not easily overturned; 3, an easy and quick adjustment, whereby either a strong, well sustained heat or a low, diffused heat may be obtained. Prof. Parrish devised a pharmaceutical stove which had these qualifications, but it is not made at present. Fig. 81 shows one which is known in commerce as the Economy gas stove. It is made by the American Meter Company, and of all of the gas stoves that have been used by the author, this is the one which is in every way most suited for pharmaceutical operations. It has a broad, low, strong base, and cannot be easily overturned, and a double ring burner, so arranged that either the small ring or both the small and large rings may be used. As it is only about four inches high, when placed upon the laboratory counter a vessel which is upon it and being heated is not elevated so that it cannot be conveniently stirred. It is nine inches square, and its consumption of gas when both rings are lighted is about ten feet per hour.

One of the greatest conveniences that a pharmacist can have at a dispensing counter, where a large supply of hot water cannot be had from a boiler, is the water heater shown in Fig. 82. If hot water is desired, the pipe at the top is connected with a hydrant, the water turned on, and the gas burner lighted below; in a few seconds warm water, and in a minute or two hot water, will run from the lower pipe. Many kinds of hot water apparatus are now to be had based on this principle. Fig. 83 shows a convenient hot water generator, well adapted for furnishing a supply of hot water in pharmacies which have not access to the waterback of a range, but can use gas. In the illustration it is shown attached to an ordinary circulating boiler, and it can be depended upon to furnish a large quantity of warm water. It is made by the American Meter Company.

FIG. 82



Water heater

The advantages of the use of illuminating gas as a source of heat may be summed up as follows: 1. It may be made to furnish a clean, smokeless flame. 2. It is cheap when compared with alcohol and other sources of heat, and is particularly economical in large cities. 3. The supply is unremitting, and the inconvenience of continually supplying fuel, which is always present in other forms of stoves, is not experienced here. 4. The supply is under almost perfect control, and, after once regulating the flow suitable for a continuous operation, little apprehension need be felt, during the operator's enforced absence, of an injurious rise or fall in the temperature.

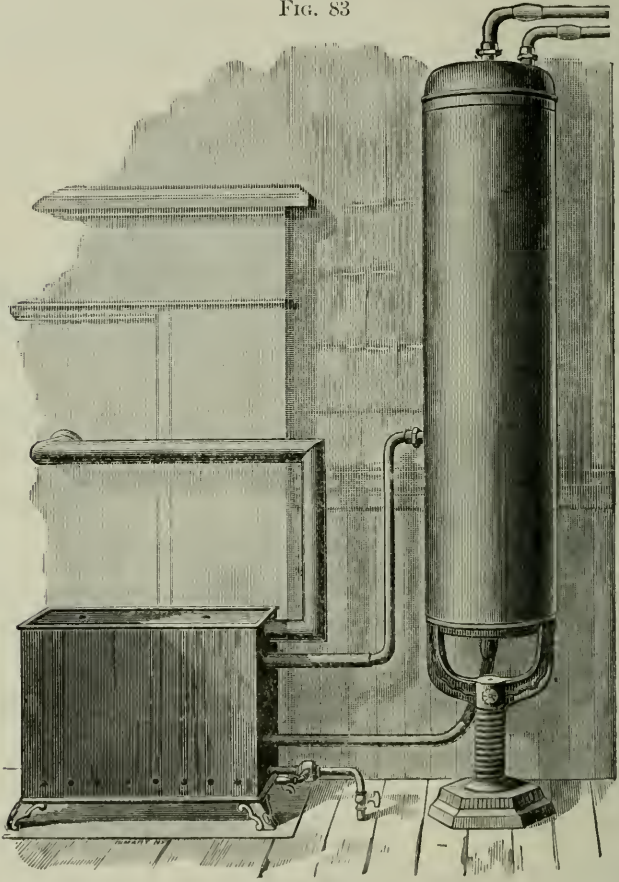
Operations and Forms of Apparatus in which Electricity is used in developing Heat

Electricity as a Source of Heat.—The enormous use of electricity as a source of light has naturally turned the minds of inventors to devising means of using it for heating purposes. Unless, however, there happens to be an electrical plant near by, this method cannot be used economically by the pharmacist, and, if illuminating gas is available, electric heating on a large scale is unprofitable. In many city stores lighted by electricity it will often be found that for convenience, cleanliness, and ease of application electrical stoves have an advantage. Fig. 84 shows a simple electrical stove which can be used for small operations. The current flows through fine wires of highly resisting metal embedded in fireproof insulating cement in the base, and the heat produced by the resistance warms the top plate of the stove.

Methods of measuring Heat

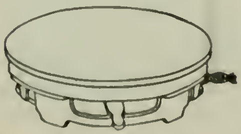
To measure degrees of temperature in pharmaceutical operations thermometers are used exclusively. A thermometer may be described as an instrument consisting of a glass tube having a capillary bore, with a cylindrical or globular bulb blown at the end, the bulb and a part of the stem containing a liquid (usually mercury), and the tube being mounted upon a graduated scale, or the tube itself graduated, in order to measure the degree of expansion of the liquid when subjected to the influence of heat. Unfortunately, the value of the degrees of thermometers in common use is not the same, there being no less than three arbitrary scales,—Centigrade, Fahrenheit, and Réaumur, the latter rarely used in English speaking countries.

FIG. 83



Hot water generator

FIG. 84



Electrical stove

The *Centigrade*, or Celsius, scale is best adapted for scientific work; it is given the first place in the U. S. P. (8th Rev.). The freezing point of water is zero, 0°, and the boiling point is 100°; the intervening space is divided into one hundred equal parts (see Fig. 85).

The *Fahrenheit* scale is much the most largely used in this country and Great Britain, and until the 1880 revision of the U. S. Pharmacopœia it was used exclusively in pharmacy. The Centigrade degrees in the Pharmacopœia are followed by those of Fahrenheit enclosed in parentheses, as 100° C. (212° F.). In Fahrenheit's thermometer the freezing point is 32°, and the boiling point is 212°, the intervening space being divided into one hundred and eighty equal parts (see Fig. 86). In Réaumur's thermometer the freezing point is 0°, and the boiling point is 80°.

Fig. 85

Centigrade thermometer

Fig. 86

Fahrenheit thermometer

Fig. 87 shows a convenient and cheap form of thermometer for pharmaceutical uses, but on account of its having a paper scale it should not be used for measuring temperatures above 300° F. as the paper will be charred.

In Figs. 88, 89, and 90 the three thermometers are shown together to facilitate comparison. The lowest figures indicate the freezing points of each, the highest the boiling points.

RULES

1. *To convert Centigrade degrees into those of Fahrenheit*, multiply by 1.8 and add 32.

2. *To convert Fahrenheit degrees into those of Centigrade*, subtract 32 and divide by 1.8.

Choice of Thermometers.—It is important that the practical pharmacist should possess a good thermometer. The best form is one in which the graduations are made on the surface of the tube. The diameter of the instrument should be the same throughout its entire length; this permits its convenient use through perforated corks in distillations and other operations where it is necessary to observe temperature, and it is not so easily broken (see Fig. 85). The thickness of the glass of the bulb is not a matter of indifference. If too thick, the thermometer will not respond quickly to changes of temperature, while if too thin, the risk of fracture is very great. The bore of the tube should be flat or elliptical, and perfectly uniform throughout. The absence of air in the tube may be known by the descent of the mercury to the lowest part of the tube when the thermometer is inverted. A strip of opaque, white enamelled glass behind the bore of the tube is of great assistance in reading the indication quickly. It is a good practice to send a thermometer to be officially tested,[1] and then to reserve it as a standard for correcting ordinary instruments. As glass usually reaches its limit of contraction in three years, such a thermometer should be at least this old before it is sent.

Fig. 91

Clinical thermometer

Fig. 91 illustrates one of the most valuable forms of the thermometer; it is called a *clinical* thermometer. The glass is triangular instead of cylindrical, and the capillary orifice is flattened so as to enlarge the diameter of the surface of the mercury, in order that it can be read easily. The normal temperature of the human body is 98.5° F., and the physician, by inserting the bulb of the thermometer under the patient's tongue and allowing it to rest there for a minute, can easily ascertain the presence or absence of symptoms of fever.

Melting Point.—By this is meant the temperature at which a substance melts or fuses. It is used as a means of identifying a body or of proving its purity. The U. S. P. (8th Rev.) cites the melting point of many bodies (see table below). Melting points may be taken with an apparatus like that shown in Fig. 92. The melted substance is drawn into the small tube and allowed to cool, or the end of the tube is sealed. The tube is attached by a rubber band to a thermometer, and both immersed in a bath of some convenient liquid. The whole is gradually heated, and the point at which the substance melts is noted. Figs. 93 and 94 show Bensemann's method of collecting a fusible body by holding the tube horizontally until the melted body cools. When heated carefully the exact point at which it melts can be seen by the liquid flowing down the side.

CHAPTER III

USES OF HEAT

THE consideration of the uses of heat in pharmacy will follow naturally the preceding chapter upon its generation and measurement, and the subject may be properly treated of under two classes,—viz., 1, those operations in which comparatively high temperatures are required, and, 2, those which require moderate or low temperatures. It will be readily noticed that the latter class will embrace nearly all of the more important pharmaceutical operations in which heat is employed.

Operations in which comparatively High Temperatures are required.—In this class of operations must be placed some which seem to be in danger of becoming lost arts through the growth of special methods, which are now conducted on a large scale by manufacturers, who supply the products of their skill so cheaply that the home made apparatus is often produced at a pecuniary loss. It will, nevertheless, be found useful to refer briefly to these operations, for a certain amount of knowledge will frequently be of service to the practical worker in emergencies and on special occasions.

The Use of the Blowpipe.—A blowpipe in its simplest form is a metallic tube, usually of brass or copper, slightly conical, gradually tapering to a minute orifice, the narrowest portion being curved so that the axis of the orifice is at right angles to that of the principal portion of the tube. It is used by placing the widest end in the mouth, and inserting the other end into the edge of the flame, and forcing a current of air through the tube, with the effect of increasing the intensity of the flame by converting it into a miniature blast. Some skill and practice are required to produce an unremitting current of air, and this is effected by keeping the muscles of the cheeks distended and constantly supplying air from the lungs as it is needed. When the blowpipe is used with a luminous flame, the interior of the flame, owing to the carbon not being wholly oxidized, has the power of deoxidizing or reducing oxides, while the outer flame has opposite or oxidizing properties. A piece of lead glass tube held in the inner flame will be blackened through the reduction of the lead oxide to the metallic state; if this stain is held in the outer flame the metal is reoxidized, dissolves in the glass, and the glass again becomes transparent. The blowpipe is

FIG. 99

Plattner's

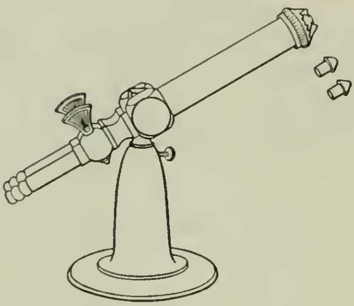
FIG. 100

Plattner's (dissected)

useful in pharmacy in working and bending glass, in testing fusible chemical substances, in soldering apparatus, etc. The various forms of blowpipes in common use are shown in Figs. 95 to 100.

The gas blowpipe, shown in Fig. 101, furnishes an excellent and very powerful blast which is capable of delicate adjustment. It has a universal ball and socket joint, which enables it to be used in any position. The very convenient foot bellows, shown in Fig. 102, may be used in connection with it for producing the blast. The sides of this bellows are of stout leather, and the reservoir of air beneath is obtained by stretching and fastening a circular piece of thin rubber cloth over the lower orifice and preventing too great expansion and rupture by enclosing it in a net. This form, with the reservoir below, is preferable to that formerly in use, which had the rubber cloth above; the advantages are greater protection against injury from falling articles, and less obstruction to the valves through drawing in dust from the floor.

Fig. 101



Gas blowpipe

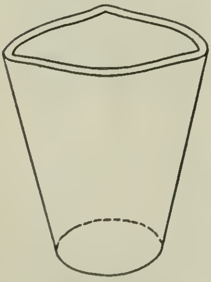
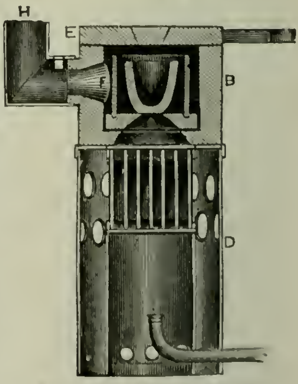
Foot bellows

Fig. 103



Hessian crucible

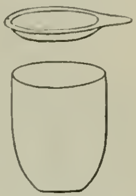
Fig. 104



Fletcher's gas crucible furnace

Crucible Operations.—A crucible is a cup-shaped vessel made of platinum, silver, black lead, iron, porcelain, wedgwoodware, or clay, and intended to withstand a very powerful heat. It is used for fusing metals or heating metallic oxides or organic substances, and is very useful in chemical analysis. The Hessian crucible (see Fig. 103) is the cheapest. It is unfitted for delicate operations, for, although capable of withstanding great heat, its porous character permits the ready absorption of many substances. The black lead crucible is more expensive. It is less porous, is infusible, and has the merit of bearing great changes in temperature without risk of fracture. Porcelain or wedgwood crucibles are fragile, and have to be very gradually cooled to prevent breakage. Fletcher's gas crucible furnace (see Fig. 104) is very useful in this connection. Of the metals used in making crucibles, platinum is superior to all. Its well known power of resisting fusion, its cleanliness, and its non-liability to be acted upon by most chemical substances render it invaluable to the chemist, notwithstanding its costliness (see Fig. 105). For lifting a hot crucible from the furnace, crucible tongs are employed (see Fig. 106).

Fig. 105



Platinum crucible

The following processes require the application of high heat:

1. *Ignition*, in the sense in which it is used in the Pharmacopœia and by chemists generally, is the process of strongly heating solid or semisolid substances, the residue left at the conclusion of the process being the object sought. The U. S. P. (8th Rev.) quantitative tests for potassium bitartrate, sodium benzoate, and sodium citrate afford examples of the use of this process.

2. *Fusion* is the process of liquefying solid bodies by the application of heat without the use of a solvent. The melting of wax, and the preparation of moulded silver nitrate, are familiar examples of this process.

3. *Calcination* is the process of separating volatile substances from fixed inorganic matter by the application of heat without fusion. Its principal application in pharmacy is in the expulsion of water and carbon dioxide from carbonates, as shown in the processes for making magnesia, lime, etc.

Fig. 106

Crucible tongs

4. *Deflagration* is the process of heating one inorganic substance with another capable of yielding oxygen (usually a nitrate or a chlorate); decomposition ensues accompanied by a violent, noisy, or sudden combustion. Deflagration is used in making some of the salts of antimony and arsenic, and in some qualitative analytical examinations.

5. *Carbonization* is the process of heating organic substances *without* exposure to air until the volatile products are driven off, and the residue assumes the black color characteristic of free carbon or charcoal. The manufacture of boneblack and wood charcoal afford good illustrations.

6. *Torrefaction* (known also as roasting) is the process whereby organic substances have some of their constituents modified by the application of a degree of heat somewhat less than that necessary to carbonize them. The most familiar example of this process is the roasting of coffee. Rhubarb in coarse, dry powder, when subjected to torrefaction, loses its cathartic properties, but retains its astringent qualities, and is known as *Torrefied Rhubarb.*

7. *Incineration* is the process of strongly heating organic substances *with* access of air until all the carbon is consumed, the ashes which remain being the object sought. The process is frequently used in

analysis to determine the amount of fixed matter in an organic substance.

8. *Sublimation* is the process of separating a volatile solid substance from one which is not volatile by the application of heat. A special chapter on this subject will be found in the succeeding pages.

Operations requiring Heat in which Lower Temperatures are used

In this class of operations will be found the most important of those requiring the application of heat; almost all medicinal substances have their properties altered by the action of heat, and many cases are met with where it is necessary to moderate the heat carefully in order to prevent the decomposition or destruction of the active agent; for the purpose of controlling heat various baths are used, as the sand bath, oil bath, solution bath, steam bath, water bath, etc.

Baths.—The *sand bath* is usually an iron vessel of hemispherical or other convenient shape, containing dry, clean sand (see Fig. 107); the vessel to be heated is embedded in the sand, and the bath is then heated to the required degree. The object of this form of bath is to equalize the temperature, and to prevent a too sudden rise or fall of heat whereby unequal expansion or contraction might cause fracture to a glass or porcelain vessel being heated. Iron wire clippings have sometimes been substituted for sand, with doubtful advantage, however.

Fig. 107

Sand bath

The practical error usually made by inexperienced operators in the use of the sand bath is in permitting too large a body of sand to rest between the bottom of the vessel to be heated and the flame; this results in an unnecessary waste of heat.

The *oil bath* is designed to furnish a regulated temperature below 260° C. (500° F.). A fixed oil is the medium usually employed for communicating the heat, but one of the best substitutes for oil is petrolatum. Most fixed oils, when heated above 177° C. (350.6° F.), evolve disagreeable fumes.

In fractional distillation on a large scale, oil baths are often used to control temperature, and the fumes arising from the heated oil are carried off by a pipe to the chimney.

The Glycerin Bath.—In order to avoid the disagreeable odors arising from hot oil, glycerin is sometimes substituted. Acrolein, an acrid, volatile product, however, is produced if glycerin is heated nearly to boiling. A temperature of 250° C. (482° F.) can be maintained in a glycerin bath without much inconvenience.

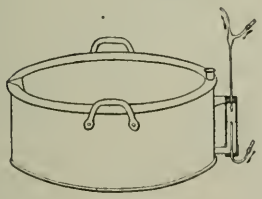
Salt water baths are sometimes used in special operations; their principle of action depends on the fact that the boiling point of a liquid is raised in proportion to the quantity of fixed salt dissolved in it. Water, as is well known, boils at 100° C. (212° F.), but if common salt is dissolved in water until it ceases to take up any more, and a saturated solution is produced, it is found that this solution does not boil until the temperature of 108.4° C. (227.1° F.) is reached. The following table shows the boiling point of certain saturated solutions as determined by Legrand and others:

Table of Boiling Points of Saturated Solutions of Various Salts

Salt	Boiling Point		Salt	Boiling Point	
	C.	F.		C.	F.
Sodium Chloride	108.4°	227.1°	Sodium Acetate	124.4°	256°
Ammonium Chloride	114.2°	237.6°	Potassium Carbonate	135°	275°
Potassium Tartrate	114.7°	238.5°	Calcium Nitrate	151°	303.8°
Potassium Nitrate	115.9°	240.2°	Potassium Acetate	169°	336.2°
Sodium Nitrate	121°	249.8°	Calcium Chloride	179°	354.2°

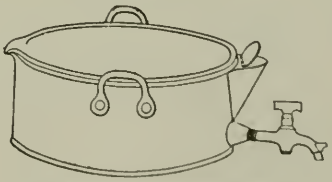
The *water bath* is one of the most useful of all the forms of pharmaceutical apparatus for regulating temperature, and the frequency with which it is directed to be used in works of authority indicates its importance as a necessary implement in the equipment of every pharmaceutical laboratory. Almost all the water baths used by pharmacists are extemporized, and these are generally crude and inconvenient; two dishes usually suffice, one of them somewhat larger in diameter than the other. Water is poured into the larger dish, and the other dish, containing the liquid to be heated, is placed in the water and the heat applied; the room is soon filled with the escaping steam, and in winter the condensation of the moisture upon the windows is alone a sufficient inconvenience to render it undesirable. Fig. 108 shows a tinned copper water bath in which this annoyance is overcome. The water level has at its lowest point a piece of block tin tube soldered in; this extends half way up the glass tube in the inside, while a perforated cork at the upper end of the glass tube permits the insertion of another piece of block tin tube; the upper tube connects with the cold water faucet and terminates in the smokeflue or with the outside air; the vapor arising from the boiling water either passes off into the chimney, as shown by the arrow, or is condensed, the loss being supplied by a small stream of water from the cold water faucet, shown by the arrow pointing downward; the lower block tin tube acts as an overflow, the excess of water being carried off by a rubber tube into the sink; all possibility of the water bath "boiling dry" is thus obviated. Vapors from the liquid in the water bath may be carried off by a hood (see Fig. 148). A simple water bath may be made by encasing a tinned copper round bottomed dish in one of larger diameter having a flat bottom. Water is poured in through a tubulure in the top, and it is replenished as required. Fig. 109 shows a similar water bath, a porcelain evaporating dish taking the place of the copper one. It is useful where a metallic

FIG. 108



Water bath

FIG. 109



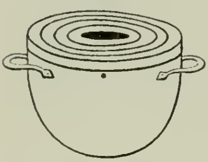
Water bath (porcelain dish)

dish would be acted on by the substance to be heated. A water bath intended for the smaller operations of analytical chemistry is shown in Fig. 110. The different sizes of the rings render it convenient for vessels of various shapes and sizes. It will be necessary to allude frequently hereafter to the uses and modifications of the water bath.

The Use of Steam in Pharmaceutical Operations

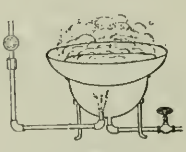
The scope of this work will not permit of any extended consideration of the use of steam in technical pharmacy, yet it is of vital interest to be acquainted not only with the theories underlying its employment, but also with the apparatus used in its practical application.

FIG. 110



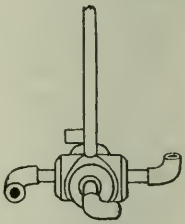
Copper water bath

FIG. 111



Open steam bath

FIG. 112



Steam distributor

When water is heated to the boiling point and steam is produced, a certain amount of heat is absorbed (or apparently lost). This has been termed *latent heat*. When steam comes in contact with surfaces having less heat than itself, it is condensed, water is produced, and the latent heat becomes *sensible* (or reappears), thus proving the well established physical law that *when a liquid assumes the gaseous state, a certain fixed and definite amount of heat disappears; and, conversely, when a gas or vapor becomes a liquid, heat to a corresponding extent is evolved.* Watts has illustrated this as follows: "When water at 0° C. is mixed with an equal weight of water at 100° C., the whole is found to have the mean of the two temperatures, or 50° C. On the other hand, 1 part by weight of *steam* at 100° C., when condensed in cold water, is found to be capable of raising 5.4 parts of the latter from the freezing point to the boiling point, or through a range of 100° C. Now, $100 \times 5.4 = 540$; that is to say, steam at 100° C. in becoming water at 100° C. parts with enough heat to raise a weight of water equal to its own (if it were possible) 540° of the Centigrade thermometer, or 540 times its own weight of water one degree of the same." When water passes into steam the same quantity of sensible heat becomes latent. A consideration of these facts in physics leads to the practical application of steam as a transmitter of heat, whereby heat from any source may be absorbed by steam and carried through suitable pipes to the vessel designed to be heated. If this vessel is filled with a cold liquid, the latent heat of the steam is rapidly communicated to the liquid, the steam is condensed, and the result is this most convenient and economical method of producing a temperature which is capable of being regulated with great exactness.

Steam Baths.—These may be divided into two classes: 1, those in which steam is used without pressure; 2, those in which steam is used under pressure.

1. *The Use of Steam without Pressure.*—In many cases open steam, as it is termed, is used (see Fig. 111). The pipe which conveys the steam from the boiler is conducted to the bottom of a hemispherical kettle, and the liquid to be heated is poured into a dish of larger diameter, which is placed upon the top; the steam is turned on, and as it condenses is carried off by the drip pipe. A temperature of about 100° C. (212° F.) can usually be maintained by this method.

Sometimes the steam pipe is conducted directly from the top into the liquid to be heated. A steam distributor, as shown in Fig. 112, may be used at the end of the pipe near the bottom of the kettle; it is made by screwing a cross upon the end of the pipe, and an elbow to each arm of the cross; the steam issues usually with some force from each elbow and effectually stirs up the liquid, and rapidly produces a uniform temperature in it. The principal disadvantages about using steam in this way are the noise at first produced by the contact of the hot steam with the cold liquid, and the increase in bulk of the liquid through the condensation of the steam.

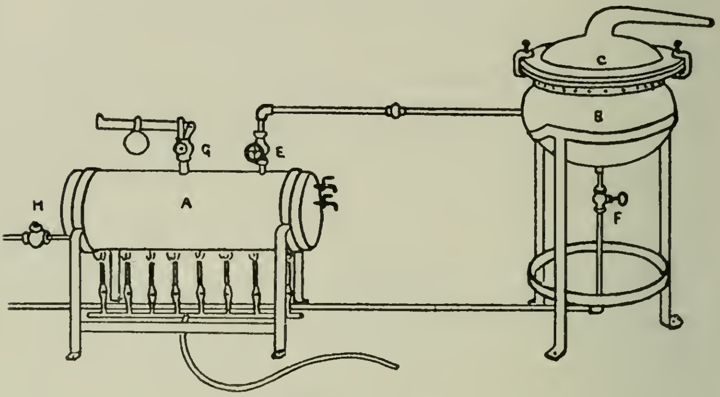
2. *The Use of Steam under Pressure.*—This is by far the most convenient method of using steam practically as a means of transmitting heat. It has been stated that steam produced in open and unconfined vessels, with the ordinary pressure of the atmosphere, has the temperature of 100° C. (212° F.). If water is heated continuously in a boiler capable of withstanding pressure, the water is prevented from boiling by the pressure of its own vapor, and the temperature of the steam rises in proportion as the pressure increases. It is usually stated that the pressure of the atmosphere is 14.7 pounds to the square inch. The following table shows the increase in temperature of steam when the pressure exceeds that of the atmosphere. Of course, the opposite effect is produced when the pressure is removed, and the water boils below the temperature of 100° C. (212° F.). (See vacuum apparatus.)

Table of the Temperatures of Superheated Steam

Pressure	Temperature of Steam		Pressure	Temperature of Steam	
Pounds per Square Inch	C.	F.	Pounds per Square Inch	C.	F
14.7	100°	212°	55	141.6°	287°
17	104.2°	219.6°	60	144.7°	292.7°
20	108.8°	228°	65	147.7°	298°
23	113°	235.4°	70	150.5°	302.9°
25	115.6°	240.1°	75	153°	307.4°
30	121.3°	250.4°	80	155.5°	312°
35	126.2°	259.3°	85	157.8°	316.1°
40	130.7°	267.3°	90	160°	320°
45	134.6°	274.4°	95	162.2°	324°
50	138.3°	281°	100	164.4°	327.9°

The principle of the use of steam under pressure is shown in the apparatus (see Fig. 113). It was designed by the author in 1872 to illustrate the subject practically upon the lecture table. A cylindrical copper boiler, A, supported by a stout iron stand, is heated by a row of six Bunsen burners; water is forced into the boiler from the hydrant through a rubber hose attached to the pipe connected with the check valve, H. The steam passes into the jacketed kettle, B, and is controlled by the steam valve, E, the exhaust steam and condensed water passing through the pipe controlled by the valve F. The safety valve, G, warns the operator by "blowing off" steam when the pressure has reached the highest point desired. C shows the dome which may be attached when a liquid is to be distilled.

Fig. 113

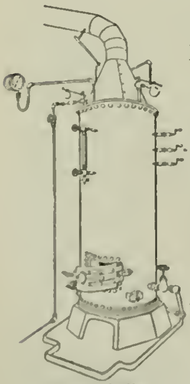


Use of steam under pressure

An upright tubular steam boiler, suited to operations in the pharmaceutical laboratory, and a sectional view of the same, are shown in Figs. 114 and 115.

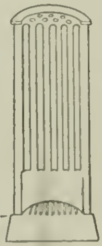
Prof. Patch contrived a very convenient upright tubular steel boiler. It is covered with asbestos composition, which acts as a non-conductor of heat, and the source of heat is a large coal oil stove; a conical coil of pipe serves to support a funnel when hot filtration is needed, while a safety valve and steam gauge assure safety. It is, of course, intended only for the laboratory of a retail druggist.

Fig. 114



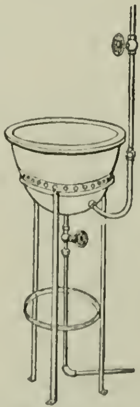
Steam boiler

Fig. 115



Sectional view

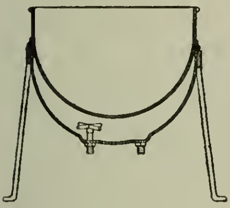
Fig. 116



Steam kettle

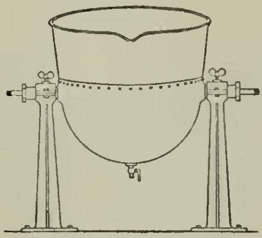
The usual form of steam kettle is shown in Fig. 116. A copper pan, tinned inside, having flaring sides to facilitate evaporation, is securely connected about midway from the bottom with another copper pan, both being riveted together. An opening for the steam pipe is made in the jacketed side to admit steam, and at the lowest point of the bottom another pipe is attached to carry off the water which is produced by the condensation of the steam. The upper edge of the kettle is protected by a flat brass ring, which is soldered and riveted to it, and which also serves to support the still top when the steam kettle is used for distillations. (See chapter on Distillation.) Care should be exercised to have the bottom of the kettle made of copper heavy enough to resist the greatest amount of steam pressure that will be likely to be used on it, as instances have been known of collapse when this was neglected. In using the steam kettle, the liquid that is to be heated is run into it by a syphon or other means; the drip or exhaust cock below is opened partially, and the steam slowly turned on. The habit of opening steam valves cautiously is one that should be sedulously cultivated, as accidents and strains to steam apparatus often arise from the sudden shocks due to want of care in this respect. While the liquid is becoming heated, the condensed water should be allowed to escape freely, and when the proper temperature is reached, the steam valve should be carefully adjusted and the exhaust valve turned so that, while all the condensed water may escape, no steam shall be allowed to go to waste by its being opened too widely. One of the greatest objections to the use of tinned copper kettles is that the coating of tin soon wears off, and the contamination of an evaporating liquid with copper is almost sure to result.

Fig. 117



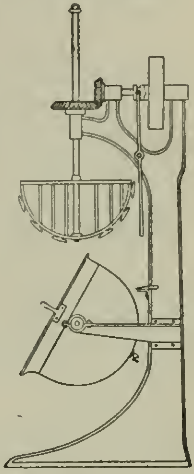
Steam kettle (sectional view)

Fig. 118



Steam kettle on trunnions

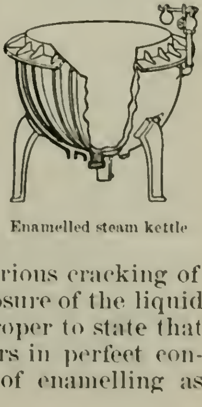
Fig. 119



Tilting steam kettle with stirrer

Fig. 117 represents a sectional view of a steam kettle, showing the space for steam and a four-arm, steam distributor with outlet. Fig. 118 shows a steam kettle mounted on trunnions. This form is very convenient when the operator wishes to pour out the contents. In the ordinary form of the kettle the contents have to be removed with a dipper. Fig. 119 shows a modern form of steam kettle with a stirring apparatus which is easily removed when not in use. The tilting kettle is very convenient.

Fig. 120



Enamelled steam kettle

The enamelled cast iron kettle shown in Fig. 120, is to be preferred on this account, although the injurious cracking of the enamel from overheating and the resulting exposure of the liquid to the iron surface beneath is an objection. It is proper to state that with care the enamel may often be retained for years in perfect condition. The great improvements in the process of enamelling as shown in modern bathtubs give promise of having pharmaceutical apparatus in the near future of excellent quality. Jacketed iron tanks lined with sheet block tin are very useful and durable, but their costliness is apt to prevent their extended use.

Pressure steam is frequently passed through coils of iron, block tin, or lead, which have been immersed in the liquid to be heated. Fig. 121 shows the usual form. It will be found very useful to the practical worker to use block tin pipe. Steam valves may be soldered to both ends of the pipe, and on account of the flexibility of the pipe it may be readily adjusted and coiled to suit available space, while the absence of danger from contamination when used for heating most medicinal liquids is an advantage which should not be overlooked. Steam, when passed through coils of various shapes, zigzag pipes, etc., is also largely used in heating liquids in special operations, in drying drugs, chemicals, etc. Figs. 122, 123, and 124 illustrate these forms. (See also chapter on Desiccation.)

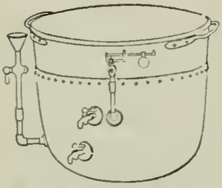
Fig. 125



Steam kettle for use over naked fire

Pressure Steam without the Use of a Boiler.—In Fig. 125 is shown a water bath jacketed kettle, which generates its own steam; it may be used over a gas burner, coal oil stove, or naked fire. Two gauge cocks indicate the quantity of water in the kettle, and the safety valve the amount of steam pressure; the funnel pipe is used for charging the kettle with water. The advantages of this kettle are apparent, the principal one being that it can be used by a pharmacist who desires to use steam heat without incurring the inconvenience and expense of installing a boiler in his store, laboratory, or cellar.

CHAPTER IV

VAPORIZATION

UNDER this head will be included those pharmaceutical operations in which volatile substances are separated from fixed bodies, or from others which are less volatile, by the action of heat at varying temperatures. Vaporization is frequently employed in pharmacy, and it will be most convenient to consider its applications in the order of their importance: 1. To Liquids. 2. To Solids.

1. When vaporization is used to separate a *volatile liquid* from a *less volatile* liquid, it is called *evaporation.*
2. When the object sought is the *volatile liquid,* it is called *distillation.*
3. When it is used to separate a *volatile liquid* from a *solid,* it is called *desiccation, exsiccation,* or *granulation.*
4. When it is used to separate a *volatile solid* from another body, it is called *sublimation.*

The following diagram may serve to impress the definitions on the memory:

Vaporization

Object Sought	Process
Liquids:	
Fixed or less volatile	Evaporation
Volatile	Distillation
Solids:	
Fixed	Desiccation Exsiccation Granulation
Volatile	Sublimation

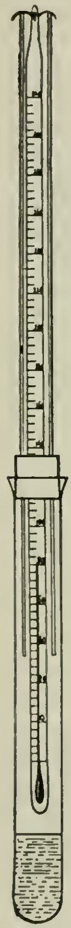
The subjects of Evaporation, Distillation, Sublimation, and Desiccation will be considered in the chapters which immediately follow. Vaporization, as applied to Granulation and Exsiccation, will be more appropriately considered after the chapters on Solution and Crystallization.

Evaporation

Although this term has in its more popular sense the signification of the separation of moisture from any body, whether solid or liquid, in pharmacy the word has a more restricted meaning, and signifies the driving off of the more volatile or less valuable portions of a liquid by the application of heat, with the object of purifying it or obtaining the less volatile portion. Illustrations are found in the concentration of syrups and liquids intended for crystallization, and in the treatment of weak tinctures in making fluidextracts and extracts.

As *ebullition,* or *boiling,* is an important form of evaporation, it will be necessary first to consider the essential points concerned therein. Ebullition in a heated liquid is caused by the formation of bubbles of vapor upon the surface of the vessel, which, rising to the surface of the liquid and bursting, permit the vapor to become diffused in the space above the boiling liquid. The *boiling point* of a liquid may be defined as the temperature at which the tension of its vapor is equal to the pressure of the atmosphere, this point being *definite,* while *evaporation* takes place in the same liquid at nearly all degrees of heat, and hence the *evaporating* point is an *indefinite* temperature. The point at which a liquid boils varies with the liquid.

Fig. 126



Boiling point test

The boiling point of a liquid is affected by the cohesion of the liquid and the degree of pressure upon its surface. Water under the ordinary pressure of the atmosphere boils at 100° C. (212° F.). When confined in a steam boiler it has been shown that water can have a temperature considerably over 200° C. (392° F.) without boiling, the bubbles being prevented from rising to the top on account of the pressure of the steam in the confined space above the liquid. On the other hand, the removal of pressure causes a liquid to boil below its normal boiling point.

Determination of Boiling Points.—One of the simplest methods of ascertaining the boiling point of a liquid is illustrated in the cut (see Fig. 126). The liquid is introduced into a test tube, and a glass tube is selected of such diameter as will permit a tube thermometer to pass easily through it and leave a small space between; the tube should be about one inch shorter than the thermometer. A short piece of wire should be passed through the glass ring of the thermometer, and slightly bent to hold it in position; a perforated cork should now be fitted tightly to the test tube, and the tube carrying the thermometer tube pushed through the perforation in the cork until the bulb of the thermometer is just above the liquid; heat should be applied cautiously by a sand bath or water bath. The vapor from the boiling liquid passes upward through the whole length of the thermometer, escaping at the top, and thus the error common to some methods, due to the difference in temperature between the portion of the thermometer in the test tube and that outside of the test tube, is measurably avoided. Boiling points are used as a means of determining the identity and purity of various substances, and the appended table gives the boiling points of substances according to the U. S. P. (8th Rev.).

Table of Boiling Points of Official Substances

Æthylis Chloridum	12.5°–13° C.	=	54.5°–55.4° F.
Æther	35.5° C.	=	96° F.
Benzinum	45°–60° C.	=	113°–140° F.
Carbonei Disulphidum	46°–47° C.	=	114.8°–116.6° F.
Acetonum	56°–57° C.	=	132.8°–134.6° F.
Chloroformum	60°–61° C.	=	140°–141.8° F.
Bromum . . . about	63° C.	=	145.4° F.
Spiritus Ætheris Nitrosi	65° C.	=	149° F.
Æther Aceticus	72°–77° C.	=	161.6°–170.6° F.
Alcohol	78° C.	=	172.4° F.
Aqua	**100° C.**	=	**212° F.**

Table of Boiling Points of Official Substances—*Continued*

Phenol Liquefactum	115°–188° C.	=	239°–370.4° F.
Acidum Aceticum Glaciale	117°–118° C.	=	242.6°–244° F.
Acidum Nitricum	120.5° C.	=	248.9° F.
Paraldehydum	121°–125° C.	=	249.8°–257° F.
Bromoformum	148° C.	=	298.4° F.
Oleum Sinapis Volatile	148°–152° C.	=	298.4°–305.6° F.
Oleum Terebinthinæ	155°–162° C.	=	311°–323.6° F.
Terebenum	160°–170° C.	=	320°–338° F.
Glycerinum (95 percent.)	165° C.	=	329° F.
Eucalyptol	176°–177° C.	=	348.8°–350.6° F.
Phenol	178°–182° C.	=	352.4°–359.6° F.
Benzaldehydum	179°–180° C.	=	354.2°–356° F.
Oleum Amygdalæ Amaræ	180° C.	=	356° F.
Acidum Trichloraceticum	195° C.	=	383° F.
Cresol (90 percent. should boil between)	195°–205° C.	=	383°–401° F.
Creosotum	200° C.	=	392° F.
Camphora	204° C.	=	399.2° F.
Guaiacol (liquid)	205° C.	=	401° F.
Menthol	212° C.	=	313.6° F.
Naphthalenum	218° C.	=	424.4° F.
Oleum Gaultheriæ	218°–221° C.	=	424.4°–429.8° F.
Methylis Salicylas	219°–221° C.	=	426.2°–429.8° F.
Safrolum	233° C.	=	451.4° F.
Cinnaldehydum	250° C.	=	482° F.
Eugenol	251°–253° C.	=	483.8°–487.4° F.
Camphora Monobromata	274° C.	=	525.2° F.
Resorcinol	276.5° C.	=	529.7° F.
Betanaphthol	286° C.	=	546.8° F.
Acetanilidum	295° C.	=	563° F.
Acidum Sulphuricum	338° C.	=	640.4° F.
Hydrargyrum	357.25° C.	=	675.05° F.
Sulphur Sublimatum	448° C.	=	838.4° F.
Zincum	940° C.	=	1724° F.

Tension of Vapors.—If a glass tube, thirty-six inches long, closed at one end, is filled with mercury, and the open end, after closing it with the finger, carefully inverted in a beaker containing mercury, it will be found that the mercury will run out from the tube into the beaker until a column of mercury about thirty inches in height is left. This column is sustained by the pressure of the atmosphere, and is, in fact, the well known mercurial barometer tube. The six inches of space in the tube above the level of the mercury is, of course, empty, or vacuous. Now, if a few drops of water are passed into the tube by a dropper, they immediately rise to the level of the mercury in the tube, and, although the temperature has not been increased, a portion of the water is vaporized, and the column of mercury is proportionately depressed. This depression is due to the elasticity or tension of the aqueous vapor. If the tube be forcibly pushed down into the mercury, the increased pressure will be found to have liquefied the vapor, and the original quantity of water is recovered; but the depression in the column of mercury may be increased by heat, and when a sufficient amount of heat has been applied to the tube to expel the mercury until none is left in the tube, it will be found that the temperature marks 100° C. (212° F.), which is exactly the boiling point of the liquid (water), showing that this point must be reached in order to overcome the pressure of the atmosphere. If alcohol or ether be substituted for water, it will be found that the mercury will be depressed in a far greater ratio,—this being due to the greater volatility and lower boiling point of these liquids. The *maximum density* of the vapor of a volatile liquid in a confined space in contact with the corresponding liquid is reached when its elastic force attains the limit beyond which pressure produces the liquefaction of the vapor. When this limit is reached, the vapor is said to be *saturated.* Maximum density varies with the temperature. If a saturated vapor in an enclosed tube is not in contact with an excess of liquid, increase of temperature lowers its density or expands it. On the other hand, when a saturated vapor is cooled, liquefaction gradually takes place, the vapor above the liquid remaining in the condition of maximum density until converted into the liquid. So that *cold* and *pressure* have the effect of *converting vapors into liquids*, while *heat* and the *removal of pressure* have the reverse effect,—*i.e.*, *the conversion of liquids into vapors.* The phenomena above described characterize evaporation into a space filled with air as well as evaporation into a vacuum, the only difference being that more time is required to produce the same effects when evaporating in contact with air, for volatile liquids are instantly converted into vapor in a vacuum, while the presence of air retards, but does not prevent, vaporization. A consideration of the foregoing facts leads to the following deductions :

1. The quantity of vapor that will form in a confined space depends upon the amount of pressure and heat to which the liquid is subjected, and when the point of maximum density of the vapor is reached, evaporation ceases if the pressure and temperature remain the same.

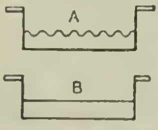
2. The rapidity of evaporation of an aqueous liquid in the open air is influenced by the condition of the aqueous vapor always present in the air. If it has the greatest density possible for the degree of heat, evaporation is retarded ; but if the aqueous vapor in the atmosphere is much below the state of maximum density, as is usually the case, evaporation is promoted.

3. Rapidity of evaporation is increased by removing the pressure of the atmosphere.

4. Increase of temperature obviously accelerates evaporation, by increasing the formation of vapor.

Evaporation of Liquids by Boiling.—In evaporating *by boiling*, temperature, pressure, etc., being equal, the rapidity of the process depends upon the *extent of surface exposed to the heat.* Fig. 127 represents a cross section of two evaporators, A and B. The corrugated bottom of A gives twice as much surface as the smooth bottom of B, and hence if the same quantity of a liquid is made to boil in each, at the same temperature, the bubbles of vapor given off from the corrugated bottom will be twice as numerous as those formed on the plain bottom. The superiority of tubular boilers over the ordinary plain or Cornish boiler also affords a good illustration of this fact (see Fig. 115).

Fig. 127



Evaporation by boiling

When a pure, volatile liquid is heated to the boiling point in the open air, its temperature remains the same until the whole of the liquid has evaporated. If, on the other hand, solid matter is dissolved in the liquid, the temperature of the solution is gradually increased until saturation is reached. This fact is well illustrated by considering boiling points of saturated solutions of various salts (see page 123), and it shows the importance of diminishing the heat in the evaporation of solutions of organic substances as evaporation progresses, as, for example, in the making of extracts, etc.

The cohesion of a liquid affects its boiling point, dense, thick, and sticky liquids offering more resistance to the escape of the bubbles of vapor than rare, mobile, or thin liquids.

The relative depth of liquid also influences the boiling point. Shallow vessels favor ebullition, because they afford proportionally less weight of liquid above the bottom of the dish for the bubbles to escape through than deep ones. Rough metallic surfaces favor evaporation by boiling, and are better than smooth surfaces, because they expose a greater amount of surface to the source of heat.

Fig. 131

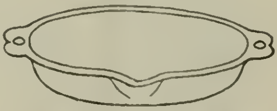
Glass evaporating dish

Evaporation below the Boiling Point.—In evaporating liquids *below their boiling point*, temperature, pressure, etc., being equal, rapidity of evaporation depends upon the *extent of surface exposed to the air*. Figs. 128 and 129 show two vessels of exactly the same diameter, but of different capacity, containing water. Both expose the same amount of surface to the air, but that of Fig. 129 contains eight times more liquid than that of Fig. 128.

If both be subjected to the same temperature, *provided it be below* 100° C. (212° F.), the water will evaporate as rapidly from one as from the other.

Proper Shape of Vessels for evaporating Liquids.—Broad, shallow vessels should be used for evaporating below the boiling point, because the extent of surface is proportionally greater in vessels of this shape. Fig. 130 is an illustration of a porcelain evaporating dish having the proper shape. The chief objection to dishes of this kind is their liability to breakage. Care should be taken to dry the bottom of the dish thoroughly before placing it over a gas flame. A glass evaporating dish is shown in Fig. 131. This should always be used in a sand bath, or should be otherwise protected from direct heat. Enamelled cast iron dishes are very useful, notwithstanding the lack of durability of the enamel. Enamelled sheet iron dishes, called "agate ware," are very light, and are much more lasting than the ordinary enamelled cast iron dishes (see Fig. 132).

Fig. 132



"Agate ware" evaporating dish

Use of Stirrers.—By stirring an evaporating liquid the surface is largely increased, while the currents of air produced at the same time greatly assist in dissipating the vapors which rise. Upon the small scale, porcelain, horn, or wooden stirrers are used (see Figs. 133 to 137), while mechanical stirrers are usually employed in the laboratory in more extensive operations (see Fig. 119). Fig. 138 also shows a rotary stirrer to be operated by steam power.

Vacuum Apparatus.—It has already been shown (page 125) that the boiling point of liquids is lowered by removing the pressure of the atmosphere. This fact is easily proved by placing under the receiver of an airpump some alcohol in a test glass containing a few pieces of broken glass, when, upon exhausting the receiver, many bubbles of vapor will rise from the surface, and the liquid will boil at the ordinary temperature. Water will boil at 84° C. (183.2° F.) upon the top of Mont Blanc, on account of the diminished pressure of the atmosphere.

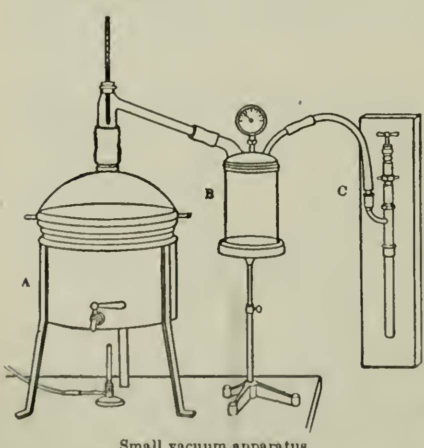
Fig. 139

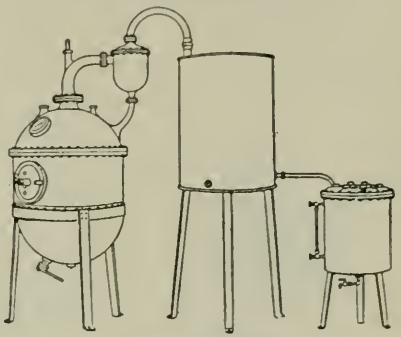


Small vacuum apparatus

The practical application of these principles is of great importance in pharmacy, and vacuum pans are frequently used in the larger laboratories for concentrating solutions which are injured by heat under the ordinary pressure of the atmosphere, and especially in evaporating solutions of organic substances, for these are almost without exception injured by heat.

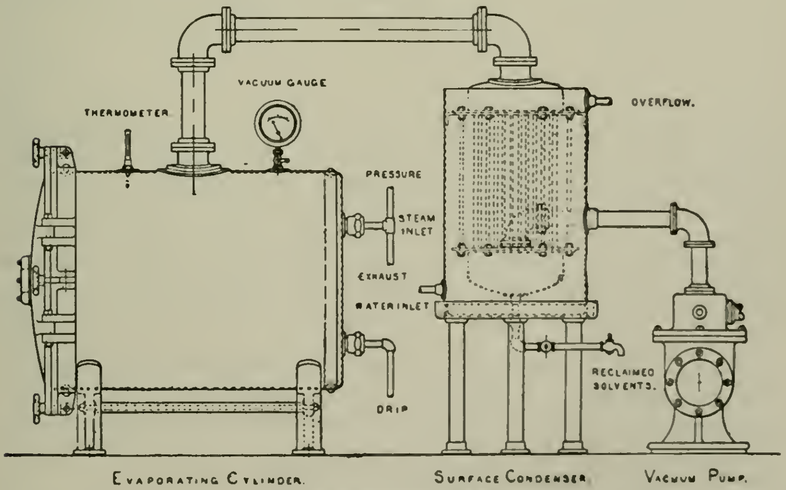
In Fig. 139 a vacuum apparatus is shown which illustrates the principle of this method of evaporation. The copper vessel, A, is used either as a steam or water bath; in this is placed a tinned copper or porcelain evaporating dish covered with a glass dome fitted with an airtight connection. A thermometer is adjusted at the top, and by means of the water pump, C, the air is exhausted ; the glass vessel, B, acts as a receiver. It is closed by a metallic lid, which is furnished with a vacuum gauge which indicates at all times the conditions, and enables the operator to increase or decrease the "vacuum." Fig. 140 shows a larger vacuum apparatus adapted for manufacturing laboratories. At the left is seen the jacketed copper still containing manhole, eyeglasses, aircock, and drain valve, connected with an overflow vessel to be used in case of the boiling over of the contents. The condenser is mounted on a tripod, and this is connected with the receiver, which is furnished with a water gauge, drain valve, and with inlets and outlets for the vacuum pump. The air is exhausted from the entire apparatus by attaching to the receiving vessel the pipe from the pump. With the aid of this apparatus, alcohol may be recovered directly from an exhausted drug by emptying the contents of a percolator into the still. Vacuum pumps operated by steam are to be found in all well equipped pharmaceutical laboratories, and pipes and attachments are just as easily connected with various forms of apparatus as are the pipes used for conveying steam under pressure (see gelatin coated pill apparatus in Part V).

Fig. 140



Vacuum apparatus

Fig. 141

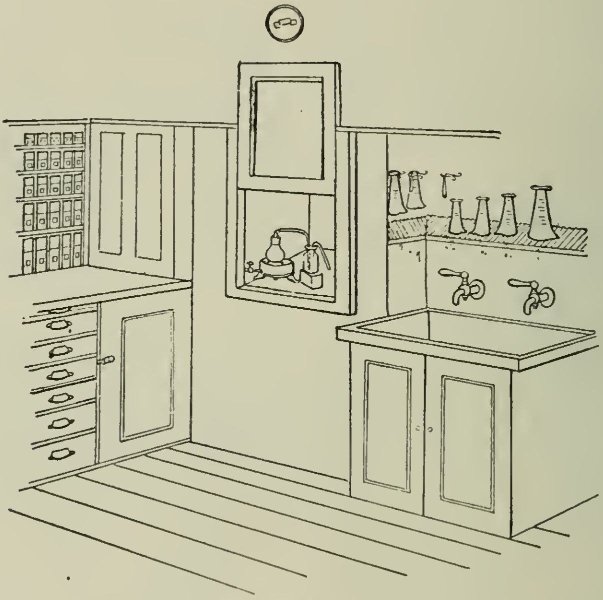


Vacuum apparatus (Stokes)

The F. J. Stokes Machine Company, of Philadelphia, have perfected a vacuum drying apparatus of much value. Fig. 141 shows in detail their application of the vacuum applied to drying substances which are moist ; the vapors may be condensed and reclaimed by the use of the condenser. These vapors may sometimes be injurious or undesirable if allowed to escape into the laboratory, and hence this plan of disposing of them is effective; the condenser may be disconnected, if found advantageous. Substances which require days to dry in heated rooms can be dried in several hours with this apparatus.

It frequently happens that the pharmacist is unable to devote much space to laboratory operations. This is particularly the case in cities or large towns, where rents are high. When pharmaceutical operations must be conducted in the store, an absolutely indispensable convenience is an *evaporating chamber* (see Fig. 142). If the arrangement of the store will admit of it, this should be built into a chimney breast. The bottom of the chamber is preferably made of a slate slab, which should have a slight inclination toward the front, and be large enough to project about two inches over the closet upon which it rests, for the purpose of preventing a liquid, spilled by accident, from running into the closet and soiling the contents. The chamber should have a gas pipe in it, and the upper part should connect, by a flue in which there is a damper, with a chimney having a good draught. A wooden or galvanized iron front having a pane of glass fitting tightly in it will prevent vapors or odors from getting into the store. The space below may be utilized as a closet for evaporating dishes, gas stoves, etc.

Fig. 142

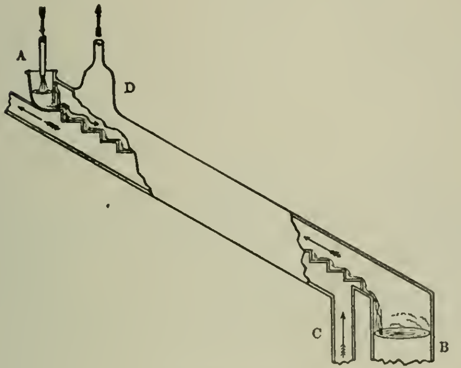


Evaporating chamber

Economical Surface Evaporation.—In large industries where economy in operating is an essential factor, various forms of apparatus must be constructed to meet this need. In Fig. 143 is shown a method of concentrating sulphuric acid, whereby the hot gases from the furnace are utilized as the source of heat. The liquid enters at A, and flows down in a thin stream over a cascade or series of steps, the vapors arising find an outlet at D, the evaporated liquid is collected in a reservoir, B, while the waste heat passes upward in the direction of the arrows through the pipe C.

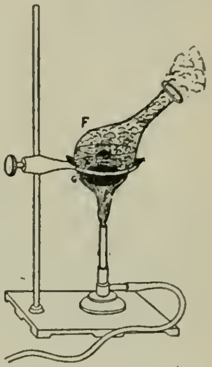
Spontaneous Evaporation.—By this term is meant the evaporation of a liquid at the ordinary temperature of the atmosphere, or without the application of strong, direct heat. It is used in cases where the residue or less volatile liquid is liable to injury or loss by the application of much heat, or in crystallization, where, by the slow vaporization of the volatile liquid, finely formed crystals may be secured, and in other less important operations. Spontaneous evaporation is usually conducted in drying rooms or closets when they are accessible; these, as will be subsequently described, are rooms or closets which are very slightly heated by the use of exhaust steam or other means; or this form of evaporation may be used by placing the liquid in shallow dishes or trays and exposing the surface to the rays of the sun during fine weather. Upon the small scale, one of the most convenient methods is to support the dish upon a wire tripod placed upon a stove, at a sufficient distance above the top of the stove to avoid injury, or if heated air from a furnace is available, it can be utilized by supporting the dish, properly protected, over the register; the upward current of dry heated air greatly assists in promoting the evaporation.

Fig. 143



Surface evaporation

Fig. 144

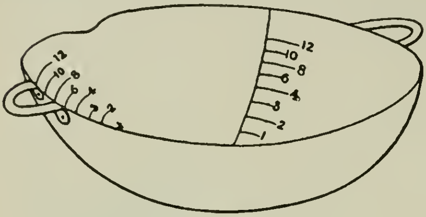


Flask evaporation

Evaporation by Direct Heat.—This method usually requires the greatest amount of care in order to avoid loss or injury by overheating. It is to be preferred, therefore, only in cases where the residue is not easily injured by such an accident. The evaporation of saline solutions in crystallization, or of weak aqueous organic solutions, may usually be performed by the application of direct heat. Careful watching, however, is necessary, and also frequent stirring, to prevent the formation of a crust upon the bottom. Fig. 144 shows a method of evaporating by direct heat by using a flask, F, supported on a piece of brass wire gauze, G, upon a retort stand.

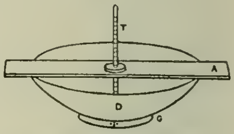
Evaporation to a Fixed Volume.—This operation cannot be performed accurately without inconvenience, and hence it is much more satisfactory to evaporate a liquid to a definite weight,—all that is necessary in the latter case being to use a tared dish, and weigh the dish and contents when evaporation has progressed to the desired point.

Fig. 145



Graduated evaporating dish

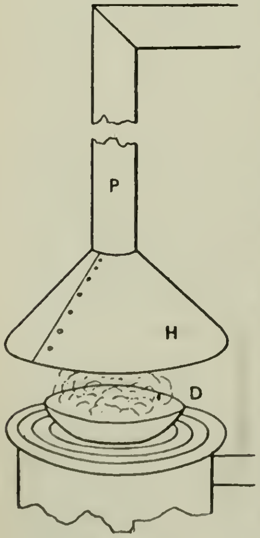
Fig. 146



Measuring evaporation

In evaporation to a definite measure, a graduated evaporating dish (see Fig. 145) may be employed, care being taken to level it by noticing that the height of the liquid is the same on each side, or the expedient illustrated in Fig. 146 may be resorted to. An ordinary evaporating dish, D, is placed upon a grommet, G (see page 139), and subjected to the heat (in this case the temperature is intended to be that of a warm room); a perforated wooden strip, A, is placed across the dish, and a glass thermometer, T, is supported in an upright position in the liquid by a perforated cork. Sufficient water is poured into the dish to equal the final measure of the liquid, and a small rubber band is slipped on the thermometer (or a piece of string tied on) to indicate the desired level of the liquid; the water is replaced by the liquid to be evaporated, and evaporation proceeded with until the liquid has been lowered to the mark on the thermometer. When the use of the thermometer is unnecessary, a notched stick may be substituted. In order to arrive at results approaching accuracy by these methods, the liquid must be allowed to cool to the temperature of the water which was used as the measure of the liquid in the beginning.

Fig. 147



Hood

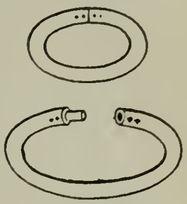
Use of Hoods.—A hood is a contrivance, usually of a conical shape, intended to collect and dispose of vapors which, from their disagreeable odors or their suffocating effects, render the atmosphere of the store or laboratory unwholesome. Fig. 147 shows a form of hood which has been found useful upon the small scale. It is made of galvanized iron, and connects by galvanized stove pipe with the strong draught of a good chimney; the stove pipe running horizontally to the chimney should have a damper in it. If any condensation of the vapors takes place in the stove pipe, the larger diameter of the circular hood will cause the drops of liquid to fall outside of the evaporating dish, and thus contamination of the contents of the dish is avoided. Hoods are usually made of wood when intended for operations upon the large scale. Fig. 148 illustrates the method of using a hood when the dish is placed upon a stove.

Fig. 148

Stove hood

Use of Grommets.—One of the inconveniences in using round bottomed evaporating dishes is due to the shape of the bottom, serious loss often occurring from the tilting of the dish and spilling of the contents. To obviate this, *grommets* should be used. These may be economically made from a cast off piece of rubber hose or tubing by bending it into a circle, placing a wooden plug in one end, tacking it securely, and inserting it in the other end and fastening it in the same manner (see Fig. 149). An elastic ring is thus formed, upon which an evaporating dish or round bottomed vessel may be safely placed. Grommets serve another very important purpose, that of preventing the fracture of a porcelain or glass dish containing a hot liquid, by being placed between the hot dish and the cold surface of a table or floor.

Fig. 149



Grommets

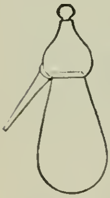
CHAPTER V

DISTILLATION

THE first part of the process of *distillation* is identical with that of evaporation, for it is simply the *vaporization* of the volatile liquid through the application of heat. The next step is distinctive and opposite, and consists in the conversion of this vapor into a liquid by the application of cold. This part of the process is called *condensation.* The elements of distillation are: 1, vaporization, and, 2, condensation. The subject of vaporization was treated of in the preceding chapter. We have now to consider condensation.

Condensation.—It has been already shown (page 124) that when a *liquid* is *vaporized* a certain amount of heat disappears or is rendered latent, and when a *vapor* is *liquefied* a corresponding degree of heat is evolved or reappears. While the practical application of this law is of great service in the use of steam for heating purposes, the opposite process of condensation shows its disadvantages, because of the relatively large quantity of cold water necessary to convert vapors into liquids. The greater the difference in temperature between the condensing surface and the vapor, the more rapid is the condensation; and it has been computed that steam at 100° C. (212° F.) requires about twenty-five times its weight of water at 20° C. (68° F.) to condense it. The proper relation between the heating and condensing surfaces of apparatus used in distillation can only be known by careful study of the laws governing vaporization and condensation, or by practical experience.

FIG. 151

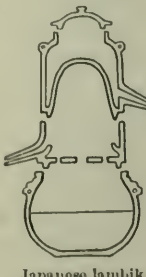


Alembic

Apparatus used in Distillation.—In considering the many kinds of apparatus used in distillation, two typical forms are presented: 1, the *alembic form*, in which the vapor is condensed in an enclosed space immediately above the heated liquid, and, 2, the *retort* form, in which the vapor is condensed in a vessel placed at one side of that containing the heated liquid, and connected with it by a suitable tube or pipe.

The Alembic.—This is probably the most ancient kind of distillatory apparatus, and in its original form it is now rarely employed. The *body*, or *cucurbit*, is usually globular or oval in shape, and at its junction with the hemispherical *head* or *dome* there is a gutter or groove. This serves to collect the condensed vapor or distillate, which is carried off by a tube, as shown in the illustration (see Fig. 151).

FIG. 152



Japanese lambik

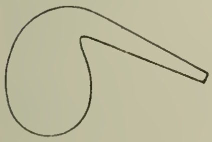
Fig. 152 shows an alembic which, according to Mr. Brady, of Newcastle, England, is still frequently employed in Japan. Into the boiler is fitted a short cylinder. This has a perforated bottom, and the gutter communicates with the spout ; the condenser has a cover, and is also furnished with a spout for carrying off the water used in cooling the dome after it has been heated by the vapors rising from the boiling liquid in the body. This still, or, as it is called by the Japanese, *lambik*, is shown because it represents the alembic probably in one of its best practical forms, and the advantages possessed by this kind of distilling apparatus are seen to be compactness and simplicity. It is, however, not fitted for distilling very volatile liquids, is very inconvenient and troublesome, because of the necessity for constantly replacing the water used in the condenser, and distillation is slow and tedious.

The Retort.—This form of distillatory apparatus has many advantages over the alembic, which it has almost entirely replaced. A retort, in its simplest form, may be described as a long necked glass flask in which the neck, after being heated thoroughly, is bent over until its axis makes an acute angle with that of the bowl of the flask. Retorts are of two kinds,—plain and tubulated. A *plain* retort is shown in Fig. 153. If it has a *tubulure* or orifice at the top of the bowl for the purpose of introducing the liquid to be distilled, it is said to be *tubulated* (see Fig. 154). Retorts are made of glass, porcelain, earthenware, platinum, iron, lead, etc., according to the purposes for which they are designed.

Porcelain and earthenware retorts are used in the distillation of phosphorus, mercury, etc. ; platinum and iron retorts, in destructive distillation ; leaden retorts, in making hydrofluoric acid, ether, etc.

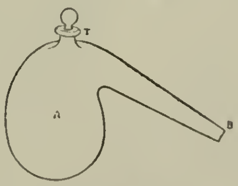
The glass retort is the only kind, however, which will be considered here in detail. The shape of a retort is an important point to regard in its selection. Retorts having deep bowls are best suited for very volatile liquids. The lower surface of the neck of the retort should form a decidedly acute angle with the surface of the bowl if tubulated ; a line drawn from the centre of the stopper should touch the centre of the bowl, A, so that when a funnel is introduced into the tubulure, T, to charge the retort, the contents may all be delivered into the bowl without soiling or splashing the neck. The neck of the retort should gradually taper to the end, and the beak, B, should never be larger in diameter than any other portion of the neck, otherwise difficulty may be experienced in making joints with adapters, receivers, or condensers (see Fig. 180). Such a fault may prevent the use of a cork ring in joining, for this ring should be made tight by forcing it up the gradually increasing diameter of the neck. The

Fig. 153



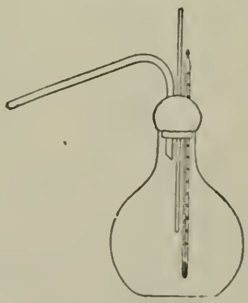
Plain retort

Fig. 154



Tubulated retort

Fig. 155



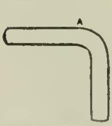
Distilling flask

glass forming the retort should be carefully annealed and have a uniform thickness. Extremes should be carefully guarded against. If the glass be too thick, the sudden changes in temperature, to which retorts are constantly subjected in distillation, may cause fracture; on the other hand, if too thin, they are easily broken in cleaning. Scratches and imperfections in the bowl should cause retorts to be rejected.[1] The objections to the use of retorts are mainly due to their peculiar shape, the principal one being the difficulty of cleaning them thoroughly. The necessity for having a variety of different shapes and sizes to suit special operations is greater than when distillation is performed with flasks and bent tubes.

Flask distillation will be usually found most practicable for pharmaceutical work. The best shape for a flask is shown in Fig. 155. The bowl should have a flat bottom, so that it will stand unsupported; the neck should be wide, to admit a large cork, so that there will be plenty of room for a wide bent tube, a thermometer, and a safety or charging tube. The advantages of using a flask instead of a retort for all distillations that will allow of it are several: it is easily cleaned, it is useful for other purposes, for instance as a measure, as a container, or as a receiver for the distillate; the tubes are readily replaced in case of breakage. One of the most important parts of this apparatus is the bent tube for conducting the vapor to the receiver or condenser. The diameter of the bent tube should be as large as the receiver or condenser will conveniently accommodate.

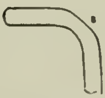
Cutting Glass Tubes.—The glass should be moderately thick and of the proper length. A glass tube may be broken neatly by scratching it across with a sharp three-cornered file, and then grasping it with both hands, one on each side of the scratch, and making a slight outward pressure, which will generally produce a clean fracture. By holding the sharp edges for a few moments in the flame the corners may be rounded so that they will pass through a cork without cutting it and making a ragged edge.

FIG. 156



Tube properly bent

FIG. 157



Tube unequally heated

FIG. 158

Tube hastily bent

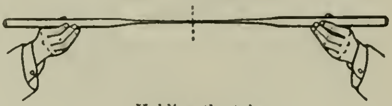
Bending Glass Tubes.—A tube may be bent by heating it properly over a gas flame. To make a symmetrical curve in a tube of large diameter requires considerable skill and practice. One end of the tube should be closed by a cork, and the part of the tube that is to be bent held just above the flame and gradually rotated between the fingers, so that it may be heated evenly throughout. It should also be passed to the right and left through the flame for the space of an inch or two on each side of the middle of the proposed bend, and very slowly allowed to curve in one direction, so that the bend shall not be too abrupt. The object of closing one end with a cork is to prevent a current of air from passing through, and, in case collapse from overheating occurs, by gently blowing in the tube the softened

---

[1] Although there is no disposition on the part of the author to weaken the force of this conventional advice, the possession of a retort having a large bubble in the bottom of the bowl, which was in successful use for ten years and has outlasted many of its more perfect fellows, supplies the needed exception.

glass may be swelled to its proper curve. Fig. 156 shows a tube properly bent, while Figs. 157 and 158 illustrate some of the defects produced by unskilled work. In Fig. 157 the tube was not rotated evenly, and at the top of the bend, B, it was hot enough to collapse. Fig. 158 represents the effects of hurry and unequal heating, the operator having forced the bend, C, before the tube was heated uniformly. A gas burner having a solid, steady flame is the best kind to use (see Fig. 73), and draughts of air should be avoided.

Fig. 159



Holding the tube

In Fig. 159 the method of holding a tube while "drawing it out" over the flame to make a tapering tube is shown. The line in the centre shows the proper place to scratch it when cold with a fine, sharp, triangular file when it is to be broken apart; by holding the edge in the flame for a moment the sharpness may be rounded off. Fig. 160 shows a "well drawn" tube; Fig. 161, one which has not been revolved evenly or heated uniformly. Fig. 162 shows the same fault and careless work besides.

Cork Fitting.—Corks for joining apparatus should be of *the best quality.* They are perforated for the passage of the glass tubes by the use of cork borers (see Fig. 163). These are cylindrical brass tubes of various sizes, sharpened at one end, and surmounted by a milled brass cap. They are furnished in sets. A small hole is drilled through both sides of the brass cap, so that an iron rod may pass directly through it and form a convenient handle. They are used by holding the cork firmly with the left hand and pushing the borer through with the right hand, using a twisting motion at the same time so as to cut a smooth round hole. The mistake frequently made in using cork borers is due to "hurry." The attempt to force the borer through quickly without rotating it sufficiently always ends in breaking off pieces of the cork. The cork borer shown in Fig. 164 is more convenient for larger corks, and may be made from a piece of steel bicycle tubing, the tool handle, I, being large enough to give the operator a firm grasp, so that the cork may be readily bored. The cutting edge of the borers should always be kept sharp and in good condition by the use of the grindstone or emery paper. When the cutters do not bore a hole of the exact size needed for the glass

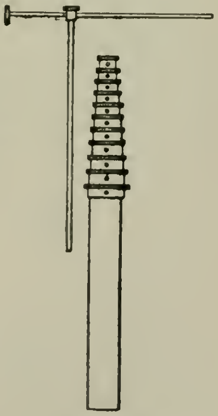
Fig. 160

Fig. 161

Fig. 162

Tubes, properly and improperly drawn

Fig. 163



Cork borers

tube, which of course should fit tightly, it is best to select a borer which will cut a smaller hole than that desired, and then to enlarge the hole by filing with a rat tail file (Fig. 165), or, if the hole is large, with a half round file. When the tubes have been fitted, the cork should usually be thoroughly soaked in hot water, for the purpose of swelling and softening it. It should never be soaked before cutting or filing. The rasp and file shown in Fig. 166 will be useful in fitting up large flasks. Rubber corks can often be used with great advantage, and they may be readily perforated by dipping the cork borer in solution of sodium or potassium hydroxide or strong ammonia water before beginning to use it. If rubber corks are well dried by wiping them thoroughly, they may be filed easily with a new, sharp, flat file. The main advantage of rubber corks is that they are practically impervious to vapors or gases, and hence require no luting. Substitutes for rubber corks may be made by keeping dry corks in melted paraffin or wax until the pores are thoroughly filled, and then cooling.

FIG. 164

Cork borer (large size)

FIG. 165

Rat tail file

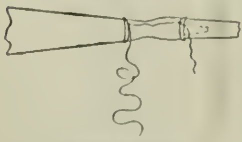
FIG. 166

Rasp and file

Lutes.—The most satisfactory lute for ordinary distillations is made by adding flaxseed meal to *boiling water* and stirring until a thick, sticky mass results. When the perforated and soaked cork containing the tubes is inserted in the neck of the flask, a small quantity of lute should be pressed into the joints, and then followed by sufficient to make the joint vapor tight, the quantity varying with the quality of the cork and the character of the vapor that is to be excluded. If future trouble from leaking is to be avoided, it is usually better to throw away a cork which will not make an almost perfect joint without lute, rather than trust to cover up serious deficiencies with lute. A neat finish may be given to the joint by dipping a finger into water, and with it smoothing the surface of the lute. In Fig. 155 the cork is shown perforated and mounted, luted and in position.

FIG. 167

FIG. 168



Bladder joints

Bladder Joints.—One of the most useful substances to the practical pharmacist who has occasion to join tubes is a strip of moistened bladder. Hogs' bladders are usually preferred, and it is now possible to get them of excellent quality prepared by being thoroughly cleaned and then soaked in an alkaline solution or in petroleum benzin to deprive them entirely of fat. In connecting two tubes of different diameters which are not to be subjected to a high heat, a bladder joint is especially useful. For an ordinary joint of inch glass tube, a strip about six inches long and an inch and a half wide should be moistened and wrapped around the proposed joint; the upper end of the bladder is then tied tightly with strong linen twine, leaving the short end of the twine at least six inches long (see Fig. 168);

this end is carried along the top of the bladder and tied tightly around the lower end of the joint; the long end of the twine is then wrapped spirally and regularly around the bladder until the lower end is reached, when it should be there tied tightly (see Fig. 167). Strips of writing paper soaked for a few moments in water, and then coated with ordinary, smooth flour paste to which 10 percent. of glycerin has been added, may also be used for joining apparatus.

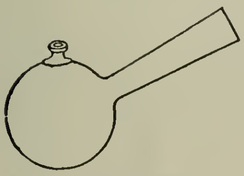
Rubber joints are preferred to bladder joints when there is no likelihood of vapor or high heat dissolving or softening the rubber, and when the tubes to be joined are nearly of the same diameter. The ease and celerity with which such joints can be made are their strong points. A piece of rubber tubing is cut of slightly less diameter than that of the tubes to be joined; by moistening the rubber on the inside with water, and stretching it over one end of the glass tube, and then inserting the end of the other glass tube, the joint is made. Success largely depends upon having the rubber tube slightly smaller in diameter than the glass tube, so that the elasticity of the rubber alone will be sufficient to make a tight joint, otherwise the rubber tube must be tied on, and then the advantage over a bladder joint is lost (see Fig. 169). In all cases it is preferable to select tubes which differ slightly in diameter, so that one may slip into the other, the narrower, of course, having the higher position, so that the vapor or liquid shall not come in direct contact with the rubber.

FIG. 169

Rubber joint

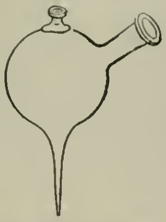
Receivers are glass vessels, usually globular in shape, intended to receive distillates. They are of three kinds,—*plain*, *tubulated*, and *quilled* (see Figs. 170 and 171). When a plain receiver is required, an ordinary flask (see Fig. 172) will answer, but if uncondensable vapors are produced, it is necessary to provide for their escape, or an explosion may occur from the accumulated pressure. This may be done in a tubulated receiver by occasionally removing the stopper, or, better, by connecting a bent glass tube with the receiver and allowing the end of the tube to dip into water, or into an acid solution if the vapors be alkaline, or into an alkaline solution if the vapors be acid. A quilled receiver is useful where the distillation is to be carried to a definite point and a certain amount of distillate is to be received, or, as in the preparation of hydrocyanic acid, the end of the quill is made to dip below the surface of cooled diluted alcohol or water, in order to condense all of the gas. In the distilla-

FIG. 170



Tubulated receiver

FIG. 171



Tubulated and quilled receiver

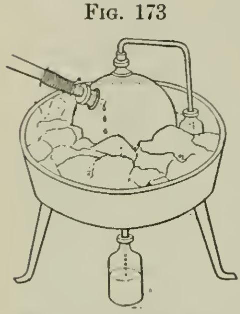
FIG. 172

Plain receiver

tion of very volatile liquids an effective mode of using a quilled receiver is shown in Fig. 173. A hole is cut in the bottom of a rather shallow tin pan and a short tube soldered into it; a perforated cork will permit the quill of the receiver to pass through it, and at the same time a tight joint should be made; ice or snow is heaped up over the receiver, and any uncondensable gases may escape from the bent tube in the tubulure or be absorbed by the liquid into which the tube dips.

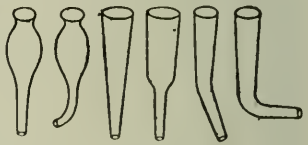
Adapters are tapering tubes of glass which are used to connect retorts with receivers. Figs. 174, 175, 176, 177, 178, and 179 show the various shapes. Good adapters may be made from retorts having broken bulbs by cutting off the broken portion, scratching the tube with a file, and extending the crack thus made entirely around it by slowly passing a red hot poker over the line marked for the fracture. Fig. 180 shows an adapter of this kind in position. Adapters are also employed to deliver the distillate from Liebig condensers into receivers or flasks.

Fig. 173



Mode of using quilled receiver

Fig. 174 Fig. 175 Fig. 176 Fig. 177 Fig. 178 Fig. 179



Adapters

Charging Retorts.—Plain retorts must be charged by using a funnel tube; this may be a funnel with an elongated tube, or a modification of it, as shown in Figs. 181, 182, and 183, or one may be improvised by selecting a tube of sufficient diameter to permit of the introduction of a small funnel (see Fig. 184). The object of using a funnel tube is to prevent the soiling of the neck of the retort; as the object of distillation is usually to purify the liquid, the latter must be delivered into the bowl of the retort without touching the neck. Fig. 185 shows the method of charging a plain retort; a small piece of rubber tube is sometimes

Fig. 181

Stoppered funnel tube

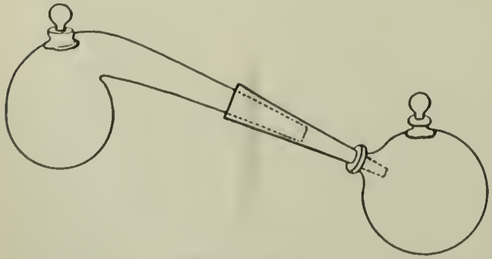
Fig. 182

Funnel tube

Fig. 183

Thistle top funnel tube

Fig. 180



Use of adapter

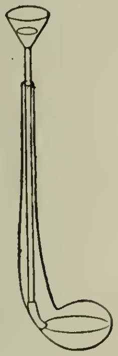
placed on the end of the funnel tube to guide the liquid safely and guard against fracture. Tubulated retorts are charged by simply placing a funnel in the tubulure and pouring the liquid through it.

Safety Tubes.—It is sometimes impossible to avoid sudden evolutions of vapor during distillations. When there is a likelihood of such occurring, it is advisable to insert a Welter's safety tube into the tubulure of the retort. This tube (see Fig. 186) is bent into the form of an S, having a bulb blown in the middle, and a thistle funnel at the top. Mercury is poured into the tube before inserting it into the tubulure of the retort, and a piece of loose cotton is placed in the thistle funnel; when undue pressure occurs, the mercury is forced into the cotton and the vapor escapes; when the retort has been thus relieved, the mercury descends into the bulb and the distillation proceeds.

Fig. 184

Improvised funnel tube

Fig. 185



Charging a plain retort

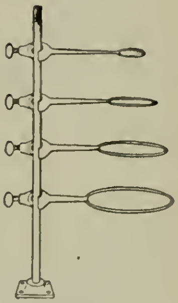
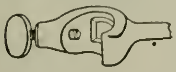
Fig. 187



Retort stand

Retort stands are used to properly support retorts, flasks, receivers, etc., during distillation, although they are also employed by pharmacists for a variety of other purposes, as in filtration, percolation, evaporation, etc. Fig. 187 shows a retort stand which has been used with much satisfaction in the laboratory of the Philadelphia College of Pharmacy. It is more substantial than those that are commonly furnished by the chemical apparatus makers. The clamp (see Fig. 188) is made upon the principle of one originally devised by S. Floyd Wiegand, and is hook shaped, so that any of the different sizes of rings may be unscrewed from the upright rod without disturbing the rest. In many of the common retort stands the bottom ring cannot be removed without first slipping off all above it. Fig. 189 shows

Fig. 188

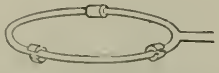


Retort ring clamp

Fig. 189

Retort ring

Fig. 190



Ring with split sections of rubber tubing the ordinary retort ring. The almost universal fault of the retort stands in common use is their extreme lightness and want of stability; the rings frequently bend under such weights as should be easily borne, and, owing to the base being too light and small, the whole stand is sometimes upset during an operation. In the stand shown in Fig. 187 the base plate is permanently fastened to the operating counter in a place known to be the most convenient; if the counter is one that must be used for other purposes, the base plate may be screwed to the under side of the counter, and a five-eighths inch hole bored through the counter, so that the centre shall coincide with the centre of the hole in the base plate. When the retort stand is not in use, the hole in the counter may be closed with a cork. The upright is made of half-inch iron tubing, and can be quickly screwed into the base plate with the hands without the use of pipe tongs. The rings and clamps are all in one piece, and are made of malleable iron, so that if dropped on the floor they are not likely to break. When used for holding a glass percolator or funnel, the danger of fracture on account of the contraction of the iron ring may be avoided by stretching three split sections of rubber tubing upon it (see Fig. 190).

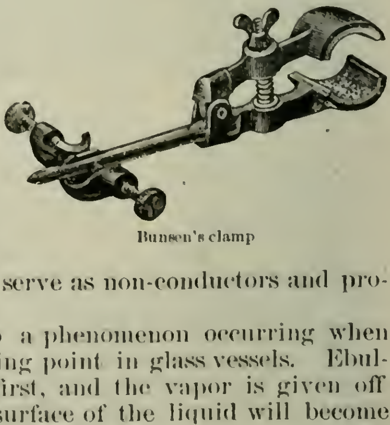
Apparatus stand (horizontal)

An apparatus stand designed by J. Percy Remington is shown in Fig. 191; the clamp is simple and effective; it is U shaped and perforated so as to permit the passage of the rod of the ring freely; the thumb screw is depended upon to firmly fasten the ring upon the upright rod, and the clamping device permits the ring to be placed in any position, pushed in or out, or turned, so that, as often happens in adjusting retorts, flasks, funnels, or percolators, if some slight change in the position of the ring is required, it can be made easily. Fig. 192 shows how the apparatus can be used for a horizontal attachment to be fastened on the wall. Fig. 193 illustrates Bunsen's clamp, which is very useful for holding condensers, retorts, etc.; the jaws of the clamp are lined with cork to serve as non-conductors and protectors against fracture.

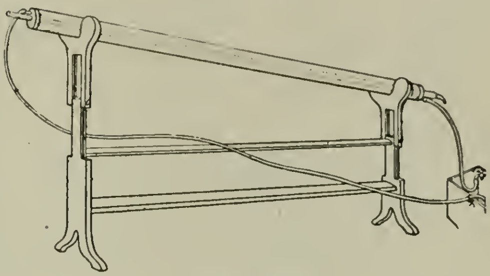
Fig. 193



Bunsen's clamp

Bumping is the term applied to a phenomenon occurring when certain liquids are heated to a boiling point in glass vessels. Ebullition often proceeds regularly at first, and the vapor is given off continuously, when suddenly the surface of the liquid will become smooth for a few seconds. This is succeeded by a slight explosion, when the accumulated vapor is violently expelled and the liquid is said to "bump." These effects occur alternately, and increase as distillation progresses, and some liquids, particularly sulphuric acid, cannot be distilled in glass vessels without using certain precautions. The exact cause of bumping has not yet been satisfactorily explained, but the fact that the forces of cohesion and adhesion in certain liquids are greater when they are boiled in glass vessels than in metallic vessels has been proved. The expedients that have been used to prevent bumping, or rather to lessen its effects, usually consist in the addition of some insoluble solid substance to the liquid, such as broken glass, a fragment of charcoal (when admissible), pieces of clay pipe, rock crystal, etc. ; these serve to break the explosive force of the vapor in its upward course, and are thus serviceable. Probably as good an expedient to use as any in pharmaceutical operations, is to add a few pieces of glass of irregular shape to the liquid before it is heated.

Fig. 194



Liebig condenser

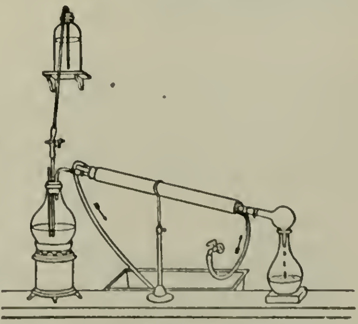
Liebig Condenser

This condenser, although now bearing the name of the great chemist, was used before his time. It consists of a long glass tube, surrounded by another tube of larger diameter ; two small openings are made, one near the bottom and the other near the top of the large tube. Connection is made with the tube leading to the bottom with a cold water supply, and the water circulates in the space between the inside of the large tube and the outside of the smaller tube, and finally has its exit at the opening near the top. Fig. 194 shows a large condenser of this form, well suited for illustrating the process of condensation practically. Both tubes are of glass, the ends being of rubber, and made by cutting two sections from a clothes wringer roller ; the lowest rubber cork is perforated at its lowest convenient point, for the introduction of a short piece of glass tubing, and the upper rubber cork is similarly perforated for the same purpose. A rubber tube connects the lower

Fig. 195

Liebig condenser (all glass, rubber joints)

Fig. 196



Liebig condenser in use

short glass tube with the cold water supply, while another rubber tube, connected with the upper short tube, carries off the warmed water. For smaller condensers the form shown in Fig. 195 answers very well ; the outer glass tube is contracted at the ends and supplied with short tubes as shown, a rubber tube or bladder joint being used to make the joint between the condenser tube and the outer tube. This form is recommended in preference to the kind frequently sold, in which a long and thin glass tube, designed to supply the cold water, is joined to the large tube at right angles. This glass tube is very easily broken off, and the condenser is then useless. If the outer case is of sheet copper and the tubes metallic, this objection is overcome, although the great advantage of using glass tubes, that of being able to watch the process of condensation and of regulating the heat accordingly, is then lost. Fig. 196 shows a glass Liebig condenser in operation, and in addition the method of using a glass tubulated receiver, with a flask to collect the distillate. The liquid which is being distilled is gradually supplied to the distilling flask by the feed tube from the contents of the bottle on the shelf. The rate of flow is controlled by a pinchcock compressing the rubber tube. An enlarged view of the best form of pinchcock to use for this purpose is shown in Figs. 197 and 198. It was contrived by Dr. Squibb to overcome the annoyances experienced in using the ordinary forms. It can be easily and quickly applied to or removed from a rubber tube without breaking a joint, and much more perfect control of the flow can be secured than by the form seen in Fig. 199, which is known as Mohr's. Hoffman's screw pinchcock (see Fig. 200) is often useful, but it cannot be applied or removed so conveniently as

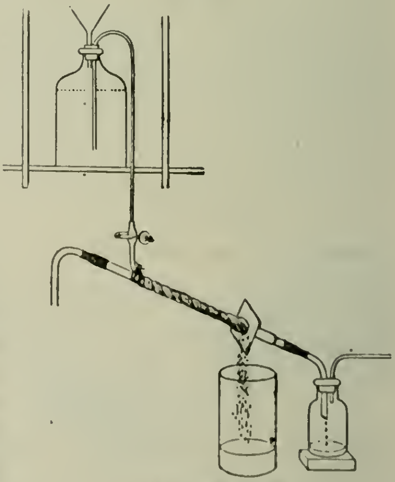
Pinchcock (Remington's)

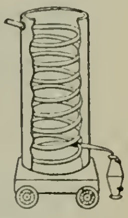
Fig. 202



Tube condenser in use

Squibb's. A section of compressed tube is shown at A. Fig. 201 shows a powerful pinchcock designed by J. Percy Remington for use upon large sized rubber tubes. Fig. 202 shows a method of refrigeration which may be used when the ordinary condensers and a steady supply of water are not to be had. A wide tube is connected with the distilling flask, and some lint, lampwick, or other absorbent material is wrapped spirally around it and tied at the ends; a square piece of cardboard is perforated so that it will fit tightly upon the tube, and it is pushed upon the lower end until it is in close contact with the lint. If water can be supplied from a faucet, a rubber tube is connected with it and conducted to the upper part of the condensing tube, and tied in such a position that a stream of water will trickle from it and be carried down by the lint until it reaches the cardboard, where it falls into the vessel prepared to receive it. If hydrant water is not available, a large bottle containing water may be placed upon a shelf, and a syphon, having a rubber tube and pinchcock, attached, as shown in the cut.

Fig. 203



Condensing worm

The Condensing Worm.—The method of condensing by the use of the worm is very old, and its advantage in securing economy of space and its ease of application are very apparent. Fig. 203 affords a good illustration of this kind of condenser used in the larger laboratories. It will be found most convenient to attach the condenser to a wooden base, mounted on wheels, of suitable height. This permits the convenient shifting of the condenser to the different stills. Block tin pipe is the best that can be used for general pharmaceutical work. Copper or tinned copper tube should be avoided, because it is impossible to prevent the action of acid vapors or liquids upon the copper. Soluble salts of copper would thus be formed and the distillate often rendered poisonous. Iron tube is not admissible, on account of the contamination from iron salts. Pure tin is not affected so easily, and the salts that possibly would be formed are not so objectionable. Block tin pipe may be wound spirally around a convenient cylindrical vessel, such as a tin can or similar object, to give it the proper shape, and then fastened to three notched uprights and placed in position. Earthenware condensing worms of all sizes, of excellent quality, are made by Doulton & Watts, Lambeth, London, England, and by John Cliff & Sons, Leeds, England; they are also made in this country. For condensing acid vapors, as in the making of spirit of nitrous ether by distillation, these condensers are undoubtedly superior to metallic ones.

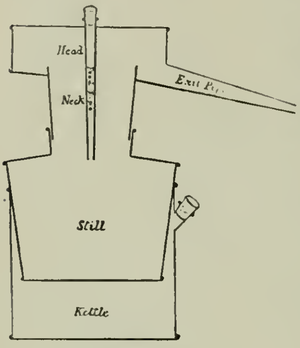
Pharmaceutical Stills

Stills are preferred in all distillatory operations where the liquids or vapors do not act chemically upon the metals of which they are made. Tinned copper is the best material to use in the construction of stills, for, although tinned iron is cheaper, the greater durability of the former renders them in the end more economical. The same typical forms may be seen in the construction of pharmaceutical stills as in glass distillatory apparatus,—*i.e.*, the alembic and retort.

Pharmaceutical Stills—Alembic Principle.—One of the most useful stills constructed on this principle was devised by Prof. Procter.

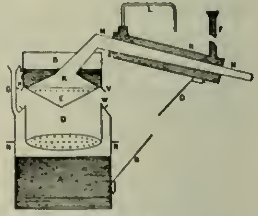
The still body was connected with the condensing head or dome by a water joint, and the sides of the dome were continued up into the head so that an alembic gutter was formed to catch the condensed liquid; this was delivered at the spout, and this spout was partly surrounded by the jacket. Water for refrigeration was supplied by a tube; this first circulated around the delivery spout, and then found an exit through a rubber tube. Wiegand's still is shown in Fig. 204. It differs from Procter's principally in the method of joining the head of the still to the body; the sides of the head are tapering, so that the head can be pressed down tightly into the body, and with the aid of flaxseed lute a tight joint can be made; the feed pipe is useful in charging the still, from the fact that it carries the liquid below the point where it would be likely to soil the condensing surface by splashing. Prof. Curtman's still (see Fig. 205) has several modifications about it which require special notice. The jacketing of the neck of the alembic, which is partially carried out in Procter's and Wiegand's stills, is extended so that it is converted into a Liebig condenser; a bent tube, L (see Fig. 205), serves to convey water partially heated from contact with the vapor over into the head, B. This modification is especially intended to strengthen alcohol which is in process of recovery from weak tinctures; the water used for refrigeration circulates around the central tube, N, in the Liebig's condenser, and then finds an outlet into the head B by means of the bent tube L. The intention is to regulate the flow of water so that it shall be sufficient to condense alcoholic vapor passing through the tube, the heated water from L being at the same time of a temperature just above that of the boiling point of alcohol (180° F.). The vapor of water coming over with the alcoholic vapor comes in contact with this heated surface, and, as the boiling point of water is 100° C. (212° F.), the temperature of the condensing surface (180° F.) is sufficient to condense the vapor of the water, but not that of the alcohol; thus the water is separated and trickles back into the still, while the alcoholic vapor passes on into the condenser.

Fig. 204



Wiegand's still

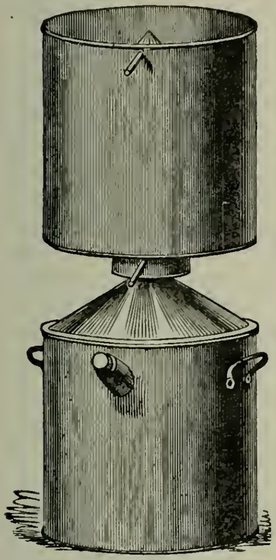
Fig. 205



Curtman's still

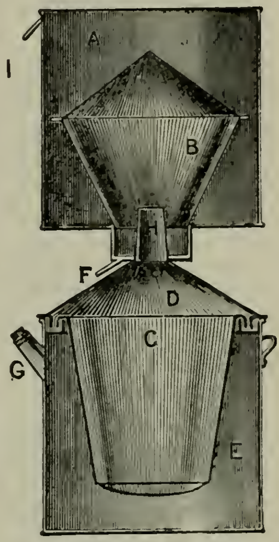
A still on the alembic principle, made by the Whitall Tatum Company, is shown in Figs. 206 and 207. E represents the boiler, the pan C being used as a water bath if required. The vapor rises through the tube H and passes into the chamber B, where it is condensed. The reservoir A is supplied with cold water, ice, or snow. The condensed liquid flows into a trough around the tube H and is discharged through F. At G there is a tubulure, closed with a screw cap, through which the boiler can be supplied with water or the liquid which is to be distilled. The reservoir A is furnished with an overflow pipe to conduct away the warm water as distillation proceeds. The still is simple in construction, but in practice it will be found advisable to attach a rubber tube to F to conduct the distillate away from the flame or other source of heat.

Fig. 206



Pharmaceutical still

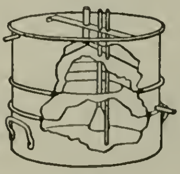
Fig. 207



Pharmaceutical still

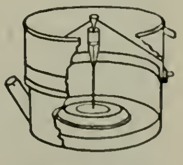
Fig. 208 represents Game's still, made by J. M. Maris & Co., of Philadelphia. This still is also constructed on the alembic principle, the special features being the tubes, as shown in the drawing, which are used to supply the still with liquid continuously during the distillation. One of the tubes connects with the reservoir and furnishes air to replace the liquid as it flows into the still; in the distilling chamber one of the pipes is shown descending nearly to the bottom of the still; one of the pipes terminates in an inverted funnel near the bottom for the purpose of lessening the possibility of the air pipe becoming closed by the splashing of a thick liquid. The mouth of this cone is about three-fourths of an inch above the bottom, and it will be seen that when sufficient liquid has been run into the still from the supplying tube to reach the bottom of the funnel tube, no more liquid falls from the reservoir, and thus the amount of liquid in the still is always limited. When the distillation reduces the quantity of liquid so that it falls below the level of the funnel tube, the liquid runs again from the reservoir, and thus the supply becomes automatic. The other parts of the still will be readily comprehended by inspecting Fig. 208.

Fig. 208



Game's still

Fig. 209



Stevens's still

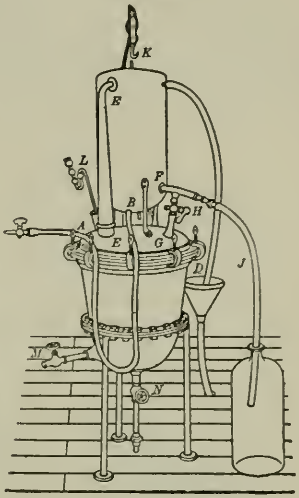
The still shown in Fig. 209 was invented by Prof. A. B. Stevens, of Ann Arbor, Michigan. As will be seen from the illustration, it is made on the alembic principle, but it has several features about it which differ from the stills heretofore described. A light copper float, having a central rod or stem, is arranged in the still body, so that it will warn the operator when the liquid in the still has evaporated below the danger point, previously adjusted. One of the best features about this still is the method of joining the two principal parts. The water joint, which is never satisfactory in actual practice, is replaced here by a rubber rod ring, which fits into a circular groove and is held in place by clamps which are easily disconnected when the distillation is over. The methods of conducting and refrigerating are similar to those indicated in the preceding descriptions of alembic stills.

Stills constructed on the alembic principle have the disadvantage of having the cold water supply directly over the source of heat, and, as the latter is usually a coal stove or gas burner, the cold water used for refrigeration is rapidly heated, and much more is required to effect condensation than is the case with stills constructed on the retort principle. Again, the delivery tube of the condensed liquid is immediately over the fire, and in recovering alcohol from weak percolates (one of the principal uses of pharmaceutical stills) the danger from alcoholic vapor taking fire is great, if constant vigilance is not exercised. Many accidents have occurred through the neglect of the operator to keep a constant supply of cold water applied to the condenser. In cities and towns where water is supplied by a tap or faucet the flow is sometimes stopped by the shutting off of the water when workmen are making repairs to the pipes, and serious accidents are thus likely to occur through the water in the condenser becoming so hot that it will not condense alcoholic or ethereal vapors, which soon come in contact with the flame, and fire or explosion results. In all stills made on the alembic principle care should be observed to connect a metal or glass tube with the delivery tube of the still, so as to lengthen it and convey the condensed liquid as far as possible away from the flame. Fortunately, water joints are now rarely employed. These usually consist of a gutter running around the top of the still body and filled with water; the head of the still is simply laid on top and held in place by a clamp; in a short time the heat evaporates the water, permitting the escape of vapor; hence watchfulness is required to renew the supply of water.

The distilling apparatus known as the Prentiss still, or alcohol reclaimer, possesses some peculiarities, a portion of the vapors being condensed immediately over the still. The still body has an upright column screwed to it; this connects by a union joint with the condenser, which is a single pipe bent into a zigzag form and terminating in a spout. The water intended for refrigeration is poured into the funnel at the top. The distinctive feature, however, is the series of perforated diaphragms which are soldered to a central rod and are placed inside of the column; these are asserted to impede the passage of and condense aqueous vapor when mixed with that which is alcoholic; the alcoholic vapor passes over and is converted into alcohol in the condenser, while the condensed water falls back into the still.

A condenser contrived by Charles Rice, in which the block tin worm is enclosed and placed immediately above the still head, is shown in Fig. 210. The still is heated by steam, which enters at *M*, *N* being the exhaust pipe. The still head is constructed of copper. The condenser is a cylindrical copper vessel, with rounded bottom and closed top, having short half-inch tubes projecting from the bottom and from the top at *B* and *C*. There are two such tubes at the bottom, one for attaching the rubber hose, *A*, bringing the water; the second, shown in the cut immediately alongside the letter *B*, is closed with a cork, and is used to permit the water to be emptied without detaching the hose from the other. At the top there are two tubes, one at *C* for attaching rubber hose to carry off the water into the wastepipe *D*; the other, which is closed with a cork, is not shown in the cut, as it is on the back of the condenser.

FIG. 210



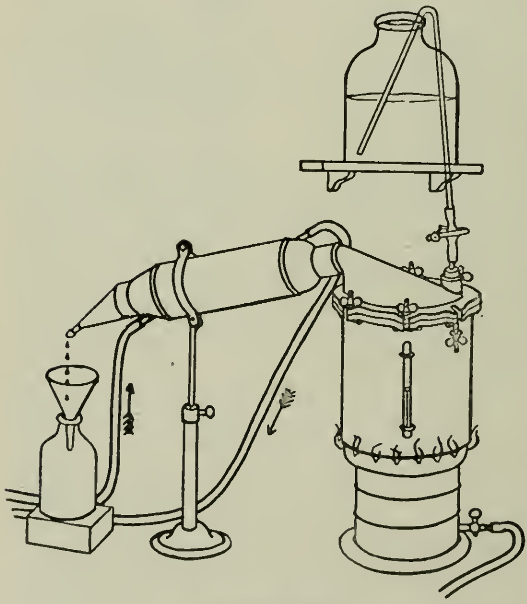
Rice's still and condenser

The head of the still carries three short tubulures, only one of which is visible in the cut. This one contains a cork bearing the safety valve, *L*. A second one is at the other side, for refilling the still when required, with another narrower tube intended for the insertion of a thermometer. The condensing pipe begins at *E*, where it rises from the head parallel with the condenser. It is made of copper as far as the point indicated by the upper *E*, where it is soldered to the *downward projecting* upper end of the block tin worm contained in the condenser and emerging from it at *F*. This arrangement makes it impossible for any condensed liquid to come in contact with anything but block tin. The worm inside the condenser is made by carefully winding block tin pipe upon a round block of wood, taking particular care to give the coil a uniform downward descent throughout. After emerging from the condenser at *F*, it extends for a short distance, where the cut shows it to be connected to the separate block tin pipe, *J*, by means of a union joint lined with tin. Half way between *F* and the end proper of the worm the pipe is tapped, and a branch, carrying the faucet *H*, leads into the still at G, where it terminates under the centre of the head in the form of an ∽, forming a trap to prevent the escape of vapors by this passage. The object of this arrangement is to cause the condensed liquid to flow back into the still as long as the faucet *H* is open, or to collect it outside by turning off the faucet. Prolonged digestions with alcohol may be made by means of this apparatus without any loss of liquid. The head is attached to the still by means of a rubber washer and iron clamps, and when it is desired to remove it the water is allowed to drain from the condenser, the clamps are taken off, and the whole is hoisted up by the tackle *K*, and moved aside.

Pharmaceutical Stills—Retort Principle.—The method of condensing vapors by cooling them in a separate vessel connected with the still by a tube or tubes has been largely employed. The simplest plan is to connect the still head with a Liebig condenser or a worm. The principal disadvantage of the former method is that considerable space is required in providing for the long tube and its refrigeration, and this is an important consideration in most laboratories. The disadvantage about the worm is one which is still greater, for, while space is economized, the spiral shape of the worm prevents the possibility of thoroughly cleaning it, and where a still is used for several purposes the odor and taste of the last liquid used in the still will be very apt to pervade and contaminate the distillate in process of collection. Kolle, in his endeavor to overcome these objections, retained the condensing tub, but, instead of using a worm, bent the pipe into a zigzag form and adjusted it in a vertical plane, the angles of the zigzag tube upon one side projecting through the sides of the tub. These projecting angles were made of separate, short pieces of tube, which were cemented to the condensing pipe. The objection to this condenser was the inconvenience of breaking and making so many joints. Mitscherlich improved Gadda's condenser by constructing a condenser from two cylindrical vessels, the inner one removable and yet capable of being connected with the outer vessel by a tight joint. Deficiency of condensing surface and the inconvenience of making vapor tight joints were objectionable in this condenser.

From a consideration of the necessity for some new plan for condensing liquids in pharmaceutical stills, whereby the above objections could be overcome, the author was led, in 1872, to employ the principle of the tubular boiler for condensation (see Fig. 211). The body of the still is made of tinned copper; the bottom is not rounded, but flat, permitting it to stand securely on an ordinary counter; the bottom is made of heavier copper than the sides, and is fastened by tucking and folding, thus making a tight joint. A glass tube water level on the side of the still shows when the liquid has been distilled to a dangerously low point, as well as heated to active ebullition, which may result in frothing. The glass tube may be removed from the lower connection by simply unscrewing the cap, and if a thick residue in the still remains, it may be transferred to a bottle or dish by allowing it to escape at the lower tube orifice, thus avoiding loss of product by waste. The still body is connected with the top by a "twine joint," a flat brass ring being soldered to the top of the still

Fig. 211



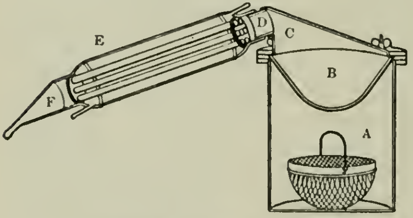
Remington still

body, and another of exactly the same size being soldered to the still top or dome. When the connection is to be made, a piece of soft, thick twine, two inches longer than the circumference of the ring, is soaked in water, and carefully laid upon the brass ring in such a way that the ends overlap; the top is then carefully laid upon the wet twine and securely fastened with clamps, which should be applied at opposite points at the same time, so as to bear equally. The new form of hinged clamps is shown in Fig. 211. They are fastened to the ring and cannot be mislaid, a disadvantage of the old form of clamps.

The *still top* differs from most others in having the opening for the escape of vapors drawn over to one side, instead of in the centre; by this arrangement the condensing surface of the dome is reduced to a minimum, and condensation *inside the still* is obviated as far as possible.

The construction of the condenser shows the application of a well known principle which has been made to do service for an opposite purpose. The substitution of a number of tubes of small diameter for one large vessel is recognized as an effective means of rapidly producing vaporization (see page 126). The principle is of equal value in condensation. The condenser has seven parallel, solid block tin tubes, surrounded by a copper case. This case is perforated twice, and a short tube is soldered in at each extremity. To the lower tube a rubber tube is attached, which is connected with a cold water faucet; a rubber tube is slipped over the upper short copper tube of the condenser for carrying off the water after it has served its purpose of condensing the vapors, which it does by circulating freely between the outer surface of the block tin tubes and the inner surface of the containing case. The proportions of this condenser are so adjusted that if any liquid likely to be used is actively boiled in the still body, and cold water is running through the condenser, there can be no escape of condensable vapor at the exit tube. In the condenser for the still holding three gallons the combined length of the tubes is about six feet, and about one hundred square inches of condensing surface are obtained. The condenser itself is fifteen inches long and about four inches wide. Straight, smooth, solid block tin parallel tubes are used because of the convenience of cleaning them. A piece of cloth wrapped on the end of a rattan or stiff wire may be rapidly pushed through each tube, which serves to clean it when a very odorous liquid has been distilled, but usually it suffices to hold the condenser under a hot water faucet for a few moments. The methods of connecting the various parts of the apparatus are simple. Two ground brass joints are made, one at the point of junction of the condenser, with the still head top, and the other where the nose piece is attached to the end of the condenser. These, on account of their comparatively small diameter, require no clamps or lute, and are vapor tight. Where a moderate heat below the boiling point of water is required the still body is placed in a kettle; and, if the quantity of liquid to be distilled is not large, a round bottomed, tinned copper water bath is clamped between the still body and still head, and the still body filled with water, the waste steam escaping through three apertures in the rim of the water bath. This water bath arrangement may be used in addition in making ointments. The automatic feeding attachment consists of a glass syphon, a rubber and a glass tube (the latter passing through a cork), and a pinchcock. The manner of using this is as follows: The still having been charged (about half full), the remainder of the liquid is placed in a vessel above the still body upon any suitable support; the syphon is placed in the liquid, then connected with the rubber tube carrying the pinchcock, and by suction or other means the syphon is filled and the pinchcock screwed down; the other end of the rubber tube is then connected with the glass tube running through the cork, which passes through the tubulure in the still head. Heat is now applied to the still body, the cold water faucet is turned on to supply the condenser with cold water through the lower rubber tube, and when the distillate comes over in a steady stream a narrow strip of paper is pasted on the glass gauge tube on the body of the still to mark the level of the liquid at starting. The pinchcock is then opened, and the level of the liquid in the still is regulated so that the liquid neither rises nor falls. This indicates that a stream of liquid from the reservoir above is running into the still exactly equal in volume to that of the distillate running from the exit tube, and the apparatus may be left to take care of itself. The empyreumatic odor which distilled and aromatic waters often possess, and which is usually caused by the solid substances lying in immediate contact with the hot still bottom, is obviated in this still by putting the substance into a hemispherical, coarse wire sieve cage (see Fig. 213). The round bottom of the cage prevents any possibility of contact with the flat bottom of the still, while circulation of the water and vapor takes place through the meshes; a handle serves to lift it out when the distillation is completed. Fig. 212 shows a dissected view of the still, which illustrates the relative position of the parts,—A, the still body; B, water bath; C, the still top, or dome; D, joint; E, condenser; F, exit tube for distillate.

Fig. 212

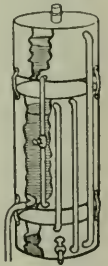


Remington still (sectional view)

Fig. 213

Wire cage

Fig. 214



Herrick's water still

A very useful automatic water still, devised by Herrick, is illustrated by Fig. 214. The lower vessel is the boiler, the middle one the condenser tank, the upper one the supply tank provided with a loose cover. The distillation of water proceeds, after it is once started, automatically. The advantages possessed by such a still are that a constant supply of distilled water can be furnished at a minimum cost. It can be operated by a gas flame, coal oil stove, or by placing it upon the top of a range or stove, or in fact by any source of heat, and a very little care suffices to keep it running. It is, of course, only suited for distilling one liquid like water, where a constant supply of liquid can be maintained, and is not intended to be used for general pharmaceutical work, such as recovering alcohol from weak percolates, etc.

Owing to the necessity for using distilled water in pharmaceutical operations, and to the widespread agitation in the public print on the subject of impure water in cities, distilled water has become an important product, and pharmacists in some localities use a water still constantly for supplying the demand. This has stimulated the manufacture of water stills, and a number of such are to be found on the market.

Fractional Distillation.—By this term is meant the process of separating by distillation liquids having different boiling points or vapor densities. When a mixed liquid, or one consisting of liquids of unequal volatility, is distilled, the first portion of the distillate contains a larger proportion of the most volatile constituent than of the others; hence the boiling point is observed to rise as the distillation proceeds; and if a means is provided for collecting the distillate in several portions, or fractions, as they are called, fractional distillation offers a process by which liquids may be purified or separated. It is impossible, however, *in a single operation* to effect this separation of the component parts of a mixed liquid perfectly, because the distillate obtained at any period of the process is nearly identical with the vapor that is rising from the hot liquid, and therefore it is made up of the condensed vapor of that part of the liquid having a boiling point at or below the temperature registered by the thermometer, plus the smaller amount of condensed vapor that is given off from the constituents having higher boiling points, but which emit sensible vapors much below the point at which they actively boil. The relative proportions of the constituents of the mixed liquids have also a bearing in determining the composition of the distillate. By collecting the fractions carefully at stated temperatures, and redistilling each by itself, a more thorough separation may be effected, and this method is usually followed when such a separation is necessary. Upon the small scale one of the simplest forms of apparatus for fractional distillation is made by taking a gas bulb (a glass flask having a bent lateral tube in the neck), and, having adjusted a perforated cork in the neck for a thermometer, passing the tube of the gas bulb into a loosely stoppered test tube, which is placed in a vessel surrounded with ice or properly refrigerated. A more efficient method is to connect the lateral ascending tube of a flask with the end of a worm, or a condenser so arranged that the liquid condensed at a certain temperature may run back into the flask. Vapors having lower boiling points pass through it uncondensed until they reach the second condenser, which is refrigerated to a degree sufficient to condense all the vapor. This method is used for manufacturing purposes upon the large scale.

Destructive distillation is the process of heating dry organic matter in a distillatory apparatus until all volatile substances are driven over. The residue is said to be carbonized. Destructive distillation is a process which is rarely employed by the pharmacist; hence it is not necessary in this work to treat the subject in detail. Glass vessels are not adapted to the process, because they will not usually stand the heat required without fracture, and the solid residue frequently fuses, is insoluble in water, and becomes so firmly attached to the bottom and sides that it cannot be removed without great difficulty. The best form of apparatus is an open vessel of cast iron, like a crucible, having a flange at the top, a dome with a corresponding flange, and a bent tube for carrying off the gaseous products. The connection is made with fireclay lute and iron clamps. The manufacture of acetic acid, creosote, methyl alcohol, etc., affords illustrations of the use of this process, which is nearly always performed on a large scale.

The application of the process of destructive distillation to wood results in the production of many valuable products, as acetone, methyl alcohol, methyl ether, acetic acid, creosote, tar, etc., while charcoal remains in the still. When applied to coal the distillate yields illuminating gas, ammonia products, coal tar, from which is obtained numerous phenol bodies, cresols, benzene, toluol, dye color bases, etc., coke remaining in the still.

The distillate from this operation represents a decomposition product,—*i.e.*, a substance which did not exist in the original matter placed in the still, but which results from the application of heat without the presence of air. A characteristic smoky odor, called empyreuma, is usually recognized in the distillate, but may be removed by purification.

CHAPTER VI

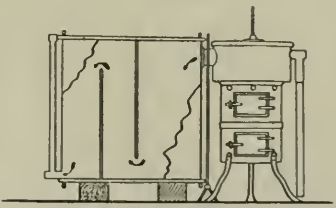
SUBLIMATION

SUBLIMATION is the process of distilling *volatile solids.* The product is termed a *sublimate.*

The objects of sublimation are as follows: 1. To purify volatile solids from admixed and fixed impurities. 2. To provide a convenient means of collecting volatile solids resulting from chemical reaction at high temperatures. The retorts or apparatus used may either be of iron or glass, or of stoneware if the degree of heat necessary will admit of the use of the latter.

Sublimation is almost exclusively confined to operations which are conducted by manufacturers on the large scale. A process was formerly official for the sublimation of benzoic acid. It consisted in introducing benzoin into a shallow tinned iron pan, and pasting over the top a sheet of filtering paper. A pasteboard hood, shaped like a hat box, was then fitted to the pan and tied or pasted with paper so that a tight joint was made. The apparatus was placed on an iron plate and subjected to a low but *uniform* heat. The vapors of benzoic acid passed through the pores of the filtering paper, were separated from impurities, and, coming in contact with a cooler atmosphere in the hood, slowly condensed, often forming crystals of great beauty.

FIG. 215

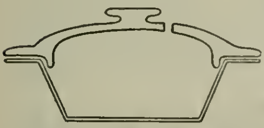


Sublimation of benzoic acid

Fig. 215 illustrates Hager's apparatus for subliming benzoic acid. The stove is shown on the right; upon the top is placed the vessel containing a mixture of benzoin and sand. A pipe enters this vessel at the upper part from the right; through this a regulated current of air is forced after the mixture has been slowly heated, and the vapors of benzoic acid are driven, as shown by the arrows, into the large chamber, where they condense and the crystals collect upon the partitions and floor.

The temperature at which the condensation of the vapor is effected in sublimation has a very important influence in determining the physical character of the sublimate, and two kinds of sublimates are produced,—1. Cake sublimates. 2. Powder sublimates.

FIG. 216

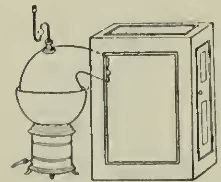


Subliming apparatus (cake)

Cake Sublimates.—If the temperature of the condensing surface and of the air in contact is but slightly below that at which the volatile body is capable of subliming, the particles will be deposited in compact masses, like corrosive sublimate, commercial sal ammoniac, or ammonium carbonate. Fig. 216 shows a simple apparatus for obtaining sublimates in cakes or masses. A shallow sheet iron dish, having its upper edge turned out so that it forms a flat ring, is provided with an earthenware cover (it will be usually found more convenient to have the iron dish made to fit the cover than the reverse), through which a hole is drilled to permit the escape of air (this may be done with a three cornered file). After the substance which is to be sublimed has been placed in the iron dish, a piece of asbestos twine, slightly longer than the circumference of the ring, is laid upon it, and this is covered with a lute composed of equal parts of potters' clay and flaxseed meal with sufficient water, the earthenware cover is pressed upon it until it adheres, and, when necessary, iron clamps are used to make a tight joint. The aperture in the cover is loosely covered with a cone of cardboard, the dish is placed in a sand bath and gradually heated. The aperture is kept open during the sublimation by occasionally probing it with a glass rod. After cooling, the sublimate will be found adhering to the earthenware top in one cake or mass, and may be removed by a spatula. The earthenware top may be replaced by a sheet iron one in cases in which the former would be likely to be fractured by excessive heat. For subliming iodine, earthenware vessels alone should be used.

Powder Sublimates.—If the apparatus for conducting sublimation is so contrived that there is a marked difference between the temperature of the air in contact with the vapor and the subliming point of the volatile body, the sublimate will be deposited very rapidly and in small particles, like calomel, sulphur, etc.

Fig. 217



Sublimiug apparatus (powder)

Fig. 217 shows a convenient apparatus for subliming camphor in powder. It is well adapted also for a lecture room illustration of the process. A wooden case has two openings made in the sides to admit sheets of glass, which are secured in place by putty in the usual manner. One of the sides has a hinged door, which fits the frame snugly; the opposite side has a tapering circular aperture, which admits the shortened beak of a retort, as shown in the cut. Camphor is placed in the retort, a safety tube is adjusted in the tubulure, and the retort is then placed deeply in a sand bath on a good gas stove. Care must be observed in heating at first, and a Bunsen burner should be at hand to heat occasionally those portions of the top of the retort and the beak upon which the sublimate is forming. When the boiling point is reached, the camphor vapor passes over rapidly, and at once falls in the form of powder upon coming in contact with the cold air in the chamber. The especial points to be observed are care in heating, and watchfulness that the beak of the retort does not become clogged with the sublimate. A judicious use of the Bunsen flame will soon melt the obstruction.

The most important, and in practice the most difficult, part of the operation of sublimation is the regulation of the heat. The temperature of the condensing surface should always be below the fusing point of the substance if distinct crystals or crusts are expected.

CHAPTER VII

DESICCATION

Desiccation is the process of depriving solid substances of moisture, and in pharmacy should be effected at as low temperatures as possible. (See Exsiccation.)

The objects of desiccating medicinal substances are threefold: 1. To aid in their preservation. 2. To reduce their bulk. 3. To facilitate their comminution.

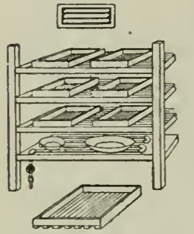
1. To Aid in Preservation.—Chemical salts frequently contain water either chemically or mechanically combined with them. An elevation in the temperature, or the absorption of water from moisture present in the air, will in some instances cause *deliquescence*, while in others contact with a dry atmosphere will cause *efflorescence*, due to the evaporation of chemically combined water; hence such salts in their natural condition are unstable; they are much more permanent when dried. Vegetable drugs soon decompose or become mouldy if allowed to remain in a moist condition, and desiccation is absolutely necessary to preserve them.

2. To Reduce Bulk.—If desiccation is performed successfully,—*i.e.*, at properly regulated temperatures under certain precautions,—the substance is merely deprived of water without suffering any loss of medicinal activity, and the reduction in bulk that follows is a practical advantage which results in adding to the strength of the medicinal substance.

3. To Facilitate Comminution.—The presence of water gives to drugs an elasticity and ability to resist disintegration, which in some cases interfere greatly with the process of bruising, grinding, or reducing the drugs to particles. One of the first steps in comminution is to dry the substance thoroughly in order to make it brittle or crisp.

The apparatus employed in desiccation is frequently of the simplest character, and the heat is usually not especially created for the purpose, for it is most economical to use the waste heat from kitchen fires or cellar furnaces or the diffused heat in lofts or unused attics. There can be no objection to this if care is taken to provide protection for the substance from dust, light, and injury during desiccation. Herbs may be dried by tying them in bunches and suspending them to the attic ceiling or to the rafters of a barn during summer weather, and this is an excellent method usually, notwithstanding its slowness, because there is no danger of the heat being strong enough to cause loss of valuable volatile principles. Roots, barks, and leaves may be dried by spreading them out upon clean tables or floors in a dry room and turning them repeatedly, so as to expose fresh surfaces to the dry air. On the large scale, and in the laboratory, special apparatus must be employed. Fig. 218 illustrates a portion of the interior of a laboratory drying room. Live steam is passed through the pipes when higher temperatures are needed, but waste or exhaust steam from steam kettles is economically and properly used. Trays of suitable size, containing the substance to be dried placed on thin muslin, are set upon the shelves of the rack. Ventilators should be provided to carry off the moist air. The space immediately over the steam boiler can often be economically used for a drying room by placing a sheet iron floor over it to secure the radiated heat, and arranging racks and trays upon it in convenient positions, or by placing the drugs in barrels in which the heads have been replaced by wire netting, or by simply enclosing the drugs in coarse bags which permit the escape of moisture.

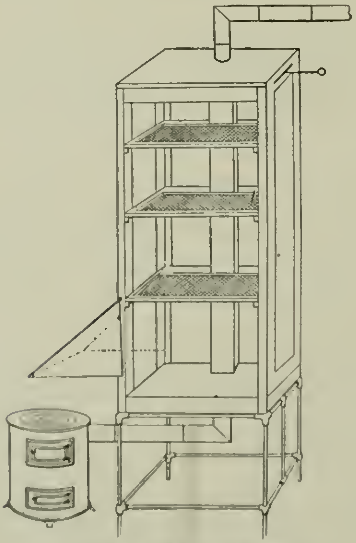
Fig. 218



Desiccating frame and trays

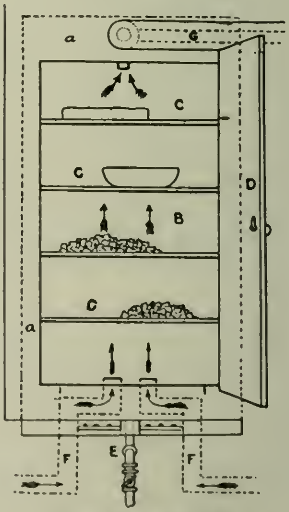
Fig. 219 shows a pharmaceutical drying closet which is simple, economical, and easily made. The heat from the flue of a pharmaceutical stove (see Fig. 65) is utilized. The frame which supports the closet is made of half-inch steam pipe, and to the uprights the retort rings (see Fig. 187) may be clamped, and the filtration of chilled oils in winter time, or warm filtration or percolation of many kinds, may be carried on. The sides of the closet are of galvanized sheet iron or of asbestos cloth, tacked to a wooden frame, and cleats at convenient intervals are arranged for the trays to slide upon. The stovepipe from the stove is connected with the flue at the bottom of the drying closet, and the heat from the smoke and gas passing up the

Fig. 219



Pharmaceutical drying closet

Fig. 220



Drying closet (gas heat)

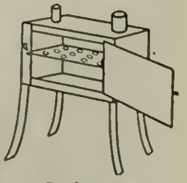
flue is thus utilized; the hood may be dropped over the top of the stove when the latter is not needed for other purposes, the heated air carrying the moisture from the substance to be dried, rising and escaping at the ventilators. Lozenges, crystallized salts, extracts, filters, etc., may all be dried in this cheap and simple closet. One practical point about desiccation is frequently overlooked. It is that substances which are being dried must be repeatedly turned over, so that the parts underneath shall be exposed to the external dry atmosphere. In the case of salts, crystals, and other bodies, if this is not done, a hard crust is formed upon the surface which is often difficult to break up.

A convenient drying closet, suitable for a small laboratory, is shown in Fig. 220. It was contrived by T. Edward Greenish, of London; it is heated by gas, and is intended to fit into a recess in the wall. The drying closet, B, is made of thin sheet iron, and provided with wire shelves, C, and a tightly fitting door, D. The closet is made of such a size that when fixed into the recess in the wall a space of about two inches is left at the back, sides, bottom, and top, the space being covered in front by the flanges *a*, *a*; these constitute, with the door, the front of the closet. E is a gas burner supplied from the pipe, and F, F are two air pipes which enter at the bottom of the closet. These pipes draw their supply of air from an *external* source, and thus the laboratory fumes and odors cannot taint the substances which are to be desiccated. The upper ends of these tubes are covered with a layer of sand two inches deep, forming a sand bath.

The gas being lighted is supplied with air from the front, and the heated air, together with the products of combustion, passes around the closet through openings made for that purpose in the sides and back of the gas chamber, up the space between the closet and the wall to a pipe, G, and thence to a chimney. The substances to be dried, or the liquids to be evaporated, are placed either upon the shelves or upon the sand bath. The air which enters by the pipes F, F, slightly warmed by the sand, will carry up any vapor therefrom to a pipe at the top of the closet, and thence to the pipe G. In order to regulate the draught of air at the back and sides of the closet, and thereby to adjust the degree of heat, the pipe G is provided with a circular damper, and the gas chamber also has in front of it an arrangement for regulating the supply of air to the gas, thus preventing sudden fluctuations of temperature. By these means the heat of the closet may be readily adjusted. If the temperature of the upper shelf is 82° F., the next lower will be 85° F., the next 88° F., the lower one 92° F., while the sand bath will register about 130° F.

A drying oven, intended for drying precipitates in analytical work, but very useful for desiccating small quantities of pharmaceutical substances, pills, lozenges, or drugs like squill, saffron, Castile soap, etc., is shown in Fig. 221. Water is poured into the tubulure at the top of the jacketed copper case, and a Bunsen burner furnishes the requisite heat when placed so that the flame touches the under surface, the legs of the oven being long enough to permit its use.

Fig. 221

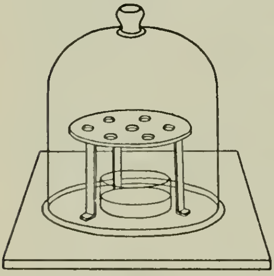


Drying oven

In Fig. 222 is shown a desiccator for use in finer laboratory operations. It consists of a bell glass having a ground rim fitting closely to a ground glass plate, a perforated porcelain dish is placed upon a tripod to hold the material to be dried, and underneath is placed a glass dish to hold sulphuric acid or other substance intended to absorb the moisture.

Loss in drying Medicinal Substances.—When drugs are powdered, loss is always experienced. This arises partly from the escape of fine particles, but principally from loss of moisture in drying. Again, in powdering almost all drugs, a portion remains which resists disintegration. This is called by the miller "gruffs," and is usually worthless and should be thrown away. The gruffs are frequently kept, however, and sent with the next lot of the same drug to be ground at the mill. The dose of a powdered drug is usually somewhat less than that of the same drug before it was pulverized, because the weight it has lost generally represents inert matter, water, etc. Powdered ipecac is a good illustration of this. The active principle *emetine* resides in the starchy cortical portion of the root; the internal ligneous cord constitutes the "gruffs" of ipecac, and is inert. The exception to this is the case of those drugs containing an active volatile constituent, like the aromatics, cloves, cinnamon, nutmeg, or like asafetida, myrrh, cubeb, etc. These drugs, when powdered, generally contain less of their active constituents than they did before they were ground. The volatile oils to which their virtues are due are driven off to a greater or less extent by the amount of heat necessary to make them brittle enough to be readily pulverized. The U. S. Pharmacopœia recognizes the importance of this fact by directing myrrh, and not powdered myrrh, in the compound iron mixture; asafetida, and not powdered asafetida, in the asafetida mixture; and in the compound tincture of cardamom by the direction to mix the unpowdered drugs, cardamom, cinnamon, caraway, and cochineal together, and reduce the mixture to powder, in preference to mixing the separate powders of these drugs. If care is exercised in desiccating, the powders of most drugs possess all their medicinal properties, and in many cases they will retain indefinitely these properties unimpaired if they are properly preserved and not unduly exposed to air, light, or moisture.

Fig. 222



Desiccator

The practice of some drug millers of establishing a loss in the weight of a drug as a regular standard, and then making up the deficiency by adding the same amount of some inert substance, is reprehensible. That the amount of moisture present in different lots of the same drug varies greatly may be seen by a glance at the following table, compiled by Mr. T. J. Covell from accurate records obtained from Dr. E. R. Squibb's drug mills. The table is valuable because it represents the loss in powdering considerable quantities of drugs:

Table showing Loss in Powdering Medicinal Substances

Substance	Greatest Loss percent. on any Single Lot	Smallest Loss percent. on any Single Lot	Average Loss percent.
Acacia	1.88	0.40	0.83
Acacia (granulated)	1.67	1.03	1.35
Aloe Capensis	19.31	7.09	11.13

CHAPTER VIII

COMMINUTION

Comminution is the process of reducing drugs to particles, or breaking up their state of aggregation.

Medicinal substances in their natural state require to be mechanically divided in order to facilitate the action of menstrua or solvents, or to permit their administration *per se* in the form of fine powders.

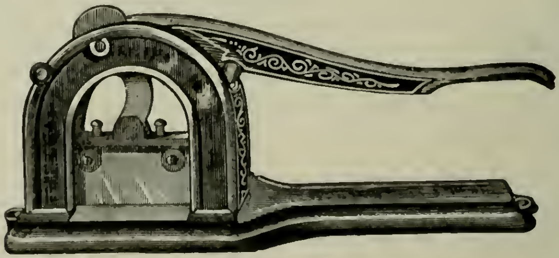
A simple illustration is offered in the case of alum. A solid lump of alum weighing one ounce, if added to a pint of water, will not dissolve nearly so quickly as will one ounce of the same alum in the same quantity of water *if finely powdered.* Vegetable substances offer very variable degrees of resistance in powdering, owing to the proportion and toughness of their ligneous fibre and the amount of cellular tissue.

Under the head of comminution will be grouped the various mechanical operations used in pharmacy by which the surface of solid substances is increased, whether by cutting, rasping, grating, chopping, crushing, rolling, stamping, grinding, powdering, triturating, levigating, elutriating, granulating, or similar processes.

By far the greater number of substances employed in medicine belong to the vegetable kingdom, and, while many of the processes of comminution used for these are also applicable to the chemical substances of the materia medica, it will be necessary in the following chapter to note the apparatus specially adapted to each class.

Cutting, Slicing, and Chopping.—This process is used principally in bringing roots, barks, leaves, herbs, etc., to the proper condition for treating with suitable solvents. For very small operations either the pruning knife or pruning shears answers a good purpose. The tobacco knife or herb cutter shown in Fig. 223 is well adapted for the purpose. It should be observed, however, that the principle upon which a knife operates successfully should be carefully carried out in constructing apparatus designed for cutting. Direct

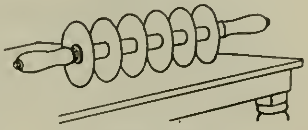
Fig. 223



Tobacco cutter

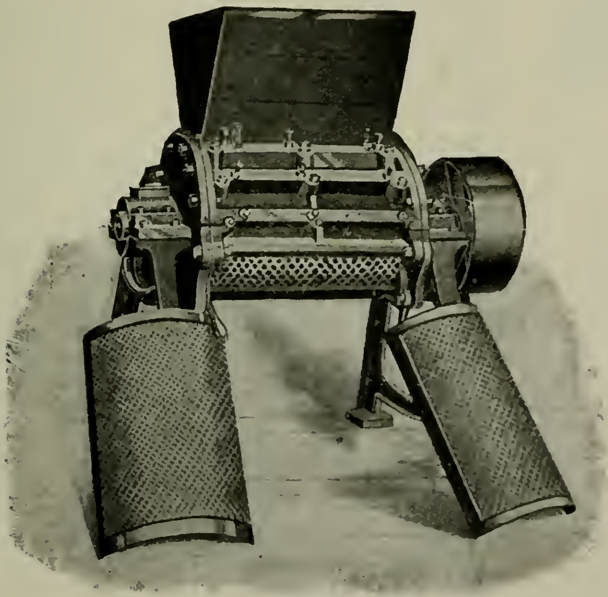
pressure without a slight drawing or sawing motion is not effective; therefore those knives which have guides arranged so that the knife edge sunders the particles at an angle are greatly preferred. Fig. 224 shows a roller knife which is very serviceable. It is made by W. Weber, Evansville, Indiana. The circular blades or knives are made of the same quality of steel that is used for saws, and are mounted upon a shaft, being separated by a series of spools or collars. The handles are of wood and mounted on the ends of the shaft, so that they are loose upon the shaft, thus permitting the handles to be grasped tightly while the roller knife revolves. The substances to be cut are placed upon a smooth board and the roller knife passed over them with more or less pressure. Upon the large scale drugs are cut with hay cutters, implements usually consisting of four or more circular blades fastened to a shaft and revolving at the end of a trough, down which the substance that is to be cut is gradually fed. Sarsaparilla root is cut in this way before it is contused. Fig. 225 shows a rotary cutter made by the Abbé Engineering Company, of New York. A cylinder to which is attached five knives revolves in a circular case, upon the inside surface of which are fastened six knives; the knives are straight but are set at a slight angle, so that a "shearing action" is exerted on the substance to be cut. The bottom

Fig. 224



Roller knife

Fig. 225



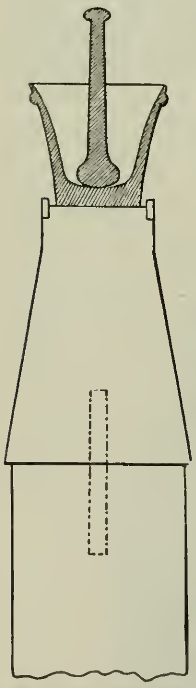
Rotary cutter

of the case consists of a perforated plate, which can be replaced, and as the knives revolve a portion of the cut substance drops through the perforations. What remains is carried around and again subjected to the action of the cutters; by selecting the perforated plates the product may be cut coarser or finer as required.

Rasping or Grating.—A half round rasp (see Fig. 166) or a nutmeg grater is very useful at the prescription counter, as it frequently enables the pharmacist to prepare a small quantity of a powder for a prescription in case the regular stock bottle is found empty or a very fresh powder is needed. The small pocket pepper mills used by European travellers, but now to be obtained in this country, for grinding whole pepper at the table will be found especially useful.

Contusion, or bruising, is an operation very frequently resorted to. It may be defined as the process of reducing a drug to particles by striking it a succession of blows. The instrument generally employed is the well known mortar and pestle, which, for contusing drugs, should be made of cast iron, bell metal, or brass. The shape best adapted for this purpose is shown in Fig. 226, the mortar being represented on a mortar block. The bottom of the mortar should be flat and heavy, so that it may rest firmly upon whatever base it is placed; the sides should flare slightly, but the mortar should be so deep that substances will not be easily forced out on to the floor by the blows of the pestle. A leather or wooden cover should be used upon the mortar when corrosive or irritating substances are contused. The pestle should be heavy and sufficiently flat on the under surface to permit the convexity nearly to coincide with the concave surface of the mortar. The inner surface of the mortar should be tinned, to prevent rusting and facilitate cleaning. The best support for an iron mortar is the top surface of a hard wood post six or eight inches in diameter and of sufficient length to pass from the top of the floor into the cellar and rest on the ground. A turned wood mortar block two feet high should rest upon the post; this block should have a flat iron hoop upon the top projecting half an inch above the surface, as suggested by Dr. H. T. Cummings, while the bottom should have an inch hole bored up through the centre for the distance of twelve inches; an inch wooden pin, two feet long, should be firmly fixed in the centre of the post for the distance of twelve inches, which would leave twelve inches of the wooden pin projecting above the floor. Now, if the mortar block is placed over it so that the pin enters the hole in the base, it will be found that a solid foundation is provided for resisting the blows of the pestle, and jarring and vibration, so destructive to balances and fragile apparatus, are prevented.

Fig. 226



Mortar and pestle (on a mortar block)

When for good reasons the post support cannot be used, the next best base is a deep, strong box filled with dry sand. The principal objection to this is the constant loss of the sand and the inconvenience of having it spilled on the floor. When it is necessary to use an iron mortar and pestle for a continuous operation, for a considerable length of time, it will be found advantageous to connect the upper part of the pestle with an elastic wooden spring attached to the ceiling, so that the labor of lifting the pestle will be lessened. This spring is preferably made from a tapering hickory strip seven or eight feet long and four inches wide at the base, the rope connecting the pestle with the end of the spring being of such length that the pestle barely touches the bottom of the mortar when the spring is stretched to its utmost tension. On account of the large number of mills scattered over the country, established for grinding drugs, and the increase of facilities for grinding and powdering drugs on the large scale, the skilful use of the mortar and pestle by the pharmacist must be regarded as a lost art. The necessity for thoroughly drying drugs before subjecting them to comminution has already been mentioned. (See Desiccation.)

Wooden mortars and pestles are occasionally used for contusing soft bodies, like prune pulp, almonds, recent fleshy roots, substances that are affected by iron, etc. Lignum vitæ is a very hard and suitable wood for this purpose, although boxwood is preferable when it can be procured, because it has less tendency to split.

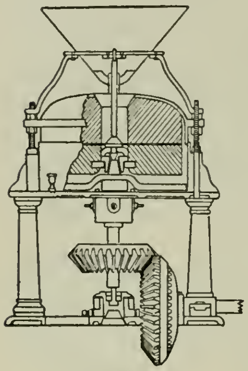
Marble mortars are also used for operations of a similar character on a somewhat larger scale; but care must be used to avoid putting substances containing acid into such mortars, on account of the reaction upon the marble and the consequent contamination of the product.

Grinding and Pulverizing.—The former term is applied to the reduction of a substance by mechanical means to *coarse* particles, the latter to the production of *fine* particles. These processes are the most important of any grouped under comminution. At present they are very largely carried on by drug millers. It is necessary for the pharmacist to be familiar with the methods employed, however, if intelligent judgment is to be exercised in the subsequent treatment of the vegetable and mineral substances of the materia medica. Before pulverizing a substance it must be dried, and the desired fineness of the powder determines the character of the preliminary treatment. In order properly to grind or powder substances upon the large scale, special knowledge and experience are required; previous acquaintance with the methods best suited to accomplish the object on the small scale, while useful to some extent, will be found inadequate. If a drug is to be coarsely ground, the necessity for thoroughly drying it is generally not so pressing as when a fine powder is to be made of the substance; drugs containing volatile oils are apt to be rendered worthless if they are dried sufficiently to enable them to be ground to a fine powder. Myrrh, cloves, cubebs, nutmegs, etc., afford good illustrations of this; hence these drugs are preferred when coarsely powdered. Within the last few years an important change in pharmaceutical practice in this respect has been effected, and preparations in which formerly very fine powders were directed are now ordered to be made from coarse powders; the processes for extracting the soluble principles having been greatly improved, the necessity no longer exists for using the very fine powders, and hence volatile principles are not sacrificed.

Drug Mills

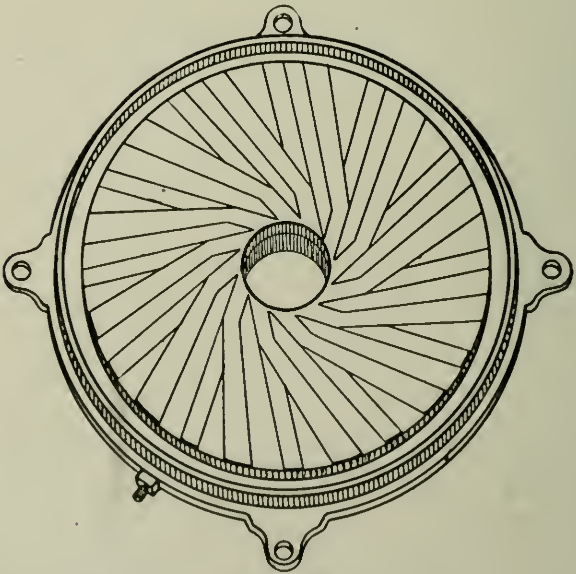
The buhrstone mill is very extensively employed in drug milling. There are two kinds, termed respectively under runners and upper runners. The principle upon which this mill operates is that of reducing the substance to particles by the friction and contusion that follow the delivery of the substance in the contracted space formed by a rapidly revolving stone disk, brought in nearly close contact with a similar disk which is stationary. In the under runners the upper stone is stationary and the lower stone revolves, the upper stone having a central circular opening through which the subtance is fed, as shown in Fig. 227, the under stone being connected with the shaft. In the upper runners the lower stone is stationary, the upper stone being perforated as in the under runners. In both, the stones revolve horizontally. The stone used must be very hard. The best buhr-mill stone is obtained from the old and celebrated quarries of La Ferté-sous-Jouarre, in France. The surfaces of the millstones are crossed with "furrows," which pass from the centre to the circumference, as shown in Fig. 228. The object of the furrows is to provide a means

Fig. 227



Buhrstone mill

Fig. 228

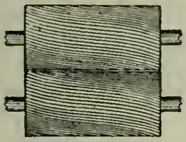


Buhrstone

for the passage of the ground particles to the outer circumference and to the trough. This is accomplished through the centrifugal force and current of air caused by the rapid revolution of the stone in motion. The fineness of the powder is regulated by raising or lowering one of the stones, this of course increasing or decreasing the space between them ; the character of the powder is also influenced by the dressing of the stone. Fig. 227 illustrates one of the best of the buhrstone mills,—Munson's under runner.

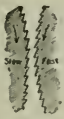
Roller mills operate by crushing, or crushing and cutting, the substance. In their simplest form they consist of two smooth faced iron rollers revolving in opposite directions, which can be brought into close contact by regulating screws. The principle has been extended and improved in modern milling, so that for grinding certain drugs this mill gives excellent results. The rollers are now made of steel, chilled iron, or biscuit (porcelain), and are corrugated or ribbed to suit special purposes. The sections of these corrugations are serrated, undulated, or crenated. The rollers revolve in the same direction or in opposite directions, and at equal or different speeds. Fig. 229 shows the position of the grooved rollers, and Fig. 230 shows a sectional view of the same. Corrugated roller mills are used in grinding drugs, but they are much more largely employed in flour mills.

Fig. 229



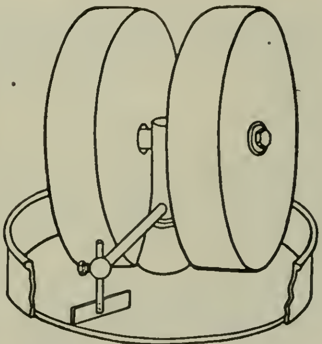
Grooved rollers

Fig. 230



Grooved rollers (cross section)

Fig. 231



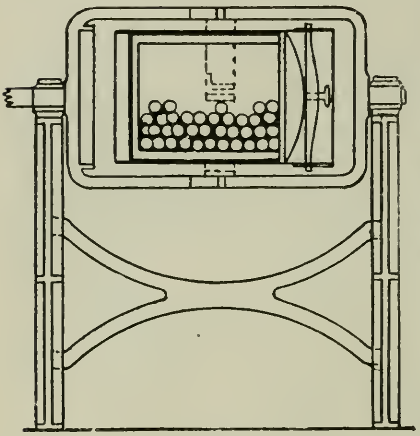
Chasers

Fig. 232

Chasers (curved grinding surface)

Chaser mills are so called because two heavy granite stones, mounted like wheels and connected by a short horizontal shaft, are made to revolve or *chase* each other upon a granite base (see Fig. 231). The stones are discoid, and the grinding surfaces are the circumferential edges of the stones and the surface of the granite base ; an iron cylinder, called a "curb," surrounds the circular base, and a "scraper," made of iron and adjusted at an angle, is connected with the shaft. It is evident that if the substance to be powdered is delivered upon the granite base in the path of the rapidly revolving stones it must speedily be reduced to powder, not only on account of the crushing weight of the heavy stones, but also because of the attrition caused by the outer edge of the stone travelling through a longer distance than the inner edge. In some mills the stones having flat, grinding surfaces have been replaced by stones having curved surfaces, and the flat base by a circular gutter curved to correspond with that of the surface of the stone. In this way the grinding surfaces have been greatly increased and rapid pulverization facilitated. Fig. 232 shows the shape of the stones of this form in use in Squibb's drug mill. In practice the chasers are enclosed in a tight box or small room. closed with air tight doors, and the substance to be powdered is fed in from the top by an elongated funnel, the spout of which delivers the material immediately upon the path of the stones. The height of the curb is increased by pasting heavy paper around it, and the fineness of the powder is influenced by the height of the curb. The revolution of the chasers produces an upward current of air; this carries over the lighter particles, which fall outside the curb and are subsequently collected as a fine powder; those particles which are larger are of course heavier and cannot rise to the height of the curb, but fall back under the stones to be reground. In this way refractory substances can be reduced to very fine powder. Chasers are more largely employed in making "dusted" or very fine powders than any other form of pulverizing apparatus.

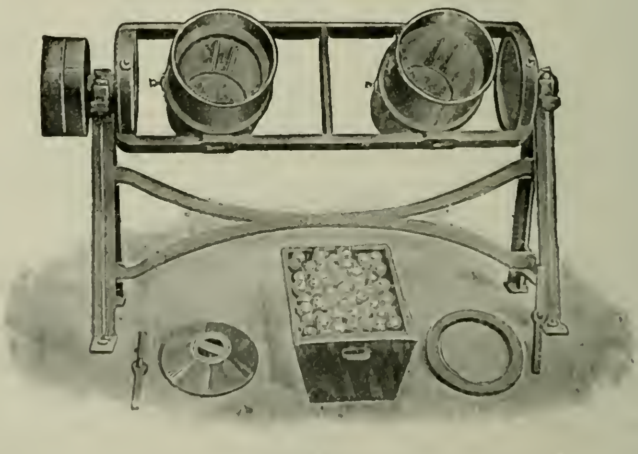
Fig. 233



Single jar mill

Pebble Mills.—These mills are operated on the principle of *attrition*, the grinding being effected by bringing the substance in contact with "pebbles" of flint or porcelain balls confined in jars or cylindrical vessels which are caused to revolve at a regulated speed. The advantages of such mills is that they afford a large grinding surface within

Fig. 234

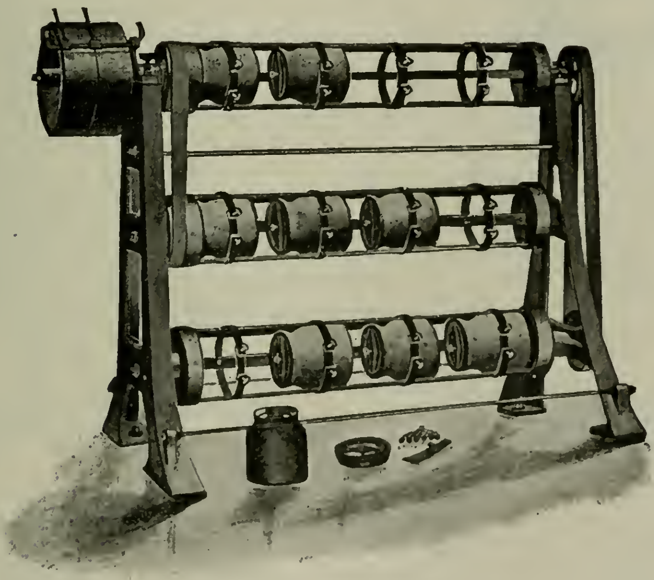


Double jar mill

a limited space. They are cleanly in their action, economical, and, on account of the simplicity of their construction, not liable to get out of order. Much depends, however, upon the hardness of the pebbles; for it must be seen that these are continually operating against each other while in action, particularly if care is not used in "feeding" the mill frequently. Such mills are adapted for grinding friable substances, extracts, chemicals, etc. Fig. 233 shows a sectional view of a single jar mill, Fig. 234 illustrates the double jar mill, while in Fig. 235 three batteries of laboratory mills are shown. The advantage of this combination is that four, six, or a dozen different substances may be ground at one time, and, as it is not necessary to put a definite weight in each jar, the quantity can be made to suit the demand.

Mills with Iron Grinding Surfaces.—Many mills have been constructed from time to time to suit special purposes. These cannot be noticed at length in a work having the scope of the present one. *Barrel mills* have been used. These consist of strong barrels lined with sheet iron, supported by strong iron shafts attached to the heads. The substance to be comminuted is placed in the barrel, and large round iron balls, like cannon balls, are introduced. Upon revolving the barrel rapidly, disintegration is effected. This principle is used also in pulverizing dried extracts and friable substances. A hollow circular iron ring, having a diameter slightly larger than that of the cannon ball which is placed inside with the charge of substance to be powdered, is made to revolve rapidly; the inertia of the cannon ball and the friction render its speed less than that of the ring, and the

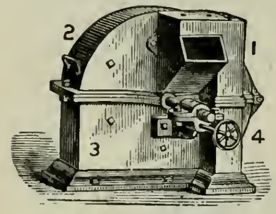
Fig. 235



Battery of pebble mills

substance is quickly ground. The *Bogardus mill* is constructed on a very ingenious principle. The grinding surfaces are two horizontal chilled iron plates, the lower one revolving, the upper one stationary ; both have corrugations having sharp edges, arranged concentrically. The peculiarity of this mill is that the centres of the grinding plates are not directly over each other as in buhrstone mills, but the centre of the lower plate is placed a few inches to one side ; by this arrangement the substance to be ground is caught by the ring edges of the revolving plate and dashed against the cutting edges of the stationary upper plate at an angle, the effect being to incise it as if cut with scissors and crush it at the same time.

Fig. 236



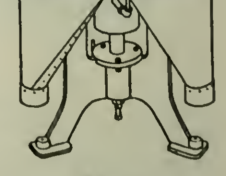
Mead's disintegrator

Mead's disintegrator differs from the mills thus far considered in the principle of construction, in the character of the grinding surfaces, and in its method of operation. The grinding is effected by hardened steel beaters riveted to a steel disk, which revolves vertically between corrugated rings ; the beaters are placed on the side of the disk nearest to the feeding trough, and catch the material as it enters the mill, beating it with great force against the corrugated rings until it is fine enough to pass between the disk and the face of the rings ; as soon as it passes here, it is on the side of the mill from whence it is discharged, and all that is fine enough is immediately driven out by the beaters on the back of the disk. That portion of the substance which is not fine enough is caught by the beaters and beaten against the screens until sufficiently fine to pass through. The screens are two inches in width, and extend around three-fourths of the diameter of the mill. They are made of square steel bars, and present a grinding surface to the beaters, but there is sufficient space between them to permit the passage of fine particles. The substance, as it is ground, falls into a receiving box below the mill, or is discharged through the floor into a room below. One prime requisite in running this mill is high speed. The disk must make three thousand revolutions a minute. The disintegrator is capable of grinding one hundred and fifty pounds of Ignatia bean, or six hundred pounds of wild cherry bark, in one hour. Fig. 236 gives an illustration of the mill, while Fig. 237 shows an enlarged view of the revolving disk and a section of the screens immediately above.

Fig. 237

Revolving disk and screens

Fig. 238



Max mill

The Max mill (Fig. 238) made by the Abbé Engineering Company, like Mead's disintegrator, acts on the principle of *percussion*. Power is conveyed by a vertical shaft, to which is attached a carrier provided with hard steel beaters, and as the substance is fed into the mill it is thrown by centrifugal force against a corrugated hard iron plate, the particles at the same time being thrown into violent contact with each other. Coarse or fine powders can be made at will.

Hand Mills

It is more difficult to construct a drug mill for the general use of the pharmacist than one for the special purposes of a drug miller. The latter has the choice of a buhrstone mill, chaser, disintegrator, iron mill, etc., which he can adjust to suit the character of the substance he desires to grind. The pharmacist's drug mill, on the other hand, is expected to do all kinds of work rapidly and well. It must, therefore, be capable of ready adjustment, possess durability, and have cutting surfaces not quickly dulled, and working parts not liable to get out of order.

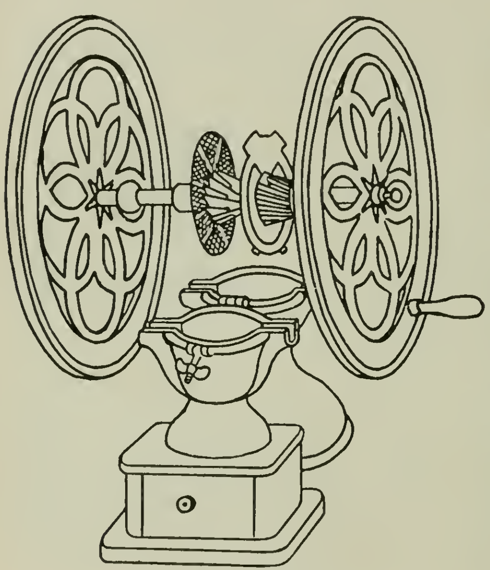
It is not easy to realize that every medicinal substance has an individuality of its own, but he who neglects the study of the physical characters of the substances of the materia medica can never expect to overcome successfully the obstacles which stand in the way of disintegration. Hand drug mills may be divided into three classes: 1. Those having vertical grinding surfaces. 2. Those having horizontal grinding surfaces. 3. Those having conical grinding surfaces. They have the following points in common: iron is the principal material of construction, the grinding surfaces are of hardened iron or steel and consist of teeth arranged in concentric rows, and the regulation of the fineness of the powder is effected by a screw or screws, by which the plates are made to approach or recede from each other.

1. Hand Drug Mills with Vertical Grinding Surfaces

Swift's Mill (old style).—This hand mill has been in use longer than any other in the American market. Its introduction marked an era in the history of pharmacy, and, although superseded now by greatly improved mills, it is still remembered with grateful feelings by those of the present generation, who had been previously accustomed to laborious mortar practice. In this mill there are two vertical grinding plates, one of which is stationary, while the other is connected with the horizontal revolving shaft; a conical breaker is also attached to the shaft, and when in position it is immediately below the lower opening of the hopper; a fly wheel with a handle is bolted to the outer end of the horizontal shaft, and furnishes the power required. The teeth are of iron and arranged in concentric rows, and the plates are made to approach each other or to separate by an adjusting screw. The supports of the mill are of ash or oak, and are durable and firm. The principal disadvantages of this mill are the difficulty of cleaning it, its slow action, its liability to become clogged, and the absence of a tight box or drawer to receive the ground drug. Two improvements have been made in the Swift's new style mills. In one the fly wheel has been made larger and heavier, in the other a double fly wheel has been attached.

Troemner's Mill, while constructed upon the same principle as Swift's, is much more thorough in its action, and requires less labor to operate it, than Swift's mill (old style). It has vertical plates, a thumb screw to regulate the fineness of the powder, a heavy fly wheel, and a close fitting drawer to receive the powdered drug. It is not so easily cleaned, however, as the next mill to be mentioned.

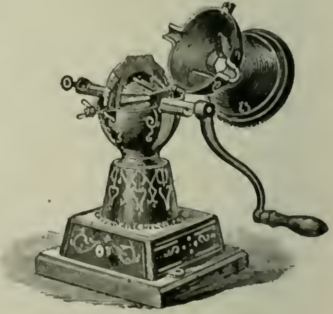
Fig. 239



Enterprise drug mill

The Enterprise Mill.—The introduction of this mill, in 1875, gave an impetus to the manufacture of hand drug mills which is still felt. The application of several new principles, and the extension and improvement of some valuable old ones, at once gained the attention of practical pharmacists. The great advantage possessed by this mill over those in the market at the time it was introduced was the ease with which the interior and the working parts could be reached. The principle of supporting the grinding plates upon a horizontal shaft, to the extremities of which heavy fly wheels were attached, and providing a means for lifting all the working parts out of the interior to facilitate their cleaning, were novel features. Fig. 239 so thoroughly illustrates this mill that it is hardly necessary to dwell upon its other features. The left hand grinding plate revolves, being geared to the shaft, while the one on the right hand is stationary. When in position for grinding they are, of course, nearly in contact. The opening of the interior is effected by simply turning the thumb screw in front. A smaller mill is shown in Fig. 240. It is very conveniently used at the dispensing counter.

Fig. 240



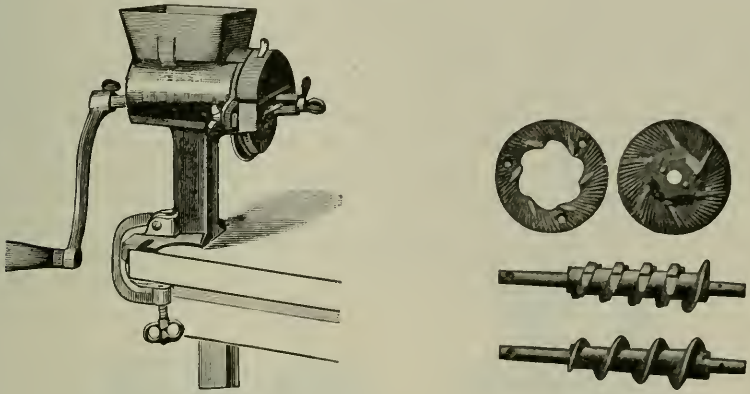
Drug mill (dispensing)

The small mill, made by the A. W. Straub Co., of Philadelphia, shown in Fig. 241, is very useful at the counter of the pharmacist for grinding small quantities of drugs; the plates and crushers are also shown. Ball bearings are used to facilitate easy running. The adjustment for making coarse or fine powders can be quickly changed, and it is the best small mill in use.

2. Hand Drug Mills having Horizontal Grinding Surfaces

Thomas's Mill.—This was one of the first hand drug mills made upon this principle. There are two horizontal grinding plates, the lower one revolving and the upper one stationary. A vertical shaft, which is geared to a horizontal shaft by bevel wheels, communicates the power to the lower plate upon revolving the fly wheel. The absence of a closed receptacle, and the difficulty of quickly cleaning the grinding surfaces, are the principal objections to this mill.

Fig. 241



Quaker City F. No. 4 mill

Plates and crushers

Swift's B Mill.—This is a comparatively new mill, very different in appearance from the old Swift's mill, and different in principle. The grinding plates are horizontal, the lower one revolving, while the upper one is stationary and forms the lower part of the hopper. It has two fly wheels, but the receptacle for the powder is an open one. A valuable feature of the Enterprise mill is present here,—*i.e.*, that of opening horizontally in the centre. The fineness of the powder is regulated by raising or lowering the lower plate by the thumb screw.

3. Hand Drug Mills having Conical Grinding Surfaces

The principle of construction in these mills is probably the best, because it avoids the fault of those constructed on the vertical plate principle, that of permitting particles to drop into the receptacle before they are finely ground, and also the fault of the horizontal plate mills, which may hold the ground particles too long, often until clogging results. The conical plate mill, if properly constructed, leaves little to be desired.

Hance's Mill is made on this principle. Formerly, the objection to this mill was the loss of time and labor consumed in getting it apart. This has been obviated by the introduction of the principle of opening it horizontally with the same kind of thumb screw and hinge that is used in the Enterprise mill. The Hance mill is better adapted for heavy work than any other of the hand drug mills, and, if desired, a belt and pulley can be attached for steam power. The lower plate is conical in shape, the summit being elongated into a breaker; the teeth are arranged in consecutive rows, a scraper being attached to the under surface of the lower plate; the upper grinding surface is situated upon the lower surface of the hopper, and corresponds in shape and in the arrangement, number, and size of teeth with the surface of the lower plate. The revolving plate is attached to the upright shaft by a simple key; this permits the easy removal of the plate when the mill is to be cleaned, yet holds it securely when in operation. Power is communicated by means of two shafts at right angles, geared with bevel cog wheels. The fineness of the powder is regulated by a thumb screw at the base, which elevates the revolving plate. The support to the mill is a strong iron frame, which is cast in one piece, and, although the mill has but a single fly wheel, this is partially compensated for by the length of the bearing for the horizontal shaft. Figs. 242 and 243 show the form which is designed to be bolted to the working table or counter; the new form, in which the mill is mounted on a box stand, may be preferred by some. Fig. 242*b* shows the upper grinding plate, and Fig. 242*a* the lower plate; a feeder is shown lying upon the counter, which is fastened to the upper portion of the lower plate by its set screw, so that seeds and similar drugs may be automatically fed to the mill.

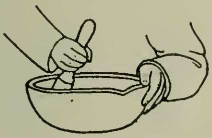
General Rules for operating Hand Mills.—Much of the dissatisfaction experienced in operating hand mills has arisen from improper methods of using them, or from failure to measure accurately the degree of resistance to disintegration possessed by the substance to be ground. One of the first requisites, as before mentioned, is to dry the substance as perfectly as its physical character will permit without injuring it. If coarse, bulky, fibrous roots, barks, or similar substances are to be ground, they must first be cut or bruised. Most substances are ground with less labor if they are first passed through the mill with the coarse adjustment, returning the portion which is sifted out, for regrinding, after setting the plates more closely together. This plan is repeated until the whole is ground. Care should be taken not to feed the substance into the hopper faster than it can be ground. The desire to get through quickly is the most frequent cause of clogging the mill, and when this occurs much time is lost, and the operator is strongly reminded of the well worn proverb about undue haste. If a considerable quantity is to be ground, two persons can operate the mill more economically than one,—one feeding the mill carefully, the other supplying the physical labor, and, after the expiration of a given time, exchanging places. Good judgment is necessary in determining the rapidity with which substances can be fed into the hopper. Resinous or oily drugs, or substances which soften by heat, require very careful treatment and cannot be fed rapidly; dry ligneous barks or roots, on the other hand, can be fed as rapidly as the extent of grinding surface of the mill and the muscle of the operator will permit. The mill should be thoroughly cleaned after each operation, particular attention being given to the grinding plates. In the case of substances which form hard lumps by heating or clogging up the plates, the quickest way is to use boiling water to soften or dissolve the lumps; the plates should then be quickly dried, to prevent rusting. By running sawdust or rice chaff through a mill, after an odorous drug has been ground, it may be speedily cleaned and freed from odor.

FIG. 244

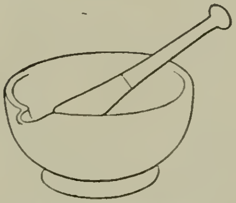


Trituration

FIG. 245

Spiral track of the pestle

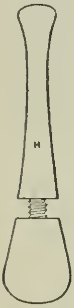
FIG. 246



Mortar for trituration

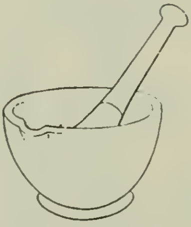
Trituration is the process of reducing substances to fine particles by rubbing them in a mortar with a pestle. The pestle is given a circular motion, accompanied by downward pressure, and the most effective method of using the pestle is to begin in the centre of the mortar and describe a circle of small diameter with the pestle on the substance, and gradually increase the size of the circle with each revolution until the side of the mortar is touched, when the motion is reversed and circles continually smaller in diameter are described until the centre is reached. This is repeated until pulverization is effected. By this treatment all the particles are brought under the action of the pestle. Fig. 244 shows the manner of holding the mortar during trituration and Fig. 245, the spiral, showing the direction traversed by the pestle in trituration as described above. The mortar and pestle best adapted for this operation have the shape shown in Fig. 246. Mortars with pestles having flattened ends are the best. Wedgwood ware is very serviceable, but is difficult to keep clean. As triturating mortars are rarely subjected to blows, porcelain mortars of proper shape are preferred. One of the principal annoyances in the use of wedgwood or porcelain mortars and pestles is that of the continual loosening of the handle of the pestle. The cement employed by the manufacturer is chiefly rosin of bad quality, and in using the pestle the particles of loosened cement often drop into the mixture in the mortar during trituration. The best plan is to pull the handle out of the pestle entirely as soon as possible and reset it. This is easily done by heating the end of the pestle in a sand bath until the cement has softened so that the handle may be extracted, then some hot cement (good sealing wax) is poured into the pestle hole, and the wooden handle is at once pressed forcibly in and held in its place by wedging or other means until the sealing wax has hardened. The hard rubber handle, which is made to screw accurately into the pestle (see Fig. 247), is a great improvement over the ordinary handle, and the additional cost is more than repaid by the comfort of using it. Where trituration is combined with contusion, as frequently happens in effecting solutions of chemical substances, a wedgwood mortar of the shape shown in Fig. 248 is well suited for the purpose. The selection of good mortars and pestles is frequently overlooked amidst the many items of detail in furnishing a pharmacy; but few implements bring more satisfaction to the operator than good mortars and pestles. It is a safe rule to examine every purchase carefully before accepting it finally, to see whether the pestle fits the mortar accurately. It should have as much bearing on the interior surface of the mortar as its size will permit, because the rapidity of the trituration depends largely on the amount of contact of the surfaces. The use of a round surfaced pestle in a flat surfaced mortar is just as great a waste of labor as that of a flat surfaced pestle in a round surfaced mortar. Trituration, as a distinct method of preparing a class of preparations, was officially recognized in the U. S. Pharmacopœia of 1880, and a new preparation, *Trituratio Elaterini*, made by triturating elaterin with sugar of milk, was introduced.

Fig. 247



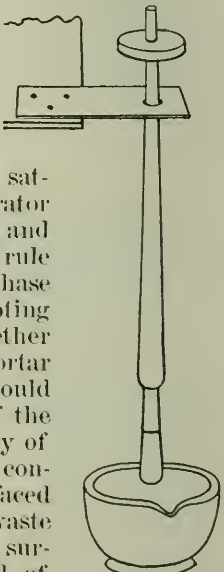
Pestle, hard rubber handle

Fig. 248



Wedgwood mortar and pestle

Fig. 249

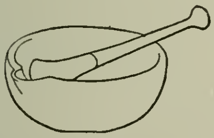


Triturating with a loaded pestle

Fig. 249 shows a device for facilitating trituration. It was communicated by Charles Rice, and is simpler and more effective than similar contrivances which have been described. It consists of an ordinary mortar and pestle, the latter having been lengthened by cutting down the mushroom top of the handle, so as to admit of its being inserted into the large end of a wooden handle, shaped somewhat like a ball bat, and between two and three feet long. The upper end of this handle should be about an inch in diameter, and during the use of the pestle is to be kept upright and steady by passing through an opening in a piece of heavy pasteboard or wood which may be tacked to the under side of some convenient shelf. The mortar should stand on a counter about three feet from the floor, and the upper end of the pestle pass through a shelf above. To stop the noise caused by the pestle striking against the sides of the opening, a piece of sole leather is attached to the under side of the shelf and the pestle passed through a hole in its centre. This also serves another purpose,—viz., when it is necessary to raise the pestle to admit of changing or stirring the contents of the mortar, the leather will clasp the enlargement of the handle so as to suspend the pestle securely out of the way of the hands. In using the apparatus, one hand grasps the handle just above its lower end, and a very slight effort is requisite to give it the necessary motion. The weight of the handle is usually sufficient to insure a proper degree of friction. If, however, more pressure is desired, the pestle can be weighted by slipping a perforated weight on to an iron pin driven in the top of the handle.

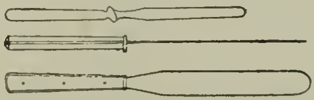
Mortars and pestles are sometimes made of green or white glass. The former are to be preferred because they are stronger; the latter, however, present a handsomer appearance. Glass mortars are not adapted to the continued trituration of hard substances. They are useful only in dissolving certain chemical substances directed in prescriptions, like corrosive sublimate, the alkaloids, etc. It is best to place the glass mortar over a dark surface, in order to show by contrast more clearly when the solution of the white object is effected.

FIG. 250



Porcelain mortar and pestle

FIGS. 251, 252, 253



Solid handle and balanced handle spatulas

Porcelain mortars and pestles (see Fig. 250) are, however, more generally useful as solution mortars. Pestles entirely of porcelain are objectionable, because they are easily broken.

Spatulas.—The process of trituration as ordinarily performed requires the use of spatulas. These consist of flexible steel blades attached to handles, and in trituration they serve to loosen the substance as it becomes packed upon the sides of the mortar. Spatulas are largely used in extemporaneous pharmacy, and they will be alluded to frequently under various special heads in Part V. The blade of a spatula is frequently broken when too much pressure is applied, but if the broken blade remaining in the handle have its sharp corners ground off upon a grindstone, or filed off, it will be just as useful for some purposes as it was when perfect.

Spatulas may now be had of excellent quality, and greatly improved in style over those formerly used. The best form is the balanced handle spatula (see Fig. 252). In this the metal of the handle and that of the blade are continuous and of the same width, so that the annoyance of the tang becoming loose in the handle, as in the old style spatulas, is avoided. The flat metal handle is enlarged by riveting smooth, flat pieces of hard wood to it to insure convenience in using. The balanced handle derives its name from the fact that when lying upon the counter the weight of the handle is sufficient to overcome the weight of the blade, so that contact of the blade with the counter is prevented. Solid handled spatulas (see Fig. 251) are also made, the whole being of one solid piece of metal, and the handle being nickel plated. A pocket spatula, which closes like a clasp knife, is also furnished by dealers.

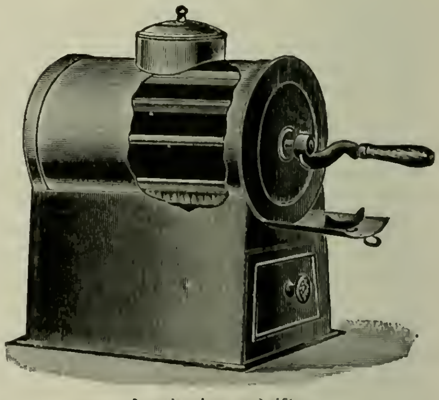
Fig. 254

Spatula, blade coated with hard rubber

Fig. 254 shows a spatula coated with hard rubber, made by Fox, Fultz & Co., for making ointments which contain corrosive substances, or substances acting on steel.

Sifting is the process of passing a powdered substance through the meshes of perforated material with the object of separating the coarser from the finer particles. Sieves are employed in this process. The frames are usually round, although sometimes they are oval, square, or rectangular. The ordinary sieve is usually made by stretching wire gauze over a flat wooden ring, and keeping it in its place by slipping over it a narrow wooden ring of slightly greater diameter, which is tacked securely. Covered sieves, or drum sieves, have tight covers for the top and bottom. The simplest pharmaceutical sieves for general use are obtained by making five rectangular frames, each four inches deep, ten inches wide, and sixteen inches long. These should be light but strong, and the bottoms covered with brass wire gauze of different degrees of fineness. A box, ten inches deep, twelve inches wide, and twenty-two inches long, with a tight cover, is provided to hold the sieves and prevent dust from escaping. Two cleats are nailed horizontally upon the sides of the box, five inches from the top, for the sieve to slide upon, and a hole is cut in the front of the box in order to permit a handle, with a hook at the end, to pass through and be attached to a screw eye in the front side of the sieve; two large corks are screwed to the back of the sieve at either end to act as buffers. The powdered substance is introduced into the proper sieve, which is placed upon the cleats, and the handle passed through the hole and hooked to the sieve; the cover is then placed in position, and the sieve pushed backward and forward, touching the back lightly.

Fig. 255



Jones's mixer and sifter

A very important point, which must not be omitted after sifting substances, is the thorough mixing of all portions of the sifted powder, in order that each part of the finished powder may have a uniform composition. The starchy portions of a drug will be powdered more quickly than the ligneous portions, and will usually pass through the sieve first; hence the sifted powder must always be thoroughly mixed. Upon the small scale this may be easily effected with a spatula or mortar and pestle; upon a larger scale special apparatus is needed. Fig. 255 shows the Jones's mixer and sifter, which is well adapted for smaller operations; the principle is that of using revolving mixers and brushes. A perforated metal plate forms the bottom of the sifter, and, when mixing, an unperforated plate is pushed over the perforated plate, so that when the powder is thoroughly mixed this plate can be pulled out, and the powder then sifts through the perforated plate into the drawer below. Hunter's sifter is one of the most effective large machines; it is shown in Fig. 256. In this the powder is sifted in the cylindrical sieve, and adhering particles or small lumps are brushed through by the revolving brushes; the revolving spiral mixers in the large box cause the particles to be thoroughly mingled. The illustration shows the method of operating so well that further description is unnecessary. In Fig. 257 is seen an enclosed sifter well adapted for many purposes, while Fig. 258 shows a sectional view of the same kind of sifter for smaller operations. The sieve is hemispherical in shape, and is contained in a tinned iron scoop (see Fig. 259, which shows the end view). Two circles of stout wire are soldered to a central axis at right angles to each other, and the axis passes through the tin handle and terminates in a crank. When a powder is placed in the scoop, and the wire rings are made to revolve by turning the axis with the hand, the particles of powder are rapidly forced through the meshes of the sieve. This apparatus is especially useful in breaking up moistened lumps in powders which are about to be percolated. (See Percolation.)

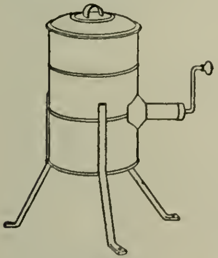
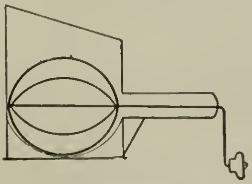
Hunter's sifter

Fig. 257



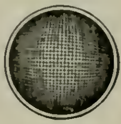
Enclosed sifter

Fig. 258



Scoop sifter

Fig. 259



Scoop sifter sieve (end view)

Fineness of Powder.—The fineness of powder is expressed, in the Pharmacopœia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable to substitute them in the text of the Pharmacopœia for those at present in use. The diameter of the wire (gauge number) used in making sieve cloth has an important influence upon the size of the mesh, and it is necessary to specify in each case the *thickness of the wire.*

These different forms of expression correspond to each other as follows:

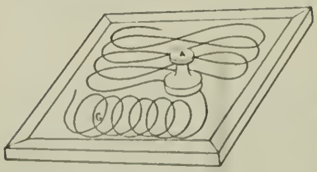
A *very fine* powder	should pass through a sieve having 80 or more meshes to the linear inch (30 meshes to the cm.) and should be made from gauge No. 38 wire	= No. 80 powder.
A *fine* powder	should pass through a sieve having 60 meshes to the linear inch (24 meshes to the cm.) and should be made from gauge No. 36 wire	= No. 60 powder.
A *moderately fine* powder	should pass through a sieve having 50 meshes to the linear inch (20 meshes to the cm.) and should be made from gauge No. 35 wire	= No. 50 powder.
A *moderately coarse* powder	should pass through a sieve having 40 meshes to the linear inch (16 meshes to the cm.) and should be made from gauge No. 33 wire	= No. 40 powder.
A *coarse* powder	should pass through a sieve having 20 meshes to the linear inch (8 meshes to the cm.) and should be made from gauge No. 28 wire	= No. 20 powder.

In certain cases, powders of a different degree of fineness (*e.g.*, No. 30, No. 12) are directed to be taken.

Not more than one-fourth of the powder is expected to pass through a sieve having ten more meshes to the inch than the one designated.

For very fine powders, bolting cloth is used for the sifting medium; and when acid substances are to be sifted, horsehair sieves are used.

Fig. 260

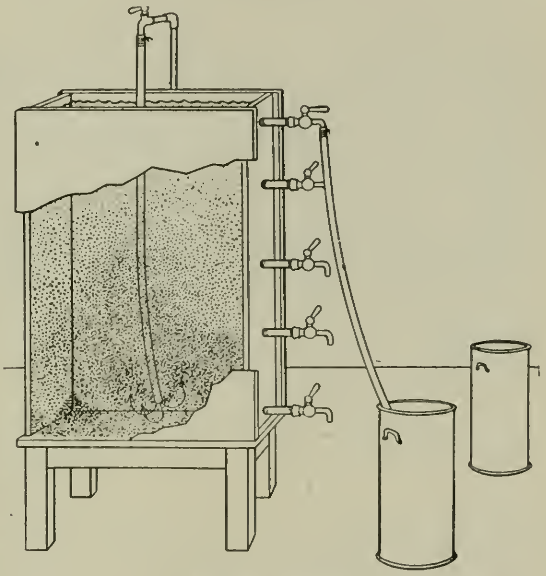


Slab and muller

Levigation is the process of reducing substances to a state of minute division by triturating them after they have been made into a paste with water or other liquid. This is effected in a shallow mortar with a flat surfaced pestle, or upon a ground glass slab with a flat surfaced glass muller (see Fig. 260). The motion imparted to the muller, A, closely resembles the figure 8; this is frequently varied with that of elongated circles which intersect each other, the object being to vary the motion so that all particles of the powder may be brought under the action of the muller upon the slab G. Certain substances, like red mercuric oxide and zinc oxide, if made into a paste with alcohol or water, are more readily reduced to fine powder in this way than by the action of the mortar and pestle. The process is termed *porphyrization* when performed with a porphyry slab and muller.

Elutriation is the process of obtaining a substance in fine powder by suspending an insoluble powder in water, allowing the heavier particles to fall to the bottom of the vessel, and decanting the liquid containing the lighter particles into another vessel, and there collecting them. It is *water sifting* practically, wherein the superior gravity of the larger particles is used as a means of separating them from the smaller. Fig. 261 illustrates elutriation. The stopcocks on the side of the tank are intended to be used for drawing off a portion of the liquid after the heavier particles have subsided; this liquid may be transferred to another tank to finally permit the fine particles to settle. Prepared chalk is a familiar illustration of an elutriated powder.

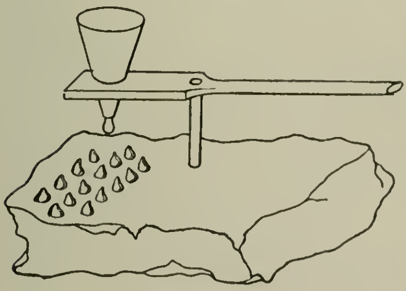
Fig. 261



Elutriating apparatus

Trochiscation is the process of making the pasty mass or magma obtained by elutriation into dry, conical masses. This is usually accomplished by the use of the little apparatus shown in Fig. 262. This consists of a tinned iron cone, supported in a circular wooden frame which has one short wooden leg and a handle. A slab of chalk or other porous substance is provided, and after filling the cone with the pasty mass the handle is taken in the hand and the leg of the frame is tapped gently upon the slab of chalk. The shock causes a conical mass of the substance to fall upon the slab, whereupon the moisture present soon becomes absorbed, so that the little cone dries quickly. A succession of taps, with a slight lateral movement, deposits the cones in regular rows, and when

Fig. 262



Trochiscator

the slab is full the first cones are found to be dry enough to be transferred, and all will soon be in the same condition. Chalk, bismuth, lake, and other insoluble powders are formed into conical nodules in this way.

Pulverization by intervention is the process of reducing substances to powder through the use of a foreign substance, from which the powder is subsequently freed by some simple method. No general process can be given for this method of pulverization, as the character of the substance must determine the method. The metal gold may be powdered by rubbing gold leaf in a mortar in contact with potassium sulphate. The latter is subsequently dissolved out with water. Camphor may be pulverized through the addition of a few drops of alcohol, chloroform, or other solvent. The foreign substance in this case is disposed of through evaporation. Metallic tin may be granulated by melting it and agitating it in a box containing powdered chalk. The latter is subsequently dissolved out with diluted acetic acid. Phosphorus may be pulverized by placing it in water contained in a small flask, then heating the water gradually until the phosphorus is melted, and shaking the flask while the phosphorus is cooling. The agitation in the presence of water keeps the particles from cohering.

CHAPTER IX

SOLUTION

Solution.—In pharmacy this term is applied to the process whereby any substance is liquefied or made to disappear when brought in contact with a liquid. The particles of the substance being uniformly diffused through the liquid, no separation takes place upon standing. The liquid used to effect this change is called a *solvent*, and, after its combination with the dissolved substance, a *solution;* if the liquid has exercised its powers as a solvent to its utmost extent, and is incapable of retaining any more of the dissolved substance, it is termed a *saturated solution.* A substance which is not acted on by a solvent is said to be *insoluble.*

Solution of Solids.—This is an operation which is very frequently performed by the pharmacist. In this place only the methods of effecting the solution of solid bodies which can be entirely dissolved in the solvent will be noticed. This excludes the operations of Infusion, Decoction, Percolation, Maceration, etc., which will be considered at length in subsequent chapters. Solution may be of two kinds : 1, Simple ; 2, Chemical.

1. Simple Solution is where the solid suffers no alteration on being dissolved, except that which depends upon its external form, and where, if the reverse operation of evaporation is applied, the solid substance is recovered unchanged. The making of syrup is an example.

2. Chemical Solution is where the properties of the dissolved body are changed by the chemical action of the solvent or some of the substances added, and the simple process of evaporation results in the production of a body having different properties, as, for example, in the official solution of mercuric nitrate.

Effects of Pulverization and Agitation.—The solution of solids may be facilitated by pulverizing them and stirring the mixture, thus increasing their extent of surface and promoting the frequent contact of the surfaces with fresh portions of the solvent. This is easily illustrated, as already noted in the chapter on Comminution, by placing half an ounce of lump alum and half an ounce of powdered alum each in a separate pint of water at the same time. A few vigorous stirs will soon cause the latter to dissolve, while the former will require a much longer time.

Effect of Heat.—The application of heat generally favors solubility, for nearly all substances are more soluble in hot liquids than in cold ones. In addition to this, the convection currents in the liquid caused by heat hasten the solution by constantly bringing fresh surfaces into contact with the liquid. In many cases the ratio of solubility is not the same for equal increments of heat.

Density of Solutions.—The effect of dissolving a solid body, specifically heavier than the solvent, is always to increase the density of the liquid in which the solid is dissolved. The specific gravity of water is 1.000. If 5 percent. of sugar is dissolved in it, the specific gravity is 1.021; if 10 percent., 1.070; if 20 percent., 1.088, etc. This fact is capable of optical proof; for if a piece of sugar is suspended near the top of some water in a beaker, the downward currents of the solution can readily be noticed if viewed by transmitted light.

Solubility of Substances in Saturated Solutions.—While a saturated solution is one which is incapable of dissolving any more of the substance which was dissolved in the liquid, it must not be assumed that the saturated solution will not dissolve *other* solids. For example, if granulated potassium nitrate be mixed with 2 percent. of copper sulphate, and then placed in a funnel having a plug of cotton in the throat, it will be found that the copper sulphate can be very easily removed by pouring on the potassium nitrate mixture a *saturated solution* of potassium nitrate. The potassium nitrate cannot suffer loss, because the liquid passing through is a saturated solution of the same substance; but copper sulphate is soluble in a saturated solution of potassium nitrate, and it is thus washed out.

Reduction in Temperature caused by Rapid Solution.—When solids dissolve rapidly in liquids without chemical action, a reduction in temperature always takes place, and cold is produced, in accordance with the well known law governing the conversion of solids into liquids, whereby sensible heat is converted into latent heat. The so-called freezing mixtures are produced in this way. Thus, if 5 parts of potassium sulphocyanide are quickly mixed with 4 parts of cold water, the temperature of the solution falls to —20° C. (—4° F.); 32 parts of sodium chloride, if mixed with 100 parts of snow, will produce a brine having a freezing point of —23° C. (—9.4° F.). Equal parts of crystallized calcium chloride and snow, when well mixed, will have a temperature as low as —45° C. (—49° F.).

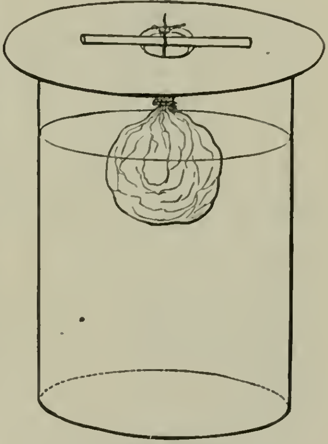
Elevation of Temperature produced by Solution accompanied by Chemical Action.—If chemical action takes place while solution is progressing, the opposite effect, or elevation of temperature, is frequently produced, as in dissolving anhydrous salts. The same fact is noticed when the solution of an alkaline oxide made by calcination is effected by treating it with an acid, as when calcined magnesia is dissolved in a solution of citric acid.

Modes of effecting Solutions of Solids.—The method usually employed by the pharmacist is one which requires the use of the solution mortar and pestle (see Fig. 216). The ordinary practice is to crush the substance into fragments in the mortar with the pestle, and then pour upon it the solvent, meanwhile stirring with the pestle until solution is effected. If definite quantities are used, and the whole of the solvent is required to dissolve the given weight of the salt, a portion only of the solvent should be added at first, and when this is saturated the solution is poured off and a fresh portion of solvent added. This operation is repeated until the solid is entirely dissolved; the solutions are then mixed. Other methods of effecting solution are to shake the solid with the liquid in a bottle or flask, or to apply heat to the substances in a suitable vessel.

Circulatory Solution.—A very excellent mode of dissolving substances, particularly where the solid is not very soluble or the relative proportion of liquid is small, is to suspend the solid near the top of the liquid upon a porous diaphragm or a suitable sieve, or tied up in a gauze bag if its nature will admit of this treatment. The substance immediately in contact with the solvent is dissolved, and the solution descends, its place being supplied by fresh portions of the solvent. A circulation is thus created and solution facilitated (see Fig. 263).

Solvents used in Pharmacy.—*Water.* The most useful of all solvents is water. It has a more extensive range than any other liquid, and the aqueous solutions are among the most important preparations of pharmacy. They are especially treated of in the following chapters, under the heads of Liquores, Aquæ, Syrupi, etc.

FIG. 263



Circulatory solution

Alcohol as a solvent is next in importance to water. It has an important advantage over water in the fact that preparations made with it keep almost indefinitely, while most aqueous solutions of organic substances soon decompose or become worthless. Resins, volatile oils, alkaloids, glucosides, salts, etc., are dissolved by alcohol, while many inert principles, like gum, albumin, and starch, are insoluble in it, so that it has also great usefulness in its negative character.

Glycerin is an excellent solvent, although its range is not so extensive as either of the preceding. It has in its concentrated state antiseptic qualities of a high order, but has not the valuable negative qualities of alcohol. It dissolves the fixed alkalies, some of the alkaline earths, a large number of neutral salts, and vegetable acids, pepsin, tannin, etc., but it also dissolves gum, albumin, starch, etc., and thus its solutions are generally loaded with inert constituents. (See Glycerites.)

Ether is a good solvent for special purposes. Oils, fats, resins, and some of the alkaloids and neutral principles are dissolved by it.

Petroleum Benzin is very similar in its solvent properties to ether.

Chloroform resembles ether and petroleum benzin as a solvent. It has an advantage over both, however, in not being inflammable.

Benzene obtained from the distillation of coal tar like ether is a good solvent for many substances.

Acetone is a good solvent for resins, oils, etc., and is used officially in making oleoresins.

Carbon Disulphide is an excellent solvent for rubber, phosphorus, etc. Its range is limited, however, and its odor and inflammability detract from its usefulness.

Acids, either strong or diluted, are used as solvents ; as in vinegars. *Oils* are also used in this way in liniments, etc.

Solubility as a Test.—The solubility of a substance in various solvents constitutes a factor whereby its identity and purity can be determined, and all pharmacopœias recognize solubility as one of the means of testing substances. The U. S. Pharmacopœia indicates the degree of solubility of a body by stating the number of parts, by weight, of the solvent required to dissolve one part of the substance. The temperature at which solution is to be effected is frequently given ; in other cases such terms as "readily soluble" or "sparingly" are used. For taking the solubility of substances at ordinary temperatures—25° C. (77° F.)—a convenient portion of the substance should be placed in a small glass flask provided with a stopper, the solvent should be added, and the flask shaken until a saturated solution is made. This is, of course, known by a portion of the substance remaining undissolved at the temperature of 25° C. (77° F.). The flask should be set aside and kept at about this temperature for a few days, and occasionally stirred to avoid supersaturation. The solution is passed through a dry, clean filter into a tared dish and weighed, the filtrate is evaporated to dryness, and the residue weighed. The difference between the weight of the solution and that of the dry residue furnishes the basis for the calculation. To illustrate, the weight of the filtrate is 12 Gm. ; the dry residue weighs 1.5 Gm. The difference, 10.5 Gm., gives the weight of the evaporated solvent ; by dividing this weight by that of the dry residue, 10.5 ÷ 1.5, the substance is found to be soluble in 7 parts of the solvent ; or, stated differently, if 1.5 parts of the substance required 10.5 parts of the liquid for solution, 1 part would require 7 parts of the liquid, 1.5 : 10.5 :: 1 : 7.

FIG. 264

Rice's lysimeter

For taking the solubility of substances in hot solvents, Dr. Rice devised an ingenious instrument which he called a lysimeter (see Fig. 264).

Table of the Solubility of Official Substances in Water and in Alcohol

Abbreviations : s. = soluble ; ins. = insoluble ; sp. = sparingly ; v. s. = very soluble ; alm. = almost ; dec. = decomposed ; r. s. = readily soluble ; p. s. = partially soluble

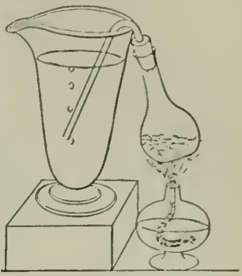
Solution of Gases in Liquids

The methods employed to effect the solution of gases in liquids differ essentially from ordinary processes of solution, and depend upon the solubility of the gas in the liquid, the relative specific gravity, and the strength of the solution desired. It is usually sufficient to conduct the gas into the liquid by a suitable tube, reaching nearly to the bottom, when more or less of the gas is absorbed by the liquid. Fig. 265 shows a simple method where the gas is readily soluble in the liquid, as in making chlorine water. For a continuous operation, as in making hydrochloric, nitric, and hydrobromic acids, and similar liquids, the well known Woulffe's, or three necked bottles are employed advantageously, the gas which escapes solution in one bottle passing over into the next. The washing bottle shown in Fig. 266 is easily made, and well adapted for purifying the gas after it is generated. B is an ordinary wide mouthed bottle, closed with a perforated rubber cork, C; a wide tube, D E, passes nearly to the bottom, and a narrow tube, A, is joined by a short piece of rubber tubing, J, to the tube leading from the generating flask, and at the other extremity is curved upward so as properly to deliver the gas into the water placed in the bottle to wash it. It escapes by the bent tube, T, which is continued until it dips into the liquid in which the gas is to be dissolved. The space between the tube A and the wide tube D E acts as a safety valve. If the pressure accumulates through the too rapid generation of the gas, or if a stoppage occurs in the delivery tube, the liquid in the bottle is first blown out through this space, and the pressure is thus relieved.

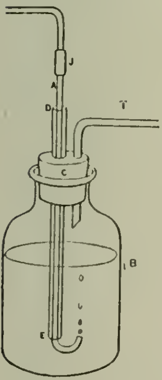
Fig. 265



Method of absorbing gas

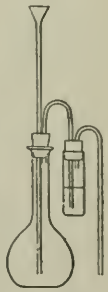
Fig. 267 shows a very convenient little apparatus for generating and washing small quantities of gases, for testing, or other purposes. The wash bottle is made from a homœopathic vial, rubber corks being used, and the bent tubes by bending ordinary glass tubing over a flame as described on page 142. The funnel tube permits the addition of fresh liquid to hasten or continue the action as the operation progresses. It is usual to add merely sufficient water to cover the orifice of the delivery tube in the wash liquid at the beginning of an operation, as the aqueous vapor carried over by the gas condenses in the wash bottle, which soon increases in quantity, and may accumulate in a long operation to an extent which will necessitate a partial discharge of its contents or the entire cessation of the process. As the apparatus suitable for each operation must be especially selected, general observations on the solution of gases will not be so useful in this chapter as a detailed process in connection with each preparation where it is described in the subsequent pages. One general rule should be noted, however,—*i.e.*, that gases are generally more rapidly and thoroughly absorbed by cold liquids than by hot ones. Hence the receiving bottle should be kept surrounded by ice or otherwise refrigerated.

Fig. 266



Wash bottle

Fig. 267



Gas generator

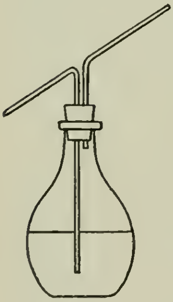
CHAPTER X

SEPARATION OF FLUIDS FROM SOLIDS

THE operations involved under this head are among those which are most frequently used in pharmacy,—*i.e.*, Lotion, Decantation, Colation, Filtration, Clarification, Expression, Percolation, etc.,—and the principles which govern the successful performance of these practical processes should be well understood. They are almost exclusively mechanical processes.

Lotion, or **Displacement Washing,** is the process of separating soluble matter from a solid by pouring a liquid upon it which will dissolve and wash out the soluble portion. The separation of the fluid from the solid is generally effected by placing an obstruction in a funnel or cylindrical vessel, such as a plug of cotton or tow, notched cork, filter paper, etc., and then, having introduced the solid into the funnel and arranged a suitable vessel beneath, the liquid is poured upon it. (See Percolation.) Precipitates are frequently purified from contaminating soluble matter in this way. A very convenient method of applying the liquid is by the use of the spritz bottle (see Fig. 268). This is usually made from a flask, but a round shouldered pint bottle of the diameter most easily grasped by the hand is preferable. Two glass tubes, one bent at an acute angle and the other at an obtuse angle, are used; one end of the former is drawn out to a capillary orifice, and the other extends nearly to the bottom of the bottle. The obtuse angled tube merely enters the bottle below the cork; the upper portion of this tube should be held in the gas flame, so as to fuse the edges of the glass and thus prevent cutting the lips when it is used. By filling the bottle with liquid, and blowing with the mouth through the tube, a stream of liquid is ejected from the capillary orifice which can be directed to any portion of a solid substance that is to be washed. It is often desirable, in order to save time, to use the liquid hot. One of the wicker covered bottles in which Farina cologne is imported answers a good purpose here to prevent burning the fingers, and if care is used to pour in a small quantity of hot liquid first and agitate it before adding the rest, so that the glass may be *gradually* warmed, there is no danger of fracturing the bottle.

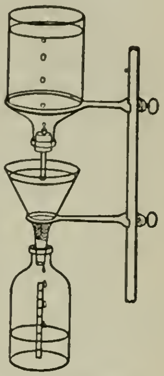
FIG. 268



Spritz bottle

Continuous Washing.—The use of the spritz bottle for small operations is convenient. A simple method of automatically supplying the wash liquid in larger quantities is shown in Fig. 269. This requires no attention from the operator except at the beginning of the operation. The bottle is furnished with a perforated cork and a short glass tube. All that is necessary is to fill the bottle and adjust it over the funnel so that the end of the tube shall be at the height desired for the liquid. On tilting the bottle slightly (if the tube selected is not too narrow in diameter) the liquid will run out into the funnel until it rises to the orifice of the tube, when the flow will cease. As the liquid gradually passes through the solid substance in the funnel, the level falls, and bubbles of air pass through the tube into the bottle, the liquid once more flows, and the operation continues until the bottle is empty. Many elaborate methods of continuous washing have been suggested, and many have been practically tried by the author, but if care is taken in the simple apparatus just described to have the tube of proper diameter, at least so wide that the force of capillary attraction shall not be strong enough to prevent the ingress of air, it is the most satisfactory of all. Bottles having narrow mouths may often be used in the same way, and the cork and tube be dispensed with. A little practice will enable the operator to make an apparatus in which the parts are adjusted to a nicety. On the large scale, Prof. B. S. Proctor's suggestion of two carboys may be used,—one above and inverted, containing the liquid, supported by a box having a circular hole cut in its side, and the other inside the box, containing the funnel and filter.

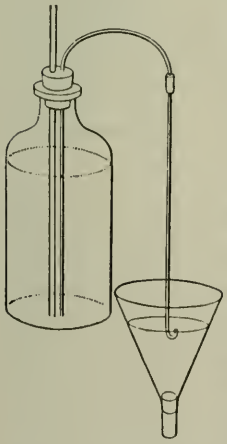
Fig. 269



Continuous washing

A modification of Gay Lussac's apparatus is one of the most successful and practical for continuous washing (see Fig. 270). The bottle containing the wash liquid is furnished with a doubly perforated cork and two glass tubes. One is bent as shown in the cut, and its lower extremity curved upward. By blowing a current of air through the other tube the syphon tube is filled, and the extremity may then be adjusted to such a height in the funnel as is desired. When the level of the liquid in the funnel falls below the orifice of the tube, bubbles of air will enter the bottle through the air tube, and the liquid will run out until it rises in the funnel to the level of the ends of the tubes, when it will cease. It will be found a practical convenience to cut the syphon tube just below the bend, so that a piece of rubber tubing may be used to form a flexible joint.

Fig. 270



Continuous washing apparatus

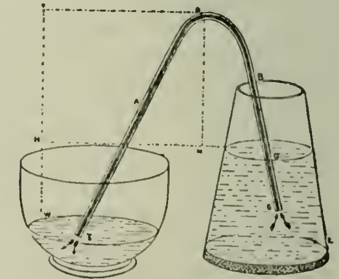
Decantation.—The process of separating a fluid from a solid by decantation is very simple, and consists usually of allowing the solid to deposit at the bottom of the vessel, and then carefully pouring off the liquid by inclining the vessel. The theory of washing by decantation shows its effectiveness, and this may be illustrated by the following example. If 360 grains of mercuric chloride dissolved in 50 fluidounces of water are mixed with 220 grains of potassium iodide dissolved in 50 fluidounces of water, double decomposition takes place, an insoluble precipitate of mercuric iodide subsides, and 100 grains of potassium chloride remain dissolved in the 100 fluidounces of water. As it is desirable to free the mercuric iodide from the contamination of potassium chloride, the supernatant liquid is poured off; if 90 fluidounces are decanted, 90 grains, or $\frac{9}{10}$ of the whole quantity of potassium chloride, are thus disposed of, and 10 grains are left. If the vessel is filled with water to 100 fluidounces, and 90 fluidounces are again poured off, 9 grains are again removed, and but 1 grain is left; this by a third washing and decantation in a similar manner would be reduced to $\frac{1}{10}$ of a grain, and thus the purification is speedily effected. Some skill is required to decant liquids neatly from vessels of various shapes, particularly if they are not furnished with lips, or if filled nearly to the brim. The *guiding rod* may be used in many cases with effect. Indeed, it is a good practice to form the habit of using a stirrer or rod as a guide in decanting, as shown in Fig. 271, for it has a tendency to steady the hand of the operator. The practice recommended by some writers of greasing the rim of the vessel to facilitate decantation is a clumsy and usually unsuccessful expedient.

The Syphon (or **Siphon**).—It often happens in washing solid substances that decantation by pouring off the liquid cannot be successfully performed, either because the vessel is too full, or because, owing to the light character of the precipitate, the inclination of the vessel is sufficient to cause a disturbance in the powder, and an admixture of the liquid and solid. In such cases, and in many others, the useful instrument known as the syphon may be resorted to. This usually consists of a glass tube bent at a rather acute angle, and having one of the limbs longer than the other. It is used by filling the syphon with liquid, and then inserting the short limb into the liquid that is to be drawn off, when a flow of liquid from the long limb is established, which need not cease until as much of the liquid is abstracted as is desired. After filling the syphon the liquid may be prevented from running out (if a tube of small diameter is used) by stopping up the end of the long limb with the forefinger of the right hand, or, if the liquid to be drawn off is not caustic or unpleasant to the taste, the short limb of the syphon may be placed in the vessel at the proper height, and suction applied by the mouth at the long end until the current is established. The principle of the action of the syphon is

FIG. 271

Use of the guiding rod

FIG. 272

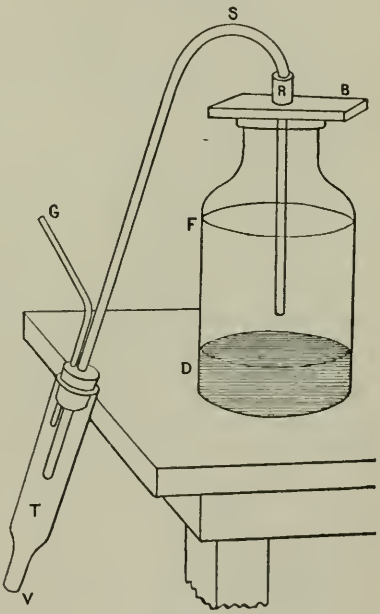


Syphon diagram

shown in Fig. 272. The combined lengths of the limbs of the syphon are not equal to the length of the glass tube, T O S, but the real syphon is only the tube acting between the levels of the liquid in the vessels. In all operations with the syphon there must be a difference in the levels of the liquid. In Fig. 272, O S represents the liquid in the short limb, and O T the liquid in the long limb. It is obvious that, if an equal limbed, narrow tube syphon is filled with liquid, and held level in liquid on the same plane, there can be no movement in the liquid ; equilibrium is established, because the tubes are equal in length and in level liquid, and the pressure of the air is the same upon all parts of the liquid. But the descending column of liquid in the long limb exceeds in weight that in the short limb, and it follows on account of the excess of weight of liquid in this limb that if it is once set flowing through the longer limb it will continue until the levels of the liquid in the two vessels are the same. It will be observed that the custom of having one limb longer than the other is not a necessity, for if there is sufficient difference between the levels of the liquid the syphon will operate with the position of the limbs reversed ; but it is a convenience in a syphon of unequal limbs always to immerse the short limb, as there is then the certainty that the other limb contains the longest column of liquid. The syphon, obviously, cannot be operated in a vacuum, nor if the length of the upward column of water exceeds thirty-three feet.

Syphons for Special Purposes.—In the larger laboratory operations the most convenient syphon is made from a six-, eight-, or ten-foot length of rubber hose. This syphon, on account of its flexibility, can be used in many operations where glass or metal would be inconvenient or inadmissible, while its durability and simplicity of operation make it a necessity. Indeed, the utility of glass syphons is greatly increased by cutting the long limb just below the bend and joining it to the other by a piece of rubber tube.

Fig. 273

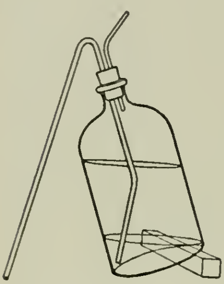


Syphon

The method, already referred to, of starting a syphon by applying suction with the mouth at the long end, or filling the syphon with liquid, is not always practicable, and various other expedients are in use. The *syphon with a bulbed lateral tube* is useful where caustic liquids are to be decanted. The finger is placed over the end of the long limb, and suction applied at the small tube until the downward current is started. Negretti's syphon has a glass syringe attachment upon the lower part of the long limb to accomplish the same purpose. Fig. 273

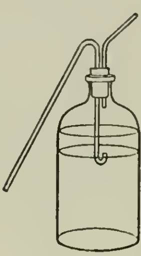
represents a modification of Mohr's syphon, the bottom having been cut from a Farina cologne bottle, T, by starting a cut with a three cornered file near the bottom and extending it around the surface with a red hot poker. The edges are now filed so that they are no longer sharp, and a cork is fitted and twice perforated to admit the longer limb of the syphon and a suction tube, G. It is started like the syphon with a lateral tube, the moistened forefinger closing the lower aperture, V, while suction is being used at G until the liquid has been started. A simple glass tube, with a short piece of rubber tube attached, is in practical hands an efficient substitute for elaborate contrivances to start the flow in a syphon; even if the liquid is caustic or disagreeable, there is no risk in careful hands if the rubber tube is held between the thumb and finger so that it can be instantly pinched tightly to prevent the upward flow of the liquid into the mouth.

FIG. 274



Syphon in bottle

FIG. 275



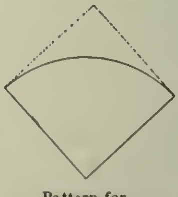
Syphon

Fig. 274 represents a form of syphon for drawing off the liquid to almost the last drop in the bottle. The shorter limb of the syphon is bent, and the syphon is started by blowing through the shorter tube in the cork. Fig. 275 shows a syphon with the shorter limb "turned up." This form has the advantage of retarding the tendency to empty itself, and, in syphoning the liquid from precipitates, there is not so much danger of stirring up the particles on the bottom.

Colation, or **Straining** (*colare*, to strain), is the process of separating a solid from a fluid by pouring the mixture upon a cloth or porous substance which will permit the fluid to pass through, but will retain the solid. This operation is frequently resorted to for separating sediment or mechanical impurities of various kinds from liquids. Gauze, fine muslin, cotton flannel, woollen felt, and other fabrics are used. Strainers are employed where the solid particles to be removed are not in very fine powder, or where complete separation is not especially desired.

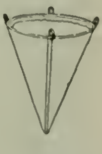
Felt strainers are usually in the shape of felted, seamless, conical bags; the material is of wool and quite thick. They form excellent strainers for melted fats, petrolatum, wax, oils, syrups, elixirs, etc., where a large quantity of substance is to be strained. Their expensiveness is, however, an objection to their use, and the difficulty of cleaning them, owing to the tenacity with which they retain odors, unfits them for general use by the apothecary, but for special purposes in a manufacturing pharmacy they are very useful.

FIG. 276



Pattern for Hippocrates's sleeve

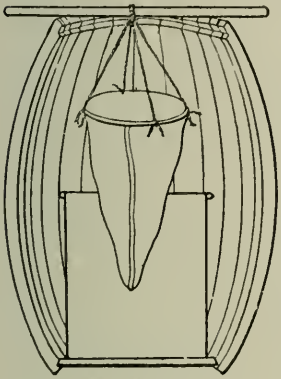
FIG. 277



Strainer, Hippocrates's sleeve

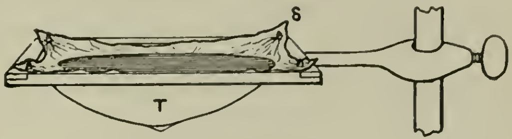
Woollen strainers made of twilled woollen cloth, flannel blanket material, etc., are more economical, because they can be cut to any size desired, and the material costs less, while if the seams are closely sewed or overseamed they will last a long time. The form known as Hippocrates's sleeve (see Fig. 277) is that generally used. Fig. 276 shows the shape and dimensions before being sewed. A wooden hoop or brass ring is required to keep the opening extended. This should be arranged so that it can be removed when the bag is to be washed. The most convenient support is a stick passed through the cords which are attached to the strainer, the whole suspended in a barrel arranged as shown in Fig. 278. The object of suspending it in the barrel is to avoid currents of air, which, in the case of many liquids, would cause evaporation from the surface and the formation of a crust, and thus impede the rapidity of colation. A tin or copper can of proper size may be placed in the barrel to collect the strained liquid.

FIG. 278



Use of strainer

FIG. 279

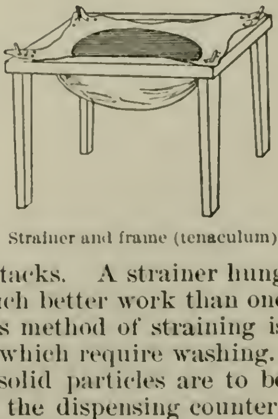


Cotton cloth strainer

Cotton flannel or Canton flannel strainers are cheaper than those of woollen, and if bleached they have the great advantage that they can be used for alkaline solutions. The unbleached cotton flannel is probably stronger, but the coloring matter naturally present, being soluble in alkalies, is apt to discolor the liquid.

Cotton cloth or muslin strainers are generally suspended on a wooden frame, (*tenaculum*) see Fig. 279. The frame should be securely joined without glue, and at each corner there should be a strong, pointed nail projecting slightly outward. The cotton cloth should always be soaked in boiling water before fastening it to the frame, to dissolve out the substances used by the manufacturer in calendering the goods. Fig. 280 shows the method of fastening the strainer to the frame. It should be secured at each corner, first upon the permanent nails, and then two tacks at the side of each nail should be driven two-thirds of their length into the frame; this partial driving of the nail is sufficient to hold the cloth and permit of the easy removal of the tacks. A strainer hung in this way will hold more liquid and do much better work than one which is tacked all around the frame. This method of straining is particularly useful in collecting precipitates which require washing.

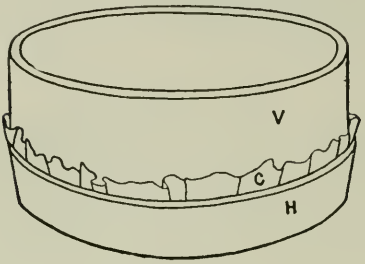
FIG. 280



Strainer and frame (tenaculum)

Colation in Smaller Operations.—When solid particles are to be separated from liquids in the operations of the dispensing counter, several methods may be used. One of the most convenient is to insert a plug of absorbent cotton in the neck of a funnel and then pass the liquid through ; a funnel with a circle of brass wire gauze soldered in it two thirds of the way down is sometimes used, although not recommended, because of the difficulty of cleaning it. A better small strainer is made by using the hard rubber sieve, V, H (see Fig. 281). The muslin gauze, C, is easily replaced, and the sieve may be placed in a funnel. The cotton cloth used by the makers of cheese, called cheese cloth, is admirably adapted for many kinds of straining. When coarse muslin strainers are used for the first time, they are prepared by soaking them in hot water and placing them in a funnel carefully so as to line the inside. Care should also be taken to see that the strainer is not too large, for if the wet strainer projects over the edge of the funnel, a syphon action may be set up and more of the liquid delivered outside of the bottle than inside. Fig. 282 shows the action of such a strainer.

Fig. 281



Prescription strainer

Careless straining

CHAPTER XI

FILTRATION

Filtration is the process of separating liquids from solids with the view of obtaining the liquids in a transparent condition. The intervention of porous substances, called *filters,* to intercept the solid particles, is necessary in performing this process. These are usually made from paper, paper pulp, sand, asbestos, ground glass, charcoal, porous stone, etc. The liquid which has passed through the filter is called the *filtrate.*

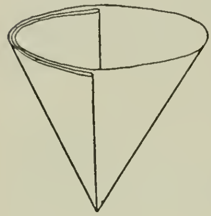
Paper filters are the most useful of all kinds for the pharmacist, and they are employed in all the finer operations requiring filtration. The solid particles are much more completely separated by filtration through good paper filters than through strainers, owing to the pores of the paper being smaller and more numerous. The paper used for this purpose is especially prepared, and is called *filtering paper.* It is made now upon a large scale, and can be had of excellent quality. Unlike a strainer, it is never used more than once; its cost is so trifling, and it is so easily ruptured when wet, that it is not worth while to attempt to save filters for subsequent use. Filtering paper is found in commerce in two forms,—in large, nearly square sheets, and in circular sheets. The former is used for large filters, and has some advantages, if the waste pieces can be put to use; but it is usually more convenient for the pharmacist to rely for constant use upon the circular sheets of different sizes. The difference in price between the two is now so trifling that the latter is almost always preferred. Two kinds of square sheet filtering paper are commonly found,—German white, a rather thin, but good paper, and heavy French, the latter very thick and porous, having a rough surface; it is the more expensive paper, but is better for special purposes. Of the round filters, the French, Swedish, German, English, and Scotch are among those best known in America. For pharmaceutical purposes the French filters are almost universally used, the "Prat Dumas" brand being the most common, the gray paper being made from a mixture of cotton, flax, wool, etc.; this paper answers sufficiently well for filtering colored liquids, fluidextracts, or tinctures, but, owing to the coloring matter it contains, it should never be used for any solution containing free alkali.

It is safer to form the habit of never using it for liquids that are intended to be colorless when filtered; of course, it is entirely unfitted for analytical work. The "Prat Dumas White" is of good quality, and it or some other good quality of white paper should always be on hand for special purposes, for filtering alkaline or alkaloidal solutions, and for the nicer operations. Very good filtering paper of English and Scotch manufacture may occasionally be procured; that made in Sweden, however, by Munktell, is preferred for the processes of ignition and analytical work; it yields the smallest amount of ash, and is practically free from soluble salts and impurities. At least a small stock should be kept by pharmacists for especially accurate work.

Methods of folding Filtering Paper.—Two kinds of paper filters are used, the *plain* and the *plaited.*

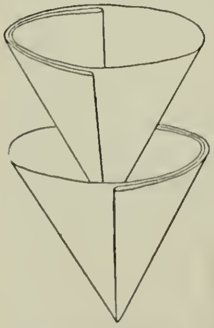
1. *The Plain Filter.*—This filter is used habitually by the analytical chemist, and is preferred by the pharmacist where precipitates are to be collected, and in some other operations (see Fig. 283); it is made by exactly doubling a circular sheet of filtering paper upon itself, and then folding this directly in the middle, so that, when opened, four equal divisions or sectors appear; the filter is used by separating one of the sectors from the other three, and placing the cone formed, into a funnel; the liquid is then poured upon the filter, and the process of separating the solid from the liquid commences. The advantages of the plain filter are, 1, simplicity and rapidity in folding, no skill being required to make one; 2, in collecting precipitates, but one-half of the surface of the filter (two sectors) is in contact with the moist precipitate, which is often closely adherent, and therefore but one-half of the surface has to be cleaned. In some cases there may be a disadvantage in the use of the plain filter, owing to the unequal rate of flow,—the tendency of the three folds being to attract the liquid to the side of the funnel upon which they rest, and thus the precipitate may be unequally washed. A stronger and more rapid filter may be made by placing one plain filter inside of another, so that the three sides of the upper one shall be in contact with one side of the lower one, and *vice versa* (see Fig. 284). If the sides of the funnel have an angle of 60°, the plain filter made as described will fit the funnel properly; but it frequently happens that the angles of funnels vary, and if an ordinary plain filter is placed in a funnel not having an angle of 60°, a portion of the filter is left unsupported, and the weight of the liquid is apt to rupture the moist paper. This difficulty may be overcome by making a fresh crease in the outside fold of the plain filter; if this is made to the right of the original crease of the 60° filter, and the inside fold pushed around a corresponding distance, a filter having a smaller angle is produced, while if the fresh crease is made to the left of the original crease a larger angled filter may be made. Rother's method of making a plain filter has the ad-

Fig. 283



Plain filter

Fig. 284

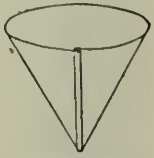


Double plain filter

Fig. 285

Rother's filter (first step)

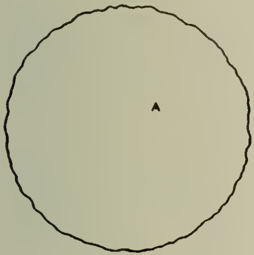
Fig. 286



Rother's filter

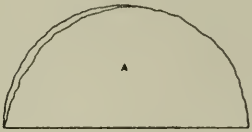
vantage of furnishing two filters from the same sheet that is usually required for one filter. To make it, the circular disk of filtering paper is cut through in the line of its diameter, and half of the disk is folded into two equal parts; the double edge of the cut sides is turned down and folded over on itself narrowly several times (see Fig. 285), and with the blade of a spatula the fold is compressed so that it will retain its shape (see Fig. 286). This filter may be used in collecting precipitates.

Fig. 287



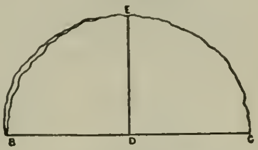
Filter

Fig. 288



Folding plaited filter

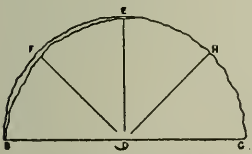
Fig. 289



Folding plaited filter

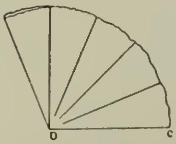
The plaited filter may well be called the "pharmacist's filter," for it is the form almost exclusively used in ordinary filtering operations.

Fig. 290



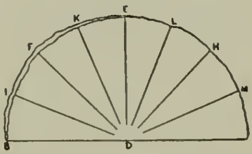
Folding plaited filter

Fig. 291



Folding plaited filter

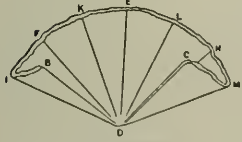
Fig. 292



Folding plaited filter

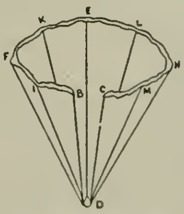
Figs. 287 to 297 show the progressive steps in the folding of a plaited filter. It is made by folding a circular sheet of filtering paper twice, as in making a plain filter.[1] The edge B D, Fig. 290, is then laid upon E D, and the crease F D is formed; in like manner C D is laid upon E D, and H D is formed. Then D B is laid upon F D, and I D is formed, and by rolling over the fold in the same direction once more until F D is laid upon E D, the crease K D is made (see Fig. 292). Now in the same way C D is laid upon H D and H D

Fig. 293



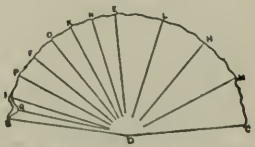
Folding plaited filter

Fig. 294



Folding plaited filter

Fig. 295



Folding plaited filter

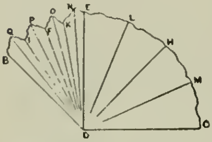
---

[1] It will be observed that in the first folding of French filters, "Prat Dumas," the disks are not perfect circles. This causes one edge to project (see Fig. 288), and facilitates the opening of the filter.

upon E D, and it will be noticed that the folded semicircle has been creased into eight equal spaces, and that the direction of each crease is the same, so that if the paper is lifted it will appear as shown in Fig. 294.

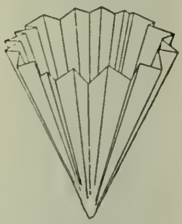
The next step is to fold each one of these spaces *back on itself* (Fig. 295). B D is laid upon F D, and then B D is turned upward and back until it is laid upon I D. This makes the crease Q D, which is the first fold in the opposite direction. Taking both folds between the forefingers and thumbs of both hands, the edges B D and I D are folded upward and back upon F D, and the crease P D is formed; then these three edges, B D, I D, and F D, are taken all together and folded back upon K D, and the crease O D is formed, and so on, each space in turn being folded back in the opposite direction, until the last one is reached. The folded filter is then held at the apex with the left hand upon a table or flat counter, and pressed and smoothed out with the right hand in order to emphasize the folds. It should then be placed in the funnel, while still *unopened*, to see whether it needs trimming; if the rough edges of the filter project above the top of the funnel, the filter must be removed, and they must be cut off neatly with a sharp knife or a pair of scissors so that the whole of the filter may be placed inside of the funnel. Having satisfied this requirement, the filter should be carefully opened out (see Fig. 297) and placed in the funnel.

Fig. 296



Folding plaited filter

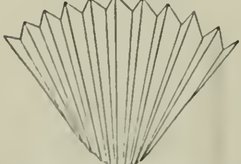
Fig. 297



Plaited filter

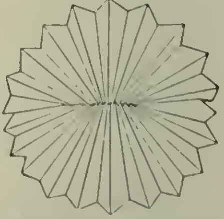
Another method of folding a plaited filter is illustrated in Figs. 298 and 299. A plain filter is folded as in Fig. 283, and the quadrant, consisting of four thicknesses of paper, beginning at the left hand side, is folded at once into narrow parallel plaits backward and forward. Fig. 298 represents the filter after being once opened, and Fig. 299 shows the inside of the filter. It will be observed that the creases do not converge to a point as in the plaited filter (see Fig. 297), and hence the apex is less likely to be weakened.

Fig. 298



Plaited filter, parallel folds

Fig. 299



Plaited filter, parallel folds

Maxims.—1. In folding a filter, care should be observed not to extend the creases entirely to the apex, but to end them at a distance of about half an inch from it, because the point at which all the creases converge would be thereby so weakened that the weight of the liquid would rupture the filter.

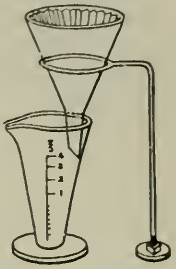
2. The filter should be moistened with water after introducing it into the funnel and before pouring upon it the liquid to be filtered (except, of course, in the case of a liquid immiscible with water).

This promotes rapid filtration, and washes the filter besides. If hot water is available, it is usually to be preferred.

3. If the liquid to be filtered contains free acid or alkali, or if it contains a very fine precipitate, or is very dense or hot, a double filter should be used. In the case of plain filters, they should be arranged as in Fig. 284. If plaited, two sheets of paper should be taken and folded as if they were single. A filter may be also strengthened by placing a small capping filter or plain filter, a piece of well washed linen or muslin folded like a plain filter, or a plug of absorbent cotton, into the funnel before introducing the filter. The apex is always the weakest, the most exposed, and yet the most important part of the filter.

4. In pouring the liquid into the filter, the stream should never be delivered directly upon the apex, but upon one of the sides, so that the force of the fall will be broken before the weakest point is reached.

Fig. 300



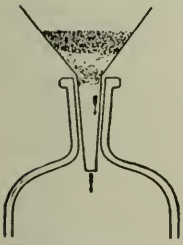
Arrangement of funnel in filtration

5. The filter should be entirely within the funnel. If the edges of the paper project above the funnel, waste from evaporation in volatile liquids, also from the increased and unnecessary absorption due to the excess of filtering paper, ensues, and in addition an untidy and careless habit is encouraged.

6. The end of the funnel should touch the side of the receiving vessel, so that the filtrate will trickle down its inside edge. By this expedient splashing will be avoided (see Fig. 300).

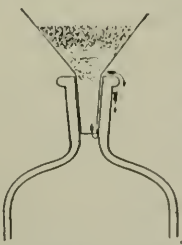
7. In filtering into a bottle, care should be observed to leave sufficient space between the neck of the funnel and the mouth of the bottle for the escape of air, otherwise filtration will be retarded or prevented ; a piece of twine placed between the two surfaces generally serves a good purpose. *The end of the funnel should project below the lowest part of the neck of the bottle* (see Fig. 301). If the diameter of the end of the funnel is too large to admit of this, or if it is only half inserted, the filtrate will be very apt to fill the intervening space and flow over the outside of the bottle, as shown by the arrows in Fig. 302.

Fig. 301



Filtering into a bottle (proper method)

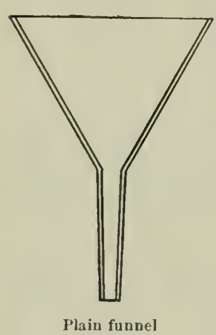
Fig. 302



Filtering into a bottle (improper method)

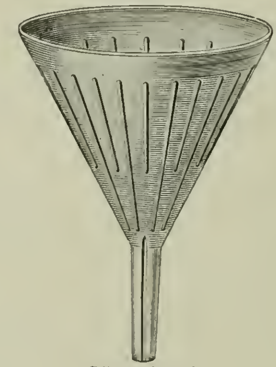
Funnels, sometimes called *tunnels*, are conical shaped instruments intended to facilitate the pouring of liquids into narrow mouthed vessels, and, as they have also an important service to perform for the pharmacist in supporting filters, they will be considered in this place. Funnels are made of tinned copper, tinned iron, hard rubber, Berlinware, porcelain, queensware, granite or agateware, earthenware, or glass. Metallic funnels have an advantage in point of durability over porcelain and glass, but a disadvantage in being acted upon chemically by liquids and in being more difficult to clean. The triangle formed by the sides of a funnel, and the line joining them, should be equilateral (see Fig. 303). The angles being each 60°, a funnel having this shape will accurately support a plain filter made in the usual way. Funnels are frequently fluted, grooved, or ribbed on the inside for the purpose of facilitating the downward flow of the filtrate (see Fig. 304), or wire frames, either fixed or folding, are arranged in a plain funnel with the same object. These aids are of doubtful utility, however, while the tendency of the raised ribs is to form a lodgement for foreign substances. *A well made plaited filter* in a plain funnel will perform as much work in the same time, and if the habit is once formed of always carefully and skilfully folding a filter, its importance in saving time and labor will be appreciated ever afterwards. One of the ribbed funnels in the market has an improvement in the neck, which, instead of being round, is triangular. This permits the free escape of air from the interior of the bottle, and is much superior to the indistinct groove which is often made on the outside surface of porcelain funnels. Plain glass funnels are more generally useful to the pharmacist than any other kind. They are easily cleaned, and dirt upon them may be quickly seen. They are very useful as percolators, and the whole process of filtration or percolation may be observed without trouble. Their only disadvantage is the ease with which they are fractured. The next kind in point of usefulness is the plain tinned copper funnel. The neck should be grooved, square or triangular, instead of round. Copper funnels are far superior to those made from tinned iron, and the difference in cost is greatly in favor of tinned copper, if true economy is considered (see Fig. 305). Hard rubber funnels are light in weight, and are not very easily broken, for they may be often dropped upon the floor without injury (see Fig. 306). They are not acted upon by chemical substances, and with ordinary care will last a lifetime. They lack one advantage of those made from glass, however, in their absence of transparency. A hard rubber funnel divided, to hold a strainer, may be used at the dispensing counter (see Fig. 307). Porcelain, queensware, or Berlinware funnels are, of course, not transparent, and they have the disadvantage, at least in the larger sizes,

Fig. 303



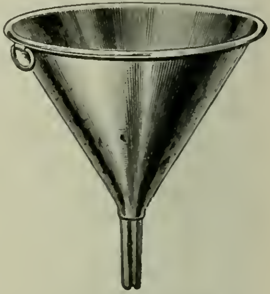
Plain funnel

Fig. 304



Ribbed funnel

Fig. 305



Tinned copper funnel

of being heavy. They are, however, not affected by liquids, but their advantages over glass are so slight (being somewhat less fragile) that they are not often employed. Earthenware funnels, if well glazed, are very useful in filtering *hot liquids.* Enamelled funnels, called granite or agateware, etc., are made from sheet iron having the surface entirely covered with a glazed composition which resists the action of most chemical substances. If carefully used, they answer for many purposes. Their greatest objection arises from the brittleness of the enamel, which is apt to chip off if the funnel is dropped upon the floor or subjected to a blow, and at the point where the neck of the funnel is joined to the body, the enamel coating is so thin that by constant use and knocking about it is soon chipped off, the exposed iron quickly rusts, and the neck breaks off from the body. Tinned iron funnels are most largely used, and are popular because of their cheapness; but it is quite possible for a pharmacist to ruin in one operation a preparation worth ten times the cost of the funnel by filtering it through a tinned iron funnel and allowing it to come in contact with the iron exposed by the wearing off of the tinned surface.

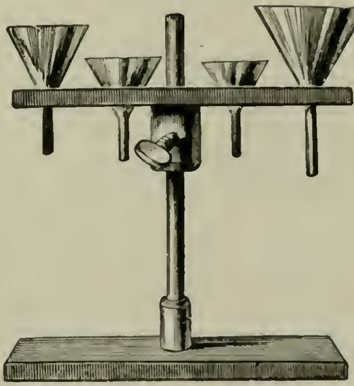
Fig. 306

Hard rubber funnel

Fig. 307

Dispensing counter funnel

Fig. 308



Funnel stand

Fig. 308 shows a funnel stand useful for small filtering operations in the laboratory or at the prescription counter.

Fig. 309 shows Bartlett's funnel, which has a perforated sleeve around the spout to permit the escape of air from the bottle in which it is placed, when the liquid is running through the funnel.

Fig. 310 shows a funnel designed for filling bottles, in which the flow of the liquid is controlled by the valve operated by the thumb. This is convenient when filling a gross of bottles arranged in rows, and if carefully used the bottles need not be soiled on the outside through overrunning, and the quantity in each bottle can be nicely adjusted.

Filters for Special Purposes.—In the course of laboratory work it frequently happens that large quantities of liquids require filtering, and the methods suitable for smaller operations cannot be profitably employed. The filtration and purification of water often become necessary. Charcoal in some form is frequently employed, not only on account of its porous character, but also because of its power of absorbing odors and depriving liquids of color. Sand, powdered glass, or asbestos forms an excellent filtering bed. A very practical and inexpensive charcoal filter is shown in Figs. 312 and 313. It was devised by Dr. Hadden, and is illustrative of a principle in filtration not heretofore treated of in this work,—*i.e.*, *upward filtration.* It is believed by the advocates of upward filtration that great economy is secured by passing the cloudy liquid upward through a filtering bed, the principle of action being that impurities settle away from the filtering medium by force of gravity, instead of accumulating upon it and clogging the pores. Figs. 312 and 313 show an external and a dissected view of the filter. A gallon tin can has a short pipe soldered to it near the bottom; the pipe has a piece of perforated tin or gauze soldered over the opening into the can, to keep it from being filled up. This can is filled with clean gravel. The smaller quart can is connected with the lower one by a raised perforated tin diaphragm, and small pieces of charcoal are packed upon the diaphragm; the upper perforated diaphragm is movable, and is intended to keep the charcoal in place. A disk of coarse cotton flannel should be placed on top of the charcoal, to keep the fine charcoal dust from working through the top to the upper tin can. This is kept in place by a screw joint and washer such as is often seen on fruit cans. About an inch from the top of the can is a small piece of pipe for delivering the filtered water. This filter is, of course, intended to be used in cities and towns, or where water is supplied under pressure. Both the supply and the exit pipe should be of proper diameter to permit the use of a rubber tube for connecting with the water supply and delivering the filtered water. The filtration of oils is often effected in a similar manner, one of the earliest applications of this principle being the oil filter or strainer of Wm. R. Warner, of Philadelphia (see Fig.

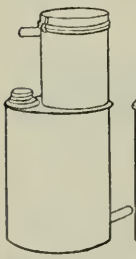
Fig. 309

Bartlett's funnel

Fig. 310

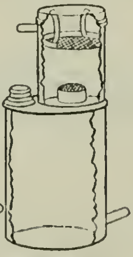
Valve funnel

Fig. 312



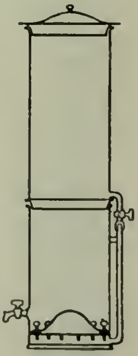
Hadden's filter

Fig. 313



Hadden's filter (interior)

Fig. 314



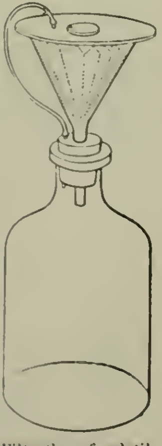
Warner's filter

314). This filter or strainer consists of an upper cylindrical tinned iron vessel, about twenty-two inches high and ten inches in diameter, with a flange rim soldered on the bottom, of rather less diameter, and about an inch wide, so as to fit firmly into the open top of another cylindrical tin vessel of the same diameter and eighteen inches high. The upper vessel is furnished with a lid, and with a tube and stopcock; this tube penetrates the side close to the bottom, and fits into another tube, which opens into the lower vessel close to its bottom and is secured to the side by a strong tubular stay. The filtering medium is a cone of hat felt projecting upward from near the bottom of the lower vessel, and secured by thumb screws passing through two tinned iron rings and the felt, which are all properly pierced for the purpose. The stopcock being closed, the upper vessel is fitted in its place, and the tube joint rendered tight by wrapping twice around it a strip of isinglass plaster well moistened. When this is dry, the upper vessel is filled with the crude oil and the stopcock opened, that the oil may flow into the open space below the filter. A heat of 120° F. is preferred to facilitate filtration or colation, and the filtered oil, as it accumulates, should be drawn off, as any large amount greatly retards the process by decreasing the force of the column bearing on the filter. For a pressure filter or strainer, Prof. B. S. Proctor uses a quadrangular cloth filter bag securely tied to the end of a tin tube five feet long. The extremity of the tube has a wire ring soldered to it, to keep the bag from slipping off.

Continuous Filtration.—Most of the expedients used in continuous washing (see page 199) are applicable to continuous filtration.

Filtration of Volatile Liquids.—It is evident that the ordinary methods of filtering liquids will not be practicable for very volatile liquids, because of the loss through evaporation, and the liability to explosion, in the case of inflammable volatile liquids, if brought in contact with flame. Funnels must be covered, and provision made for the escape of the confined air in the receiving vessel. The following method is preferred to the elaborate expedients usually recommended. A glass tube (one of those usually sold as julep tubes answers very well) is arranged in a glass or metallic funnel, so that the tube will lie close to the side of the funnel and allow one end to project above the filter, but not above the edge of the funnel. It may be held in its place by a ring of absorbent cotton gently thrust into the throat of the funnel. Or a rubber cover perforated to admit a tube is placed on top, and connection between the bottle and funnel effected as shown in Fig. 315. For larger operations, Dr. Hadden's water filter or Warner's oil filter (see pages 211 and 212), slightly modified to suit the liquid, might be used. A very neat method of filtering volatile liquids is provided in the apparatus contrived by E. H. Hance, of Philadelphia. This consists of a cylindrical vessel, provided with a tubulure and stopcock below, and a ground glass cover above; a flange near the top affords support for a perforated filter support or funnel containing a filter.

Fig. 315

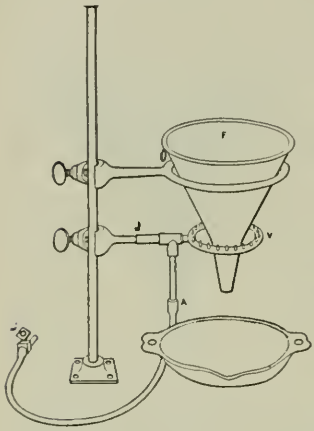


Filtration of volatile liquids

When not needed for filtration, the receiving vessel is very useful for many other purposes.

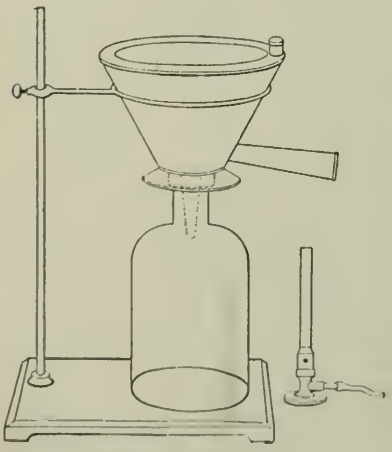
Hot Filtration.—This process is not resorted to as frequently as it might be with advantage, because of the difficulties which are asserted to attend it. These have been greatly overestimated, for by the use of simple, properly contrived apparatus many preparations which heretofore have been dispensed, bearing an unsightly cloudy appearance, can be greatly improved. Yellow wax is frequently full of mechanical impurities; ordinary straining will not deprive it of these, but it may be filtered through paper and thoroughly purified. Jellies, benzoinated lard, petrolatum, cerates, ointments, etc., may thus be filtered. One of the simplest and most easily managed forms of apparatus (see Fig. 316) is made by filing off the ring from one of the ring supports of a retort stand, J, and slipping on to the arm a brass circular jet, V, attached to a tee carrying the gas supply pipe, A. A tinned copper or tinned iron funnel is supported by an appropriate ring at a suitable distance above the jet. The filter is placed in the funnel, a receiving vessel adjusted below, and the hot liquid poured into the filter. It is plain that the liquid can be heated to almost any degree, and the filtration conducted at a much higher temperature (if need be) than by the jacketed hot water funnel (see Fig. 317), and, on the other hand, the heat may be regulated so that it will be very moderate. The hot water funnel is an old device, and consists simply of a jacketed funnel having a wide tube soldered at the lowest point, and an opening in the upper edge for the water supply. A burner or lamp flame will heat the water contained between the funnels, and a regulated heat not exceeding that of boiling water is obtained (see Fig. 317).

Fig. 316



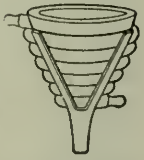
Hot filtration

Fig. 317



Jacketed hot water funnel

Fig. 318



Hot filtration (use of coil)

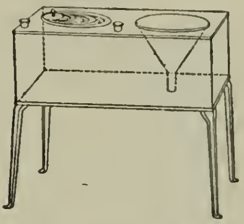
Fig. 318 shows another form of funnel to be used for hot filtration, the coil of pipe may be used for steam or hot water, by connecting it with a suitable supply.

A modification of Dr. Hare's hot water filter, which permits the use of glass funnels of different sizes, is shown in Fig. 319. It is simply a tinned copper box, with two sides shaped like a trapezoid, and supported upon four legs. There are three one-inch tubulures in the bottom, and the top has three openings which centre with the tubulures; beginning with the deepest, the diameters are four, three, and two inches. Three glass funnels of different sizes are selected, and the corks for the tubulures in the bottom, having been chosen, are perforated so as to permit the necks of the funnels to pass through and form perfectly tight joints. Water is placed in the box and heated by the burner, as shown in the cut. When not needed for hot filtration, solid corks may be used to close the tubulures, and the box used as a water bath, covers being placed over the openings which are not in use. Fig. 320 shows a combined water bath and hot water filter.

FIG 319

Hot filtration

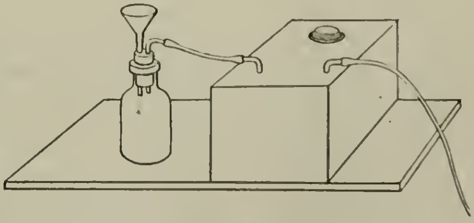
FIG. 320



Hot filtration (water bath)

Rapid Filtering Apparatus.—Of late years much attention has been given to methods for increasing the rapidity of filtration. Most of the plans suggested depend upon the principle of filtering into a partial vacuum, but the means used to obtain this vacuous space are very varied. A simple method, applicable to operations on the small scale, consists in fitting a good cork to a wide mouthed bottle and perforating it so that the neck of a funnel will accurately pass through it; another perforation permits the insertion of a piece of glass tube of small diameter. A plain filter of well washed coarse linen or muslin cloth is then carefully adjusted in the funnel, and a plain filter of paper placed upon it. The liquid is poured upon the filter, and, a rubber tube having been fitted to the glass tube, suction is applied by the mouth. By pinching the rubber tube a partial vacuum is maintained in the bottle, and filtration is hastened. An improvement upon this would be to use a rubber stopper instead of cork, and instead of pinching the rubber tube to use a screw pinchcock.

FIG. 321



Rapid filtration

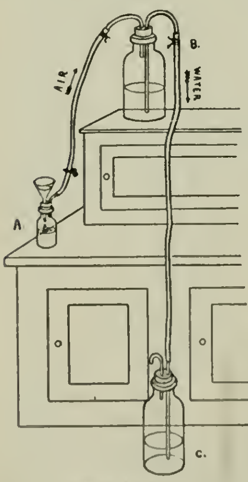
Water Pumps acting by a Fall of Water.—One of the first practical efforts made in the direction of using water power was seen in Bunsen's pump. The action depends upon the principle that a column of water descending through a tube from a height is capable of sucking with it the air contained in a lateral tube, if the latter is properly arranged. A cheap home made apparatus, which depends upon a fall of water for its usefulness, is shown in Fig. 321. It consists of a common wide mouthed half-gallon jar, and a tinned iron can holding three, four, or five gallons; a castor oil can answers very well. The screw cap is for readily filling the can; the exhaust pipe on the right reaches inside of the can, nearly to the bottom, the other tube is soldered on the head of the can connecting with the interior. The jar, having a funnel fitting into it through an airtight stopper, is connected with the can by means of a bent glass tube and rubber tube. The can is filled with water, and the solution to be filtered is placed in the funnel. The exhaust pipe is connected with a rubber tube eight or ten feet long and a quarter of an inch in diameter (the longer the tube the more rapid is the filtration). When the syphon thus formed is started, the flow of the water from the can carries with it the air from the bottle.

Fig. 322

Lux's aspirator

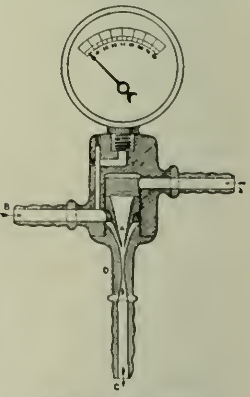
Lux's aspirator (see Fig. 322) is constructed by fitting two accurately perforated rubber stoppers to the ends of a piece of wide glass tubing; four short glass tubes are inserted in the stoppers, as shown in the cut. One of the tubes is for the supply of water, another carries it off, the third tube is connected with the vessel to be exhausted, while the fourth tube may be put to the same use, or connected with a vacuum gauge or closed with a stopper. If the air is to be aspirated by one of the lower tubes, the vessel to be exhausted must stand on a higher level than the aspirator. The length of the exit tube determines the power of the aspirator. It should have a bore of one-fifth of an inch and be at least ten feet long, and it should be provided with a screw pinchcock to regulate the flow of water. A very simple apparatus is shown in Fig. 323. A very moderate fall of water is needed here. It is, however, adapted only to small operations. Two rather large bottles, of equal capacity, are selected; these are connected by rubber tubing as shown in the illustration. Into the neck of each a tightly fitting stopper is adjusted carrying a glass tube. A bottle, provided with a tightly fitting stopper carrying a small bent tube and a funnel, is attached to a rubber tube provided with a con-

Fig. 323



Rapid filtration

Fig. 324

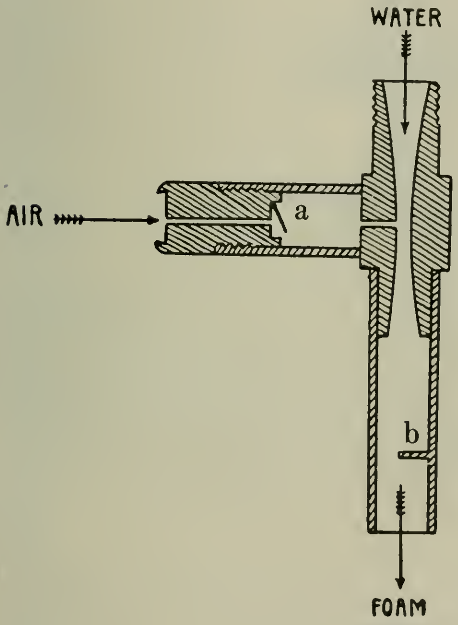


Fisher's vacuum pump

veniently situated pinchcock. One of the large bottles is filled with water and placed on an elevated shelf, when the water will flow down to the other bottle. And if the connections are made as shown in the cut, it will aspirate through the funnel; and if the funnel is full of liquid, it will cause the latter to run through quite rapidly. When the lower bottle is full, it is substituted for the upper one, and the connection with the vessel to be exhausted, transferred to it.

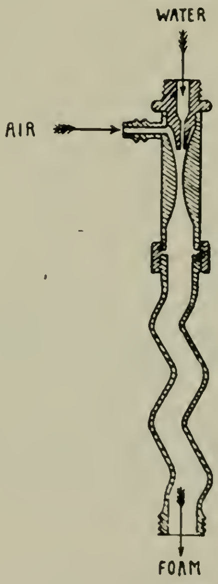
Water Pumps acting by Pressure.—It is usually inconvenient to operate aspirators which depend upon a fall of water through a long tube, except in high buildings. Hence, water pumps which are operated by pressure are generally preferred in cities and towns, or in localities where water is supplied under pressure. The following are selected from the great variety in use as being good illustrations of the principle. Those made of glass are not recommended, because of their extreme liability to breakage. Fisher's vacuum pump is well shown in Fig. 324. A, B, C, are intended to receive rubber tubing, and the neck, D, may be fastened by a clamp to a retort stand or other upright fixture. Water from the hydrant enters at A, passes through the nipple at *a*, and, being forced through the contracted portion, *b*, draws with it the air from the tube, B, which is attached to the filter. A communication is also made with the vacuum gauge, as shown in the cut, to mark the degree of exhaustion. Fig. 325 shows another modification of a vacuum pump. The valve at a pre-

Fig. 325



Chapman's pump

Fig. 326



Richards's pump

vents the water from flowing into the bottle which carries the filter when the pressure of water ceases or is reduced. Fig. 326 illustrates a form of pump largely used in analytical laboratories for hastening filtration. The zigzag form of the tube serves the same purpose as the projection in the lower portion of the outlet tube of the Chapman pump,—*i.e.,* to break the direction of the solid stream of flowing water and assist in drawing the air from the bottle. Schutté and Goehring, of Philadelphia, have contrived an apparatus which is somewhat more convenient from their having placed it upon a base and deflected the lower tube laterally. This permits the use of the apparatus in many places where Fisher's pump could not be used. It is shown in Fig. 327. W represents the water supply tube, D the outlet, and A the aspirating tube.

Vacuum pump

CHAPTER XII

CLARIFICATION AND DECOLORATION

Clarification is the process of separating from liquids, without the use of filters or strainers, solid substances which interfere with their transparency. The processes of clarification and decoloration from a pharmaceutical point of view have declined in importance of late years, owing to the fact that chemical and other substances requiring the processes are supplied in a purified condition so cheaply that it is absolutely impossible for the pharmacist to compete with the manufacturer who operates on the large scale and uses apparatus and methods which are thorough and economical. This is particularly the case with sugar and the alkaloids. Formerly the apothecary bought raw sugar and clarified the syrup; now the difference in price between raw sugar and that which is pure is so slight that no one ever makes syrup from raw sugar. The decoloration of alkaloidal solutions and the manufacture of alkaloids cannot be economically attempted on the small scale by the pharmacist, because of the want of continuity of the process; the manufacturer, on the other hand, can use the animal charcoal repeatedly until its power is exhausted, and in other ways practise economy not possible to the apothecary. It is, nevertheless, very important to comprehend thoroughly the principles underlying both processes.

Clarification may be effected in several ways:

1. By the application of heat. 2. By increasing the fluidity of the liquid. 3. Through the use of albumin. 4. Through the use of gelatin. 5. Through the use of milk. 6. Through the use of paper pulp. 7. By fermentation. 8. By subsidence through long standing.

1. *By the Application of Heat.*—When a viscid liquid is heated, its specific gravity is diminished, and frequently particles which were suspended in it, and interfered with the transparency of the liquid, will separate, the heavier ones falling to the bottom, and the lighter ones rising; in the latter case, ebullition facilitates the separation, the minute bubbles of steam becoming enveloped in the viscid particles rise through their buoyancy, and a scum is formed which may be readily separated. The official process for the clarification of honey (Mel Depuratum) is a good illustration of the use of heat in this connection.

2. *By increasing the Fluidity of the Liquid.*—Clarification by this method depends upon decreasing the specific gravity of the liquid by the addition of water, alcohol, or other liquid lighter specifically than the one to which it is added; this causes the suspended particles to subside, and the clear liquid may then be decanted.

3. *The Use of Albumin.*—The property possessed by albumin of remaining liquid at ordinary temperatures and becoming coagulated by heat renders it one of the most useful substances that can be em-

ployed in the process of clarification. Its action is mechanical, and where albumin exists naturally in the liquid, as in many fruit and vegetable juices, the simple heating of the liquid suffices to coagulate the albumin, which envelops the particles that render the liquid cloudy, and these rise to the top and are skimmed off. Albumin, or white of egg, is frequently added to liquids to clarify them ; in such cases it should always be added before the liquid is heated. This is best accomplished by adding about an equal bulk of the liquid to the albumin, then introducing the mixture into a muslin strainer and squeezing it through the meshes of the cloth by gathering up the corners and spirally twisting the strainer, when the organization of the albumin is destroyed, and a smooth mixture results ; the strained solution is then added to the liquid to be clarified, and the whole heated gradually (usually until it boils), without stirring, until coagulation is effected. In most cases the white of one egg is sufficient for a gallon of liquid. The error most frequently made by operators is the use of an excess of albumin. Care must be taken not to use albumin as a clarifying agent in those cases where the active principle of a liquid forms a precipitate by combining with it.

4. *The Use of Gelatin.*—Gelatin is used when tannin is present and is the cause of cloudiness, or when it is desirable for other reasons to remove it. Its action depends upon the fact that gelatin forms with tannin an insoluble compound ; this is, indeed, the basis of leather. Isinglass, one of the purest kinds of gelatin, is the preferred form ; it is frequently employed for clarifying infusions containing tannin, such as tea and coffee, etc. It is used by adding a weak solution of the gelatin in hot water to the liquid before it is heated, and allowing the liquid to cool. The insoluble compound formed must always be strained or filtered out.

5. *The Use of Milk.*—The presence of casein in milk, and the fact that acids precipitate it in the form of a curdy precipitate, are taken advantage of in the use of milk as a clarifying agent. It is employed particularly for vinous preparations, sour wines, etc., and should not be used in excess.

6. *The use of paper pulp* does not depend upon chemical combination, its action being purely mechanical. Paper pulp for filtering is best prepared by placing filtering paper (the saved trimmings and scraps left from making filters answer well) into a mortar or other vessel, and pouring enough solution of sodium or potassium hydroxide on it to saturate it, then stirring it with the pestle until it is reduced to a pulp. This should then be washed by placing a loose plug of absorbent cotton in a funnel and pouring in the mixture. When it has drained, hot water should be poured upon it until all traces of alkalinity are washed out ; the dried purified pulp may then be placed in stoppered wide mouthed bottles until needed. It is used as a clarifying agent by adding a portion to the cloudy liquid, agitating the mixture, and allowing the whole to stand quietly until the liquid is clear ; or, as a filtering agent, after the addition of the pulp, the mixture may be thrown upon a wetted muslin strainer, and if the liquid which passes through at first is not clear, it may be returned until it becomes so. It will be found that particles of pulp will partially fill up the meshes of the strainer, and an excellent filtering bed is

thus formed. Care should be taken, therefore, not to stir up the mixture after it is placed on the strainer.

7. *By Fermentation.*—The changes in the composition of juices after they have been fermented usually lead to the deposition of those substances which previously interfered with the transparency of the juices; the generation of alcohol through fermentation produces a liquid in which the substances are insoluble, hence the formation of a deposit. The preparation of syrup of raspberry affords a good illustration of the principle of clarifying juices by fermentation, while in the manufacture of wines the principle has been known and practised for centuries. (See Fruit Juices, Chapter LIV.)

8. *By Subsidence through Long Standing.*—This method involves the least possible amount of labor and expense, and it is resorted to very frequently (particularly upon the large scale) when haste is unnecessary, and whenever the liquid keeps well enough to withstand the tendency to spoil during the time necessary to effect complete separation. The deposit formed is called a *sediment.* This term is not synonymous with *precipitate. Sediment is solid matter separated merely by the action of gravity from a liquid in which it has been suspended. A precipitate, on the other hand, is solid matter separated from a solution by heat, light, or chemical action.* The fixed oils are clarified by subsidence; in the vegetable oils the sediment consists principally of albuminous and gummy substances which have been separated with the oil during the process of expression.

Decoloration is *the process of depriving liquids or solids in solution of color by the use of animal charcoal.* Decoloration is used in the abstraction of coloring matter from fatty bodies, oils, petrolatum, syrups, honey, etc. Animal charcoal, or bone black, which is produced by heating bones in close vessels out of contact with air, and then grinding them, is generally preferred in decolorizing operations. Wood charcoal possesses but little power in this direction. It has been generally settled that the decolorizing property is owing to the formation of insoluble compounds of the coloring matter when it is brought in contact with porous charcoal. Animal charcoal varies greatly in its power. The official purified animal charcoal is often not so powerful as a decolorizer as the animal charcoal from which it was made; but bones contain calcium phosphate and calcium carbonate, and the object of the purifying process is to separate these salts, because, in many of the delicate operations of pharmacy, particularly the decoloration of vegetable acid solutions, these salts would be dissolved by the acids, and the solutions thus contaminated. The most powerful animal charcoal is produced by calcining dried blood and other animal matter with pearlash, and afterwards washing out the pearlash with water, and subsequently with an acid solution. The charcoal need not be dried before using. For other information about the properties of charcoal, see *Carbo Animalis* and *Carbo Animalis Purificatus*, U. S. Dispensatory, 18th edition, page 326. For most decolorizing operations of the pharmacist on the small scale, the solutions, melted fats, oils, etc., can be introduced directly upon the animal charcoal, which is placed in a funnel and prevented from falling through by the insertion of a plug of absorbent cotton, or it may be arranged in an ordinary percolator, and the cold liquid percolated through the charcoal, or the liquid simply agitated with the charcoal and the mixture filtered. It is very important to remember that charcoal absorbs a number of valuable principles used in medicine,—*e.g.*, *bitter substances*, like gentiopicrin, aloin ; *astringents*, like tannin ; *alkaloids*, like quinine, morphine, strychnine, cocaine, etc. Charcoal has even been used as an antidote for poisoning with the alkaloids. It should always be used, in decoloration, with discrimination and judgment, or it may be found that in striving to improve the appearance of a preparation by lessening the color its value has been sacrificed.

CHAPTER XIII

SEPARATION OF IMMISCIBLE LIQUIDS

THE separation of liquids which are mutually soluble is usually effected by distillation, if one or both of the liquids are volatile (see page 140) ; but the separation of liquids which do not mix with each other is generally a simpler process, and the object of this chapter is to show the methods at present in use.

Use of the Pipette.—This simple instrument consists of a narrow tube with its lower end drawn out to a capillary orifice, and a bulb, either globular or elongated, blown in it near the top ; the upper edge is usually surrounded by a smooth glass ring to strengthen it. It is used by dipping the lower orifice into the liquid that is to be separated and applying suction with the mouth at the upper end ; the liquid rises, fills the bulb, and, if the end of the moistened forefinger is applied to the top, the liquid may be carried some distance without running out. Fig. 328 shows the ordinary form of the instrument. Fig. 329 can be readily made from a glass syringe tube, a perforated cork, and a piece of tube, by one unskilled in glass blowing. Fig. 330 shows a pipette which has a piece of sheet rubber tied over the thistle shaped top. If pressure is applied to the rubber, the air is partially expelled ; if the point of the pipette is then applied to the liquid and the pressure relaxed, the liquid will rise, and it may be transferred to another vessel. A modification of this, where a rubber bulb is attached to the pipette and used in a similar manner, is seen in Fig. 42.

Plain pipette

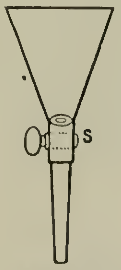
FIG. 329

Syringe pipette

FIG. 330

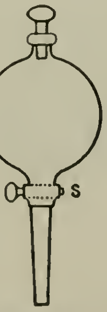
Pipette (sheet rubber top)

FIG. 331



Separating funnel

FIG. 332



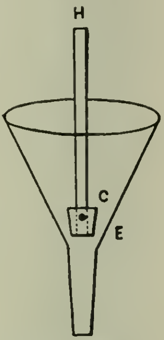
Globe separator

Use of the Glass Syringe.—The glass ear syringe, having a bulb blown near the orifice, is very useful in collecting a small quantity of oil floating on top of a liquid contained in a beaker or open vessel. The piston of the syringe should be well soaked in warm water before attempting this simple but delicate operation.

Fig. 333

Pear shaped separator

Fig. 334



Mitchell's separator

Use of the Separating Funnel.—This instrument, as indicated by its name, is used to facilitate the separation of immiscible liquids. It is generally a funnel having a glass stopcock in its neck (see Fig. 331). The mixed liquid is poured into the funnel, which is placed in position where it can come to rest, and the lower liquid is then allowed to run off by opening the stopcock. With careful use, liquids can be separated with great accuracy in this way. Where the liquid is valuable or very volatile, as in some of the oils, the globe separator (see Fig. 332), or the pear shaped separator (see Fig. 333), which can be securely stoppered and evaporation prevented, is preferred. In the assay processes, when immiscible liquids are to be separated, this latter form is invaluable, because, on account of the narrowing of the lower portion, the point of separation of the liquids can be more accurately fixed.

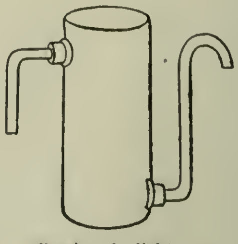
Mitchell's Separator.—Dr. Mitchell devised a cheap but efficient substitute for the separating funnel (see Fig. 334). A good, well pressed cork, C, is fitted into the throat of a funnel, E, and the end of a penholder handle, H, or other suitable wooden rod, is whittled to a flat wedge, and this forced into the cork tightly. The lower portion of the holder is notched, and the upper part of the cork is tied securely to it, or a wooden pin may be driven through it and the cork, to fasten it. It is used by forcing the cork C into the neck of the funnel, pouring in the liquids, and, when they have separated, lifting the handle H carefully until the lower liquid has entirely escaped, and then pushing it down tightly to stop the flow.

Florentine Receiver.—The separation of volatile oils from the water which usually accompanies them during distillation is a very important part of their process of manufacture. Where the volatile oil is lighter than water, the form shown in Fig. 335 is used. The mixed oil and water collect in the glass receiver during distillation, the oil floating on the top, while the water ascends the bent tube from

Fig. 335

Florentine receiver

Fig. 336



Receiver for light and heavy oils

the bottom ; further addition of distillate causes an overflow, and the water from the bottom of the receiver is discharged through the tube into a suitable vessel ; then the receiver becomes filled again gradually as distillation progresses. The process of separation is continued automatically. Where the oil is heavier than water, the method is reversed, and provision must be made for the escape of the water near the top of the receiving vessel. Labor may be saved by the use of a long necked funnel, or by placing a funnel in a wide tube, so that the mixed oil and water may be conveyed at once to the bottom without the liability of some particles of oil being carried over through the lateral tube and necessitating a second separation.

Fig. 336 shows a receiver which can be used for either light or heavy oils, one or the other tube being stopped with a cork, as the case requires.

CHAPTER XIV

PRECIPITATION

PRECIPITATION is the process of separating solid particles from a solution by the action of heat, light, or chemical substances. The separated solid is termed a *precipitate;* the added liquid or substance which produces the precipitate, the *precipitant;* the liquid which remains in the vessel above the precipitate, the *supernatant liquid.*

The precipitate usually falls to the bottom of the vessel. It may, however, remain suspended or rise to the top.

The objects of precipitation in pharmacy are,—

1. To obtain conveniently solid substances in the form of fine powder. Example, the precipitation of calcium carbonate.
2. To effect the purification of solids. Example, the precipitation of pepsin from its solution by sodium chloride.
3. To obtain through chemical reaction substances which are insoluble in the supernatant liquid. Example, the official preparation of red mercuric iodide.

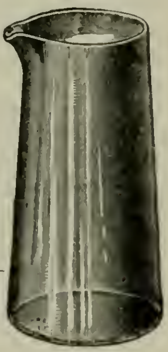
Precipitation is largely used in testing, as it frequently affords the most ready means of recognizing chemical substances or of ascertaining their purity. A great many pharmacopœial tests are based upon this process. The color, quantity, and character of the precipitate are all taken into account. The terms *curdy, granular, flocculent, gelatinous, crystalline, bulky,* and others, which are sufficiently distinctive, are used to define the peculiar form which the precipitate assumes when thrown out of solution. A *magma* is a thick, tenacious precipitate left after the liquid is decanted.

Methods of Effecting Precipitation.—Precipitation may be produced in many ways. If solutions containing albuminous matter be *heated*, a flocculent precipitate of coagulated albumin will be thrown down; while if solution of the silver salts be exposed to the *light*, precipitation is apt to take place. Precipitation will usually occur when a hot saturated solution of an amorphous substance is allowed to cool, as in the preparation of antimony oxysulphide, or when to a solution is added a liquid in which the dissolved substance is insoluble, as when strong alcohol is added to a small quantity of mucilage of acacia, or water to an alcoholic solution of guaiac.

Precipitation is most generally effected by the reaction of chemical substances, and some of the most interesting processes in pharmacy are the results of this method of producing precipitates. When acid solutions are brought in contact with alkaline solutions, insoluble precipitates are sometimes formed, as the solution of oxalic acid with lime water, forming calcium oxalate. By far the most common method is to mix a solution of one salt with a solution of another, thereby producing an insoluble precipitate, as in the official process for preparing red mercuric iodide, where solution of mercuric chloride and solution of potassium iodide are together poured into water. The methods of producing precipitates are numerous, and will be noted in detail under the head of the respective substances.

Vessels used in Precipitation.—Precipitating vessels should be deep, comparatively narrow, and broader at the bottom than at the top (see Fig. 337). This construction permits the precipitate to occupy less height in the vessel, by causing it to spread out upon the bottom; thus the supernatant liquid can be more thoroughly decanted, the particles of the precipitate will lie in closer contact, and a better opportunity is given for the escape of imprisoned air or gas, which frequently exercises a buoyant effect on the particles and prevents their subsiding rapidly and closely. Upon the large scale, cedar tanks, of the shape just described, may be used; these may have wooden spigots introduced, a foot or so apart, so that the supernatant liquid may be conveniently run off.

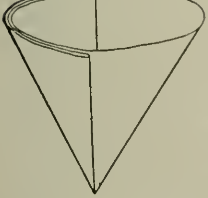
Fig. 337



Precipitating jar

Manner of conducting the Process.—If two solutions are used, and it is known that they contain the exact quantity of solid substance to react mutually without leaving an excess of one or the other, the order in which the liquids are mixed is immaterial; but when this is not the case, and the precipitant is to be added until precipitation ceases, it is necessary to proceed with caution. The precipitant is then added gradually, and, where acid or alkaline solutions are used, litmus paper is useful in indicating the approach of an excess. In other cases the precipitate may be allowed to subside, and the precipitant slowly dropped into the clear liquid above until it is noticed that further addition is without effect. If the precipitate is too bulky to subside quickly, the whole may be vigorously stirred until thoroughly mixed, a small portion transferred to a small plain filter (see Fig. 338), and the filtrate tested by a further addition of precipitant. If this small portion is weighed, or measured, or is a known proportion of the whole, a simple multiplication will determine about the quantity necessary to complete the precipitation. Ammonia water is one of the most useful of alkaline precipitants, because an excess is at once noticed by the odor. This is easily done by blowing the air from the surface of the liquid, thoroughly stirring up the mixture, and then noting whether it smells of ammonia.

Fig. 338



Filter (for precipitates)

The Production of Heavy and Light Precipitates.—Hot, dense solutions usually produce heavy precipitates, and such precipitates are more readily washed from adherent contaminating salts than those which are light and bulky. An additional advantage is, that they occupy less space, and consequently their dose is less bulky. A good example of this is found in the manufacture and use of heavy and light magnesium carbonate.

Collecting and washing Precipitates.—In small operations precipitates are collected upon plain filters (see Fig. 338). The special advantages of such filters in this respect have been already pointed out on page 206. On a larger scale muslin strainers are generally used. These are suspended on frames, as shown in Figs. 339 and 340. In washing precipitates which are placed on strainers of this kind, care must be observed to close up the fissures which usually appear in the magma after it has been allowed to stand a short time, by stirring the precipitate thoroughly before adding more water. (See Lotion, Decantation, pages 198 and 199).

CHAPTER XV

CRYSTALLIZATION

Crystallization is the process whereby substances are caused to assume certain determinate forms called *crystals.* These are distinctive, and when perfect are bounded by geometrical surfaces. Those substances which are *not* crystallizable are termed *amorphous.* The objects of the process are to increase the purity and to enhance the beauty of chemical substances. The descriptions of the crystalline forms assumed by bodies form the basis of the interesting science of *crystallography.* In a work of this kind it is impossible to give more than a very brief sketch of the outlines of the classification, since the practical process of crystallization must receive the most attention. (See Dana's Mineralogy, Kopp's Kyrstallographie, Miller's Mineralogy, etc.). Every crystallizable body invariably assumes its own characteristic form, or in some form directly derived from it or related to it by a simple law, and in order to classify them crystallographers recognize at the present time six systems, to one or other of which every crystal is referred. A seventh system is sometimes conceded, but the occurrence of crystals belonging to it has not been demonstrated with certainty.

The following definitions should be well understood : The plane surfaces bounding a crystal are termed *faces;* when two contiguous faces intersect, an *edge* is formed ; an *angle* is formed when three or more faces intersect.

The faces, edges, or angles of a perfect crystal have equal faces, edges, or angles opposite to them, and if the middle points of the opposite faces or edges, or the opposite angles, be joined by straight lines, the point at which these lines intersect will be the centre of the crystal. The lines drawn through this point are called *axes.*

When *the same* body crystallizes in two or more forms belonging to different systems, it is said to be *dimorphous, trimorphous, polymorphous,* etc. When *different* substances crystallize in the same form, they are said to be *isomorphous.*

Prismatic (or prism-like) *crystals* are those which are extended principally in the direction of their longest axis. *Tabular crystals* are those crystallizing in flat plates ; *laminar,* those crystallizing in thin plates ; *acicular,* those which are needle shaped, etc.

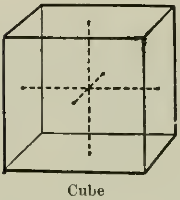
Other terms are used to describe the physical characters of crystals, which are readily understood and are not technical in their meaning.

The systems of classification are based upon the length and relative position of the axes of the crystal. Those in which the three axes intersect at right angles are termed *orthometric ;* and when the angles caused by their intersection are oblique, they are called *clinometric.*

Systems in Crystallography

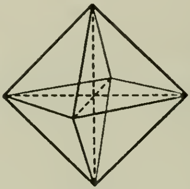
I. Monometric, or Regular System.—The crystals have three axes of *equal* length intersecting at right angles (see Figs. 341, 342, 343, and 344).

Fig. 341



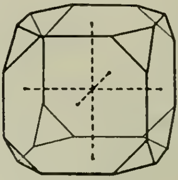
Cube

Fig. 342



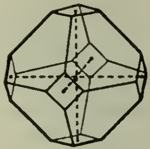
Octahedron

Fig. 343



Truncated cube

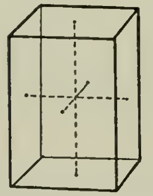
Fig. 344



Truncated octahedron

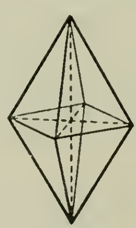
II. Dimetric, or Quadratic System.—The crystals have three axes, two of which are *equal*, the other *different* in length, all intersecting at right angles (see Figs. 345, 346, 347, and 348).

Fig. 345



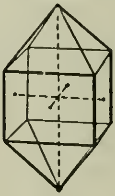
Right square or dimetric prism

Fig. 346



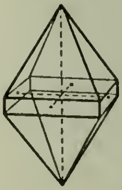
Dimetric octahedron

Fig. 347



Square prism, pyramidal summits

Fig. 348



Square prism, pyramidal summits

III. Trimetric, or Rhombic System.—The crystals have three axes of *unequal* length, all intersecting at right angles (see Figs. 349, 350, 351, and 352).

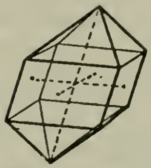
Monoclinic prism (partly truncated)

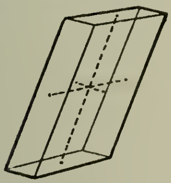
FIG. 360



Monoclinic prism, pyramidal summits

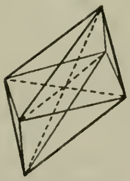
VI. Triclinic, or Doubly Oblique Prismatic System.—The crystals have three axes of *unequal* length, all obliquely inclined to one another (see Figs. 361, 362, 363, and 364).

FIG. 361



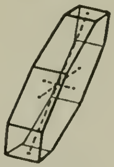
Triclinic prism

FIG. 362



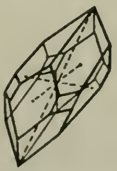
Triclinic octahedron

FIG. 363



Triclinic prism (truncated)

FIG. 364



Triclinic octahedron (partly truncated)

The Diclinic System, if recognized, would have three axes, two at right angles to each other, the third oblique to the other two.

Determination of Crystalline Form.—The method of determining the position of a crystal in one or other of the systems above noted is to measure the inclination of the angles which the faces of the crystal make with one another. From the data obtained the length and inclination of the axes are calculated. The hand goniometer or Wollaston's reflecting goniometer is used to measure the angles.

Cleavage.—If a crystal of potassium ferrocyanide or a piece of mica is broken and examined, it will be noticed that the cohesion of the particles is less in one direction than in any other, and if the blade of a knife is inserted in the edge, the crystal may be easily split or cleft. Other crystals possess this property, but to a greatly varying extent. Perfect crystals may sometimes be formed by cleavage.

The process of crystallization generally takes place when a body passes from a liquid or a gaseous condition into the solid state. A few instances are known where amorphous solids become crystalline without becoming liquefied, as in iron or brass wire, sulphur, barley sugar.

Methods of Obtaining Crystals.—1. By fusion and partial cooling. 2. By sublimation. 3. By deposition from supersaturated solutions as they cool. 4. By deposition from solutions during evaporation. 5. By deposition from solutions upon passing through them a galvanic current. 6. By precipitation. 7. By the addition of a substance having a strong affinity for water.

1. **By Fusion and Partial Cooling.**—Substances which have low melting points, like sulphur, camphor, and iodine, and some of the metals, like bismuth, antimony, etc., may be crystallized in this way. To obtain crystals of a substance like sulphur, it should be melted in a deep vessel and then allowed to cool, so that a crust will be formed; a hole is then made in the crust, and a smaller one on the opposite side; the vessel is now inclined toward the side having the larger hole, and the melted substance runs off; when the surfaces inside are examined, they will be found studded with crystals. If the quantity of material used is large, and the mass has been gradually cooled, the crystals will be large and distinct. The crust should be perforated as soon as it is fairly formed, and the fluid contents quickly removed.

2. **By Sublimation.**—This is one of the most useful methods of obtaining crystals (see Sublimation, page 161).

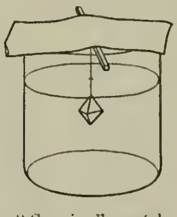
3. **By Deposition from Supersaturated Solutions.**—This is the method by far most frequently employed to obtain crystals. The solution of the substance is generally effected by the use of heat (see Solution). This solution should be filtered, and evaporated to the proper degree, and this latter part of the operation is the most important in determining the size and beauty of the crystals. As a rule, concentrated solutions produce small, ill defined crystals, while comparatively dilute solutions, provided they are supersaturated, produce crystals of more perfect form. The proper degree of concentration must always depend upon the solubility of the substance. If very soluble, the solution should not be saturated at the boiling temperature, or the crystals will be very small and so thoroughly interlaced that it will be difficult to wash them; if a portion of the evaporating solution is transferred to a glass or porcelain plate and allowed to cool, the rapidity with which the small quantity of solution crystallizes, and the amount of crystals obtained, form a basis for judgment. Upon the large scale, in order to secure a uniform product, it will be found that the specific gravity of the solution at a definite temperature, the temperature of the air, and the quantity of the solution must be considered. These points, however, can be obtained only by experience, and after a practical trial with each substance. It is a good habit to keep a record at each operation of the specific gravity and temperature of the solution which is set aside to crystallize, and note the character of the product. If the substance

is not very soluble, the solution should be evaporated until a *pellicle* or crust is formed upon the top, and then set aside.

Perfect rest for a solution designed for crystallization must be secured, if well defined crystals are wanted, and the solution must not be cooled quickly. When small crystals are desired, as in the case of magnesium or zinc sulphate, the solution should be cooled quickly, with constant agitation. This produces a great many nuclei, and prevents the gradual deposition of the particles in regular order upon one nucleus, which is so essential to the formation of the perfect crystal. There are several plans to choose from, for preventing rapid cooling. If the liquid is placed in an evaporating dish, and heated in a sand bath or water bath until evaporated to the proper point, the whole may be set away without disturbing them, to cool slowly together; or the dish may be placed in a warm room which is slowly cooled; or it may be embedded in a blanket or in woollen cloths, covered, and set aside. Having arranged the dish, it must be left absolutely undisturbed until all the crystals have separated. If jarred or knocked after the crust has once formed, the crystals will be mere confused masses.

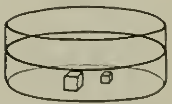
Use of Nuclei.—It has long been known that if a smooth glass rod having a single scratch upon it be placed in a solution ready to crystallize, crystals will first attach themselves to the scratched part, and the smooth part of the rod will frequently not have any separate crystals upon it. Rough surfaces, by offering more points of adhesion, attract the nuclei upon which the crystalline body is subsequently deposited. It is for this reason that strips of wood or lead are frequently suspended in liquids intended for crystallization, while in the manufacture of rock candy, threads are usually strung across the crystallizing tubs at regular intervals, columnar masses of fine crystals being thus produced. Perfect geometrical crystals may be obtained by the practice of "nursing," which consists in selecting from the ordinary stock as perfect a crystal as can be found for the nucleus, and then suspending it by a horsehair or piece of sewing silk in a warm saturated solution of the salt. Prof. J. U. Lloyd contributed to New Remedies, in 1879, pages 98, 133, 162, some interesting notes on the production of perfect crystals. Figs. 365 and 366 illustrate the method of "growing" perfect crystals.

FIG. 365



"Growing" crystals

FIG. 366



"Growing" crystals

Retarded Crystallization.—Warm saturated solutions of various salts, particularly if contained in chemically clean vessels, protected from the dust, and left at absolute rest until cooled, usually fail to crystallize. If the receptacle is shaken or jarred, or if a crystal from which the solution has been made, or any other solid substance, is dropped into it, crystallization sometimes takes place in an instant, and considerable heat is evolved. This is particularly noticed with salts capable of crystallizing with more than one molecule of water, as sodium sulphate, sodium carbonate, etc.

4. **By Deposition from Solutions during Evaporation.**—This process is not so frequently resorted to as that of cooling from hot saturated solutions, but it is especially useful where the liquid is more volatile than water, as alcohol, ether, petroleum benzin, chloroform, and upon the small scale for experimental purposes, or in the processes of original investigation. There are some instances in manufacturing pharmacy where the method is used, but in the case of volatile liquids the expense attending their loss, if spontaneously evaporated, is great, and, as a usual thing, rapid evaporation or recovery of the solvent by distillation cannot be used where large and distinct crystals are desired. Beautiful crystals are often made from aqueous solutions of substances that are allowed to evaporate slowly in a warm room for several months. The quantity of liquid and the amount of solid in solution have a great influence in enhancing the beauty of the product. For this reason it is usually impossible for the pharmacist operating on the small scale to vie with the manufacturer in producing massive crystals ; there is compensation, however, to the pharmacist in obtaining increased knowledge of the properties of medicinal chemicals and absolute knowledge of their purity.

5. **By Deposition from Solutions upon passing Feeble Electrical Currents through them.**—This method is mentioned in this connection because Becquerel and others have produced crystals of metals and metallic oxides by the slow but continuous action of feeble electrical currents through the solutions, kept up for months, sometimes for years. Gold and copper may be beautifully crystallized in this way.

6. **By Precipitation.**—Crystals are produced in some cases by the precipitation resulting from the mixture of certain solutions, and in other ways. (See Precipitation.) The crystals formed by this method are granular, and, on account of their rapid growth, are not well defined. A crystalline precipitate of acid potassium tartrate is produced when solution of potassium hydroxide is added to a strong solution of tartaric acid.

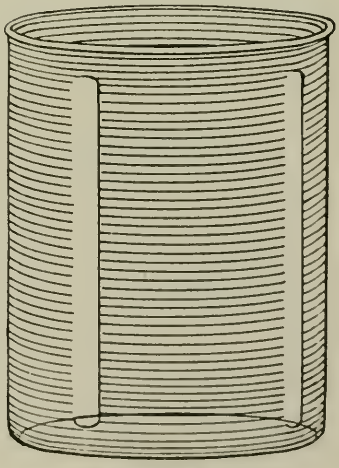
7. **By the Addition of a Substance having a Strong Affinity for the Liquids of the Solution.**—This method of effecting the crystallization of a solid is resorted to in some special cases. If calcium chloride is added to an aqueous solution of sodium chloride, the latter crystallizes out. Alcohol mixed with a solution of potassium nitrate causes the crystallization of the salt, because alcohol and water unite, and the potassium nitrate is not soluble in the mixture. The crystallization of sugar is frequently observed in syrups to which alcohol in the form of a tincture or fluidextract has been added, and this is often a source of annoyance to the pharmacist.

Water of Crystallization.—Many substances in the act of crystallizing combine with water, and the water so combined is termed *water of crystallization.* The same substance does not always contain the same number of molecules of water of crystallization. Sodium carbonate, for instance, usually contains ten molecules. At higher temperatures it may be made to crystallize with eight or with but five molecules, and under some circumstances it contains but one molecule of water. This combination with water must be carefully distinguished from the mechanical retention of water in the interstices of crystals, which takes place particularly where the crystals are large and have been formed rapidly. Water retained in this way is termed *interstitial water*, or *water of decrepitation*, because it is the cause of the *decrepitation* of bodies when exposed to heat. The sudden expansion of the water causes the substance to crackle and burst into fragments. Crystals containing combined water lose part of it on exposure to the atmosphere, and the transparency noticed when the crystal was fresh is replaced by opacity and the formation of a dry powder on the surface. This change is termed *efflorescence*. There are very few substances which will part with all their water of crystallization at ordinary temperatures, nearly all requiring a high heat to effect the object. The act of driving off the water and reducing the crystals to the form of a dry powder is called *exsiccation*. Some substances absorb water from the atmosphere, and, instead of becoming dry, grow moist, and in some cases are converted entirely into liquids. Such substances are said to be *hygroscopic*, and the act is termed *deliquescence*. A good example is found in potassium carbonate which has been exposed to moist air.

Mother Liquor.—The liquid remaining after the crystals have formed is called mother liquor, and still contains some of the salt in solution. This liquid retains as much of the solid as the solubility of the latter and the temperature will permit. It may be evaporated, and another crop of crystals obtained, if desired. Where two salts are in solution, it is obvious that the more soluble salt must exist in largest proportion in the mother liquor. Hence salts are frequently separated from each other by taking advantage of their difference in solubility. Thus cinchonine is separated from quinine. The process is termed *fractional crystallization*.

Crystallizing vessels should be deep, and made of rough glazed stoneware or porcelain. On the large scale, wooden tanks or vats are employed. The Appert glass tanks with heavy glass covers are very useful, as they cannot color the crystals or liquid (see Fig. 367). In the crystallization of alum the staves of the vats are retained in place by iron hoops, which may be tightened or loosened by screw bolts. After the solid crust of alum is formed around the sides and bottom, the hoops are loosened, the staves removed, and a hole chiselled through the side crust near the bottom, to permit the mother water to escape.

FIG. 367



Appert glass tank

Collection, Draining, Washing, and Drying of Crystals.—Upon the small scale it is usually sufficient, after the mother water is decanted, to break the crust of crystals, and, having dropped a few pieces of clean broken glass in the throat of the funnel, to place the crystals upon them and drain thoroughly. They are then to be washed by pouring water carefully and sparingly upon them. If the crystals are very soluble in water, and it is necessary to free them entirely from mother liquor, they must either be washed with alcohol or some liquid in which they are not so soluble, or with ice cold water, used very carefully but quickly by pouring it drop by drop upon the crystals, so that the smallest quantity will suffice. After draining, they may be transferred to a double sheet of filtering paper, placed on a bed of two or three newspapers or cloths, loosely covered, and removed to a dry atmosphere. If the crystals are liable to effloresce, they should be turned several times, and bottled as soon as fairly dry. Deliquescent crystals, like those of chromium trioxide, may be dried by spreading them on a clean, red pressed brick in a dry room. The mother water will be gradually absorbed by the brick, and as soon as the crystals are dry they are transferred to a close vessel.

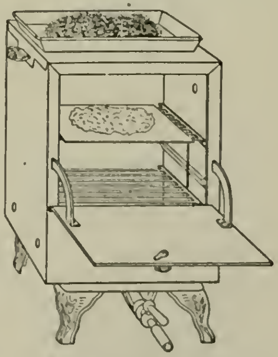
Intermediate crystallization is a term used to define the process of crystallizing a substance which is comparatively insoluble in simple solvents, by causing it to dissolve in a hot solution of another substance. Of course the latter should be very soluble. The whole of the ordinarily insoluble salt will entirely crystallize out at the first attempt. Red mercuric iodide may be made to crystallize in this way in brilliant scarlet crystals by dissolving it in a hot solution of sodium chloride, potassium iodide, or mercuric nitrate.

CHAPTER XVI

GRANULATION AND EXSICCATION

By granulation is meant the process of heating the solution of a chemical substance, with constant stirring, until the moisture has evaporated, and a sabulous, coarse grained powder is produced. It is a convenient method of obtaining many substances in the form of powder. Indeed, the practical advantages of granulated powders are so well recognized now at the prescription counter, that their use in preference to large crystals is rapidly extending. This is particularly the case with salts which are not very soluble in water, or which are commonly found in commerce in hard, tough, crystalline lumps or masses. The process of granulation is one which requires care, but no great amount of skill. The solution of the substance is generally evaporated rapidly until a pellicle forms upon the surface. Then the heat is moderated, in order to prevent spurting and caking. Great care must be exercised at this stage of the process to stir the mass constantly, as the tendency to form a crust on the bottom is very great, and when this hard crust is broken up by the stirrer it is very difficult to avoid the formation of lumps; but if the crust is not allowed to form, by keeping the bottom of the dish clean through constant stirring, the salt will separate in distinct grains, which will not adhere to each other. Toward the end of the process the heat should be very moderate, and the product should be introduced at once into a clean, warm, dry bottle.

Fig. 368



Oven for drying granulated effervescent salts

Granulated effervescent salts were formerly made by mixing the dry powders with dry tartaric acid and sodium bicarbonate and moistening the mixture with strong alcohol. The pasty mass was passed through a sieve, and the granules dried quickly in a hot room, sifted, and filled into bottles, which were hermetically sealed to prevent the access of moist air.

The use of alcohol in making granulated effervescent salts is expensive, and an improvement was made by using citric acid to replace a part of the tartaric acid. The molecule of water of crystallization in citric acid is liberated when heated in contact with the sodium bicarbonate, and this furnishes just sufficient water to make a pasty mass, without causing much loss of carbonic acid; by quickly drying the granules further chemical action is prevented.

In 1903 E. Fullerton Cook improved this method by mixing the powders on a glass plate and gently heating in an oven. When the mixture becomes moist, it is manipulated with a wooden spatula to make it uniform in consistence, and rubbed through a coarse tinned iron sieve and the granules dried in the oven. Fig. 368 shows a convenient oven for this use. A gas stove or wickless blue flame stove may be employed, and it is possible for a pharmacist to make granulated effervescent salts on the small scale.

Exsiccation is the process of depriving a solid crystalline substance of its water of crystallization or moisture by heating it strongly.

The product is usually a fine powder, and the original crystalline condition of the substance may be restored by redissolving it and evaporating the solution. The process is conducted by exposing the crystals to the air or a warm temperature until they are effloresced, and then gradually heating, with stirring, until they cease to lose weight; the residue is then powdered and kept in well stoppered bottles. The object of exsiccation is to increase the strength of substances and thereby fit them for special applications. For instance, exsiccated ferrous sulphate is preferred as an ingredient in pills, because sixty grains contain as much ferrous sulphate as one hundred grains of crystallized ferrous sulphate, and the pills can therefore be made one-third smaller. The mass is also much more readily formed from the finely powdered exsiccated salt.

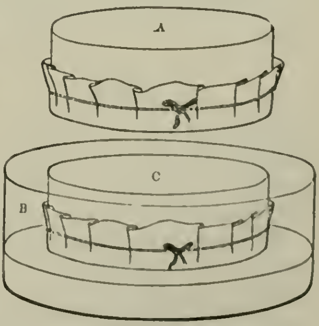
CHAPTER XVII

DIALYSIS

DIALYSIS is the process of separating crystallizable substances from those which do not crystallize, by placing a mixture of their solutions upon a porous diaphragm which has its under surface in contact with water. This remarkable process was discovered by Graham in 1861. He termed the substances which had the power of passing through the septum or diaphragm *crystalloids*, because they always have the crystalline form, and those which remained upon the diaphragm *colloids*, from their resemblance to gelatin and because they never crystallize. He also pointed out the differences between the two classes. Crystalline bodies, or crystalloids, are diffusible, brittle, hard, with clearly defined angles and flat faces. Their solutions are free from viscosity, and their reactions energetic and quickly effected. (Example, strychnine.) Colloidal bodies, on the other hand, are not diffusible. They are tough, with more or less softness of texture. The mathematically arranged angles and faces of crystals are replaced in colloids by rounded, irregular outlines, the fracture often being curved or conchoidal. Water of crystallization is replaced by water of gelatination, and the solution of colloids is, when concentrated, viscous or gummy, and their reactions are sluggish or inert. (Examples, gum, glue, starch, dextrin, gelatin, albumin, extractive matter.)

A thin layer of gelatin interposed between two liquids offers no obstacle to the passage of the crystalloids from one to the other, while it completely prevents the passage of the colloids. This property belongs not only to gelatin, but to other substances having a similar molecular constitution, as bladder, parchment, etc., of which the most convenient is the texture known as *parchment paper*, prepared by immersing unsized paper in a *cold* mixture of two measures of sulphuric acid and one of water, and subsequently washing it thoroughly to free it from acid.

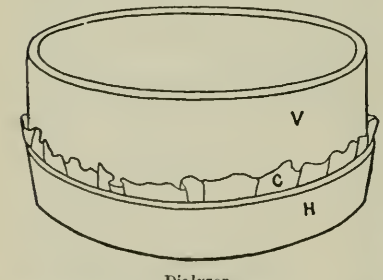
FIG. 370



Dialyzer

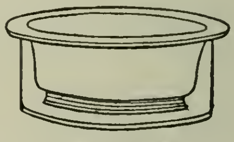
Upon the principles stated above Prof. Graham contrived a very simple apparatus which he called the dialyzer (see Fig. 370). It consists of two parts, one a circular glass recipient (B), about a foot in diameter and six inches deep, the other (A) a similar circular vessel, from six to ten inches in diameter and about two inches deep, made of hard rubber, celluloid, glass, or some similar substance, and the bottom of a circular piece of parchment paper, the edges of which are brought over the lower rim of the inner vessel nearly to the top, and fastened securely outside of it by a string or by a narrow rubber band. The first part, or circular basin, is to receive distilled water, and should contain from five to ten times the quantity of the liquid that may be introduced into the smaller vessel. The latter is to float upon the surface of the water in the former, and is to receive the liquid to be submitted to dialysis, which should not be more than half an inch deep on the paper bottom. It is important that the parchment paper employed should have no rent or aperture, and should be brought well up and secured on the outside of the inner vessel to prevent the liquid from passing between them. If any liquid containing a mixture of colloidal and crystalloidal matter be placed in the floating vessel, after some hours it will be found that a portion of the latter has passed through the parchment paper, and is held in solution by the distilled water of the larger vessel, while the colloidal matter remains. The distilled water thus impregnated is called the *diffusate.* The parchment paper, or any similar material used as the septum, is applicable to the dialysis of substances held in aqueous solution only, and will not answer for alcoholic or ethereal liquids. The hard rubber sieve, which has been already noticed (see Fig. 371), makes an excellent dialyzer if floated upon pure water in an evaporating dish or beaker. Fig. 372 shows another form, in which the glass dialyzer has its upper edge expanded into a flat shoulder which rests upon the upper edge of the round dish, sometimes called the "exarysator," containing the water. This has the advantage of keeping the diffusate covered while the dialysis is progressing. It is obvious that very different arrangements might be made to accomplish the same ends. Thus, a thoroughly clean bladder three-fourths filled with a mixture, suspended in a jar of distilled water, would yield similar results. Graham's apparatus is preferable to others only for its convenience.

Fig. 371



Dialyzer

Fig. 372



Dialyzer (glass)

The following applications of the process of dialysis have been made: 1. It facilitates in many instances to a considerable extent the separation of the active matter of any artificial or natural mixture from the inert and useless, the former being very often crystalline and the latter colloidal. Thus, infusions or decoctions of medicines, such as opium, belladonna, aconite, etc., submitted to dialysis might give up more or less completely their crystalline principles, such as the salts of morphine, atropine, aconitine, etc., to the water, while the gummy, resinoid, extractive, and coloring matters, etc., might remain behind. In effecting the analysis of organic bodies, one of the most embarrassing problems is to get rid of the inert principles which interfere with the action of chemical reagents, and the process of dialysis may here often be brought to the aid of the operator. 2. In searching for poisons in organic mixtures, as in the contents of the stomach, in which the application of tests is often rendered abortive by the colloidal matter present, the problem of the presence of the poison may sometimes be solved by submitting the suspected matter to dialysis. The poison will often be found in the diffusate separated from the other matters, and may then be detected by the ordinary tests. 3. In pharmaceutical operations it often happens that salts and other crystallizable substances are thrown away as refuse matter because they would not repay the cost of time and material necessary for their recovery. It is possible that by this simple, inexpensive process these substances may be separated from the useless matters and thus saved. 4. An economical application has been made of the process, by the restoration of salted meat to the fresh state. If some salt beef with its brine be enclosed in a bag of material suitable for dialysis, as of untanned leather, and the bag be immersed in sea water, in the course of some days the beef will have been rendered sufficiently fresh for use, the salt having passed out into the sea water. B. F. McIntyre, of New York, gave a great deal of attention to the practical applications of dialysis, and introduced a class of preparations called *Dialysates.* These were prepared from various drugs by dialysis, and it was claimed that they contained the active crystallizable constituents in their original combination, deprived of inert colloidal substances.

Dialyzed iron, or *Ferrum Dialysatum*, is a colloidal preparation made by placing a mixture of basic ferric chloride and ammonium chloride upon a septum. The crystalloids (ammonium chloride and ferric chloride), with any free acid, pass into the diffusate, leaving the neutral colloidal liquids upon the septum.

CHAPTER XVIII

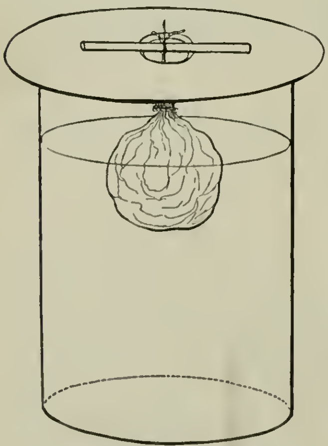
EXTRACTION

UNDER this head are included those operations which have for their object the separation of the soluble principles from drugs by treating them with a liquid capable of dissolving them, which is called the *menstruum.* Extraction differs from solution in the fact that the presence of insoluble matter is implied in the former, and the soluble constituents must therefore be *extracted* or separated, by appropriate methods, from those which are insoluble. The principal modes of extraction employed in pharmacy at present are as follows: 1. Maceration and expression. 2. Percolation. 3. Digestion. 4. Infusion. 5. Decoction. Maceration and expression are old processes, and they will be considered first; percolation is much more important and useful, and will be treated of in a separate chapter; digestion is merely a modified form of maceration. Infusion and decoction are processes which are used in producing separate classes of official preparations. Hence they will be considered in Part II.

Maceration

The process of *maceration*, which is of ancient origin, consists simply in soaking the properly comminuted drug or substance in the menstruum until it is thoroughly penetrated and the soluble portions softened and dissolved. The usual method is to introduce the drug or substance into a bottle with the menstruum, cork it tightly, and agitate it occasionally for a period ranging from two to fourteen days; then to pour off the liquid, express the residue to avoid waste, and filter the mixed liquids. An advantage is sometimes gained by suspending the ground drug, tied in a bag, in the upper part of the menstruum (see Fig. 373). This is sometimes termed *circulatory maceration.* Maceration is the process directed by the German Pharmacopœia in preparing tinctures. The drugs are ordered in all cases to be macerated in definite weights of alcohol for a week in a closed bottle, in a shady place, with frequent agitation, at a temperature of about 15° C. The liquid is then separated by straining or expressing from the insoluble residue, and, after having been allowed to settle, it is filtered. Evaporation during filtration is to be avoided as much as possible. Maceration has no advantages over percolation in making the greater number of

FIG. 373



Circulatory maceration

liquid preparations from drugs, except in the hands of the careless or unskilful. If an operator possesses no knowledge whatever of the process of percolation, it is safer to trust to maceration, for here no particular skill or judgment is necessary; the soaking process is completed in due time, and the separation of the absorbed liquid, while laborious and uncleanly, has at least the merit of leaving the tincture uniform in strength; if the process of expression is not thoroughly performed, pecuniary loss results, but the finished preparation is uniform. On the other hand, in percolation, if the operator has, through careless packing, failed to exhaust thoroughly the drug with the amount of menstruum used, a portion of the activity of the drug remains in the residue, which is thrown out, and the preparation is thus deficient in strength. In making tinctures by maceration, the practice of weighing liquids, as directed in the German Pharmacopœia, is seen to the best advantage, although, of course, the principal objection to preparations made from weighed liquids still exists,—the necessity for a calculation to determine the dose as compared with that of the drug. The tincture must always be administered by measure, and hence a teaspoonful or a fluidrachm should bear a certain relation to the drug, which is readily ascertained without resorting to a problem in specific gravity.

Digestion is that form of maceration which consists in the application of a gentle heat to the substance which is being treated. It is used in those cases where a moderately elevated temperature is unobjectionable, the heat increasing the solvent powers of the menstruum.

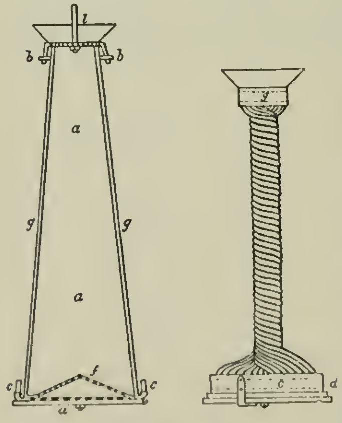
CHAPTER XIX

EXPRESSION

Expression is the process of *forcibly* separating liquids from solids. It is generally effected by the use of a press, although for many pharmaceutical operations, upon the small scale, the use of straining cloths with hand pressure suffices. Pressing cloths are generally employed but they are troublesome, and of late years strong efforts have been made to construct presses which could be used without them. At least six mechanical principles are recognized in the operation of expression as now practised: namely, by the use of—1. The spiral twist press. 2. The screw press. 3. The roller press. 4. The wedge press. 5. The lever press. 6. The hydraulic press.

1. **The Spiral Twist Press.**—The principle of this press is best and most practically illustrated in the usual process of expressing a substance contained in a cloth with the hands. The mixture to be expressed is placed in a bag or a cloth held in one hand by the four corners, which are gathered together, and the lower portion, or bag, is rotated with the other hand, so that, beginning at the top, the point of smallest diameter, the strainer is spirally twisted, the pressure forcing the liquid between the meshes of the cloth. Figs. 374 and 375 show Gigot's press, in which this principle is used upon a larger scale. Upon the left hand is shown a sectional view of the press as it appears when filled with material. The perforated cone, *f*, forms the bottom of a conical strong cloth tube; the upper end is connected with a funnel, *l*, which is so constructed that none of the material that has passed down into the bag can leak back. The lower portion of the cloth is secured to a ring, which may be fastened, so that it will not rotate when the press is used. If the upper end of the cloth is twisted, the space occupied by the material is contracted, and the liquid oozes through the meshes of the cloth. The dry residue is discharged by untwisting the cloth and unhinging the bottom, which opens downward.

Fig. 374 Fig. 375



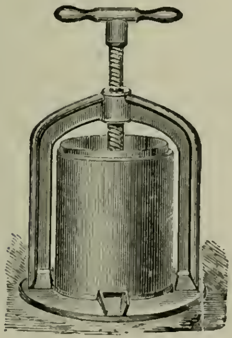
Gigot's press

2. **The Screw Press** is the most useful of all forms for pharmaceutical work where very great power is not desired. The screw is always used in combination with one or more levers, and this form of press is employed in great variety to accomplish special purposes. There are two forms of screw presses: 1. Single screw presses. 2.

Double screw presses. Each of these forms may be subdivided into those in which the position of the screw or screws is *vertical*, and those in which the position of the screw or screws is *horizontal*.

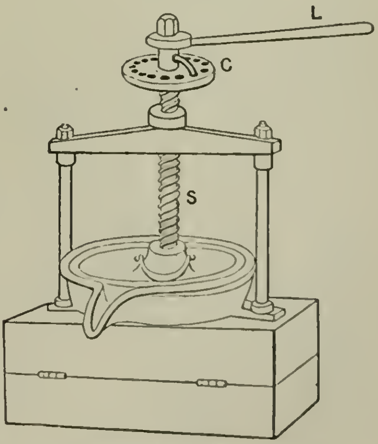
Single Screw Presses.—In this form of press the single screw is generally used in a vertical position, and operated with a lever or a combination of levers. It is the simplest kind of press, and if well made will admirably answer the general purposes of the pharmacist. The screw should have a square faced thread, and be well made. The plunger should be disconnected from the end of the screw, or else move freely around it. The parts of the press which come in direct contact with the material to be pressed should be coated with tin or porcelain, so that liquids containing acid or tannin shall not be affected injuriously. Fig. 376 shows a press of this description, made by H. Troemner, of Philadelphia. A perforated tin case accompanies the press. This may be used when pressing bulky drugs, like arnica flowers, and press cloths may be abandoned. The best material for press cloths is that which is especially made for the purpose. It is twilled and elastic in one direction, and, if proper care be taken when enveloping the material and introducing it into the press, the same cloth may be used many times, as the pressure causes the meshes to open without breaking the threads. The manufacturers of linseed oil use press cloth largely. For small operations, in the absence of press cloth, which is very expensive, new Russia crash may be used. The press cloth should be moistened, if possible, with some of the same liquid expressed at a previous operation. Water answers very well if the liquid is aqueous. The substance to be pressed is laid upon cloth and one corner of the cloth laid over it. The opposite corner is then placed upon the first; next one of the remaining corners is laid in the same way upon the first two, followed by its opposite. The corners should be folded over so that a square, somewhat flat package is produced, in size somewhat smaller than the press plate, especial care being observed to suit the quantity of material to the capacity of the press. If too much is taken, the

Fig. 376



Troemner's press

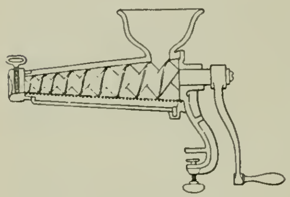
Fig. 378



German single screw press

press cloth will be too small to permit of folding it over sufficiently; the corners of the package will therefore not withstand the pressure, portions of the material itself will ooze out, and the whole operation must be repeated. The principal objection to the single screw press is, that unless the material in the press is nearly homogeneous, so that the press cake is equally pressed upon at all points, unequal action results, the press block is pressed against one side of the case, causing violent friction and resistance, and the thread of the screw binds upon one side, full pressure thus being defeated; while the main objection to the vertical screw is that the press block and plate must be in a horizontal position, so that the liquid pressed out adheres to the cloth, and cannot be collected readily without tilting the press. Fig. 378 is an illustration of a German single screw press which is well adapted to pressing the residues from macerated tinctures. The large lip of the containing vessel is a practical convenience, while the lever, L, in combination with the catch, C, gives unusual power and ease in working, for a small press. In the horizontal screw press, the jaws being vertical, there can be no obstruction to the dropping of the expressed liquid, which may be caught in a vessel placed immediately under it. Oberdoffer, of Hamburg, Germany, makes a very powerful horizontal screw and compound lever press. Fig. 379 illustrates a horizontal screw press, made by the Enterprise Manufacturing Company, of Philadelphia, which is operated without a press cloth. It consists essentially of a tapering cylinder, with a hopper on the upper side at its large end, and a strong screw fitting closely to the inner surface of the case, the thread of which diminishes in size as the screw becomes smaller. Along the under side of the cylinder is formed a channel adapted to receive a perforated brass plate. This latter has a transverse concavity corresponding to that of the inner surface of the cylinder, and the perforations allow the escape of the expressed fluids into the channel or gutter beneath, from which it escapes by a proper outlet. The substance to be expressed is placed in the hopper, and, the crank attached to the screw being turned in the proper direction, the thread of the screw compresses the substance into a smaller and smaller space, until finally it is discharged at the farther end of the cylinder in a comparatively dry state. A large screw, passing through a removable end of the conical cylinder, regulates the size of the outlet, and serves to increase or diminish the amount of pressure to which the mass is subjected by the screw. The brass plate in the bottom of the machine can be replaced by others having perforations of different sizes. Clogging of the holes by bits of wood, stems, or seeds is prevented by the shear-like action of the edge of the screw thread, which shaves off the protruding fragment, while the rest is forced through the perforation. To increase the power of the press upon slippery substances, the inside of the casing has a few longitudinal or spiral grooves at a greater or less angle to the direction of the screw thread. Arrangements are provided for detaching the casing from the screw, and for attaching

Fig. 379

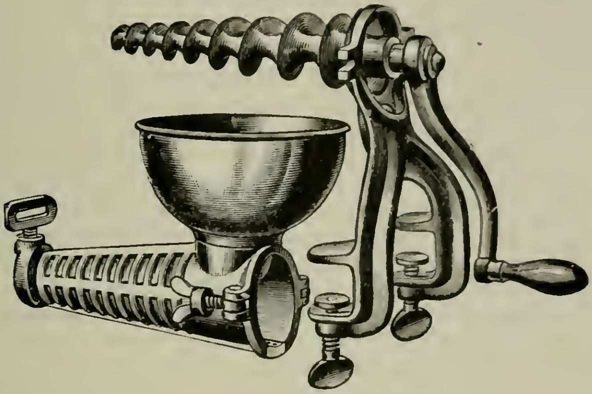


Enterprise press

the whole to the edge of a table or bench. Fig. 380 shows the press as taken apart.

Double screw presses are preferred by many. These are always of the horizontal screw form, and in Fig. 381 is shown one made as proposed by Chas. T. George, of Harrisburg, Pa. A strong and substantial framework, made of ash wood, forms the base. Two pieces of timber rest upon this frame, one firmly attached by an iron rod and keepers to one end of the frame or table, and the other free or movable, both blocks being bored at the same distance from the end with smooth holes to receive the two iron screws.

Fig. 380



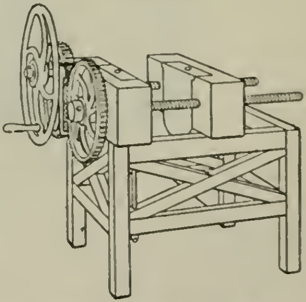
Enterprise press

Upon the movable block, and opposite the holes, a female nut of bell metal is firmly fixed. Upon the inner face of the two timber blocks, iron castings, saddle shaped and hollow, are inserted, flush with the face of the block, each capable of holding six pints of boiling water, and each casting having a hole on top to receive hot water or steam. A brass petcock is fixed at the bottom to discharge the chilled water.

The two iron screws pass through the holes of both blocks of timber, the head of each screw having an iron cogwheel attached to it; into the cogs of each wheel a pinion wheel is firmly fixed, which in turn is fastened to a short shaft having at its end an iron flywheel.

By turning this wheel both screws are evenly and rapidly rotated without danger of bending or breaking, and consequently one block is drawn surely and with great power against the other, thus expressing whatever drug may be placed in a sack of strong linen towelling between the two blocks of timber.

Fig. 381



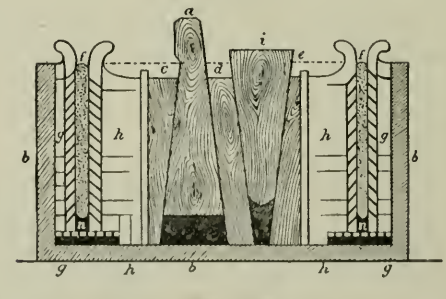
George's double screw press

It is apparent that the double screw press is very powerful, and, the pressure being equalized, good results are obtained.

3. **The Roller Press** is used upon the large scale for pressing oily seeds, fatty substances, etc. Its principle is thoroughly shown in the well known clothes wringer, which, although made for the laundry, serves as a very efficient press for many substances. Care must be taken to apply the force gradually to the bag containing the berries or other material to be pressed, and not to use it upon substances which will soften or dissolve the rubber rollers.

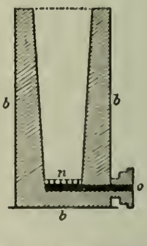
4. **The Wedge Press.**—This form of press is powerful, economical, and inexpensive. It is objectionable principally on account of the noise necessarily made in driving the wedges. Fig. 382, taken from Knapp's Technology, illustrates the wedge press. The filled cloths are laid between strong plates, *h* and *g*, and placed in a square space cut in a solid block of oak wood or in a cast iron case, *b*, and the plates are forced nearer and nearer to each other by driving in the wooden wedges which occupy the remaining space. One of these wedges, *a*, serves to facilitate the disconnection of the apparatus, the strokes which drive in the wedge *i* tending, from the reverse position of *a*, to drive the latter out; *c*, *e*, and *d* are intermediate pieces to prevent the wedges from coming into immediate contact. The pressing plates are each provided with three side ribs. The immovable ones, *g*, *g*, press against the sides of the case, and the movable ones, *h*, *h*, against the intermediate wedges, *c*, *c*, and are pierced with numerous holes to allow the liquid to flow out more easily. On filling the press, the wedge *a* must be suspended (by a string) at a distance from the bottom, so that the apparatus may be easily taken to pieces. The liquid trickles from the pressing plates through the pierced horizontal plates, *n*, *n*, upon which these rest, into the pipe *o*. Both *a* and *i* are driven by separate stampers, which are raised by a toothed wheel, or mallets may be used.

Fig. 382



Wedge press

Fig. 383



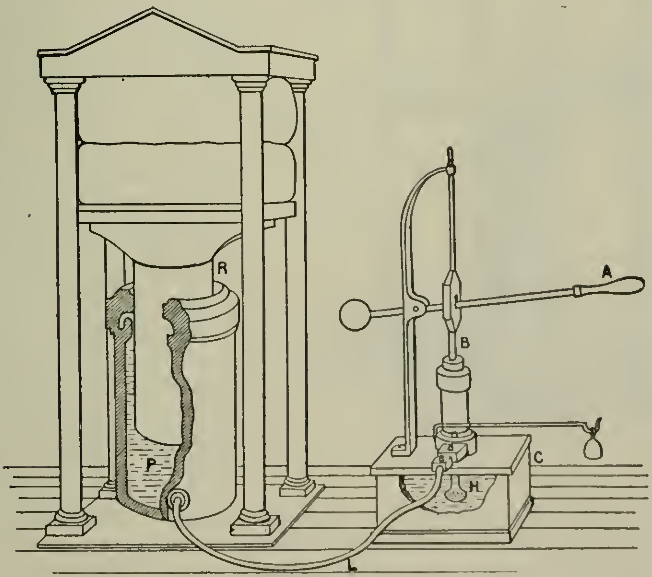
Wedge press (end view)

5. **The Lever Press.**—The only advantages possessed by this press over those previously noticed are its cheapness, and that it may be made by any one possessed of even moderate mechanical abilities. Prof. Procter recommended the following method of construction. "A piece of timber twelve feet long, and with lateral dimensions sufficiently great to be inflexible with the force to be applied to it, has *one* of its ends securely attached to a wall or upright post in such a manner as to admit of the motion of the other end. The pressing

box being placed about one foot from the fixed end, on a firm block of wood, is subjected to the action of the lever by placing a piece of wood vertically between the piston block of the pressing box and the lever. It is obvious that a weight of one hundred pounds at the opposite end causes a downward pressure equal to eleven hundred pounds at the box. The pressing box most usually employed is a cylinder, closed at one end, made of thick tinned iron, secured with bands of the same material, which are soldered on, and between these, numerous holes are perforated. This cylinder is set in a tin dish with a lateral spout. The piston block is constructed of hard oak wood with the grain running transversely to its axis." The objection to this press is that, compared with other presses, it yields but little power in proportion to the space occupied; but as an offset to this it can be made to work simply and quickly.

6. **The Hydrostatic or Hydraulic Press.**—Of the presses heretofore mentioned, each has some especial advantage or use, but each has also some fault or objectionable feature. The spiral twist is not powerful, and its action is limited. The screw presses of both varieties have friction to contend with. The friction of a screw increases with the intensity of the pressure applied, and when a certain limit is reached all further force applied is wasted, and, if persisted in, involves the destruction of the press. The roller press is very limited in its action; the lever press is unwieldy and not powerful; the wedge press is noisy and can be used only for special purposes. The hydrostatic press is costly, but after the first cost it is the most economical, because the greatest power is obtained at the expense of

FIG. 384

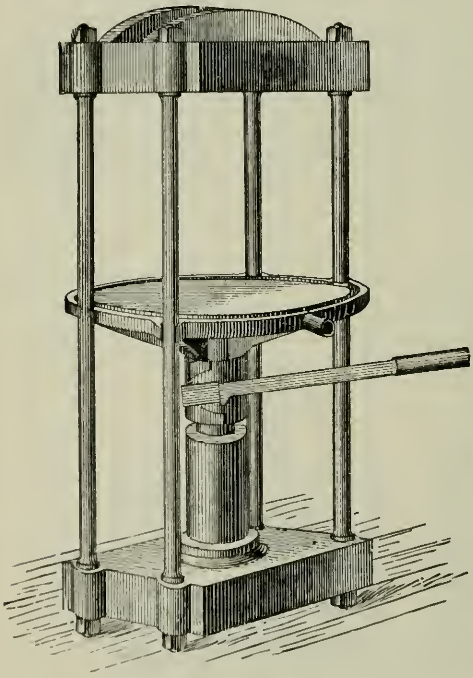


Hydraulic press

the least labor. The principle is shown in Fig. 384. It must be remembered that the molecules of fluids move freely in contact with one another almost without friction, and, according to Pascal's law, "Pressure exerted anywhere upon a mass of liquid is transmitted undiminished in all directions, and acts with the same force on all equal surfaces and in a direction at right angles to those surfaces."

Although it has been proved that liquids are to a slight extent compressible, it has also been shown that they are *perfectly elastic;* so that if a plug be forced into a liquid which entirely fills the vessel, the pressure is felt equally upon every square inch of the surface of the vessel and upon every square inch of the surface of any body immersed in the liquid, and if the pressure is removed from the plug it will be immediately forced out of the vessel and the liquid will at once regain its original volume. Now, if a vessel is constructed having two columns communicating at the bottom, as in Fig. 384, and if water or other fluid is placed in it, it will be found that a pressure of one pound applied at the piston in the tube, B, will be communicated to every portion of the lower surface of the ram, R. If the area of R is ten times greater than that of B, it follows that a pressure of one hundred pounds on A, conveyed through the lever, exerts an upward pressure of one thousand pounds on R. By increasing the area of the ram the power may be greatly multiplied, so that pressure applied by one man on the lever may be communicated to the liquid and made to exert an upward pressure of several tons. Fig. 385 shows a pharmaceutical press made by R. Dudgeon, of New York, constructed on the principle of hydrostatic pressure. In order to economize space, by an ingenious system of valves one of the cylinders is contained within the other, and by pumping the oil into the outer vessel the ram carrying the platen is forced upward. The platen has a groove around its edge communicating with a spout for carrying off the expressed liquid. Press cloths may be used to contain the material to be pressed, or a very strong perforated case is supplied. The upper plate is very strongly secured by bolts and nuts, and press blocks covered with tinned iron are employed to fit into the perforated case if desired. The weight of one man, one hun-

Fig. 385



Dudgeon's press

dred and fifty pounds, applied to the end of the lever will produce an upward pressure equivalent to ten tons. This is the most powerful press available for pharmaceutical purposes, and, although expensive, its first cost will be more than offset by its durability and by its economy of power whenever pressure greater than that afforded by the smaller presses is needed.

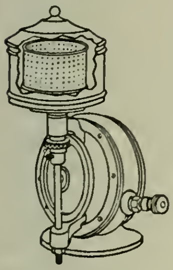
The following maxims should be observed in operating presses:

1. All moving parts of the press should be well lubricated before attempting expression.

2. Pressure should be *gradually* increased; sudden strains should always be avoided. If this precaution is neglected, either the press cloth or press bag will burst, the finer solid particles will be forced through the meshes, or breakage of press plates or press will result.

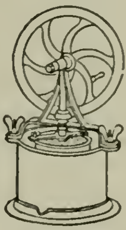
3. Pressure, to secure the best results, should be unrelaxed, but intermittent. After apparently reaching the limit of compression, the action of the press should cease, and if the pressure be maintained unrelaxed it will be found that in a short time further pressure may be applied and more liquid separated. In this way, by alternately exerting pressure and resting, the utmost limit of the power of the press may be gradually reached without undue strain. Screw presses have more ability to retain pressure than hydraulic presses; the valves of the latter frequently leak slightly, and the pressure has to be continually renewed.

Fig. 386



Centrifuge (under driven)

Fig. 387



Centrifuge (over driven)

Centrifugal Machines or Centrifuges.—For separating liquids from solids the principle of centrifugal motion has been successfully used. The machine consists of a central, perforated cylindrical cage surrounded by a case; the cage is attached to a vertical shaft, which is capable of being speeded to several thousand revolutions a minute. The wet material is placed in the cage, the machine started, and the liquid forced by the rapid motion through the perforations into the space between the outer case and the cage. Figs. 386 and 387 show two kinds of centrifuges, Fig. 386 illustrating the "under driven" type, which is run by water power, and Fig. 387 showing the "over driven" type.

CHAPTER XX

PERCOLATION

Percolation, or **Displacement,** is the process whereby a powder contained in a suitable vessel is deprived of its soluble constituents by the descent of a solvent through it. The importance of this process cannot be overestimated, as the progress made in pharmacy in America during the last century is largely due to the study and development of percolation, and the introduction of preparations which are the direct outgrowth of the process.

History.—The practice of exhausting wood ashes of their soluble constituents by pouring water upon them after their introduction into a conical shaped wooden vessel called a lye hopper is an ancient one, and the process is still practised and known as *lixiviation.* The first attempt on record to apply the principle to powdered drugs was made by Count Real, who about the year 1815 invented a press which consisted of a metallic cylinder with a stopcock in the bottom and containing a perforated diaphragm for supporting the substance, and with a tight cover at the top, to which was attached an upright tube, ten or twelve feet high, having a funnel soldered to its upper extremity. The cylinder was packed with the coarsely ground drug, and water poured into the tube. The pressure of the column of water was so great, however, that the principal difficulty in using the apparatus was in securing tight joints, and in preventing the incomplete exhaustion of the drug on account of the too rapid passage of the water through it. M. Robiquet subsequently made some experiments to determine the power of ether as a solvent in extracting the fixed oil from the bitter almond. He observed that ether poured on powdered bitter almond displaced the fixed oil without mixing materially with it, and he published his observation. It was reserved, however, for the Boullay brothers, of Paris, in 1833, to apply the ideas of Real and Robiquet to drugs and medicinal substances in general, and to them belongs the credit of first demonstrating the value of the process of percolation in its pharmaceutical applications. The researches of the Boullays at once attracted the attention of American pharmacists, and the labors of Duhamel, Procter, Grahame, Squibb, and others during the last century, and the adoption of the process in the Pharmacopœias of 1840, 1850, 1860, 1870, 1880, 1890, and in the 8th Revision, sufficiently show the character of the growth in favor of percolation. In Great Britain, France, and Germany the process is well known, and is practised to some extent, but maceration still holds in these countries the chief place as a means of extracting the soluble principles of drugs.

Principle of Action.—*When a powder placed in a cylindrical vessel with a porous diaphragm below, is treated from above with a liquid capable of dissolving a portion of its substance, that portion of the fluid first in* *contact, in passing downward, exercises its solvent power on the successive layers of the powder until saturated, and is impelled downward by the combined force of its own gravity and that of the column of liquid above it, minus the capillary force with which the powder tends to retain it.* If the quantity of liquid added is not more than enough to satisfy the capillarity of the powder, no liquid will pass the diaphragm; but the careful addition of liquid upon the top displaces that absorbed in the powder without mixing materially with it, and takes its place, to be in turn displaced by a fresh portion of liquid. The instrument used to hold the powder is called a *percolator;* the liquid poured on top of the powder, the *menstruum;* the liquid coming from the percolator impregnated with the soluble principles, the *percolate.* In order thoroughly to understand the process of percolation as applied to powdered drugs, it must be remembered that the soluble principles of vegetable substances are in a hard and dry condition, and are generally contained in cells which are more or less disintegrated by the process of grinding. If the soluble principles could be perfectly separated from the insoluble cellular substance by any means, and be deposited in the interstices of the ground particles, percolation would indeed be a rapid process, for the descending column of liquid would immediately dissolve the soluble principles, which would be found in the receiving vessel, while the insoluble substances would remain in the percolator, and the separation would then be easily accomplished. But the powdering of the drug only partially separates the soluble principles from the insoluble, and the finest dust of the powder always contains a larger proportion of the soluble principles than of the insoluble substance, because the latter, often being largely ligneous, offers the greatest amount of resistance to disintegration. Hence the first portion of the percolate is always the most dense, the most highly colored, and contains the largest proportion of the soluble principles, because the first portion of menstruum, in its descent through the powder, has the first opportunity to come in contact with the largest proportion of the soluble principles, which are to be found in the finer dust scattered through the powder, and in the thoroughly disintegrated particles, which offer but slight resistance to the passage of the menstruum. In every well conducted experiment in percolation it will be noticed that, as the operation proceeds, each succeeding portion of percolate is less highly colored and less active than the one preceding it; and in the case of drugs containing easily dissolved coloring matter, an examination of the percolate will show that the shading is very marked, the lowest portion being very dense and dark colored, the upper portion almost colorless, while in the intermediate liquid the gradations of the tint are clearly perceptible.

The directions of the United States Pharmacopœia upon percolation are as follows:

"*Percolation*, as directed in this Pharmacopœia, consists in subjecting a substance or a mixture of substances, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of a certain menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall be charged with the soluble portion of it, and pass from the percolator free from insoluble matter.

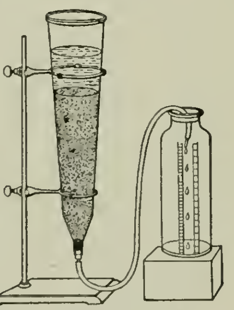
"When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator, will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

"*Percolators.*—The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel shaped termination at the smaller end. (See Fig. 388.) The neck of this funnel end should be rather short, and should gradually and regularly become narrower toward the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it from within until the end of the cork is flush with the outer edge of the orifice. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 Cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding the tube in position.

Fig. 388

Official percolator

Fig. 389



Official percolation

"The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a *conical* percolator is preferable. A *cylindrical* or only slightly tapering percolator may be used for drugs which are not liable to swell, and when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum.

"The percolator is prepared for percolation by gently pressing a small tuft of cotton into the neck above the cork, and this may then be moistened by pouring a few drops of the menstruum upon the cotton, to facilitate the passage of the first portion of percolate, which is often very dense.

"*The Process.*—The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and the powder thoroughly stirred with a spatula, or other suitable instrument, until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, while No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions be accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable (see Fig. 389). A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

"When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity has been obtained."

Shape of the Percolator.—In the U. S. P. 1880 the shape and size of the cylindrical percolator preferred for pharmacopœial operations were definitely fixed (see Fig. 388). There can be no question that the glass cylindrical percolators (see Fig. 390) commonly furnished by the manufacturers are proportionally too broad for use in percolating drugs for fluidextracts where the quantity of drug is large in proportion to the quantity of menstruum; but for ordinary tinctures, where the conditions are reversed, they answer admirably. The inference then is obvious, the pharmacist should have percolators not only of different sizes, but also of different shapes. Fig. 391 shows the narrow percolator recommended by Prof. Oldberg. It is narrower than the cylindrical percolator directed by the U. S. P. (8th Rev.). The studies on percolation during the last half century have been directed toward simplifying the process, and the elaborate apparatus of Count Real and others has been replaced by the ordinary percolator and funnel. The conical percolator of the Pharmacopœia is understood to be a glass funnel (see Fig. 392).

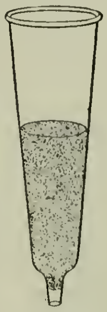
Fig. 394



Ordinary percolator (200 Gm. of powder)

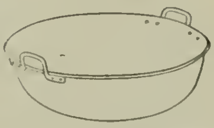
Fig. 395

Conical percolator (200 Gm. of powder)

Judgment is required in selecting a percolator for an operation. In making a fluidextract a comparatively narrow percolator should be chosen, because it is desirable that the menstruum should traverse a higher column of powder, for every drop of the menstruum must be economically applied. The rate of flow of the percolator is thereby proportionally diminished, the percolate becomes saturated more rapidly, and thus the operation is more easily controlled, provided the limit has not been exceeded. *The character of the drug influences the limit.* For instance, one which contains a large quantity of soluble matter, like kino, could not be successfully percolated in a narrow percolator, because the percolate would soon become so dense that it would cease to descend. In making tinctures and weaker preparations, a wider percolator is to be preferred, because the quantity of menstruum is greatly in excess of the quantity necessary to exhaust the drug, and more rapid action is desirable. Figs. 393, 394, and 395 show three percolators of the same height, but of very different shapes. Exactly the same weight of powder is represented in each. The great difference in the height of the columns of powder will be readily noticed, and illustrates the necessity for judgment in selecting percolators. If a fluidextract from the drug is to be made, the tall percolator, Fig. 393, should be selected; if a strong tincture, Fig. 394 indicates the shape; while for a weak tincture, the funnel shown in Fig. 395 would be preferred; it being understood that in each case the drug is not an exceptionally difficult one to percolate.

Comminution.—The degree of comminution proper for each substance must depend upon the physical structure of the drug, the ease with which the menstruum dissolves the active or desirable constituents, the length of time required to exhaust the powder, and the relative proportion of menstruum to drug. Nux vomica and ignatia are drugs having a tough, horny structure, in which the soluble constituents are embedded. If these drugs are to be quickly exhausted of their soluble principles, they must be in fine powder. On the other hand, gentian and rhubarb are drugs which part easily with their active constitutents, because their structure is loose and quickly penetrated by the menstruum. Therefore these may be readily exhausted when in coarse powder. The relative proportion of menstruum to drug also has a bearing in determining the fineness of the powder, for it is clear that if a fluidextract is to be made in which one hundred volumes shall represent *one hundred* parts by weight of the drug, the powder should be a finer one than would be required for a tincture where one hundred volumes are used to exhaust *ten* parts by weight of the drug. In all cases, whether coarse or fine powder is directed, the powder should be *uniformly divided;* and where the degree of fineness is specified, but a small proportion of the powder should be capable of passing through a sieve of the next higher grade of fineness, and this small proportion should be thoroughly distributed through the powder. The object of this is to permit the uniform descent of the liquid, for fine particles offer more resistance to the passage of the menstruum than coarse ones; and if the powder is not uniform, and the finer particles are deposited upon one side of the percolator, imperfect exhaustion may occur, through the passage of the greater portion of the menstruum upon the side of least resistance,—*i.e.*, through the coarser particles.

FIG. 396



Pan for moistening powders

Moistening of the Powder.—The general rule in percolation is to moisten the powder, and there are very few instances in the official processes where it is not directed. The object of moistening the powder is very apparent. If a perfectly dry sponge is held in the hand and a gentle stream of water poured upon it, it will be noticed that very little water is absorbed by it; but if the sponge is thoroughly soaked, and all the water squeezed out that possibly can be, it will be found that it will greedily absorb water. Most drugs are vegetable substances which in their natural state were moist. The process of desiccation has hardened and dried the tissues, so that, like the sponge, they do not absorb moisture quickly, and when compressed, as they are when packed in a percolator, the resistance is still greater. If a dry powder, like ground orange peel, is tightly packed in a glass percolator and water poured upon it, it will be noticed that the water will penetrate the powder but a short distance. Its further passage is prevented by the particles which are immediately in contact with the water, which have become swollen to such a degree that they press tightly against the sides of the percolator, and thus entirely overcome the gravitating force and penetrating power of the water. If, on the other hand, the powdered orange peel is moistened *with sufficient water to satisfy its tendency to swell, before it is packed* in the percolator, the addition of water is followed by its slow percolation through the mass without stoppage, and the utility of moistening the powder is thus proved.

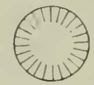
Fig. 396 shows a copper pan having a nearly flat bottom which is used by manufacturing pharmacists for moistening powders. The powdered drug is placed in the pan and the proper quantity of menstruum poured upon it, the whole is then thoroughly mixed by rubbing between the hands, or by using a scoop. After the powdered drug is moistened it should be passed through a riddle or coarse sieve several times, to render it uniform. The sifter shown in Fig. 258 has been found very efficient for this purpose where small quantities of drugs are to be percolated.

The special cases in which the powder should not be moistened are those in which the addition of menstruum would produce adhesiveness and cause the powder to form lumps that could not be easily penetrated, those in which the moistened powder would offer too little resistance to the passage of the menstruum, and those in which the menstruum is too volatile or too inflammable to render moistening desirable or safe. An instance of the first case is found in the so-called cold percolation of sugar in making syrups; instances of the second and third cases, in the preparation of the oleoresins where acetone is used as the menstruum.

Fig. 397

Notched cork

Fig. 398



Scored paper

Packing the Powder.—The official directions with regard to this important part of the process of percolation vary continually. Where the degree of pressure is immaterial, no special directions are given. Where there is a likelihood of too much pressure being exerted, so that percolation would cease before it should, the directions are, "pack it moderately;" on the other hand, if there is danger of the operator allowing the menstruum to pass through too rapidly, so that the drug would not be exhausted of its active principles, the directions are, "pack it firmly." The proper degree of pressure can be judged only from the character of the drug and the nature of the menstruum. If a porous, spongy drug is to be percolated with a menstruum largely aqueous, it must be moderately packed; but if the menstruum is alcoholic, it must be firmly packed. Before beginning to pack the powder, the throat of the funnel or of the percolator must be obstructed by a loose plug of absorbent cotton or a deeply notched cork (see Fig. 397), or by some other method. The manner of inserting this obstruction is not very material. The cotton, however, should be dry and loosely inserted, and the cork either dry or moistened with the menstruum, care being taken not to moisten the cotton or cork with water unless the menstruum is aqueous, because if the drug to be percolated is resinous, the first portions of percolate which come through will be precipitated by the water in the cotton or on the cork. Instances have occurred where the percolation has been stopped from this cause. Where the notched cork is used, it is well to place over the top of the cork, when it is in place, a small circle of scored filtering paper (see Fig. 398). This is slightly larger in diameter than the cork, and the edges are therefore reflected up the sides. A small quantity of the moistened powder will keep the cotton or the filtering paper and cork in place.

The moistened powder should be carefully deposited in the percolator in layers, each succeeding layer being packed according to the directions, "moderately" or "firmly," as the case may be, care being taken to use the same degree of pressure with each layer. Fig.

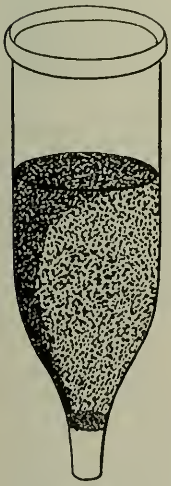
399 shows a convenient utensil for packing a percolator. It should be made of hard wood, preferably lignum vitæ; for the narrow percolators a longer packer must be used. The skill used in this part of the process will be proved by the manner in which the menstruum permeates the moistened powder. If the descent is regular and uniform, it is shown in a glass percolator by the line marking the descent of the menstruum being perfectly horizontal. If the line is irregular, it is easy to point out just where the pressure was insufficient or too great. Fig. 400 shows loose and irregular packing, too much pressure being made on the right side, the menstruum descending upon the left side unequally and escaping unsaturated. Fig. 401 illustrates a percolator which has been properly packed, the liquid descending uniformly.

FIG. 399

Packer

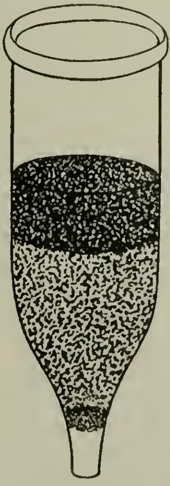
Adding the Menstruum.—When the last portion of moistened powder is introduced into the percolator, a sheet of filtering paper, scored at the edges and slightly larger in diameter than the surface of the powder, should be laid upon it, for the purpose of causing the even distribution of the menstruum. A weight of some kind is usually placed upon the paper, to keep it from floating out of place. Clean pebbles, a bottle stopper, or a small glass funnel may be used, but in Fig. 402 is shown a glass percolating weight, which has been made for this purpose by the Whitall Tatum Company. It is easily cleaned, is not readily broken, and does not take up much room. Where the percolator is large enough to hold the whole of the menstruum, it may be at once added carefully. When this is not the case, and the menstruum must be added in divided portions, care must be observed to follow with the succeeding portion before the first has entirely disappeared, or otherwise fissures may appear in the powder, and the menstruum will of course then seek the outlet offering the least obstruction, and will leak through the fissures instead of percolating through the powder. This is more apt to occur in percolating very fine powders than in percolating coarse ones, although liable to take place in either. Where a large quantity of menstruum is required, a contrivance for continually supplying the menstruum should be used, in the form of an inverted bottle or flask (see Fig. 269), or any of the methods for continuous washing may be employed.

FIG. 400



Imperfect packing

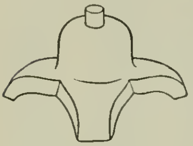
FIG. 401



Proper packing

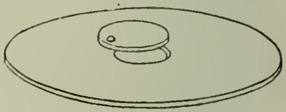
Previous Maceration.—This is recommended when the structure of the powder is tough, when the soluble principles are not easily extracted by the menstruum, or when a comparatively large quantity of powder is to be exhausted by a small quantity of menstruum. It is obvious that maceration is going on constantly while the menstruum is traversing the powder during its gradual descent, and when the amount of menstruum is more than sufficient to exhaust the drug, previous maceration is merely a waste of time. Nevertheless, the framers of the Pharmacopœia, in order to prevent the possibility of an unskilful or ignorant operator failing to exhaust a drug with the quantity of menstruum directed, have adopted in most cases the precaution of ordering previous maceration for a short time. This is best performed by moistening the drug, introducing it loosely into the percolator, and covering it closely to prevent loss by evaporation. This course has the additional advantage of allowing the drug to swell at the same time.

Fig. 402



Percolating weight

Fig. 403



Sheet rubber cover

A cover made of sheet rubber (see Fig. 403), with a circular opening, is very useful in this connection. No attempt should ever be made to produce fluidextracts on the small scale without previous maceration.

Finishing the Process.—The official directions are frequently definite in fixing the quantity of percolate to be received from a given quantity of powder, but the oft repeated direction to "add the menstruum until the substance is exhausted" at once raises the question, When is a drug exhausted of its activity? This question can be properly answered only by knowing beforehand what the active principles of the drug are. A few examples will sufficiently illustrate this. The activity of nux vomica, opium, and cinchona resides in the bitter alkaloids. Hence the *absence of bitterness* in the percolate in such cases indicates exhaustion. Cochineal and saffron are valued in pharmacy for nothing but the coloring matter contained in them. Hence the *absence of color* in the percolate shows the close of the process. Nutgall, kino, krameria, etc., contain tannin, and this is the only valuable principle. The *absence of astringency* in the percolate in these cases, therefore, shows the operator that percolation can be stopped. The exhaustion of resinous drugs may be known by the absence of precipitation when the percolate is dropped into water. Where two or more active principles exist in a drug, the latter is not exhausted until the percolate is free from all of them. *The intelligent practice of the process of percolation, therefore, requires an accurate knowledge of the constituents and physical properties of medicinal substances.*

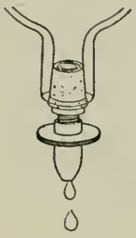
Choice of Menstrua.—Much labor has been bestowed by investigators in ascertaining the exact proportions of the usual solvents—water, alcohol, glycerin, etc.—that are best adapted for depriving drugs of such of their soluble principles as are desirable, and at the same time leaving untouched in the residue those principles which are either inert or objectionable. The special menstruum which is exactly adapted to the peculiar characteristics of the drug, and which will cause the retention of the soluble principles in a permanent form under the varying conditions of climate, and at the same time permit exposure to light, heat, and air without injury, can be determined only by experiment and experience. When new galenical preparations are proposed, the menstruum selected must therefore be merely tentative, and general principles must guide, until positive knowledge is secured. Alcohol would be indicated for active resinous drugs, diluted alcohol for simple bitter tonics, cathartics, etc., and diluted alcohol with glycerin for astringent drugs, etc. The selection of proper menstrua will be noticed, as occasion demands, in the chapters upon infusions, tinctures, extracts, fluidextracts, etc.

Absorbed Menstruum.—The amount of menstruum which a powder will absorb and retain after percolation ceases can never be accurately predetermined. If it is important to know beforehand the percentage of menstruum capable of being absorbed, a practical trial should be made upon the small scale, using the same powder and menstruum.

Substances possess very different capacities for retaining menstruum. Those having a light, spongy structure hold more than hard ligneous drugs, and even the same drug will often vary in its capacity in this respect, while the amount of moisture present in the drug before it is percolated is never a constant quantity, varying sometimes as much as 8 to 20 percent. The advantages of percolation over maceration are very apparent in respect to the character of the liquid left in the residue. In maceration the liquid left in the residue is finished tincture. In percolation it is merely menstruum, the active portions of the drug having been dissolved in the preceding percolate. In large operations, from an economical point of view, it is desirable to recover absorbed menstrua when the residues contain sufficient alcohol to make it worth the necessary time and labor. Distillation is then resorted to, or the residue is treated with weak alcohol and subsequently with water. Where water causes swelling of the substance and a stoppage of the percolation, the residue may be mixed with clean sawdust, rice chaff, or other inert dry substance, and then percolated with water. Recovered distilled alcohol may be purified by treating it with potassium permanganate ; twelve grains dissolved in a gallon of the percolate, and allowed to stand a few days, are usually sufficient. The purified alcohol may be decanted or filtered. Care must always be taken not to use unpurified recovered alcohol which is odorous on account of containing volatile oil obtained from a drug, or which may be otherwise impure.

Controlling the Flow of the Percolate.—The necessity for some method of controlling the flow of the percolate is apparent. In simple percolation this is effected by the degree of pressure used in packing the moistened drug. Judgment and experience are absolutely necessary to guide the operator. Various mechanical expedients have been used to accomplish the same purpose. The official method has been described (see Fig. 389). In metallic percolators stopcocks have been employed. A narrow homœopathic vial, having a one-eighth inch hole in the side, a half inch from the bottom, is passed through a perforated cork fitting tightly in the neck of the percolator ; by pulling the vial down, the hole is stopped by the encircling cork ; by pushing it up, the hole is exposed so that the percolate runs through the vial, and thus the flow may be controlled. Fig. 404 illustrates a method of controlling the flow of a percolate which has proved in the author's experience very useful. The well known sprinkler, made of white metal, used for liquid dentifrice bottles was first tried, and subsequently the form shown in Fig. 404 was selected. It is made by A. H. Wirz, Philadelphia. The flow of liquid can be perfectly controlled by its use. In the U. S. P. (8th Rev.) the following directions are found :

Fig. 404



Sprinkler controller

"*Rate of Flow.*—It is obvious that the success of the process of percolation largely depends upon the regulation of the flow of the percolate ; if this should be too rapid, incomplete exhaustion will result, but if too slow, valuable time may be wasted. The rate of flow for extracts and fluidextracts for 1000 Gm. of powder should range from two to five drops a minute ; for official quantities of tinctures and preparations of about the same strength, from eight to fifteen drops a minute, and the word "slowly" throughout the text is understood to mean a rate of flow corresponding to this ; it is evident that the proper rate of flow should vary with the quantity and character of the drug employed and the density of the menstruum."

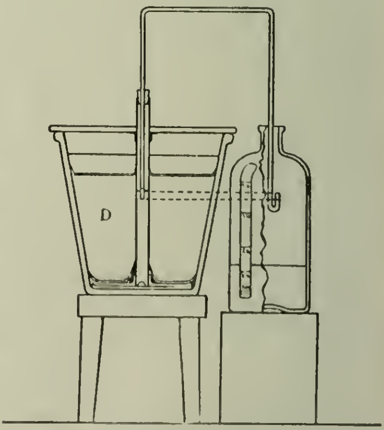
Special Percolators

Stoppered Percolator.—Many modifications in the ordinary cylindrical or conical percolator have been suggested from time to time to suit special requirements. In Fig. 405 is shown a glass percolator proposed by Dursse, the special merit of which lies in the manner in which evaporation is prevented. This is effected by means of the ground glass cover. The upper part of the percolator, R, is strengthened by a deep band ; the glass cover, C, is carefully ground so as accurately to fit the percolator and make a nearly tight joint, which can be improved by moistening the edge with glycerin. If the percolate should flow too freely, it can generally be checked by screwing in the cover of the percolator ; should it flow too slowly, a small piece of twine inserted between the cover and the side will permit the necessary pressure of the atmosphere. The graceful outlines of this percolator, and the evident care used in its manufacture, may be mentioned as points in its favor.

Fig. 405

Dursse's percolator

Fig. 406



Well tube percolator (Squibb)

Well Tube Percolator.—An excellent method of percolation which was used by Dr. E. R. Squibb for a number of years, and is still employed, is shown in Fig. 406. It is based upon the principle of drawing water from a well automatically as fast as it accumulates.

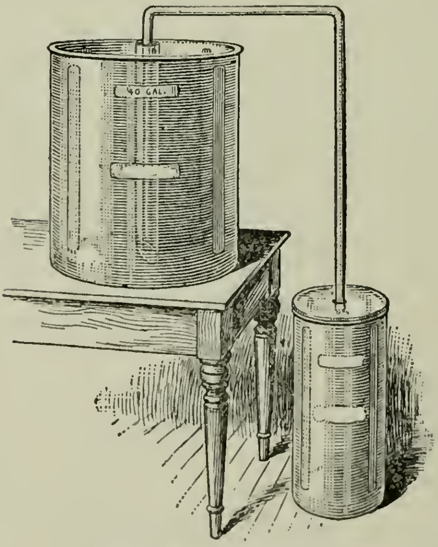
This is effected by the use of a well tube placed in the centre of an ordinary jar or pot and held in its place by the powdered drug which is packed around it. The menstruum is poured upon the drug, and, after percolating through, collects in the well tube, from which it is drawn off by an ingeniously constructed syphon. The practical value of this method warrants a detailed description. It may be used for either large or small operations.

The percolator is a stoneware pot of about two gallons' capacity, capable of holding six pounds of most drugs, and mounted on a suitable stand. A disk of blanket is cut of such a size and shape as to lie flat upon the bottom and cover it entirely. Another disk, of the same material, but a little larger, is made with a crucial incision (X) in the centre, so that it may be stretched over the end of the well tube. This is a piece of glass tube about twelve inches long, having an internal diameter of half an inch, and irregularly notched or gnawed off obliquely at the lower end. One end of this well tube is pushed through the crucial cut in the centre of the upper disk of blanket, and this blanket is pushed to the other end of the tube, so that the corners made by the crucial cut are reflected up against the outside of the tube. These corners are then tied firmly to the tube by passing twine around them, or are secured by a stout rubber band, made of a section of rubber tubing of proper size. A disk of filtering paper, larger than the upper blanket, with a crucial cut in the centre, and scored round the edge so as to lie flat against the sides of the percolator where reflected up against them, is pushed down upon the upper blanket, the well tube passing through the cut in the centre. If now a cork be temporarily placed in the well tube to keep out the moistened powder, the percolator is ready to receive its charge, which is packed around the well tube and upon the disks of paper and blanket so as to occupy the main body of the percolator. When the charge, having been properly moistened, rubbed, and sifted, so as to be entirely uniform and free from wet lumps, is packed around the well tube loosely or firmly according to the nature of the substance and the menstruum, its surface is covered by a disk of muslin or paper, cut so as to lie flat and smoothly upon the surface. The object of this is to distribute the menstruum as it is poured on, and to prevent the stream from breaking up and deranging the surface. Should this paper disk show a tendency to float in the stratum of menstruum, it may be held down by a few fragments of glass. The percolator is then ready to receive the menstruum or weak percolate, and a stratum of the liquid should be carefully kept covering the entire surface until the whole mass of the substance to be percolated is saturated. The cork is to be taken from the well tube before the liquid is poured on, and then the liquid will flow down into the substance like a piston, pushing the interstitial air before it, the air passing out through the blankets and the well tube; finally the liquid will rise in the well tube until its surface is within an inch or so of the surface of the liquid outside.

The whole substance is now in a perfect condition for maceration, and the surface should be left covered with the liquid to the depth of at least half an inch. A short section of rather thick rubber tubing should be stretched over the upper end of the well tube, and slipped down so as to support the centre of the cover. A tightly fitting cover, made of sheet rubber a quarter of an inch thick, with a hole in the centre for the well tube, is then put on. The syphon is made of glass tubing of about an eighth of an inch bore, bent twice at right angles, the two legs being each about twelve inches long. The outer leg is a little longer than the inner one, and turned up upon itself for about three-quarters of an inch, as shown in Fig. 406. The legs should have only such a difference in length that the inner one will reach the bottom of the well tube when required, and when measured upon the outer one will reach to about midway of its turned up end.

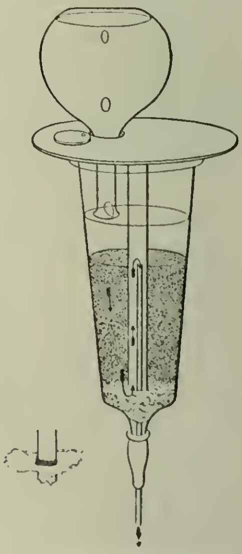
This construction prevents the syphon from emptying itself at any time, for when the liquid is drawn over by the syphon until the surface of liquid in the well tube falls to a level with the end of the turned up portion, as shown by the lines in Fig. 406, the columns of liquid in the syphon will be of equal length and will counterbalance each other, and the flow will cease without emptying the syphon. But as soon as the level of the liquid in the well is raised by fresh additions of menstruum on the substance, the flow will recommence at a rate proportionate to the difference of levels, and may be readjusted to the required rate by slipping the syphon up or down in the cork in the upper end of the well tube. This cork should be bored to fit the syphon so tightly as to hold it in any position, and should have a groove filed longitudinally on its outer side, to allow free exit of air. Fig. 407 shows the well tube percolator made of Appert glass, furnished by the Mississippi Glass Company, of New York.

Fig. 407



Appert glass well tube percolator

Fig. 408

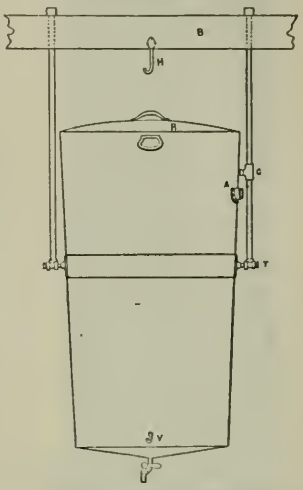


Double tube percolator

If it is desirable at any stage in the percolation to stop the process, the syphon may be gently lifted until the leg in the well tube is above the level of the percolate there, when the flow will cease. It may be started by simply pushing the leg down into the tube again. This is a practical convenience which is greatly appreciated. If the syphon should accidentally empty itself, the flow is easily started by attaching a short rubber tube to the curved end and applying suction.

Double Tube Percolator.—This differs from the well tube percolator just described in the use of an ordinary percolator, the absence of the syphon, and the substitution of a simple, straight tube which is free to move up and down inside of the well tube at the discretion of the operator. Fig. 408 illustrates its mode of action. A central well tube having the lower end irregularly broken is placed in an ordinary glass percolator, upon a tuft of absorbent cotton, or, as in Dr. Squibb's percolator, a circular piece of muslin is securely tied upon the tube a short distance from the bottom, as shown in the small cut in Fig. 408, and the end of the tube rests upon a perforated cork fitting tightly in the neck of the percolator, as proposed by W. S. Thompson in his description of a similar apparatus. The control of the flow of the percolate is effected by raising or lowering the small tube which passes into the well tube, and which is held in place by passing through the perforated cork in the neck of the percolator already mentioned, or through a perforated rubber nipple slipped over the end, as suggested by Windolph, or through a piece of rubber tubing. If previous maceration is directed, the narrow tube may be pushed up until the upper orifice is above the level of the menstruum, and of course above the level of the percolate in the well tube. When it is desirable to begin percolating, the tube is gently rotated with a downward movement until the level of the percolate is reached, and then percolation proceeds regularly, the course of the menstruum being indicated by the arrows in Fig. 408. The rapidity of the flow is increased by lowering the tube, and decreased by raising it.

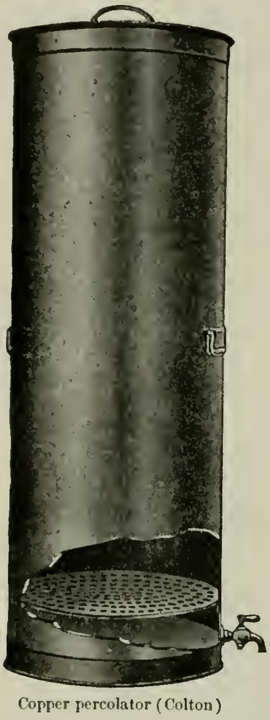
Fig. 409



Suspended percolator (Hance's)

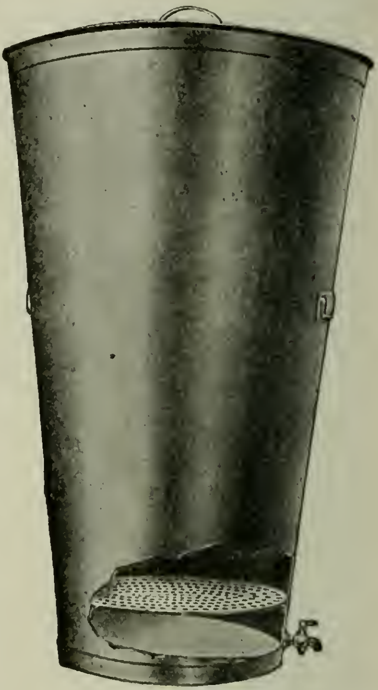
Suspended Percolator.—In large operations it is necessary to employ means to facilitate not only the percolation, but also the packing and emptying and other subordinate but essential parts of the process. Fig. 409 shows a percolator in use by Hance Brothers & White. The large percolator of tinned copper is suspended by trunnions, T, which are fastened to a stout band encircling the percolator slightly above the centre; two steam pipe supports are secured to a strong beam, B, above, and the trunnions rest in tees, which are screwed to the end of the pipe supports. The sliding tee, G, is dropped into the cup shaped catch, A, when it is desired to retain the percolator in an upright position. The special advantage in this arrangement is observed, however, when an operation is concluded. A residue car may then be wheeled opposite to the percolator, and the tee pushed up so as to permit the percolator to swing on the trunnions. The percolator may then be turned upside down with the greatest ease, and fastened by attaching the bottom to the hook H; its conical shape facilitates the discharge of the residue.

Fig. 410



Copper percolator (Colton)

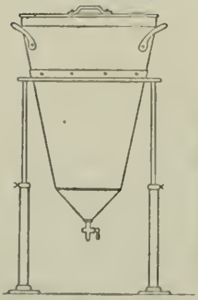
Fig. 411



Copper percolator (Colton)

Percolation on the Large Scale.—It is obvious that somewhat different appliances must be used in percolating large quantities of drugs. While ordinary glass percolators cannot be made of very large size, well tube percolation is well adapted for large operations, but tinned copper percolators are most frequently employed; in the latter brass stopcocks are mainly depended upon for controlling the flow of the percolate, but these are objectionable because of the difficulty in cleaning them, and on account of the liability of becoming enveloped in evaporated percolate it is often difficult to start or control the flow accurately. Figs. 410 and 411 illustrate copper percolators, made by Arthur Colton, of Detroit, with diaphragms for supporting the disk of flannel or cloth. They are intended to be placed upon counters or tables. Fig. 412 shows an ordinary copper percolator supported by a ring on two columns,

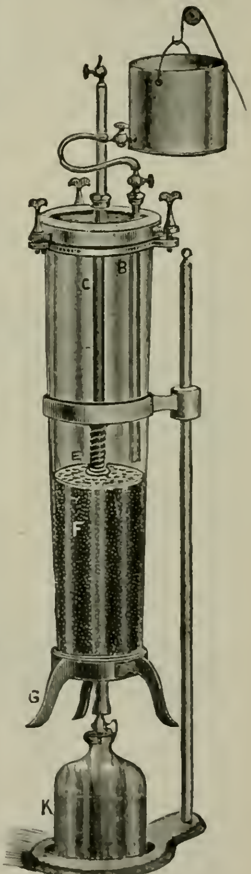
Fig. 412



Copper percolator

with sufficient space below to accommodate the receiving bottles. These may be made so as to be supported on trunnions (see Fig. 409). The exhausted powder or marc is then easily turned out into a vessel placed on the floor.

Fig. 413



Pressure percolator (Suits)

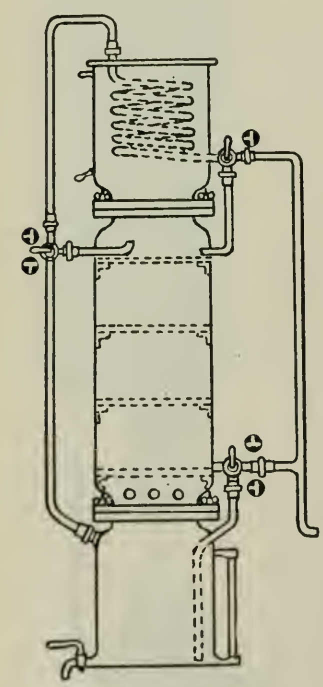
Pressure Percolators.—Percolation by pressure has come into vogue in various parts of the country, and there are at the present time several forms of pressure percolators upon the market, each one differing somewhat from the others in detail, but all based upon the same principle,—that of forcing the menstruum through the powder at a greater rate of speed than it would pass if it depended alone on the force of gravity.

The pressure is usually exerted through a column of menstruum entering the percolator at the top, the menstruum being supplied and the column sustained from a reservoir of the liquid suspended above it at a height of from three to ten feet. It will be noticed that Count Real's apparatus, invented in 1815, was based upon this principle (see page 252), and since then Stearns, Rosenwasser, Berry, Suits, Anderson, and others have advocated or introduced apparatus under various names by which percolation is carried on under pressure. It must suffice in this place to describe briefly one pressure percolator, that of Suits, full and detailed information being readily obtained from the manufacturers of any of them. Fig. 413 shows one of the best forms, the glass percolator B, protected by three iron bands, having at the top a tight cover made of plated sheet copper, having two stopcocks; the cover is made airtight by being clamped between two flat sheet rubber rings; the bottom of the percolator has a stopcock cemented in it; the moistened powder, F, is kept in place and some pressure exerted by means of the porous metal diaphragm, the spring E, and the metal tube, C, which passes through an air tight joint in the top. The tripod, G, is not used during the percolation, but is useful in supporting the percolator while packing. It is possible with this apparatus to macerate the powder under pressure, and at the end, after all of the menstruum has been run into the percolator and hydrostatic pressure is no longer available, a convenient rubber bulb airpump may be used to force air into the percolator to maintain the pressure. This apparatus may be used to great advantage in filtering oils under pressure, or as a bottle filler. After an extended practical trial of percolation by pressure, the author has reached the conclusion, that, while there are some percolating operations in which it can be used with advantage, for the great majority the pressure is unnecessary, just as perfect results being reached by the use of as simple a percolator as a glass funnel or cylinder of the well known form.

Percolation with Hot Extraction.—In some cases it is desirable to exhaust drugs with hot menstrua. Lewin's extraction apparatus is shown in Fig. 414. The lower vessel is a still; immediately above it is the percolator, having three movable sieves for the reception of the substance to be extracted; above the percolator is the condenser. By the use of the three-way stopcocks, the percolation, distillation, and extraction may be controlled at will.

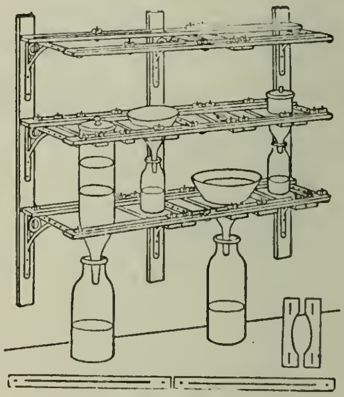
Methods of supporting Percolators.—The ordinary retort stands are often used to support percolators, but these are generally flimsy and unsatisfactory. The one shown in Fig. 187, particularly if used with split rubber tube sections, as seen in Fig. 190, is much to be preferred. The stand shown in Fig. 415 was devised by the author in 1875, and has been in constant use since. It is conveniently fastened to the wall in front of the working counter. Two long strips having slots down the centre are supported on brackets, and short cross strips having their inside edges hollowed out are fastened to the long strips by thumb screws. This arrangement permits the adjustment of the cross strips so that either a large or a small percolator or funnel can be supported, as shown in the cut, at any desired height. This stand is capable of enlargement by means of additional brackets and strips. If a wall counter is not available, a frame may be made extending over an ordinary counter, which will serve as well for a support, care being taken that the strips and frame are heavy enough to bear without strain any weight likely to be placed upon the stand. The special advantage of a percolating stand is, that it enables all percolating and filtering operations to be carried on with convenience in one place, thus saving time and labor.

Fig. 414



Lewin's extraction apparatus

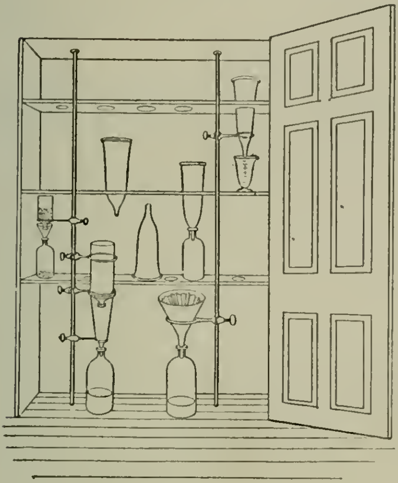
Fig. 415



Percolator stand

Percolation Closet.—The retort rings shown in Fig. 187 have been used by James T. Shinn in a convenient percolation closet, shown in Fig. 416. Two lengths of ordinary five-eighths-inch iron steampipe are fastened securely to the top and bottom of the closet, at a convenient distance from the shelves. The retort rings may be adjusted to the desired height, and it is thus possible to carry on several percolations or filtrations at the same time, away from the other operations of the store, in a closet with a closed door.

Fig. 416

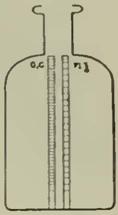


Percolation closet (Shinn)

Fig. 417

Receiving flask

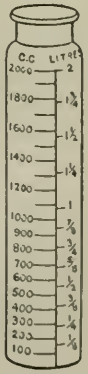
Fig. 418



Receiving bottle (paper scale)

Receiving Bottles.—A series of bottles of various sizes should be reserved for use in receiving percolates. Where especial accuracy is necessary, a flask with a double mark on the neck should be used (see Fig 417). Bottles with comparatively wide necks are to be preferred for receiving bottles. A paper strip may be pasted on the side, and accurately measured quantities of water poured in, carefully marking the height of each addition; upon the opposite side corresponding metric quantities may also be placed (see Fig. 418). J. M. Maris & Co. furnish narrow receiving bottles (metric and old form, and both systems on the same bottle) (Fig. 419). The graduations are accurately engraved on the glass, and arranged, at the author's suggestion, to suit the quantities usually made by the pharmacist. These, unlike the home made receivers, are permanently marked and of elegant appearance.

Fig. 419



Receiving bottle (all glass)

Repercolation.—This, as its name indicates, is the process of percolating substances with percolates, or, as defined by Dr. E. R. Squibb, the author of the process, "the successive application of the same percolating menstruum to fresh portions of the substance to be percolated." The principal object of repercolation is to effect the saving of alcohol and alcoholic menstrua by accomplishing the saturation of the menstrua, as nearly as possible, by passing the unsaturated or weaker percolate from one portion of the drug through another portion, and again passing the unsaturated or weaker percolate from this second portion through a third portion.

The weak percolate from this last portion is generally set aside, to be used in succeeding operations upon the same drug in the place of fresh menstruum. This process is useful only in those operations where the relative proportion of menstruum used is small, as in the fluidextracts and similar concentrated preparations. Practical illustrations of the use of this process may be seen by referring to the chapter on Fluidextracts.

Fractional Percolation.—This is a term employed by Prof. C. Lewis Diehl and others to define percolation when applied to two successive portions of powder, the principle of action being identical with that of repercolation.

PART II

OFFICIAL PHARMACY

THE various processes which are used in making the official preparations having been considered in Part I., as solution, filtration, digestion, percolation, maceration, expression, etc., it is most appropriate now to take up these preparations and classify them. Those which form natural groups will be brought together in such a manner as to facilitate the study of their general features. Each chapter will begin with a definition and description of the class of preparations of which it treats; then will follow a table giving a succinct view of the individual preparations forming the class; and after this, the official processes will be found arranged alphabetically. Detailed comments upon the preparations are reserved for the subsequent chapters, the object being at this time to familiarize the student with the *various forms* of official preparations and fix their general characteristics upon the mind. A table of abbreviated unofficial formulas will be found after each class, containing mainly preparations of the U. S. P. 1890 which were dropped at the last revision, and also those of the British Pharmacopœia (1898). The following diagram will serve to give a complete view of the classification; it should be carefully examined at the outset, and referred to again after the classes have been studied in detail:

OFFICIAL PREPARATIONS[1]

LIQUIDS

Made without percolation or maceration

Aqueous Solutions
- Waters
- Solutions

Aqueous Solutions containing Sweet or Viscid Substances
- Syrups
- Honeys
- Mucilages
- Emulsions
- Mixtures
- Glycerites

Alcoholic Solutions
- Spirits
- Elixirs

Ethereal Solutions
- *Collodions*

Oleaginous Solutions
- *Liniments*
- *Oleates*

Made by percolation or maceration

Aqueous Liquids
- Infusions
- Decoctions

Alcoholic Liquids
- Tinctures
- Wines
- Fluidextracts

Oleoresinous Liquids
- Oleoresins

Acetous Liquids
- Vinegars

SOLIDS

Made by percolation or maceration
- Extracts
- Resins

Made without percolation or maceration[2]
- Powders
- Triturations
- Masses
- Confections
- Pills
- Troches
- *Cerates*
- *Ointments*
- *Plasters*
- *Papers*
- Suppositories

[2] The preparations in this class are mostly extemporaneous, and will be considered under Part V.

CHAPTER XXI

AQUEOUS SOLUTIONS

Aquæ *Waters*

THE class of preparations termed *waters* are known also as medicated, aromatic, or distilled waters, and may be simply defined as *aqueous solutions of volatile substances.* The German Pharmacopœia and French Codex, however, recognize as waters solutions of non-volatile substances. The volatile substances used in the preparation of waters are either solid, liquid, or gaseous, and the following methods have been employed in effecting their solution: 1. Simple solution in cold water. 2. Solution in hot water. 3. Filtration through an absorbent powder. 4. Filtration through pulped or shredded filter paper. 5. Percolation through cotton saturated with the substance. 6. Distillation.

Most of the medicated waters are used as pleasant vehicles and solvents for the administration of various remedies, and are solutions of aromatic volatile oils. There are *eighteen* official waters, excluding ordinary water.[1]

1. Simple Solution in Cold Water.—This method is resorted to when the proportion of the volatile substance is small enough to dissolve *easily* in the quantity of water required. Where a volatile liquid is the medicating substance, the process consists in agitating it with the water until dissolved, and then filtering the solution. The method of making medicated waters by agitation with an excess of volatile oil, permitting the excess to remain and drawing off the water as required, is not recommended on account of the liability of the oil to deteriorate through exposure to light and air. In the case of the gaseous solutions, the gas is passed through the water until a solution of the desired strength is obtained. (See Solution of Gases, p. 196.) Of the eighteen official waters, four are distilled, three are solutions of gases, six are solutions of volatile oils, two are diluted distilled waters, one is a solution of a volatile solid, and two are solutions of volatile liquids.

Official Waters made by Simple Solution

Name	Proportion of Liquid dissolved	Use and Dose
Aqua Amygdalæ Amaræ	0.1 percent. of Oil of Bitter Almond	Pleasantly flavored vehicle, fʒi (4 Cc.)
Chloroformi	Saturated solution	Sedative and vehicle, fʒiv (16 Cc.)
Creosoti	1 percent. of Creosote	Antiseptic and used locally, fʒi to fʒiv (4 Cc. to 16 Cc.)

---

[1] Chlorine water will be found under the official Latin title Liquor Chlori Compositus in the class Liquores, but as it is mainly composed of volatile substances it is also included in this table.

Official Waters made by passing Gases through Water

Name	Proportion of Gas dissolved	Use
Aqua Ammoniæ	10 percent. of gaseous Ammonia	Stimulant, caustic, 15♏ (1 Cc.)
Ammoniæ Fortior	28 percent. of gaseous Ammonia	Rubefacient, escharotic
Hydrogenii Dioxidi	3 percent. of pure Dioxide	Antiseptic, fʒi (4 Cc.)
Liquor Chlori Compositus[1]	About 0.4 percent. of gaseous Chlorine	Antiseptic, stimulant, fʒi (4 Cc.)

2. **Solution in Hot Water.**—This method is founded upon the fact that most of the volatile oils are much more soluble in hot water than in water of ordinary temperature ; hence, if the volatile oil is thoroughly agitated with hot water in a suitable vessel, such as a tin can or a bottle, and allowed to stand until the excess has separated, if care is used, the water will be found to be saturated ; it may then be decanted and filtered.

3. **Filtration through an Absorbent Powder** is the process which has been most frequently employed ; the object of using the powder is to divide thoroughly the oil, or volatile liquid, and expose a greater surface, so that the water in filtering through it may become completely saturated. The powder most frequently used is magnesium carbonate, but this is sometimes objectionable on account of being slightly soluble in water. Calcium phosphate, kaolin, powdered glass, silica, powdered pumice-stone, charcoal, paper pulp, precipitated chalk, sugar, etc., have been suggested as substitutes, but there are quite as forcible objections to be urged against these as against the magnesium carbonate. Where solutions of alkaloids or of silver nitrate are needed, distilled water alone should be used. The present official method directs the use of purified talc, but purified magnesium carbonate is preferable.

4. **Filtration through Pulped or Shredded Filter Paper.**—This process is permitted by the U. S. Pharmacopœia (8th Revision) and consists in dropping the volatile oil upon white filter paper, tearing this into shreds, transferring it to a flask or stoneware jug, adding boiling water in portions, and shaking thoroughly. When the liquid is cold, it is filtered and the quantity adjusted by pouring distilled water through the filter.

5. **Percolation through Cotton impregnated with the Substance.**—This was the process directed to be used in the U. S. P. 1880 ; it was abandoned in the revision of 1890 on account of its inconvenience and wastefulness. The oil or volatile liquid is distributed upon the fibres of cotton, which are then pulled apart in order to secure thorough division ; the saturated cotton is packed in a funnel, and the water poured upon it. In its passage downward the water dissolves the oil and passes out impregnated with the odorous substance. The presence of undissolved floating oily drops in the finished preparation has constituted one of the greatest objections to this process. It is an improvement to insert a plug of dry cotton in the throat of the funnel before placing the saturated cotton in position ; this prevents the oily drops which may escape solution from being

---

[1] Chlorine water will be found under the official Latin title Liquor Chlori Compositus in the class Liquores, but as it is mainly composed of volatile substances it is also included in this table.

carried down by the water as it percolates through. Too much care cannot be exercised in selecting the volatile oils, which should be fresh and of the best quality.

Official Waters made by Filtration through an Absorbent Powder

Name	Proportion	Use and Dose
Aqua Anisi	0.2 percent. of Oil of Anise	Pleasant vehicle, f℥iv (16 Cc.)
Camphoræ	0.8 percent. of Camphor dissolved in Alcohol	Mild antispasmodic, f℥ii (8 Cc.)
Cinnamomi	0.2 percent. of Oil of Cinnamon	Pleasant vehicle, f℥iv (16 Cc.)
Fœniculi	0.2 percent. of Oil of Fennel	Pleasant vehicle, f℥iv (16 Cc.)
Menthæ Piperitæ	0.2 percent. of Oil of Peppermint	Pleasant vehicle, f℥iv (16 Cc.)
Menthæ Viridis	0.2 percent. of Oil of Spearmint	Pleasant vehicle, f℥iv (16 Cc.)

6. **Distillation.**—This is the best process for preparing medicated waters, and should be used wherever practicable. If the fresh drug can be procured, it should always be used in preference to that which has been dried, because in the process of desiccation there is usually a loss of the agreeable volatile constituents. Metallic distillatory apparatus is preferably employed (see page 151). If the drug containing the oil-cells has a loose structure and is quickly penetrated by hot water, so that the oil-cells are easily ruptured, the drug may be introduced without previous contusion or grinding; it will usually be found, however, most economical to cut or grind the drug coarsely. Most distilled waters acquire an unpleasant empyreumatic odor as soon as they are distilled; this passes off gradually upon exposure to air, if care has been taken not to expose the drug to the action of direct heat during distillation. If no precautions are taken to protect the drug from partial burning, the odor of the carbonized substance will always be noticeable in the distilled water, rendering the product worthless. Fig. 213 shows a copper wire cage contrived by the author to obviate the difficulty just described; the surface of the cage is hemispherical; it rests, after being partially filled with the drug, upon the flat bottom of the still, and thus the contact of the substance with the heated surface is avoided; the meshes of the cage are coarse enough to permit the free passage of vapors and the boiling water through them. Although distillation by the use of steam may be most convenient upon the large scale, Vuaflart and Machet have shown that rose and orange flower waters distilled over a naked fire keep better than those distilled by steam heat.

Preservation.—Distilled waters should not be made in larger quantities than can be used within a reasonable time, because they deteriorate when long kept, a flocculent precipitate forming in them, and ultimately they lose all traces of their usually agreeable odor. Microscopic plants belonging to the order Confervoideæ will often be found in medicated waters. These are usually tufts of articulated filaments, propagated by very minute spores from the atmosphere, which have found lodgement in the water. Their presence renders the medicated water unsightly, and when in large proportion they must be regarded as injurious. If the water is heated and introduced into a sterilized bottle with a side opening (like a douche-bottle) to which a sterilized rubber tube with a pinchcock is attached, and a tuft of cotton pushed into the *neck* of the bottle, any spores originally present in the water will be killed by the heat, and the future growth of confervæ will be prevented by the interception of the spores by the cotton. It usually suffices, however, to heat the medicated water and introduce it at once into small bottles, which are to be completely filled, tightly sealed, and kept in a cool, dark place. Alcohol is sometimes added as a preservative, but this generally serves its purpose only a short time, as it cannot be added in sufficient quantity to preserve the water permanently, on account of its interference with the therapeutic action. The small percentage of alcohol in the medicated water is converted into acetic acid when long kept, and thus the preparation is soured. Glycerin and syrup have been suggested as preservatives. In the writer's experience they are not of much value unless used in large and inadmissible quantities.

Official Waters made by Distillation

Name	Proportion of Material used	Use and Dose
Aqua Aurantii Florum Fortior	Water saturated with Oil of Fresh Orange Flowers	Used for making Orange Flower Water, fʒii (16 Cc.)
Aurantii Florum	Stronger Orange Flower Water, Distilled Water, each, 1 vol.	Mild sedative vehicle, f℥ss. (16 Cc.)
Destillata	800 parts distilled from 1000 of water	Solvent
Hamamelidis	8500 Cc. distilled from 10,000 Gm. Hamamelis bark with the addition of 1500 Cc. of Alcohol	Used as a lotion
Rosæ Fortior	Water saturated with Oil of Rose Petals	Used for making Rose Water fʒii (8 Cc.)
Rosæ	Stronger Rose Water, Distilled Water, each, 1 vol.	Pleasant vehicle, f℥ss (16 Cc.)

AQUA AMYGDALÆ AMARÆ. U.S. Bitter Almond Water

	Metric	Old form
* **Oil of Bitter Almond**	1 Cc.	15 minim
Distilled Water	999 Cc.	2 pints
To make	1000 Cc.	2 pints

Dissolve the Oil in the Distilled Water by agitation, and filte through a well-wetted filter.

Average dose.—1 fluidrachm (4 Cc.).

AQUA ANISI. U.S. Anise Water

	Metric	Old form
* **Oil of Anise**	2 Cc.	30 minims
Purified Talc	15 Gm.	220 grains
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Oil of Anise with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Anise Water is perfectly clear.

Average dose.—4 fluidrachms (16 Cc.).

AQUA AURANTII FLORUM. U.S. Orange Flower Water

	Old form
* **Stronger Orange Flower Water**	8 fl. oz.
Distilled Water, each, one volume	
To make	1 pint

Mix them immediately before use.

Average dose.— 4 fluidrachms (16 Cc.).

AQUA AURANTII FLORUM FORTIOR. U.S. Stronger Orange Flower Water

[Triple Orange Flower Water]

Water saturated with the volatile oil of fresh orange flowers obtained as a by-product in the distillation of the oil of orange flowers. It should be kept in bottles loosely stoppered with a pledget of purified cotton, and in a dark place.

Stronger Orange Flower Water should be neutral to litmus paper, and have a strong odor of fresh orange flowers.

It should be colorless and clear, or only faintly opalescent, not mucilaginous, and should give no reaction with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of *metallic impurities*).

Average dose.— 2 fluidrachms (8 Cc.).

AQUA CAMPHORÆ. U.S. Camphor Water

	Metric	Old form
* **Camphor**	8 Gm.	117 grains
Alcohol	8 Cc.	123 minims
Purified Talc	15 Gm.	220 grains
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Camphor in the Alcohol, triturate the solution with the Purified Talc, and, after allowing the greater part of the Alcohol to evaporate spontaneously, continue the trituration with the Water, gradually added; then pour the mixture upon a well-wetted filter, and pass the filtrate through the filter repeatedly until the Camphor Water is perfectly clear.

Average dose.— 2 fluidrachms (8 Cc.).

AQUA CHLOROFORMI. U.S. Chloroform Water

* **Chloroform,**
Distilled Water, each, a sufficient quantity

Add enough Chloroform to a convenient quantity of Distilled Water, contained in a dark amber-colored bottle, to maintain a slight excess of the former after the contents have been repeatedly and thoroughly agitated.

When Chloroform Water is required for use pour off the needed quantity of the solution, refill the bottle with Distilled Water, and saturate it by thorough agitation, taking care that there be always an excess of Chloroform present.

Average dose.— 4 fluidrachms (16 Cc.).

AQUA CINNAMOMI. U.S. Cinnamon Water

	Metric	Old form
* **Oil of Cinnamon**	2 Cc.	30 minims
Purified Talc	15 Gm.	220 grains
Distilled Water a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Oil of Cinnamon with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Cinnamon Water is perfectly clear.

Average dose.—4 fluidrachms (16 Cc.).

AQUA CREOSOTI. U.S. Creosote Water

	Metric	Old form
* **Creosote**	10 Cc.	154 minims
Distilled Water	990 Cc.	31 fl. oz. 5½ fl. dr.
To make	1000 Cc.	2 pints

Agitate the Creosote vigorously with the Distilled Water, and filter through a well-wetted filter. Creosote Water should be freshly prepared when dispensed.

Average dose.—2 fluidrachms (8 Cc.).

AQUA DESTILLATA. U.S. Distilled Water

	Metric	Old form
* **Water**	1000 Vol.	10 pints
To make	800 Vol.	8 pints

Distil the Water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first 100 volumes [old form 1 pint], and reject this portion. Then collect 800 volumes [old form 8 pints] and keep the Distilled Water in glass-stoppered bottles, which have been rinsed with hot distilled water immediately before being filled.

AQUA FŒNICULI. U.S. Fennel Water

	Metric	Old form
* **Oil of Fennel**	2 Cc.	30 minims
Purified Talc	15 Gm.	220 grains
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Oil of Fennel with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Fennel Water is perfectly clear.

Average dose.—4 fluidrachms (16 Cc.).

AQUA HAMAMELIDIS. U.S. Hamamelis Water

	Metric	Old form
* **Hamamelis Bark**	10000 Gm.	21 lb.
Water	20000 Cc.	40 pints
Alcohol	1500 Cc.	3 pints
To make	10000 Cc.	20 pints

Macerate the Hamamelis Bark in the Water during twenty-four hours; then distil until 8500 Cc. [old form 17 pints] of distillate are obtained, add the Alcohol, and mix thoroughly.

If 1 Cc. of Hamamelis Water be added to 5 Cc. of sulphuric acid containing a little salicylic acid in solution, no red color should appear (absence of *formaldehyde*)

Average dose.—2 fluidrachms (8 Cc.).

AQUA HYDROGENII DIOXIDI. U.S. Solution of Hydrogen Dioxide

[Solution of Hydrogen Peroxide]

A slightly acid, aqueous solution of Hydrogen Dioxide [H_2O_2 = 33.76], which should contain, when freshly prepared, about 3 percent., by weight, of absolute Hydrogen Dioxide, corresponding to about 10 volumes of available oxygen. It should be kept in a cool place. Upon removing the stopper from the bottle not more than a slight pressure should be observed.

(For tests, see Part III.)

AQUA MENTHÆ PIPERITÆ. U.S. Peppermint Water

	Metric	Old form
***Oil of Peppermint**	2 Cc.	30 minims
Purified Talc	15 Gm.	220 grains
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Oil of Peppermint with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Peppermint Water is perfectly clear.

Average dose.— 4 fluidrachms (16 Cc.).

AQUA MENTHÆ VIRIDIS. U.S. Spearmint Water

	Metric	Old form
***Oil of Spearmint**	2 Cc.	30 minims
Purified Talc	15 Gm.	220 grains
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Oil of Spearmint with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Spearmint Water is perfectly clear.

Average dose.— 4 fluidrachms (16 Cc.).

AQUA ROSÆ. U.S. Rose Water

	Old form
***Stronger Rose Water**,	
Distilled Water, of each, one volume	8 fl. oz.

Mix them immediately before use.

Average dose.— 4 fluidrachms (16 Cc.).

AQUA ROSÆ FORTIOR. U.S. Stronger Rose Water

[Triple Rose Water]

Water saturated with the volatile oil of rose petals, obtained by distillation.

Stronger Rose Water should be kept in bottles loosely stoppered with a pledget of purified cotton, and in a dark place.

Stronger Rose Water should be colorless and clear, not mucilaginous, and should have the odor of roses, free from empyreuma. It should give no reaction with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of *metallic impurities*).

Average dose.— 2 fluidrachms (8 Cc.).

Unofficial Waters

Name	Character of Preparation	Use and Dose
Aqua Anethi. Br.	A distillate obtained from an infusion of Dill Fruit	A pleasant vehicle
Carui. Br.	A distillate obtained from an infusion of Caraway Fruit	A pleasant vehicle
Lauro-cerasi. Br.	A distillate obtained from an infusion of Cherry-Laurel Leaves, containing one-tenth percent. of hydrocyanic acid	A sedative narcotic, 30 ♏ (2 Cc.)
Pimentæ. Br.	A distillate obtained from an infusion of Pimento.	A pleasant vehicle
Sambuci. Br.	A distillate obtained from an infusion of fresh Elder Flowers	A pleasant vehicle

Liquores *Solutions*

Under this head the U. S. Pharmacopœia places all aqueous solutions of non-volatile substances except such as naturally form separate distinctive classes, as the syrups, infusions, and decoctions.

This classification is adopted only in the U. S. Pharmacopœia, the British standard embracing, in addition, gaseous and saccharine solutions, as Liquor Ammoniæ, Liquor Calcis Saccharatus, etc., while the German Pharmacopœia does not adopt any definite method, solutions of volatile and non-volatile substances both being in the class Aquæ and also in the class Liquores, Aqua Rosæ and Aqua Plumbi together, and Liquor Ammonii Caustici and Liquor Natri Caustici in the same class. Liquor Formaldehydi was added to this class in the U. S. P. (8th Rev.) as upon heating, paraformaldehyde, a solid substance, is formed.

The official solutions constitute a most interesting group of preparations. They are usually very active medicinal agents, and some of them are powerful poisons. The number of official solutions is *twenty-five.* The following tables exhibit in condensed form a view of the class Liquores, U. S. P., arranged alphabetically in two classes: 1. Simple aqueous solutions, in which the solid dissolved is not altered in any respect, except so far as depends upon its external form. 2. Chemical aqueous solutions, or those in which the properties of the dissolved body or bodies are changed by chemical action or heat (see page 189).

LIQUORES, U. S. P.

1. Simple Solutions (aqueous)

Liquor Acidi Arsenosi	1 percent. As_2O_3, 5 percent. diluted HCl
Antisepticus	Hydroalcoholic solution of Boric Acid, Benzoic Acid, Thymol, Eucalyptol, and Oils of Peppermint, Gaultheria, and Thyme
Arseni et Hydrargyri Iodidi	1 percent. AsI_3, 1 percent. HgI_2
Calcis	Saturated solution $Ca(OH)_2$
Iodi Compositus	5 percent. I, 10 percent. KI
Plumbi Subacetatis Dilutus	4 percent. of Solution Lead Subacetate.
Potassii Hydroxidi	5 percent. Potassium Hydroxide.
Sodii Hydroxidi	5 percent. Sodium Hydroxide
Sodii Arsenatis	1 percent. Exsiccated Sodium Arsenate

2. Chemical Solutions (aqueous)

Liquor Ammonii Acetatis	7 percent. Ammonium Acetate (Ammonium Carbonate with Diluted Acetic Acid)
Chlori Compositus	0.4 percent. Chlorine ($KClO_3$ with HCl and Water)

Liquor Cresolis Compositus . . .	50 percent. Cresol with Linseed Oil and KOH
Ferri Chloridi	29 percent. anhydrous Ferric Chloride (Iron, HCl, HNO_3, and Distilled Water)
Ferri et Ammonii Acetatis . .	Ferric Chloride, Diluted Acetic Acid, Ammonium Acetate, Aromatic Elixir, Glycerin, and Water
Ferri Subsulphatis	13.57 percent. Metallic Iron (Ferrous Sulphate, H_2SO_4, HNO_3, and Distilled Water)
Ferri Tersulphatis	36 percent. normal Ferric Sulphate (Ferrous Sulphate, H_2SO_4, HNO_3, and Distilled Water)
Formaldehydi	37 percent. by weight absolute Formaldehyde
Hydrargyri Nitratis	60 percent. Mercuric Nitrate and 11 percent. free Nitric Acid (Red Mercuric Oxide, HNO_3, and Distilled Water)
Magnesii Citratis	Magnesium Carbonate, Citric Acid, Syrup of Citric Acid, Potassium Bicarbonate, Water
Plumbi Subacetatis	25 percent. Lead Subacetate (Lead Acetate, Lead Oxide, and Distilled Water)
Potassii Arsenitis	Potassium Arsenite corresponding to 1 percent. As_2O_3 (Arsenic Trioxide, Potassium Bicarbonate, Compound Tincture of Lavender, and Distilled Water)
Potassii Citratis	8 percent. anhydrous Potassium Citrate (Potassium Bicarbonate, Citric Acid, and Distilled Water)
Sodæ Chlorinatæ	2.4 percent. by weight available Chlorine (Chlorinated Lime, Monohydrated Sodium Carbonate, and Water)
Sodii Phosphatis Compositus .	Representing 100 percent. Sodium Phosphate (Sodium Phosphate, Sodium Nitrate, Citric Acid, and Distilled Water)
Zinci Chloridi	50 percent. by weight Zinc Chloride (Zinc, Nitric Acid, Precipitated Zinc Carbonate, HCl, and Distilled Water)

The official solutions vary so greatly in their properties and method of preparation, that no general formula or comments can be given here to aid the student in studying them individually which would compare in value with the careful consideration that should be given each separate formula. These processes will be found under the head of the bases entering into them in Part III. For general manipulations of solutions, see page 189.

Table of Unofficial Solutions[1]

Name	Ingredients	Preparation
Liquor Acidi Chromici. Br.	25 Gm. Chromic Anhydride; 75 Cc. Distilled Water	Dissolve
Ammonii Citratis. Br.	87.5 Gm. Ammonium Carbonate; 125 Gm. Citric Acid; Distilled Water to make 1000 Cc.	Dissolve the Citric Acid in five times its weight of Distilled Water; neutralize with Ammonium Carbonate; add Distilled Water to make 1000 Cc.
Atropinæ Sulphatis. Br.	1 Gm. Atropine Sulphate; 0.12 Gm. Salicylic Acid; Distilled Water to make 100 Cc.	Dissolve the Atropine Sulphate and the Salicylic Acid in enough recently boiled Distilled Water to make 100 Cc.

---

[1] In this list are included preparations of the U. S. P. 1890, not included in the Eighth Decennial Revision and of the 1898 British Pharmacopœia. The British Pharmacopœia includes, under the title of Liquor, preparations made by percolation and maceration, and more properly classed with concentrated tinctures or 50 percent. fluidextracts.

Table of Unofficial Solutions—*Continued*

Name	Ingredients	Preparation
Liquor Bismuthi et Ammonii Citratis. Br.	70 Gm. Bismuth Oxynitrate; 70 Gm. Potassium Citrate; 20 Gm. Potassium Carbonate; 50 Cc. Nitric Acid; Ammonia Water and Distilled Water enough to make 1000 Cc.	Dissolve the Bismuth Oxynitrate in the Diluted Nitric Acid, add Distilled Water until the solution is slightly opalescent, and then add an aqueous solution of the Potassium Citrate and Carbonate, heat to boiling, cool, separate, precipitate, and wash, and while moist dissolve in just enough Ammonia Water and add Distilled Water to make 1000 Cc.
Calcis Chlorinatæ. Br.	500 Gm. Chlorinated Lime; 5 liters Distilled Water	Mix, shake occasionally during three hours, and filter
Calumbæ Concentratus. Br.	500 Gm. Calumba, No. 5 powder; 225 Cc. Alcohol; Distilled Water to make 1000 Cc.	Prepare a cold aqueous infusion by maceration, heat the liquid to boiling, add the Alcohol, filter, adding enough Distilled Water to make 1000 Cc.
Caoutchouc. Br.	50 Gm. India Rubber; 500 Cc. Benzol; 500 Cc. Carbon Disulphide	Cut the India Rubber into shreds and dissolve it in the mixed liquids
Chiratæ Concentratus. Br.	500 Gm. Chiretta, No. 40 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Cuspariæ Concentratus. Br.	500 Gm. Cusparia Bark, No. 40 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Epispasticus. Br.	500 Gm. Cantharides, No. 20 powder; Acetic Ether to make 1000 Cc.	Percolate with the Acetic Ether, after twenty-four hours' maceration, until the liquid measures 1000 Cc.
Ethyl Nitritis. Br.	3 percent., by weight, of Ethyl Nitrite in Absolute Alcohol 95 parts and Glycerin 5 parts	Mix them
Ferri Acetatis. U. S. P. 1890	1000 Gm. Solution of Ferric Sulphate; 260 Gm. Glacial Acetic Acid; 850 Cc. Ammonia Water; Distilled Water to make 1000 Gm.	Add the well diluted Solution of Ferric Sulphate to the diluted Ammonia Water, wash and collect the precipitate and add it gradually to the Glacial Acetic Acid, contained in a tared jar. When dissolved add enough Distilled Water to make the liquid weigh 1000 Gm.
Ferri Citratis. U. S. P. 1890	1050 Gm. Solution of Ferric Sulphate; 300 Gm. Citric Acid; 880 Cc. Ammonia Water; Water to make 1000 Gm.	Add the well diluted Solution of Ferric Sulphate to the diluted Ammonia Water, wash, and collect the precipitate and add it to the Citric Acid contained in a porcelain dish. Heat gently until dissolved and add enough Water to make the liquid weigh 1000 Gm.
Ferri Nitratis. U. S. P. 1890	180 Gm. Solution of Ferric Sulphate; 160 Cc. Ammonia Water; 71 Gm. Nitric Acid; Distilled Water to make 1000 Gm.	Add the well diluted Solution of Ferric Sulphate to the diluted Ammonia Water, wash and collect the precipitate and add it to the Nitric Acid contained in a porcelain dish. Stir until dissolved and add enough Distilled Water to make the liquid weigh 1000 Gm.
Ferri Perchloridi. Br.	250 Cc. Strong Solution of Ferric Chloride; Distilled Water to make 1000 Cc.	Mix them
Hydrargyri Perchloridi. Br.	1 Gm. Mercuric Chloride; 875 Cc. Distilled Water	Dissolve
Krameriæ Concentratus. Br.	500 Gm. Krameria Root, No. 40 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Magnesii Carbonatis. Br.	40 Gm. Magnesium Sulphate; 50 Gm. Sodium Carbonate; Distilled Water a sufficient quantity to make about 400 Cc.	Add a solution of the Sodium Carbonate to a hot solution of the Magnesium Sulphate, collect and wash the precipitate, dissolve it in 400 Cc. Distilled Water, into which carbonic acid gas, under pressure, has been introduced, and store in tightly stoppered bottles

Table of Unofficial Solutions—*Continued*

Name	Ingredients	Preparation
Liquor Morphinæ Acetatis. Br.	1 Gm. Morphine Acetate; 2 Cc. Diluted Acetic Acid; 25 Cc. Alcohol; Distilled Water to make 100 Cc.	Mix the Diluted Acetic Acid with the Alcohol and an equal volume of Distilled Water; dissolve the Morphine Acetate in the liquid and add enough Distilled Water to make 100 Cc.
Morphinæ Hydrochloridi. Br.	1 Gm. Morphine Hydrochloride; 2 Cc. Diluted Hydrochloric Acid; 25 Cc. Alcohol; Distilled Water to make 100 Cc.	Mix the Diluted Hydrochloric Acid with the Alcohol and an equal volume of Distilled Water; dissolve the Morphine Hydrochloride in the liquid and add enough Distilled Water to make 100 Cc.
Morphinæ Tartratis. Br.	1 Gm. Morphine Tartrate; 25 Cc. Alcohol; Distilled Water to make 100 Cc.	Dissolve the Morphine Tartrate in the Alcohol, mixed with an equal volume of Distilled Water, and add enough Distilled Water to make 100 Cc.
Pancreatis. Br.	Fresh Pancreas of the Pig; 1000 Cc. 20 percent. Alcohol	Digest 250 Gm. of cleaned and finely divided pancreas in 1000 Cc. of 20 percent. Alcohol during seven days and filter
Picis Carbonis. Br.	200 Gm. Prepared Coal Tar; 100 Gm. Quillaia Bark, No. 20 powder; Alcohol to make 1000 Cc.	Percolate the Quillaia with Alcohol to make 1000 Cc. of tincture, to which add the Coal Tar, prepared by heating at 48.9° C. (120° F.) during one hour and digest, with occasional stirring, during two days. Finally filter
Potassii Permanganatis. Br.	10 Gm. Potassium Permanganate; Distilled Water to make 1000 Cc.	Dissolve the Potassium Permanganate in enough Distilled Water to make 1000 Cc.
Quassiæ Concentratus. Br.	100 Gm. Quassia Wood, No. 40 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Rhei Concentratus. Br.	500 Gm. Rhubarb, No. 5 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Sarsæ Compositus Concentratus. Br.	1000 Gm. Sarsaparilla, cut and bruised; 100 Gm. Sassafras Root; 100 Gm. Guaiacum Wood; both in shavings; 100 Gm. Dried Licorice Root, bruised; 50 Gm. Mezereon Bark, cut; 225 Cc. Alcohol; Distilled Water to make 1000 Cc.	Infuse the Sarsaparilla in 3 successive portions of 5000 Cc. each of Distilled Water at 71.1° C. (160° F.) Boil the other solid ingredients with Water until exhausted, and rapidly evaporate the mixed infusion and decoction until it measures 800 Cc. Add the Alcohol, set aside for fourteen days, and filter
Senegæ Concentratus. Br.	500 Gm. Senega Root, No. 20 powder; about 28 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Sennæ Concentratus. Br.	1000 Gm. Senna; 125 Cc. Tincture of Ginger; 100 Cc. Alcohol; Distilled Water to make 1000 Cc.	Pack the Senna, divided into 3 equal portions, in separate percolators, macerate for twenty-four hours, then percolate the first with Distilled Water, using the liquid obtained as menstruum for the second, and the percolate from the second as menstruum for the third. Continue the operation until 800 Cc. have been obtained from the third percolator; heat the liquid to 82.2° C. (180° F.), cool, add the Tincture of Ginger and Alcohol, set aside for seven days, and filter
Serpentariæ Concentratus. Br.	500 Gm. Serpentary Rhizome, No. 40 powder; 20 percent. Alcohol to make 1000 Cc.	Percolate with the menstruum, after three days' maceration, until the liquid measures 1000 Cc.
Sodii Ethylatis. Br.	1 Gm. Sodium (clean and bright); 20 Cc. Absolute Alcohol	Cautiously dissolve the Sodium in the Absolute Alcohol, contained in a flask, the latter being kept cool by a stream of cold water
Sodii Silicatis. U. S. P. 1890	A nearly saturated solution	

Table of Unofficial Solutions—*Continued*

Name	Ingredients	Preparation
Liquor Strychninæ Hydrochloridi. Br.	1 Gm. Strychnine Hydrochloride; 25 Cc. Alcohol; Distilled Water to make 100 Cc.	Dissolve the Strychnine Hydrochloride in the Alcohol and sufficient Distilled Water to make 100 Cc.
Thyroidei. Br.	Fresh and healthy thyroid gland of the sheep; Glycerin and 0.5 percent. solution of Phenol in Distilled Water	Carefully select healthy and normal thyroid glands, bruise them in a mortar, and for each entire gland add 2 Cc. of Glycerin and 2 Cc. of 0.5 percent. solution of Phenol. Allow the mixture to stand in a flask during twenty-four hours, then strain with pressure, and add the solution of Phenol to make the liquid measure 6 Cc. for each gland used

CHAPTER XXII

AQUEOUS SOLUTIONS CONTAINING SWEET OR VISCID SUBSTANCES

Syrupi *Syrups*

Syrups are concentrated solutions of sugar in water or aqueous liquids. The liquids used sometimes contain acetic or other organic acids, and occasionally a small quantity of alcohol. When water *alone* is used in making the solution of sugar, the preparation is termed *syrup*, or *simple syrup*. When the water contains soluble principles from various medicinal substances, the syrup is called a *medicated* syrup. A *flavored* syrup is one which is not medicinal in its action, but which is made by the introduction of various aromatic or pleasantly flavored substances. Syrups are useful preparations, because their sweet taste facilitates administration, while the presence of a large percentage of sugar renders them permanent if they are properly made.

Selection of the Sugar.—The sugar which should be used exclusively in making syrups is clearly defined by the Pharmacopœia. It is described as in white, dry, hard, distinctly crystalline granules, permanent in the air, odorless, having a purely sweet taste, and a neutral reaction. This description applies to that known commercially as "granulated," and the official tests prescribed should be carefully observed. (See Saccharum.) Sugar must be free from ultramarine, Prussian blue, and insoluble substances, the presence of impurities, particularly ultramarine, has been proved to interfere with the stability and quality of syrups. The direction that the sugar should be dry is all-important, because the permanency of syrups largely depends upon their containing the correct proportion of sugar and water. If an insufficient amount of sugar is present, the syrups will ferment; if they contain too much, crystallization of the excess takes place at first, while the subsequent growth of the crystals is accompanied by an abstraction of sugar from the liquid, and the result is such a weakening of the syrup that fermentation results, as in the first instance. *Damp sugar* should never be used unless the amount of moisture has been carefully ascertained, and an allowance made for it.

Preparation of Syrups.—Syrups are prepared in various ways, and the choice of the proper method must always depend upon the physical and chemical characteristics of the substances entering into the preparation. Five methods are officially recognized, which may be summarized as follows: 1. By solution with heat. 2. By agitation without heat. 3. By the simple addition of a medicating liquid to syrup. 4. By digestion or maceration. 5. By percolation.

1. **By Solution with Heat.**—This is the usual method of making syrups when the valuable constituent is not volatile nor injured by

heat, and when it is desirable to make the syrup rapidly. The sugar is usually dissolved in the water or aqueous solution and heated until solution is effected, skimmed, strained, and the proper quantity of water added to make the desired weight or measure. If the syrup is made from an infusion, a decoction, or an aqueous solution containing organic matter, it is usually proper to heat the syrup to the boiling point, in order to coagulate albuminous matter; this is separated subsequently by straining. If the albumin or other impurities were suffered to remain in the syrup, fermentation would probably be induced in warm weather. Saccharometers (see page 82) are very useful in making syrups by the hot process where the specific gravity of the finished syrup is known. The saccharometer may be floated in the syrup *while boiling*, and thus the exact degree of concentration determined without waiting to cool the syrup and having to heat it again subsequently to concentrate it further.

2. **By Agitation without Heat.**—This process is directed by the Pharmacopœia to be used in those cases where heat will cause the loss of valuable volatile constituents. The aqueous solution is usually directed to be added to the sugar in a bottle, and the whole well shaken together until the sugar is dissolved. This is best effected by allowing the tightly corked bottle to lie upon its side when not being agitated. If a large quantity of syrup is required, it may be advantageously made in a churn.

3. **By the Simple Addition of Medicating Liquid to Syrup.**—This method is resorted to in those cases in which fluidextracts, tinctures, or other liquids are added to syrup in order to medicate it. Syrups made in this way usually show precipitates in time, owing to the fact that alcohol enters into most of the liquids thus used, and the resinous and oily substances dissolved by the alcohol often precipitate when mixed with the syrup, producing unsightly preparations.

4. **By Maceration or Digestion.**—In the U. S. P. 1880 but two official syrups were made by digestion,—senna and tolu. This method is not recommended as either accurate or efficient. A solution of a comparatively insoluble substance, like tolu, can always be effected in a more rapid and thorough manner by dissolving the substance in alcohol, suspending the resinous tincture in a mixture of absorbent powder and water, filtering, and dissolving sugar in the filtrate, as in the U. S. P. process (8th Revision).

5. **Percolation in making Syrups.**—This method originated with Orynski, and is conducted as follows: Into the lower orifice of an ordinary percolator is introduced a small piece of sponge or purified cotton, the sugar (granulated) is then poured in, and upon this the water, the apparatus being arranged as is usual in the process of percolation. The percolator may be covered loosely, and the operation will proceed without further attention, the syrup coming through drop by drop. If it should be necessary to use crushed sugar, the percolator must be corked at the lower orifice, and the sugar and water introduced and allowed to macerate until the former has dissolved down to *half its bulk*, when the cork may be removed and the liquid allowed to drop. If, after the liquid has all passed, there remains a quantity of undissolved sugar in the percolator,

enough percolate may be poured back to dissolve it, afterwards adding sufficient water to bring the whole up to the required measure.

To be successful in using this process, care in several particulars must be exercised : 1. The percolator used should be cylindrical or semicylindrical, and cone-shaped as it nears the lower orifice. 2. The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. 3. The sponge or purified cotton must be introduced with care. If pressed in too tightly, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (from imperfect filtration).

Preservation of Syrups.—Syrups should never be made in larger quantities than can be used within a few months, except in those cases where special facilities can be employed for their preservation. A low temperature is the best preservative for syrups; concentration without supersaturation is also a condition favorable to preservation. The addition of such substances as boric acid, salicylic acid, alcohol, fluorides, calcium sulphite, etc., to prevent the fermentation of syrups, is not recommended, for if used in sufficient quantity to act as preservatives they communicate their own flavor to the syrup or are otherwise objectionable. The practice of restoring syrups which have been spoiled through fermentation by heating them and "working them over" is a reprehensible one. The practice of good pharmacy demands the possession of sufficient moral courage to find a place for fermented syrups where they will do the least harm—*i.e.*, in the sink and gutter-pipe.

A simple and practical method of preserving syrups, which is very effective, is as follows : A number of bottles are provided holding not more than a pint each, even when the quantity of syrup is large; the bottles are thoroughly cleaned, and kept hot by immersion in boiling water until ready for use; a sufficient number of good corks, which have been thoroughly soaked in hot water, and of the proper size for the bottles, should be at hand. The syrup should be heated to the boiling point (strained, if necessary, and reheated), and poured into the hot bottles until they are filled to the brim. The corks are inserted by forcibly pressing them into the necks of the bottles, thereby displacing a small portion of the syrup, and are tied down with twine in the usual manner. Then, while the necks of the bottles are still hot (and before the syrup can contract in volume through cooling) they are dipped into melted sealing-wax contained in a suitable vessel. By this method the germs which are supposed to produce fermentation are destroyed by the heat, and no air can find its way to the syrup, as the bottles are hermetically sealed. Fruit-juices may be preserved in the same way.

Official Syrups.—There are TWENTY-NINE official syrups. Of this number, ELEVEN are made by the *simple addition of medicating liquid to syrup*, NINE by *agitation of the sugar with the medicating liquid without heat*, and NINE by *solution with heat*. The alternative process of percolation is permitted by the Pharmacopœia in EIGHT syrups.

Official Syrups, arranged in Classes according to the Methods employed in their Preparation

Name and Method of Preparation	Sub-Classes	Ingredients
Simple Addition of Medicating Liquid to Syrup		
Syrupus Acidi Hydriodici	Simple Admixture	(Containing 1 percent. Absolute Hydriodic Acid) 100 Gm. Diluted Hydriodic Acid; 300 Gm. Water; 600 Gm. Syrup
Amygdalæ	“ “	10 Cc. Spirit of Bitter Almond; 100 Cc. Orange Flower Water; Syrup, to 1000 Cc.
Ferri, Quininæ et Strychninæ Phosphatum	“ “	250 Cc. Glycerite of the Phosphates of Iron, Quinine and Strychnine; Syrup, to 1000 Cc.
Acidi Citrici	From tincture and Citric Acid	10 Gm. Citric Acid; 10 Cc. Distilled Water; 10 Cc. Tincture of Fresh Lemon Peel; Syrup, to 1000 Cc.
Lactucarii	From tincture	100 Cc. Tincture of Lactucarium; 1 Gm. Citric Acid; 50 Cc. Orange Flower Water; 200 Cc. Glycerin; Syrup, to 1000 Cc.
Rhei Aromaticus	From aromatic tincture	150 Cc. Aromatic Tincture of Rhubarb; 1 Gm. Potassium Carbonate; 850 Cc. Syrup
Krameriæ	From fluidextract	450 Cc. Fluidextract of Krameria; 550 Cc. Syrup
Rhei	“ “	100 Cc. Fluidextract of Rhubarb; 4 Cc. Spirit of Cinnamon; 10 Gm. Potassium Carbonate; 50 Cc. Water; Syrup, to 1000 Cc.
Rubi	“ “	250 Cc. Fluidextract of Rubus; 750 Cc. Syrup
Senegæ	“ “	200 Cc. Fluidextract of Senega; 800 Cc. Syrup
Sennæ	“ “	250 Cc. Fluidextract of Senna; 5 Cc. Oil of Coriander; Syrup, to 1000 Cc.
Agitation of Sugar with Medicating Liquid without heat		
Syrupus Aurantii Florum	Simple solution	850 Gm. Sugar; Orange Flower Water to make 1000 Cc.
Hypophosphitum	Simple solution or admixture	45 Gm. Calcium Hypophosphite; 15 Gm. Potassium Hypophosphite; 15 Gm. Sodium Hypophosphite; 2 Gm. Diluted Hypophosphorous Acid; 650 Gm. Sugar; 5 Cc. Tincture of Fresh Lemon Peel; Water, to 1000 Cc.
Hypophosphitum Compositus	Simple solution or admixture	35 Gm. Calcium Hypophosphite; 17.5 Gm. Potassium Hypophosphite; 17.5 Gm. Sodium Hypophosphite; 2.25 Gm. Ferric Hypophosphite; 2.25 Gm. Manganese Hypophosphite; 1.10 Gm. Quinine; 0.115 Gm. Strychnine; 3.75 Gm. Sodium Citrate; 15 Cc. Diluted Hypophosphorous Acid; 775 Gm. Sugar; Water, to 1000 Cc.
Pruni Virginianæ	From cold aqueous infusion	150 Gm. Wild Cherry; 700 Gm. Sugar; 150 Cc. Glycerin; Water, to 1000 Cc.
Calcii Lactophosphatis	Solution involving chemical reaction	60 Cc. Lactic Acid; 36 Cc. Phosphoric Acid; 50 Cc. Orange Flower Water; 25 Gm. Precipitated Calcium Carbonate; 725 Gm. Sugar; Water, to 1000 Cc.
Aurantii	From tincture	50 Cc. Tincture of Sweet Orange Peel; 5 Gm. Citric Acid; 10 Gm. Magnesium Carbonate; 820 Gm. Sugar; Water, to 1000 Cc.
Ipecacuanhæ	From fluidextract	70 Cc. Fluidextract of Ipecac; 10 Cc. Acetic Acid; 100 Cc. Glycerin; 700 Gm. Sugar; Water, to 1000 Cc.
Rosæ	“ “	125 Fluidextract of Rose; 10 Cc. Diluted Sulphuric Acid; 750 Gm. Sugar; Water, to 1000 Cc.
Scillæ Compositus	From fluidextracts	80 Cc. Fluidextract of Squill; 80 Cc. Fluidextract of Senega; 2 Gm. Antimony and Potassium Tartrate; 20 Gm. Purified Talc; 750 Gm. Sugar; Water, to 1000 Cc.
Solution with Heat		
Syrupus	Simple solution	850 Gm. Sugar; Distilled Water, to 1000 Cc.
Acaciæ	Simple solution and filtering	100 Gm. Acacia; 800 Gm. Sugar; Distilled Water, to 1000 Cc.

Official Syrups—*Continued*

Name and Method of Preparation	Sub-Classes	Ingredients
Syrupus Calcis	Simple solution and filtering	65 Gm. Lime; 350 Gm. Sugar; Water, to 1000 Cc.
Picis Liquidæ	Maceration and filtering	5 Gm. Tar; 10 Gm. Magnesium Carbonate; 850 Gm. Sugar; Alcohol, Water, to 1000 Cc.
Scillæ	Containing Acetic Acid	450 Cc. Vinegar of Squill; 800 Gm. Sugar; Water, to 1000 Cc.
Ferri Iodidi	Solution involving chemical action, preserved by Sugar	(Containing 5 percent. Ferrous Iodide) 12.5 Gm. Iron Wire; 41.5 Gm. Iodine; 20 Cc. Diluted Hypophosphorous Acid; 600 Gm. Sugar; Distilled Water, to 1000 Gm.
Tolutanus	From tincture	50 Cc. Tincture of Tolu; 10 Gm. Magnesium Carbonate; 820 Gm. of Sugar; Water, to 1000 Cc.
Sarsaparillæ Compositus	From fluidextracts	200 Cc. Fluidextract of Sarsaparilla; 15 Cc. Fluidextract of Glycyrrhiza; 15 Cc. Fluidextract of Senna; 650 Gm. Sugar; 0.2 Cc. Oil of Sassafras; 0.2 Cc. Oil of Anise; 0.2 Cc. Oil of Gaultheria; Water, to 1000 Cc.
Zingiberis	From fluidextract	30 Cc. Fluidextract of Ginger; 10 Gm. Magnesium Carbonate; 820 Gm. Sugar; Alcohol, Water, to 1000 Cc.

Unofficial Syrups

Name	Ingredients	Method of Preparation
Syrupus Allii. U. S. P. 1890	200 Gm. Fresh Garlic, sliced and bruised; 800 Gm. Sugar; Diluted Acetic Acid to make 1000 Cc.	Macerate the Garlic in 300 Cc. Diluted Acetic Acid during four days, express, mix residue with 200 Cc. more of the Acid, again express, and filter mixed liquids. Dissolve the Sugar in the filtrate and add enough Acid to measure 1000 Cc.
Althææ. U. S. P. 1890	50 Gm. Althæa, cut; 30 Cc. Alcohol; 100 Cc. Glycerin; 700 Gm. Sugar; Water to make 1000 Cc.	Macerate the Washed Althæa in 400 Cc. of Water, to which the Alcohol has been added, during one hour, stirring frequently, and then strain without expression. Dissolve the Sugar in the strained liquid, by agitation, add the Glycerin and enough Water to measure 1000 Cc.
Aromaticus. Br.	250 Cc. Tincture of Orange; 250 Cc. Cinnamon Water; 500 Cc. Syrup	Mix the Tincture and Cinnamon Water, add a little powdered talc, filter, and add the Syrup
Cascaræ Aromaticus. Br.	400 Cc. Liquid Extract of Cascara Sagrada; 100 Cc. Tincture of Orange; 50 Cc. Alcohol; 150 Cc. Cinnamon Water; 300 Cc. Syrup	Mix them
Chloral. Br.	91.43 Gm. Chloral Hydrate; 93.75 Cc. Distilled Water; Syrup to make 500 Cc.	Dissolve the Chloral Hydrate in the Distilled Water, and add enough Syrup to make 500 Cc.
Codeinæ. Br.	4.57 Gm. Codeine Phosphate; 12.5 Cc. Distilled Water; 987.5 Cc. Syrup	Dissolve the Codeine Phosphate in the Distilled Water, add the Syrup, and mix
Ferri Phosphatis. Br.	8.6 Gm. Iron Wire; 62.5 Cc. Phosphoric Acid (66.3 percent.); 700 Cc. Syrup; Distilled Water to make 1000 Cc.	Dissolve the Iron Wire in the Phosphoric Acid, previously diluted with an equal volume of Distilled Water, filter the Solution into the Syrup, and add Distilled Water to make 1000 Cc.
Glucosi. Br.	25 Gm. Liquid Glucose; 50 Gm. Syrup	Mix with the aid of gentle heat
Hemidesmi. Br.	100 Gm. Hemidesmus Root, bruised; 700 Gm. Sugar; Distilled Water to make 1050 Gm.	Infuse the drug in 500 Cc. of boiling Water during four hours and strain. Allow the liquid to become clear by settling, and dissolve the Sugar in the clear liquid with the aid of a gentle heat

Unofficial Syrups—*Continued*

Name and Method of Preparation	Sub-Classes	Ingredients
Syrupus Hypophosphitum cum Ferro. U. S. P. 1890	10 Gm. Ferrous Lactate; 10 Gm. Potassium Citrate; Syrup of Hypophosphites to make 1000 Cc.	Rub the Ferrous Lactate and Potassium Citrate with a little of the Syrup until dissolved, and add enough of the Syrup to make 1000 Cc.
Limonis. Br.	20 Gm. fresh, grated Lemon Peel; Alcohol, a sufficient quantity; 500 Cc. Lemon Juice; 760 Gm. Sugar	Macerate the Lemon Peel in enough Alcohol to measure 40 Cc., during seven days, and filter. Dissolve the Sugar in the Lemon Juice with the aid of gentle heat, and when the syrup is cold add to it the Alcoholic solution and mix
Rhœados. Br.	260 Gm. Red-Poppy Petals; 720 Gm. Sugar; 50 Cc. Alcohol; Distilled Water to make 1160 Gm.	Infuse the Red-Poppy Petals in 400 Cc. of heated Water, and afterwards allow it to stand for twelve hours, stirring frequently, strain, dissolve the Sugar in the liquid, add the Alcohol, and enough Distilled Water to make 1160 Gm.
Rubi Idæi. U. S. P. 1890	Fresh, ripe Raspberries; Sugar, a sufficient quantity	Crush the Raspberries and allow them to stand at about 20° C. (68° F.) until the filtered juice will mix clear with half its volume of alcohol. Then separate the juice, filter, and for every 40 parts of filtrate add 60 parts of Sugar, heat the mixture to boiling, strain, and preserve in well-stoppered bottles

SYRUPUS. U.S. Syrup

	Metric	Old form
* **Sugar,** in dry crystalline granules	850 Gm.	7 lbs. 1½ oz. av.
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	8 pints

Dissolve the Sugar, with the aid of heat, in 450 Cc. [old form 58 fl. oz.] of Distilled Water, raise the temperature to the boiling point, strain the liquid, and pass enough Distilled Water through the strainer to make the product, when cold, measure 1000 Cc. [old form 8 pints]. Mix thoroughly.

Syrup may also be prepared in the following manner:

Press down into the neck of a percolator of suitable size a pledget of purified cotton, not too tightly, in such a manner that the cotton shall nearly fill the neck of the percolator, and moisten it with a few drops of Distilled Water; introduce the Sugar into the percolator, make its surface level without shaking or jarring, then carefully pour upon it 450 Cc. [old form 58 fl. oz.] of Distilled Water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Return the first portions of the percolate until it runs through clear, and when all the liquid has passed, follow it by Distilled Water, added in portions, so that all the Sugar may be dissolved, and the product measure 1000 Cc. [old form 8 pints]. Mix thoroughly.

Syrup thus prepared has a specific gravity of about 1.313 at 25° C. (77° F.).

SYRUPUS ACACIÆ. U.S. Syrup of Acacia

	Metric	Old form
* **Acacia,** in selected pieces	100 Gm.	3 oz. av. 148 gr.
Sugar	800 Gm.	26 oz. av. 309 gr.
Distilled Water	430 Cc.	13 fl. oz. 365 min.
To make	1000 Cc.	2 pints

Introduce the Acacia into an enamelled or porcelain dish, add the Distilled Water, and stir occasionally until the Acacia is dissolved; then, having added the Sugar, place the dish on a water-bath and apply heat, gradually increasing the temperature, and stirring from time to time until the Sugar is dissolved. Strain the Syrup, if necessary, and add sufficient Distilled Water to make the product measure 1000 Cc. [old form 2 pints].

Syrup of Acacia should be made in small quantities, and stored in small, tightly stoppered bottles, in a cool place.

SYRUPUS ACIDI CITRICI. U.S. Syrup of Citric Acid

	Metric	Old form
* **Citric Acid**	10 Gm.	146 grains
Distilled Water	10 Cc.	2½ fl. dr.
Tincture of Fresh Lemon Peel	10 Cc.	2½ fl. dr.
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Citric Acid in the Distilled Water and mix the solution with 500 Cc. [old form 1 pint] of Syrup, then add the Tincture of Fresh Lemon Peel, and lastly enough Syrup to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

SYRUPUS ACIDI HYDRIODICI. U.S. Syrup of Hydriodic Acid

A syrupy liquid containing about 1 percent., by weight, of absolute Hydriodic Acid [$HI = 126.9$], or about 1.19 Gm. in 100 Cc.

	Metric	Old form
* **Diluted Hydriodic Acid**	100 Gm.	3 fl. oz. 3 fl. dr.
Water	300 Gm.	11 fl. oz. 2 fl. dr.
Syrup	600 Gm.	17 fl. oz. 3 fl. dr.
To make	1000 Gm.	2 pints

Mix them.

(For tests and comments, see Part III.)

SYRUPUS AMYGDALÆ. U.S. Syrup of Almond

	Metric	Old form
* **Spirit of Bitter Almond**	10 Cc.	154 minims
Orange Flower Water	100 Cc.	3 fl. oz. 96 min.
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix them.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS AURANTII. U.S. Syrup of Orange

	Metric	Old form
* **Tincture of Sweet Orange Peel**	50 Cc.	1 fl. oz. 288 min.
Citric Acid	5 Gm.	73 grains
Magnesium Carbonate	10 Gm.	146 grains
Sugar	820 Gm.	27 oz. av. 163 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Magnesium Carbonate in a mortar with the Tincture, add gradually 400 Cc. [old form 12 fl. oz. 384 min.] of Water, filter, and add sufficient Water through the filter to obtain 450 Cc. [old form 14½ fl. oz.] of filtrate; in this dissolve the Citric Acid and Sugar by agitation without heat, and add sufficient Water to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

SYRUPUS AURANTII FLORUM. U.S. Syrup of Orange Flowers

	Metric	Old form
* **Sugar**	850 Gm.	28 oz. av. 164 gr.
Orange Flower Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Sugar in 450 Cc. [old form 14½ fl. oz.] of Orange Flower Water by agitation, without heat, add enough Orange Flower Water to make the product measure 1000 Cc. [old form 2 pints], and mix thoroughly.

Syrup of Orange Flowers may also be prepared in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus.* Pour 450 Cc. [old form 14½ fl. oz.] of Orange Flower Water upon the Sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by Orange Flower Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

SYRUPUS CALCII LACTOPHOSPHATIS. U.S. Syrup of Calcium Lactophosphate

	Metric	Old form
* **Precipitated Calcium Carbonate**	25 Gm.	365 grains
Lactic Acid	60 Cc.	1 fl. oz. 442 min.
Phosphoric Acid	36 Cc.	1 fl. oz. 73 min.
Orange Flower Water	50 Cc.	1 fl. oz. 288 min.
Sugar	725 Gm.	24 oz. av. 88 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

To the Lactic Acid mixed with 100 Cc. [old form 3 fl. oz. 96 min.] of Water and contained in a capacious mortar, gradually add the Calcium Carbonate, in portions, stirring until it is dissolved. Then add the Phosphoric Acid, diluted with 50 Cc. [old form 1 fl. oz. 300 min.] of Water, and triturate until the precipitate first formed is dissolved. Add 100 Cc. [old form 3 fl. oz. 96 min.] of Water, and filter, rinsing the mortar with 50 Cc. [old form 1 fl. oz. 300 min.] of Water, and passing the rinsings through the filter. To the mixed filtrates add the Orange Flower Water, and, having added the Sugar, dissolve it by agitation, without heat, and strain. Lastly, pass enough Water through the strainer to make the product measure 1000 Cc. [old form 2 pints], and mix thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS CALCIS. U.S. Syrup of Lime. Syrup of Calcium Hydroxide

	Metric	Old form
* **Lime**	65 Gm.	2 oz. av. 74 gr.
Sugar	350 Gm.	11 oz. av. 300 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Slake the Lime by the addition of 35 Cc. [old form 1 fl. oz. 60 min.] of Water with the aid of heat, then mix it and the Sugar thoroughly in a mortar, so as to form a homogeneous powder; add the mixture to 500 Cc. [old form 1 pint] of boiling Water, contained in a bright copper or tinned-iron vessel, and boil for five minutes, constantly stirring. Dilute the liquid with sufficient Water to make it measure 950 Cc. [old form 31 fl. oz.], and filter through white paper, closely covering the funnel during filtration. Then add through the filter enough Water to make the product measure 1000 Cc. [old form 2 pints], and mix thoroughly.

Keep the Syrup in well-stoppered bottles.

(For tests and comments, see Part III.)

SYRUPUS FERRI IODIDI. U.S. Syrup of Ferrous Iodide

A syrupy liquid containing about 5 percent., by weight, of Ferrous Iodide [$FeI_2 = 307.30$], or about 6.74 Gm. in 100 Cc.

	Metric	Old form
* **Iron**, in the form of fine, bright wire, and cut into small pieces	12.5 Gm.	246 gr.
Iodine	41.5 Gm.	1 oz. av. 380 gr.
Diluted Hypophosphorous Acid	20.0 Cc.	414 minims
Sugar	600.0 Gm.	26 oz. av. 428 gr.
Distilled Water, a sufficient quantity,		
To make	1000 Gm.	2 pints

Introduce the Iron into a flask of thin glass, having a capacity of about 500 Cc. [old form 1 pint], add to it 150 Cc. [old form 6½ fl. oz.] of Distilled Water, and afterwards the Iodine. Shake the mixture occasionally, checking the reaction, if necessary, by the affusion of cold water, and, when the solution has acquired a greenish color, and has lost the odor of Iodine, heat it to boiling and add at once 50 Gm. [old form 2 oz. av. 111 gr.] of the Sugar; when this has dissolved, filter the solution into the remainder of the Sugar contained in a porcelain dish. Rinse the flask and Iron Wire with 125 Cc. [old form 5 fl. oz.] of Distilled Water and pass the washings through the filter into the Sugar. Stir the mixture with a porcelain or wooden spatula, heating the liquid on a water-bath until complete solution is effected, and, having passed the syrup through a clean muslin strainer into a tared bottle, add the Diluted Hypophosphorous Acid, and sufficient Distilled Water to make the product weigh 1000 Gm. [old form, or measure, 2 pints].

(For tests and comments, see Part III.)

SYRUPUS FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Syrup of the Phosphates of Iron, Quinine and Strychnine

[Easton's Syrup]

	Metric	Old form
* **Glycerite of the Phosphates of Iron, Quinine and Strychnine**	250 Cc.	8 fl. oz.
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix them. Strain, if necessary.

Average dose.—1 fluidrachm (4 Cc.).

SYRUPUS HYPOPHOSPHITUM. U.S. Syrup of Hypophosphites

	Metric	Old form
* **Calcium Hypophosphite**	45 Gm.	1 oz. av. 220 gr.
Potassium Hypophosphite	15 Gm	219 grains
Sodium Hypophosphite	15 Gm.	219 grains
Diluted Hypophosphorus Acid	2 Gm.	30 minims
Sugar	650 Gm.	21 oz. av. 305 gr.
Tincture of Fresh Lemon Peel	5 Cc.	77 minims
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Hypophosphites with 450 Cc. [old form 14½ fl. oz.] of Water, until they are dissolved, add the Tincture of Fresh Lemon Peel, and the Hypophosphorous Acid, and filter the liquid. In the filtrate dissolve the Sugar by agitation, without heat, and add enough Water, through the filter, to make the product measure 1000 Cc. [old form 2 pints]. Strain, if necessary.

Syrup of Hypophosphites may also be prepared in the following manner :

Prepare a percolator or funnel in the manner described under *Syrupus.* Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS. U.S. Compound Syrup of Hypophosphites

	Metric	Old form
* **Calcium Hypophosphite**	35.00 Gm.	1 oz. av. 74 gr.
Potassium Hypophosphite	17.50 Gm.	255 grains
Sodium Hypophosphite	17.50 Gm.	255 grains
Ferric Hypophosphite	2.25 Gm.	33 grains
Manganese Hypophosphite	2.25 Gm.	33 grains
Quinine	1.10 Gm.	16 grains
Strychnine	0.115 Gm.	1$\frac{7}{10}$ grains
Sodium Citrate	3.75 Gm.	56 grains
Diluted Hypophosphorous Acid	15.00 Cc.	230 minims
Sugar	775.00 Gm.	25 oz. av. 90 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Rub the Ferric and Manganese Hypophosphites with the Sodium Citrate, add 30 Cc. [old form 460 min.] of Water and warm the mixture for a few minutes, until a clear greenish solution is obtained. Dissolve the Calcium, Potassium, and Sodium Hypophosphites in 400 Cc. [old form 12 fl. oz., 384 min.] of Water to which 5 Cc. [old form 77 min.] of Diluted Hypophosphorous Acid has previously been added; then dissolve the Quinine and Strychnine in 30 Cc. [old form 460 min.] of Water with the aid of 10 Cc. [old form 154 min.] of Diluted Hypophosphorous Acid, and finally dissolve the Sugar, with agitation, in these solutions, previously mixed.

Strain the Syrup, if necessary, and add sufficient Water, through the strainer, to make the product measure 1000 Cc. [old form 2 pints].

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS IPECACUANHÆ. U.S. Syrup of Ipecac

	Metric	Old form
* **Fluidextract of Ipecac**	70 Cc.	2 fl. oz. 115 min.
Acetic Acid	10 Cc.	154 minims
Glycerin	100 Cc.	3 fl. oz. 96 min.
Sugar	700 Gm.	23 oz. av. 160 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dilute the Fluidextract of Ipecac with 300 Cc. [old form 9 fl. oz. 288 min.] of Water to which the Acetic Acid has previously been added, and mix them thoroughly by shaking; set the liquid aside in a cool place for twenty-four hours. Then filter, and pass enough Water through the filter to obtain 450 Cc. [old form 14½ fl. oz.] of filtrate. To this liquid add the Glycerin, dissolve the Sugar in the mixture, and add enough Water to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly, and strain, if necessary.

Syrup of Ipecac may also be prepared in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus.*

Mix the filtrate obtained as directed in the preceding formula with the Glycerin, pour the mixture upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— { Expectorant, 15 minims (1 Cc.).
Emetic, 4 fluidrachms (15 Cc.).

SYRUPUS KRAMERIÆ. U.S. Syrup of Krameria

	Metric	Old form
* **Fluidextract of Krameria**	450 Cc.	14 fl. oz. 3 fl. dr.
Syrup	550 Cc.	17 fl. oz. 5 fl. dr.
To make	1000 Cc.	2 pints

Mix them.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS LACTUCARII. U.S. Syrup of Lactucarium

	Metric	Old form
* **Tincture of Lactucarium**	100 Cc.	3 fl. oz. 96 min.
Glycerin	200 Cc.	6 fl. oz. 192 min.
Citric Acid	1 Gm.	15 grains
Orange Flower Water	50 Cc.	1 fl. oz. 288 min.
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Tincture of Lactucarium with the Glycerin, add the Orange Flower Water in which the Citric Acid has been previously dissolved, and filter, if necessary. Finally, add a sufficient quantity of Syrup to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS PICIS LIQUIDÆ. U.S. Syrup of Tar

	Metric	Old form
***Tar**	5 Gm.	73 grains
Alcohol	50 Cc.	1 fl. oz. 288 min.
Magnesium Carbonate	10 Gm.	146 grains
Sugar	850 Gm.	28 oz. av. 164 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Tar intimately, in a mortar, with 10 Gm. [old form 146 gr.] of clean white sand, add 100 Cc. [old form 3 fl. oz. 96 min.] of Water, and, after kneading the mass thoroughly with the pestle, pour off the Water and throw it away. Treat the residue with the Alcohol, and, when the Tar is dissolved, add the Magnesium Carbonate and 50 Gm. [old form 1 oz. av. 293 gr.] of Sugar, and after thorough trituration add 400 Cc. [old form 12 fl. oz. 384 min.] of Water; stir the mixture occasionally during two hours, and filter. Dissolve the remainder of the Sugar in the clear filtrate by gentle heat, strain, and add sufficient Water to make the product measure 1000 Cc. [old form 2 pints].

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS PRUNI VIRGINIANÆ. U.S. Syrup of Wild Cherry

	Metric	Old form
***Wild Cherry,** in No. 20 powder	150 Gm.	5 oz. av.
Sugar	700 Gm.	23 oz. av. 160 gr.
Glycerin	150 Cc.	4 fl. oz. 384 min.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Wild Cherry with a sufficient quantity of Water, and macerate for twenty-four hours in a covered vessel; introduce the Glycerin into a graduated receiving bottle; pack the Wild Cherry firmly in a cylindrical percolator, and gradually pour Water upon it; continue the percolation (shaking the percolate occasionally with the Glycerin), until the liquid measures 450 Cc. [old form 14½ fl. oz.]. Dissolve the Sugar in the liquid by agitation, without heat, strain, and pass enough Water through the strainer to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Syrup of Wild Cherry may also be prepared in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus.* Pour the percolate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS RHEI. U.S. Syrup of Rhubarb

	Metric	Old form
***Fluidextract of Rhubarb**	100 Cc.	3 fl. oz. 96 min.
Spirit of Cinnamon	4 Cc.	1 fl. dr.
Potassium Carbonate	10 Gm.	146 grains
Water	50 Cc.	1 fl. oz. 288 min.
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Spirit of Cinnamon with the Fluidextract of Rhubarb, and add to it the Potassium Carbonate previously dissolved in the Water, and lastly enough Syrup to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS RHEI AROMATICUS. U.S. Aromatic Syrup of Rhubarb

	Metric	Old form
* **Aromatic Tincture of Rhubarb**	150 Cc.	4 fl. oz. 384 min.
Potassium Carbonate	1 Gm.	15 grains
Syrup	850 Cc.	27 fl. oz. 96 min.
To make	1000 Cc.	2 pints

Dissolve the Potassium Carbonate in the Aromatic Tincture of Rhubarb. Filter, if necessary, and add sufficient Syrup to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

SYRUPUS ROSÆ. U.S. Syrup of Rose

	Metric	Old form
* **Fluidextract of Rose**	125 Cc.	4 fl. oz.
Diluted Sulphuric Acid	10 Cc.	154 minims
Sugar	750 Gm.	25 oz. av.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Fluidextract of Rose and Diluted Sulphuric Acid with 300 Cc. [old form 9 fl. oz. 288 min.] of Water ; after allowing the mixture to stand two hours, filter, and dissolve the Sugar in the clear filtrate, by agitation. Finally, add a sufficient quantity of Water to make the product measure 1000 Cc. [old form 2 pints]. Strain, if necessary.

SYRUPUS RUBI. U.S. Syrup of Rubus

	Metric	Old form
* **Fluidextract of Rubus**	250 Cc.	8 fl. oz.
Syrup	750 Cc.	24 fl. oz.
To make	1000 Cc.	2 pints

Mix them.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS SARSAPARILLÆ COMPOSITUS. U.S. Compound Syrup of Sarsaparilla

	Metric	Old form
* **Fluidextract of Sarsaparilla**	200.0 Cc.	6½ fl. oz.
Fluidextract of Glycyrrhiza	15.0 Cc.	½ fl. oz.
Fluidextract of Senna	15.0 Cc.	½ fl. oz.
Sugar	650.0 Gm.	21 oz. av. 305 gr.
Oil of Sassafras	0.2 Cc.	4 drops
Oil of Anise	0.2 Cc.	4 drops
Oil of Gaultheria	0.2 Cc.	4 drops
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Add the Oils (equivalent to about *four drops* each) to the mixed Fluidextracts and shake the liquid thoroughly. Then add enough

Water to make up the volume to 600 Cc. [old form 19 fl. oz.], and mix well. Set the mixture aside for one hour, and then filter it. Dissolve the Sugar in the filtrate with the aid of a gentle heat, allow the liquid to cool, strain, and add enough Water, through the strainer, to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 4 fluidrachms (16 Cc.).

SYRUPUS SCILLÆ. U.S. Syrup of Squill

	Metric	Old form
***Vinegar of Squill**	**450 Cc.**	14½ fl. oz.
Sugar	**800 Gm.**	26 oz. av. 309 gr.
Water, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Dissolve the Sugar in the Vinegar of Squill with the aid of a gentle heat, then strain, and, when the strained liquid is cold, add enough Water, through the strainer, to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 30 minims (2 Cc.).

SYRUPUS SCILLÆ COMPOSITUS. U.S. Compound Syrup of Squill

[HIVE SYRUP]

	Metric	Old form
***Fluidextract of Squill**	**80 Cc.**	2 fl. oz. 4½ fl. dr.
Fluidextract of Senega	**80 Cc.**	2 fl. oz. 4½ fl. dr.
Antimony and Potassium Tartrate	**2 Gm.**	29 grains
Purified Talc	**20 Gm.**	292 grains
Sugar	**750 Gm.**	25 oz. av.
Water, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix the Fluidextracts, evaporate them, in a tared dish, on a water-bath, to 100 Gm. [old form 3 oz. av. 148 gr.], and mix the residue with 350 Cc. [old form 11 fl. oz.] of Water. When the mixture is cold, incorporate with it, intimately, the Purified Talc, filter, pass enough Water through the filter to obtain 400 Cc. [old form 12 fl. oz. 6½ fl. dr.] of clear filtrate, and add to this the Antimony and Potassium Tartrate previously dissolved in 25 Cc. [old form 6½ fl. dr.] of hot Water. Dissolve the Sugar in this liquid by agitation, without heat, strain, and add enough Water, through the strainer, to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Compound Syrup of Squill may also be prepared in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the filtrate obtained as directed in the preceding formula, and mixed with the solution of Antimony and Potassium Tartrate, upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 30 minims (2 Cc.).

SYRUPUS SENEGÆ. U.S. Syrup of Senega

	Metric	Old form
***Fluidextract of Senega**	200 Cc.	6 fl. oz. 192 min.
Syrup	800 Cc.	25 fl. oz. 288 min.
To make	1000 Cc.	2 pints

Mix them.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS SENNÆ. U.S. Syrup of Senna

	Metric	Old form
***Fluidextract of Senna**	250 Cc.	8 fl. oz.
Oil of Coriander	5 Cc.	77 minims
Syrup, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Oil of Coriander with the Fluidextract of Senna and add a sufficient quantity of Syrup to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 1 fluidrachm (4 Cc.).

SYRUPUS TOLUTANUS. U.S. Syrup of Tolu

	Metric	Old form
***Tincture of Tolu**	50 Cc.	1 fl. oz. 288 min.
Magnesium Carbonate	10 Gm.	146 grains
Sugar	820 Gm.	27 oz. av. 163 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Rub the Tincture of Tolu, in a mortar, with the Magnesium Carbonate and 60 Gm. [old form 2 oz. av.] of the Sugar. Then gradually add 450 Cc. [old form 14½ fl. oz.] of Water, with constant trituration, and filter. Dissolve the remainder of the Sugar in the clear filtrate, with the aid of a gentle heat, strain the Syrup while hot, and add a sufficient quantity of Water to make the product measure 1000 Cc. [old form 2 pints].

Syrup of Tolu may also be made in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus.* Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 4 fluidrachms (16 Cc.).

SYRUPUS ZINGIBERIS. U.S. Syrup of Ginger

	Metric	Old form
***Fluidextract of Ginger**	30 Cc.	461 minims
Alcohol	20 Cc.	307 minims
Magnesium Carbonate	10 Gm.	146 grains
Sugar	820 Gm.	27 oz. av. 163 gr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Fluidextract of Ginger and the Alcohol, then triturate the liquid in a mortar with the Magnesium Carbonate and 60 Gm. [old form 2 oz. av.] of the Sugar. Then gradually add 450 Cc. [old form 14½ fl. oz.] of Water, with constant trituration, and filter. Dissolve the remainder of the Sugar in the clear filtrate, with the aid of a gentle heat, strain the Syrup while hot, and add a sufficient quantity of Water to make the product measure 1000 Cc. [old form 2 pints].

Syrup of Ginger may also be made in the following manner:

Prepare a percolator or funnel in the manner described under *Syrupus.* Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and when all the liquid has passed, follow it with Water, until the product measures 1000 Cc. [old form 2 pints]. Mix thoroughly.

Average dose.— 4 fluidrachms (16 Cc.).

Mellita *Honeys*

Official honeys are thick liquid preparations closely allied to the syrups, differing merely in the use of honey as a base, instead of syrup. Their advantages over syrups are not very apparent, particularly since of late years the difficulty of obtaining pure honey has greatly increased. *Three* honeys are official.

Official Honeys

Name	Proportions and definition	Preparation
Mel	Commercial Honey	A saccharine secretion deposited in the honeycomb by *Apis mellifera*
Depuratum	Clarified Honey	Heat Honey, mixed with paper-pulp, over a water-bath, remove the scum and strain; then mix with 5 percent. of its weight of Glycerin
Rosæ	120 Cc. Fluidextract of Rose and enough Clarified Honey to make 1000 Gm.	Mix thoroughly

Unofficial Honey

Name	Proportions and definition	Preparation
Mel Boracis. Br.	50 Gm. Borax, in fine powder; 25 Gm. Glycerin; 400 Gm. Clarified Honey	Mix them

MEL DEPURATUM. U.S. Clarified Honey

[Mel Despumatum, Pharm. 1890]

* **Honey,** a convenient quantity
Distilled Water,
Glycerin, each, a sufficient quantity

Mix the Honey intimately with 2 percent. of its weight of paper pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then apply the heat of a water-bath, and as long as any scum rises to the surface, carefully remove this. Finally, add enough Distilled Water to make up the loss incurred by evaporation, strain, and mix the strained liquid with 5 percent. of its weight of glycerin.

Clarified Honey should conform to the tests of purity given under *Mel.*

MEL ROSÆ. U.S. **Honey of Rose**

	Metric	Old form
* **Fluidextract of Rose**	120 Cc.	5 fl. oz.
Clarified Honey, a sufficient quantity,		
To make	1000 Gm.	2 pints

Into a tared vessel introduce the Fluidextract of Rose, then add enough Clarified Honey to make the contents weigh 1000 Gm. [or to measure, old form, 2 pints], and mix thoroughly.

Average dose.— 1 fluidrachm (4 Cc.).

Mucilagines *Mucilages*

The official mucilages are thick, viscid, adhesive liquids, produced by dissolving gum in water, or by extracting with water the mucilaginous principles from vegetable substances. There are *four* official mucilages. *Two* are made without the application of heat, and *two* with heat. The mucilages are all prone to decomposition, and should never be made in larger quantities than can be used immediately.

Official Mucilages

Name	Proportions		Process
Mucilago Acaciæ	340 Gm. Acacia; 330 Gm. Lime Water; Water sufficient to make 1000 Gm.	Without heat	Wash the Acacia with cold water; then add the Lime Water and enough Water to make the mixture weigh 1000 Gm.; agitate until dissolved, and strain
Sassafras Medullæ	2 Gm. Sassafras Pith; Water to make 100 Cc.		Macerate for three hours, and strain without expression
Tragacanthæ	6 Gm. Tragacanth; 18 Gm. Glycerin; Water sufficient to make 100 Gm.	With heat	Mix the Glycerin with 75 Cc. Water, heat to boiling, add the Tragacanth, macerate for twenty-four hours with stirring. Then add enough Water to make the mixture weigh 100 Gm.; strain forcibly through muslin
Ulmi	6 Gm. Elm; Water 100 Cc.		Digest the Elm with the Water, on a water-bath, in a covered vessel, during one hour, then strain

MUCILAGO ACACIÆ. U.S. **Mucilage of Acacia**

	Metric	Old form
* **Acacia,** in small fragments	340 Gm.	12 oz. av. 392 gr.
Lime Water	330 Gm.	11 fl. oz.
Water, a sufficient quantity,		
To make	1000 Gm.	2 pints

Wash the Acacia with cold Water, and allow it to drain. Add the Lime Water to it, and enough Water to make the mixture weigh 1000 Gm. [or measure, old form, 2 pints], agitate or stir it occasionally until the Acacia is dissolved, and strain. Keep the product in well-stoppered, completely filled bottles, in a cool place.

Average dose.— 4 fluidrachms (16 Cc.).

MUCILAGO SASSAFRAS MEDULLÆ. U.S. **Mucilage of Sassafras Pith**

	Metric	Old form
* **Sassafras Pith**	2 Gm.	27 grains
Water	100 Cc.	3 fl. oz.

Macerate the Sassafras Pith in the Water during three hours, and strain without expression. This preparation should be freshly made when wanted.

Average dose.— 4 fluidrachms (16 Cc.).

MUCILAGO TRAGACANTHÆ. U.S. Mucilage of Tragacanth

	Metric	Old form
***Tragacanth**	6 Gm.	90 grains
Glycerin	18 Gm.	½ fl. oz.
Water, a sufficient quantity,		
To make	100 Gm.	about 4 fl. oz.

Mix the Glycerin with 75 Cc. [old form 2½ fl. oz.] of Water in a tared vessel, heat the mixture to boiling, add the Tragacanth, and macerate during twenty-four hours, stirring occasionally. Then add enough Water to make the mixture weigh 100 Gm. [or measure, old form, about 4 fl. oz.], beat it until it has a uniform consistence, and strain it forcibly through muslin.

Average dose.— 4 fluidrachms (16 Cc.).

MUCILAGO ULMI. U.S. Mucilage of Elm

	Metric	Old form
***Elm,** bruised	6 Gm.	82 grains
Water	100 Cc.	3 fl. oz.

Digest the Elm with the Water, on a water-bath, in a covered vessel, during one hour, then strain. This preparation should be freshly made when wanted.

Average dose.— 4 fluidrachms (16 Cc.).

Emulsa *Emulsions*

The U. S. Pharmacopœia of 1890 introduced emulsions as a separate class of preparations; formerly they were included under the general heading of Misturæ. The necessity for differentiation in nomenclature, as preparations of established merit multiply, is apparent. Emulsions are aqueous liquids in which oleaginous substances are suspended by the intervention of gum, yolk of egg, or other viscid matter. Their method of preparation is fully considered under Part V, Extemporaneous liquids. There are *six* official emulsions.

Official Emulsions

Name	Proportions	Description
Emulsum Amygdalæ	60 Gm. Sweet Almond; 10 Gm. Acacia; 30 Gm. Sugar; Water sufficient to make 1000 Cc.	Simple seed emulsion
Asafœtidæ	40 Gm. Asafetida with 1000 Cc. Water	Simple gum-resin emulsion
Chloroformi	40 Cc. Chloroform; 60 Cc. Expressed Oil of Almond; 10 Gm. Tragacanth; Water to make 1000 Cc.	Tragacanth emulsion
Olei Morrhuæ	500 Cc. Cod Liver Oil; 125 Gm. Acacia; 100 Cc. Syrup; 4 Cc. Oil of Gaultheria; Water to make 1000 Cc.	Acacia emulsion
Olei Morrhuæ cum Hypophosphitibus	500 Cc. Cod Liver Oil; 125 Gm. Acacia; 10 Gm. Calcium Hypophosphite; 5 Gm. Potassium Hypophosphite; 5 Gm. Sodium Hypophosphite; 100 Cc. Syrup; 4 Cc. Oil of Gaultheria; Water to make 1000 Cc.	
Olei Terebinthinæ	15 Cc. Rectified Oil of Turpentine; 5 Cc. Expressed Oil of Almond; 25 Cc. Syrup; 15 Gm. Acacia; Water to make 100 Cc.	

Unofficial Emulsion

Name	Proportions	Description
Emulsum Ammoniaci. U. S. P. 1890	40 Gm. Ammoniac, with Water to make 1000 Cc.	Simple gum-resin emulsion
Mistura Ammoniaci. Br.	(See page 304)	

EMULSUM AMYGDALÆ. U. S. Emulsion of Almond

[Milk of Almond]

	Metric	Old form
* **Sweet Almond**	60 Gm.	219 grains
Acacia, in fine powder	10 Gm.	37 grains
Sugar	30 Gm.	109 grains
Water, a sufficient quantity,		
To make	1000 Cc.	8 fl. oz.

Having blanched the Almond, add the Acacia and Sugar, and beat them in a mortar, until they are thoroughly mixed. Then rub the mass with 900 Cc. [old form 7 fl. oz.] of Water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure 1000 Cc. [old form 8 fl. oz]. Mix the whole thoroughly. This Emulsion should be freshly prepared when required.

Average dose.— 4 fluidounces (120 Cc.).

EMULSUM ASAFŒTIDÆ. U.S. Emulsion of Asafetida

[Milk of Asafetida]

	Metric	Old form
* **Asafetida,** in selected tears	40 Gm.	146 grains
Water, a sufficient quantity,		
To make	1000 Cc.	8 fl. oz.

Rub the Asafetida, in a mortar, with 900 Cc. [old form 7 fl. oz.] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and rinse the mortar and strainer with enough Water to make the product measure 1000 Cc. [old form 8 fl. oz.]. Mix the whole thoroughly.

Average dose.— 4 fluidrachms (16 Cc.).

EMULSUM CHLOROFORMI. U.S. Emulsion of Chloroform

	Metric	Old form
* **Chloroform**	40 Cc.	153 minims
Expressed Oil of Almond	60 Cc.	230 minims
Tragacanth, in very fine powder	10 Gm.	37 grains
Water, a sufficient quantity,		
To make	1000 Cc.	8 fl. oz.

Introduce the Tragacanth into a perfectly dry bottle of sufficient capacity, add the Chloroform, and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about 250 Cc. [old form 2 fl. oz.] of Water, and incorporate it by vigorous shaking. Next add the Expressed Oil of Almond, in several portions, shaking after each addition, and when the Oil has been thoroughly emulsified, add enough Water, in divided portions, shaking after each addition, to make the product measure 1000 Cc. [old form 8 fl. oz.].

Average dose.— 2 fluidrachms (8 Cc.).

EMULSUM OLEI MORRHUÆ. U.S. Emulsion of Cod Liver Oil

	Metric	Old form
* **Cod Liver Oil**	500 Cc.	1 pint
Acacia, in fine powder	125 Gm.	4 oz. av. 76 gr.
Syrup	100 Cc.	3 fl. oz. 96 min.
Oil of Gaultheria	4 Cc.	1 fl. dr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Rub the Acacia with the Cod Liver Oil, in a dry mortar, until uniformly mixed, then add at once 250 Cc. [old form 8 fl. oz.] of Water and triturate lightly and rapidly until a thick homogeneous emulsion is produced; to this add the Oil of Gaultheria and the Syrup, with enough Water to make the product measure 1000 Cc. [old form 2 pints], and mix thoroughly.

NOTE.—The Oil of Gaultheria may be replaced, if desired, by a suitable quantity of Oil of Bitter Almond or other suitable flavoring.

Average dose.— 2 fluidrachms (8 Cc.).

EMULSUM OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS. U.S. Emulsion of Cod Liver Oil with Hypophosphites

	Metric	Old form
* **Cod Liver Oil**	500 Cc.	1 pint
Acacia, in fine powder	125 Gm.	4 oz. av. 76 gr.
Calcium Hypophosphite	10 Gm.	146 grains
Potassium Hypophosphite	5 Gm.	73 grains
Sodium Hypophosphite	5 Gm.	73 grains
Syrup	100 Cc.	3 fl. oz. 96 min.
Oil of Gaultheria	4 Cc.	1 fl. dr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Rub the Acacia with the Cod Liver Oil, in a dry mortar, until uniformly mixed, then add at once 250 Cc. [old form 8 fl. oz.] of Water and triturate lightly and rapidly until a thick, homogeneous emulsion is produced, add the Oil of Gaultheria and incorporate thoroughly; dissolve the Hypophosphites in 100 Cc. [old form 3 fl. oz. 96 min.] of Water, mix the solution with the Syrup, and add the liquid gradually to the emulsion with continued trituration. Lastly, add enough Water to make the product measure 1000 Cc. [old form 2 pints], and mix thoroughly.

NOTE.—The Oil of Gaultheria may be replaced, if desired, by a suitable quantity of Oil of Bitter Almond or other suitable flavoring.

Average dose.— 2 fluidrachms (8 Cc.).

EMULSUM OLEI TEREBINTHINÆ. U.S. Emulsion of Oil of Turpentine

	Metric	Old form
* **Rectified Oil of Turpentine**	15 Cc.	1 fl. oz. 96 min.
Expressed Oil of Almond	5 Cc.	192 min.
Syrup	25 Cc.	2 fl. oz.
Acacia, in fine powder	15 Gm.	1 oz. av. 110 gr.
Water, a sufficient quantity,		
To make	100 Cc.	8 fl. oz.

Introduce the Acacia into a perfectly dry bottle of sufficient capacity, add the Rectified Oil of Turpentine and the Expressed Oil of Almond, and shake the bottle thoroughly. Then add about 30 Cc. [old form $2\frac{3}{4}$ fl. oz.] of Water and incorporate it by vigorous shaking. When the Oil has been completely emulsified, add first the Syrup, in several portions, shaking after each addition, and then enough Water, in divided portions, shaking after each addition, to make the product measure 100 Cc. [old form 8 fl. oz.].

Average dose.— 1 fluidrachm (4 Cc.).

Misturæ *Mixtures*

Mixtures, in a properly restricted sense, are aqueous liquid preparations intended for internal use, which contain suspended insoluble substances. The main object in introducing this class into the Pharmacopœia was to secure uniformity in the formulas of certain well-known and largely used preparations. They are not permanent, as a rule, and it is not wise to keep them on hand for any considerable length of time. They belong properly under the head of Extemporaneous Preparations. (See Mixtures, Part V.) There are *four* official mixtures.

Official Mixtures

Name	Proportions	Description
Mistura Cretæ	20 Gm. Compound Chalk Powder; 40 Cc. Cinnamon Water; Water to make 100 Cc.	Mixtures containing insoluble powders in suspension
Ferri Composita	6 Gm. Ferrous Sulphate; 8 Gm. Potassium Carbonate; 18 Gm. Myrrh; 18 Gm. Sugar; 60 Cc. Spirit of Lavender; Rose Water to make 1000 Cc.	
Glycyrrhizæ Composita	30 Gm. Pure Extract of Glycyrrhiza; 50 Cc. Syrup; 30 Gm. Acacia; 120 Cc. Camphorated Tincture of Opium; 60 Cc. Wine of Antimony; 30 Cc. Spirit of Nitrous Ether; Water to make 1000 Cc.	
Rhei et Sodæ	35 Gm. Sodium Bicarbonate; 15 Cc. Fluidextract of Rhubarb; 3 Cc. Fluidextract of Ipecac; 350 Cc. Glycerin; 35 Cc. Spirit of Peppermint; Water to make 1000 Cc.	Mixture not containing insoluble powders in suspension

Unofficial Mixtures[1]

Name	Ingredients	Method of Preparation
Mistura Ammoniaci. Br.	5 Gm. Ammoniacum, in coarse powder; 10 Cc. Syrup of Tolu; 150 Cc. Distilled Water	Form a smooth mixture, by triturating the Ammoniacum with a little Water, and gradually add the remainder of the Distilled Water and Syrup of Tolu
Creosoti. Br.	1 Cc. Creosote; 1 Cc. Spirit of Juniper; 30 Cc. Syrup; Distilled Water to make 480 Cc.	Shake the Creosote with 420 Cc. of Water; add the other ingredients and enough Distilled Water to make 480 Cc.
Guaiaci. Br.	10 Gm. Guaiacum Resin; 10 Gm. Sugar; 1.6 Gm. Tragacanth; 400 Cc. Cinnamon Water	Triturate the Guaiacum Resin with the Sugar and the Tragacanth, and gradually add the Cinnamon Water
Olei Ricini. Br.	75 Cc. Castor Oil; 37.5 Cc. Mucilage of Gum Acacia; 25 Cc. Stronger Orange Flower Water; 62.5 Cc. Cinnamon Water	Add the Castor Oil and the mixed Waters, alternately, to the Mucilage, contained in a mortar, triturating constantly

---

[1] In the British Pharmacopœia (1898) preparations are included in the class Misturæ which should more properly be placed under the head Emulsa.

Unofficial Mixtures—*Continued*

Name	Ingredients	Method of Preparation
Sennæ Composita. Br.	250 Gm. Magnesium Sulphate; 50 Cc. Liquid Extract of Liquorice; 100 Cc. Compound Tincture of Cardamoms; 50 Cc. Aromatic Spirit of Ammonia; Infusion of Senna to make 1000 Cc.	Dissolve the Magnesium Sulphate in 500 Cc. Infusion of Senna, add the other ingredients and enough Infusion of Senna to make 1000 Cc.
Spiritus Vini Gallici. Br.	113 Cc. Brandy; 113 Cc. Cinnamon Water; 14 Gm. Sugar; 2 yolks of eggs	Rub the yolks of eggs and Sugar together; add the Cinnamon Water and Brandy, and mix

MISTURA CRETÆ. U.S. Chalk Mixture

	Metric	Old form
* **Compound Chalk Powder**	20 Gm.	365 grains
Cinnamon Water	40 Cc.	1½ fl. oz.
Water, a sufficient quantity,		
To make	100 Cc.	4 fl. oz.

Rub the Compound Chalk Powder, in a mortar, with the Cinnamon Water and about 20 Cc. [old form 6 fl. dr.] of Water gradually added, to a uniform mixture; transfer this to a graduated vessel, and rinse the mortar with enough Water to make the product measure 100 Cc. [old form 4 fl. oz.]. Mix the whole thoroughly. This preparation should be freshly made when wanted.

Average dose.— 4 fluidrachms (16 Cc.).

MISTURA FERRI COMPOSITA. U.S. Compound Iron Mixture

[Griffith's Mixture]

	Metric	Old form
* **Ferrous Sulphate,** in clear crystals	6 Gm.	11 grains
Myrrh, in small pieces	18 Gm.	33 grains
Sugar	18 Gm.	33 grains
Potassium Carbonate	8 Gm.	15 grains
Spirit of Lavender	60 Cc.	2 fl. dr.
Rose Water, a sufficient quantity,		
To make	1000 Cc.	4 fl. oz.

Rub the Myrrh, Sugar, and Potassium Carbonate, in a mortar, with 700 Cc. [old form 2½ fl. oz.] of Rose Water, at first very gradually added, so that a uniform mixture may result. Transfer this to a graduated vessel, add the Spirit of Lavender, then the Ferrous Sulphate, previously dissolved in about 50 Cc. [old form 1½ fl. dr.] of Rose Water, and, lastly, enough Rose Water to make the product measure 1000 Cc. [old form 4 fl. oz.]. Mix the whole thoroughly. This preparation should be freshly made when wanted.

Average dose.— 4 fluidrachms (16 Cc.).

MISTURA GLYCYRRHIZÆ COMPOSITA. U.S. Compound Mixture of Glycyrrhiza

[Brown Mixture]

	Metric	Old form
* **Pure Extract of Glycyrrhiza**	30 Gm.	1 oz. av.
Syrup	50 Cc.	1½ fl. oz.
Acacia, granulated	30 Gm.	1 oz. av.
Camphorated Tincture of Opium	120 Cc.	3 fl. oz. 7 fl. dr.
Wine of Antimony	60 Cc.	1 fl. oz. 442 min.
Spirit of Nitrous Ether	30 Cc.	460 min.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Rub the Pure Extract of Glycyrrhiza and Acacia, in a mortar, with 500 Cc. [old form 1 pint] of Water, until they are dissolved. Transfer the solution to a graduated vessel containing the other ingredients, and rinse the mortar with enough Water to make the product measure 1000 Cc. [old form 2 pints]. Mix the whole thoroughly.

Average dose.— 2 fluidrachms (8 Cc.).

MISTURA RHEI ET SODÆ. U.S. Mixture of Rhubarb and Soda

	Metric	Old form
* **Sodium Bicarbonate**	35 Gm.	1 oz. av. 74 gr.
Fluidextract of Rhubarb	15 Cc.	230 minims
Fluidextract of Ipecac	3 Cc.	46 minims
Glycerin	350 Cc.	11 fl. oz. 96 min.
Spirit of Peppermint	35 Cc.	1 fl. oz. 1 fl. dr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Sodium Bicarbonate in about 400 Cc. [old form 13 fl. oz.] of Water. Then add the Fluidextracts, the Glycerin, and the Spirit of Peppermint, and, lastly, enough Water to make the product measure 1000 Cc. [old form 2 pints].

Average dose.— 1 fluidrachm (4 Cc.).

Glycerita *Glycerites*

Glycerites are mixtures of medicinal substances with glycerin. Glycerin is a valuable solvent, and one of the principal advantages of the glycerites is that they afford a rapid and simple method of making aqueous solutions of substances which are not otherwise easily soluble. The solutions of phenol, gallic acid, tannic acid, tar, etc., in glycerin are permanent preparations, and they could be made very concentrated if necessary ; the ease with which they can be diluted with water or alcohol, without precipitation, renders such glycerites especially useful at the prescription counter. *Five* glycerites formerly official and *one* new one (Glycerite of the Phosphates of Iron, Quinine and Strychnine) were admitted to the U. S. P. (8th Rev.).

Official Glycerites

Name	Proportion
Glyceritum Acidi Tannici	20 Gm. Tannic Acid ; 80 Gm. Glycerin
Amyli	10 Gm. Starch ; 80 Gm. Glycerin ; 10 Cc. Water. (A translucent jelly)
Boroglycerini	310 Gm. Boric Acid ; 960 Gm. Glycerin
Ferri, Quininæ et Strychninæ Phosphatum	80 Gm. Soluble Ferric Phosphate ; 104 Gm. Quinine ; 0.8 Gm. Strychnine ; 200 Cc. Phosphoric Acid ; 500 Cc. Glycerin ; Water to make 1000 Cc.
Hydrastis	1000 Gm. Hydrastis ; 500 Cc. Glycerin ; Alcohol and Water to make 1000 Cc.
Phenolis	20 Cc. Liquefied Phenol ; 80 Cc. Glycerin

Unofficial Glycerites

Name	Ingredients	Method of Preparation
Glyceritum Aluminis. Br.	20 Gm. Alum; 7.5 Cc. Distilled Water; 120 Cc. Glycerin	Effect solution, warming slightly if necessary, set aside and pour off the clear liquid
Boracis. Br.	20 Gm. Borax; 120 Cc. Glycerin	Triturate together until dissolved
Pepsini. Br.	80 Gm. Pepsin; 10 Cc. Hydrochloric Acid; 525 Cc. Glycerin; Distilled Water to make 875 Cc.	Mix the Acid, Glycerin, and 260 Cc. of the Water, add the Pepsin, and set aside for one week. Then filter and add Distilled Water to filtrate to make 875 Cc.
Plumbi Subacetatis. Br.	100 Gm. Lead Acetate; 70 Gm. Lead Oxide; 400 Cc. Glycerin; 240 Cc. Distilled Water	Mix, boil for fifteen minutes, filter, and evaporate, at a temperature not exceeding 105.5° C. (222° F.), until the product weighs 655 Gm.
Tragacanthæ. Br.	10 Gm. Tragacanth, in powder; 30 Cc. Glycerin; 10 Cc. Distilled Water	Mix the Glycerin and Tragacanth, add the Distilled Water, and triturate until homogeneous
Vitelli. U.S. P. 1890	45 Gm. Fresh Yolk of Egg; 55 Gm. Glycerin	Triturate together, in a mortar, until thoroughly mixed

GLYCERITUM ACIDI TANNICI. U.S. Glycerite of Tannic Acid

	Metric	Old form
***Tannic Acid**	20 Gm.	4 oz. av
Glycerin	80 Gm.	16 oz. av.
To make	100 Gm.	20 oz. av.

Triturate the Tannic Acid with the Glycerin to a smooth paste, transfer this to a porcelain dish, avoiding contact with metallic utensils, and apply the heat of a water-bath, until the Tannic Acid is completely dissolved. Then transfer the solution to a bottle.

Average dose.—15 minims (1 Cc.).

GLYCERITUM AMYLI. U.S. Glycerite of Starch

	Metric	Old form
***Starch**	10 Gm.	290 grains
Water	10 Cc.	5 fl. dr.
Glycerin	80 Gm.	4 fl. oz.

Triturate the Starch with the Water, until a homogeneous mixture is produced. Then gradually add this to the Glycerin, contained in a porcelain dish, and heated to about 140° C. (284° F.). Continue the heat, with constant stirring, keeping it below 144° C. (291.2° F.), until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers.

GLYCERITUM BOROGLYCERINI. U.S. Glycerite of Boroglycerin

	Metric	Old form
***Boric Acid,** in fine powder	310 Gm.	5 oz. av.
Glycerin, a sufficient quantity,		
To make	1000 Gm.	16 oz. av.

Heat 460 Gm. [old form 7 oz. av. 158 gr.] of Glycerin, in a tared porcelain dish, to a temperature not exceeding 150° C. (302° F.), and add the Boric Acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has been reduced to the weight of 500

Gm. [old form 8 oz. av.], add to it 500 Gm. [old form 8 oz. av.] of Glycerin, mix thoroughly, and transfer it to suitable vessels.

GLYCERITUM FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Glycerite of the Phosphates of Iron, Quinine and Strychnine

	Metric	Old form
* **Soluble Ferric Phosphate**	80.0 Gm.	1 oz. av. 146 gr.
Quinine	104.0 Gm.	1 oz. av. 322 gr.
Strychnine	0.8 Gm.	5$\frac{3}{10}$ grains
Phosphoric Acid	200.0 Cc.	3 fl. oz. 96 min.
Glycerin	500.0 Cc.	8 fl. oz.
Water, a sufficient quantity,		
To make	1000 Cc.	1 pint

Heat the Soluble Ferric Phosphate with 200 Cc. [old form 6 fl. oz. 192 min.] of Water, in a porcelain dish, at a temperature not exceeding 70° C. (158° F.), until it is dissolved. Then add the Phosphoric Acid with the Strychnine and Quinine and sufficient Water to make the product measure 500 Cc. [old form 8 fl. oz.], and stir until solution is effected. Mix the solution with the Glycerin, and filter if necessary.

Average dose.—15 minims (1 Cc.).

GLYCERITUM HYDRASTIS. U.S. Glycerite of Hydrastis

	Metric	Old form
* **Hydrastis,** in No. 60 powder	1000 Gm.	25 oz. av.
Glycerin	500 Cc.	12 fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	24 fl. oz.

Moisten the Hydrastis with 350 Cc. [old form 8½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Hydrastis is practically exhausted. Remove nearly all of the Alcohol by distillation or evaporation, pour the thick concentrated liquid into 500 Cc. [old form 12 fl. oz.] of ice-cold Water, and set it aside, in a cold place, for twenty-four hours. Then filter, pass enough cold Water through the filter to make the filtrate measure 500 Cc. [old form 12 fl. oz.], add the Glycerin, and mix thoroughly.

Average dose.—30 minims (2 Cc.).

GLYCERITUM PHENOLIS. U.S. Glycerite of Phenol

[Glyceritum Acidi Carbolici, Pharm. 1890]

	Metric	Old form
* **Liquefied Phenol**	20 Cc.	2 fl. oz.
Glycerin	80 Cc.	8 fl. oz.
To make	100 Cc.	10 fl. oz.

Add the Liquefied Phenol to the Glycerin, and stir until thoroughly mixed.

Average dose.—5 minims (0.3 Cc.).

CHAPTER XXIII

ALCOHOLIC SOLUTIONS

Spiritus *Spirits*

SPIRITS from a pharmaceutical point of view are simply *alcoholic* solutions of volatile substances. Like the medicated waters, the active ingredient may be solid, liquid, or gaseous. None are made by percolation, but they are officially prepared in five ways: 1. By simple solution. 2. By solution with maceration. 3. By gaseous solution. 4. By chemical reaction. 5. By distillation. The number of official spirits is *twenty.*

1. **By Simple Solution.**—This is the most usual method of making spirits; of the official preparations of this class, *fourteen*, or about three-fourths of the whole number, are prepared in this way, while *eight* of the fourteen are merely solutions of volatile oils in alcohol of different strengths, without any other addition. No skill is required to make these, but a great deal of conscientious care must be used in the selection of the volatile oils, that they be of the best quality, and recently distilled. Filtration is usually unnecessary.

Official Spirits made by Simple Solution

Name	Proportion	Use and Dose
Spiritus Ætheris	325 Cc. Ether; 675 Cc. Alcohol	Stimulant fʒi (4 Cc.)
Ætheris Compositus	325 Cc. Ether; 650 Cc. Alcohol; 25 Cc. Ethereal Oil	Anodyne, stimulant, fʒi (4 Cc.)
Ammoniæ Aromaticus	34 Gm. Ammonium Carbonate; 90 Cc. Ammonia Water; 10 Cc. Oil of Lemon; 1 Cc. Oil of Lavender Flowers; 1 Cc. Oil of Nutmeg; 700 Cc. Alcohol; Distilled Water to make 1000 Cc.	Antacid, 30♏ (2 Cc.)
Amygdalæ Amaræ	10 Cc. Oil of Bitter Almond; 800 Cc. Alcohol; Distilled Water to make 1000 Cc.	Flavor, 8♏ (0.5 Cc.)
Anisi	100 Cc. Oil of Anise; 900 Cc. Alcohol.	Carminative, fʒi (4 Cc.)
Aurantii Compositus	200 Cc. Oil of Orange Peel; 50 Cc. Oil of Lemon; 20 Cc. Oil of Coriander; 5 Cc. Oil of Anise; Alcohol sufficient to make 1000 Cc.	Flavor. Used in making Aromatic Elixir
Camphoræ	100 Gm. Camphor; Alcohol sufficient to make 1000 Cc.	Stimulant, 5 to 60♏ (0.3 to 4 Cc.)
Chloroformi	60 Cc. Chloroform; 940 Cc. Alcohol	Sedative, stimulant, 10 to 60♏ (0.6 to 4 Cc.)
Cinnamomi	100 Cc. Oil of Cinnamon; 900 Cc. Alcohol	Stimulant, 5 to 15♏ (0.3 to 1 Cc.)
Gaultheriæ	50 Cc. Oil of Gaultheria; 950 Cc. Alcohol	Flavor, 5 to 15♏ (0.3 to 1 Cc.)
Glycerylis Nitratis	1 Gm. Glyceryl Trinitrate to 99 Gm. Alcohol	Cardiac stimulant, 1 to 2♏ (0.05 to 0.1 Cc.)
Juniperi	50 Cc. Oil of Juniper; 950 Cc. Alcohol	Stimulant, diuretic, fʒi to fʒii (4 Cc. to 8 Cc.)
Juniperi Compositus	8 Cc. Oil of Juniper; 1 Cc. Oil of Caraway; 1 Cc. Oil of Fennel; 1400 Cc. Alcohol; Water, sufficient to make 2000 Cc.	Stimulant, diuretic, fʒii to fʒiv (8 Cc. to 16 Cc.)
Lavandulæ	50 Cc. Oil of Lavender Flowers; 950 Cc. Alcohol	Flavor, fʒss to fʒi (2 Cc. to 4 Cc.)

2. **Solution with Maceration.**—This method is employed in the Pharmacopœia when it is desirable to solely introduce the coloring matter of the drug into the preparation. This has been done in order to bestow individuality, and in deference to popular feeling in favor of high colors. It is very doubtful whether either object is worthy of consideration.

Official Spirits made by Solution with Maceration

Name	Preparation	Use and Dose
Spiritus Menthæ Piperitæ	100 Cc. Oil of Peppermint; 10 Gm. Peppermint, bruised; Alcohol to make 1000 Cc.	Carminative, 10 to 20♏ (0.6 to 1.2 Cc.)
Menthæ Viridis	100 Cc. Oil of Spearmint; 10 Gm. Spearmint, bruised; Alcohol to make 1000 Cc.	Carminative, 10 to 20♏ (0.6 Cc. to 1.2 Cc.)

3. **By Gaseous Solution.**—The only official representative of this class is the Spirit of Ammonia, and it is the only preparation in the Pharmacopœia that is made by converting a gaseous aqueous solution into a gaseous alcoholic solution by expelling the dissolved gas from water by heat and causing it to be redissolved in alcohol. The spirit is assayed by the use of half-normal volumetric solution of sulphuric acid, and brought to the standard strength of 10 percent. of gaseous ammonia.

Official Spirit made by Gaseous Solution

Name	Preparation	Use and Dose
Spiritus Ammoniæ	Stronger Water of Ammonia; Heat; Alcohol, 10 percent. Gas; assay.	Stimulant, 5 to 30♏ (0.3 to 2 Cc.)

4. **By Chemical Reaction.**—There is but *one* spirit in the Pharmacopœia made by chemical reaction, and that is Spirit of Nitrous Ether. As explained elsewhere (Part IV.), it is the product of the action of nitric acid upon alcohol, and is an alcoholic solution of ethyl nitrite.

Official Spirit made by Chemical Reaction

Name	Preparation	Use and Dose
Spiritus Ætheris Nitrosi	About 4 percent. Ethyl Nitrite	Diaphoretic, diuretic, fʒss to fʒi (2 Cc. to 4 Cc.)

5. **By Distillation.**—This method of making spirits is the oldest and in many respects the best in use. When the desirable volatile principles which are present in the preparation when finished can be vaporized at the temperature of boiling alcohol or diluted alcohol, distillation is preferred. In the case of liquids containing some oils of high boiling points, it is necessary to obtain the oils by distillation with water and afterwards mix the distillate with alcohol. It is certain, however, that spirits made by the admixture of volatile oils with alcohol, as in Class 1, are often deficient in the more delicate

and volatile principles found in the substances from which they are distilled. These principles are often soluble in water and insoluble in the oil, and necessarily in the distillation of the volatile oil with water they must be found in the water, and are absent from the oil. This is well illustrated in the case of oil of neroli and orange flower water; the latter has much the more fragrant odor when compared with the oil obtained in the same distillation from the same flowers and subjected to the same temperature. The only official spirits made by distillation are *two* in number,—Whisky and Brandy.

Official Spirits made by Distillation

Name	Preparation	Use and Dose
Spiritus Frumenti	By distillation from fermented grain; must be at least four years old.	Stimulant, f℥ss to f℥i (15 to 30 Cc.)
Vini Gallici	By distillation from fermented grapes; must be at least four years old.	Stimulant, f℥ss to f℥i (15 to 30 Cc.)

Unofficial Spirits

Name	Ingredients	Method of Preparation
Spiritus Ammoniæ Fetidus. Br.	75 Gm. Asafetida; 100 Cc. Strong Solution of Ammonia (32.5 percent.); Alcohol (90 percent.) to make 1000 Cc.	Macerate the Asafetida in 750 Cc. Alcohol for twenty-four hours, distil off the Alcohol; add the residue to the Strong Solution of Ammonia and enough Alcohol to make 1000 Cc.
Armoraciæ Compositus. Br.	125 Gm. Horseradish Root, scraped; 125 Gm. Dried Bitter Orange Peel; 3.15 Gm. Nutmeg; 625 Cc. Alcohol; 750 Cc. Distilled Water	Mix and distil 1000 Cc.
Aurantii. U. S. P. 1890	50 Cc. Oil of Orange Peel; 950 Cc. Alcohol	Mix them
Cajuputi. Br.	50 Cc. Oil of Cajuput; Alcohol to make 500 Cc.	Mix them
Limonis. U. S. P. 1890	50 Cc. Oil of Lemon; 50 Gm. freshly grated Lemon Peel; Alcohol to make 1000 Cc.	Mix the Oil with 900 Cc. Alcohol, add the Lemon Peel, and macerate during twenty-four hours. Filter and add Alcohol to make 1000 Cc.
Myrciæ. U. S. P. 1890 (Bay Rum)	16 Cc. Oil of Myrcia; 1 Cc. Oil of Orange Peel; 1 Cc. Oil of Pimenta; 1220 Cc. Alcohol; Water to make 2000 Cc.	Mix the Oils with the Alcohol, gradually add the Water, set aside for eight days, and filter
Myristicæ. U. S. P. 1890	50 Cc. Oil of Myristica; 950 Cc. Alcohol	Mix them
Phosphori. U. S. P. 1890	1.2 Gm. Phosphorus; Absolute Alcohol to make 1000 Cc.	Add the carefully weighed Phosphorus to 1000 Cc. Absolute Alcohol contained in a flask; connect with upright condenser and boil the liquid until the Phosphorus is dissolved; then, if necessary, add Absolute Alcohol to make 1000 Cc. and preserve in small, tightly stoppered bottles
Rectificatus. Br.	A liquid containing 90 parts, by volume, of Ethyl Hydroxide, and 10 parts, by volume, of Water	Obtained by distillation of fermented saccharine liquids
Rosmarini. Br.	50 Cc. Oil of Rosemary; Alcohol to make 500 Cc.	Mix them

SPIRITUS ÆTHERIS. U.S. Spirit of Ether

	Metric	Old form
* **Ether**	325 Cc.	4 fl. oz.
Alcohol	675 Cc.	8¼ fl. oz.
To make	1000 Cc.	12¼ fl. oz.

Mix them.

Average dose.—1 fluidrachm (4 Cc.).

SPIRITUS ÆTHERIS COMPOSITUS. U.S. Compound Spirit of Ether

	Metric	Old form
* **Ether**	325 Cc.	8 fl. oz.
Alcohol	650 Cc.	16 fl. oz.
Ethereal Oil	25 Cc.	5 fl. dr.
To make	1000 Cc.	24½ fl. oz.

Mix them. For Hoffmann's Anodyne see page 768.

Average dose.—1 fluidrachm (4 Cc.).

SPIRITUS ÆTHERIS NITROSI. U.S. Spirit of Nitrous Ether

[SWEET SPIRIT OF NITRE]

An Alcoholic solution of Ethyl Nitrite [$NO.OC_2H_5 = 74.51$], yielding, when freshly prepared and tested by the process given below, not less than 4 percent. of ethyl nitrite.

	Metric	Old form
* **Sodium Nitrite**	100.0 Gm.	3 oz. av. 231 gr.
Sulphuric Acid	40.0 Cc.	1 fl. oz. 169 min.
Monohydrated Sodium Carbonate	0.6 Gm.	9 grains
Potassium Carbonate, completely deprived of water by drying	3.0 Gm.	46 grains
Alcohol,		
Water, each, a sufficient quantity		

Mix the Sulphuric Acid with 120 Cc. [old form 4¼ fl. oz.] of Water, cool the liquid, add 85 Cc. [old form 2 fl. oz. 7 fl. dr.] of Alcohol previously diluted with an equal volume of Water, and introduce the solution into a 1000 Cc. [old form 2 pints] flask, surrounded by a mixture of ice and water. Dissolve the Sodium Nitrite in 280 Cc. [old form 9½ fl. oz.] of Water, filter, and, having poured the filtrate into a separatory funnel, allow the liquid to slowly drop into the flask containing the acid mixture. When all has been added and the reaction is complete, allow any crystals which may have formed to settle at the bottom of the flask, and decant the cold mixture of ethyl nitrite and aqueous solution quickly to the previously cleaned separatory funnel, and draw off and discard the aqueous liquid. Wash the separated ethyl nitrite, first, with 20 Cc. [old form 5½ fl. dr.] of ice-cold Water, and then remove any traces of acid by washing it with 15 Cc. [old form 4 fl. dr.] of ice-cold Water, in which the Monohydrated Sodium Carbonate has previously been dissolved. Carefully separate the ethyl nitrite from the aqueous liquid, and agitate it in a well-stoppered vial with the Potassium Carbonate to remove traces of water. Then cool the liquid, decant, and pour the ethyl nitrite immediately into a tared bottle containing 500 Gm. [old form 17 oz. av. 279 gr.] of Alcohol. Ascertain the weight of the ethyl nitrite poured into the Alcohol by noting the increase in weight of the tared bottle and contents, and then add enough Alcohol to make the mixture weigh *22 times* the weight of the ethyl nitrite added. Lastly, transfer the product to small, well-stoppered, dark amber-colored vials, and keep these in a cool place, remote from lights or fire.

(For tests and comments, see Part IV.)

SPIRITUS AMMONIÆ. U.S. **Spirit of Ammonia**

An alcoholic solution of Ammonia [$NH_3 = 16.93$] containing 10 percent., by weight, of the gas. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 percent. of gaseous Ammonia.

	Metric	Old form
* **Stronger Ammonia Water**	**250 Cc.**	8 fl. oz.
Alcohol, recently distilled, and after distillation kept in glass vessels, a sufficient quantity		

Pour the Stronger Ammonia Water into a flask provided with a safety funnel, and connected, by means of a glass condenser, with a well-cooled receiver containing 500 Cc. [old form 1 pint] of Alcohol, the delivery tube of the condenser reaching nearly to the bottom of the receiver. Heat the flask carefully, and very gradually, to a temperature not exceeding 60° C. (140° F.), and maintain it at that temperature until Ammonia ceases to be evolved. Then disconnect the receiver, and, having ascertained the strength of a portion of the contents by the method of assay (see Part III.), add enough Alcohol to make the product contain 10 percent., by weight, of Ammonia gas. Keep the Spirit in glass-stoppered bottles, in a cool place.

(For tests and comments, see Part III.)

SPIRITUS AMMONIÆ AROMATICUS. U.S. **Aromatic Spirit of Ammonia**

	Metric	Old form
* **Ammonium Carbonate,** in translucent pieces	**34 Gm.**	1 oz. av. 59 gr.
Ammonia Water	**90 Cc.**	2 fl. oz. 7 fl. dr.
Oil of Lemon	**10 Cc.**	2½ fl. dr.
Oil of Lavender Flowers	**1 Cc.**	15 minims
Oil of Myristica	**1 Cc.**	15 minims
Alcohol	**700 Cc.**	22 fl. oz. 3 fl. dr.
Distilled Water, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

To the Ammonia Water, contained in a flask, add 140 Cc. [old form 4½ fl. oz.] of Distilled Water, and afterwards the Ammonium Carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the Ammonium Carbonate is dissolved, and allow to stand for twelve hours. Introduce the Alcohol into a graduated bottle of suitable capacity, add first the Oils, then gradually the solution of Ammonium Carbonate, and afterwards enough Distilled Water to make the product measure 1000 Cc. [old form 2 pints]. Set the liquid aside during twenty-four hours in a cool place, occasionally agitating, then filter it through paper, in a well-covered funnel.

(If the white crystalline precipitate which often falls when the water is added has not disappeared after the liquid has stood twenty-four hours, shake thoroughly and allow it to stand a day longer before filtering.)

Keep the product in glass-stoppered bottles, in a cool place.

(For tests and comments, see Part III.)

Average dose.— 30 minims (2 Cc.).

SPIRITUS AMYGDALÆ AMARÆ. U.S. Spirit of Bitter Almond

	Metric	Old form
* **Oil of Bitter Almond**	10 Cc.	154 minims
Alcohol	800 Cc.	25½ fl. oz.
Distilled Water,		
To make	1000 Cc.	2 pints

Dissolve the Oil in the Alcohol, and add enough Distilled Water to make the product measure 1000 Cc. [old form 2 pints].

Average dose.— 8 minims (0.5 Cc.).

SPIRITUS ANISI. U.S. Spirit of Anise

	Metric	Old form
* **Oil of Anise**	100 Cc.	1 fl. oz.
Alcohol	900 Cc.	9 fl. oz.
To make	1000 Cc.	10 fl. oz.

Mix them.

Average dose.— 1 fluidrachm (4 Cc.).

SPIRITUS AURANTII COMPOSITUS U.S. Compound Spirit of Orange

	Metric	Old form
* **Oil of Orange Peel**	200 Cc.	6 fl. oz. 3 fl. dr.
Oil of Lemon	50 Cc.	1 fl. oz. 5 fl. dr.
Oil of Coriander	20 Cc.	5 fl. dr.
Oil of Anise	5 Cc.	77 minims
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place.

SPIRITUS CAMPHORÆ. U.S. Spirit of Camphor

	Metric	Old form
* **Camphor**	100 Gm.	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Camphor in 800 Cc. [old form 25½ fl. oz.] of Alcohol, filter through paper, and pass enough Alcohol through the filter to make the product measure 1000 Cc. [old form 2 pints].

Average dose.— 15 minims (1 Cc.).

SPIRITUS CHLOROFORMI. U.S. Spirit of Chloroform

	Metric	Old form
* **Chloroform**	60 Cc.	1 fl. oz. 7½ fl. dr.
Alcohol	940 Cc.	30 fl. oz. ½ fl. dr.
To make	1000 Cc.	2 pints

Mix them.

Average dose.— 30 minims (2 Cc.).

SPIRITUS CINNAMOMI. U.S. Spirit of Cinnamon

	Metric	Old form
***Oil of Cinnamon**	100 Cc.	1 fl. oz.
Alcohol	900 Cc.	9 fl. oz.
To make	1000 Cc.	10 fl. oz.

Mix them.

Average dose.— 30 minims (2 Cc.).

SPIRITUS FRUMENTI. U. S. Whisky

An alcoholic liquid obtained by the distillation of the fermented mash of grain—such as Indian corn, rye, wheat, and barley, or their mixtures.

(For tests and comments, see Part IV.)

SPIRITUS GAULTHERIÆ. U. S. Spirit of Gaultheria

[SPIRIT OF WINTERGREEN]

	Metric	Old form
***Oil of Gaultheria**	50 Cc.	1 fl. oz.
Alcohol	950 Cc.	19 fl. oz.
To make	1000 Cc.	20 fl. oz.

Mix them.

Average dose.— 30 minims (2 Cc.).

SPIRITUS GLYCERYLIS NITRATIS. U. S. Spirit of Glyceryl Trinitrate
Spirit of Nitroglycerin

[SPIRITUS GLONOINI, PHARM. 1890]

An alcoholic solution containing 1 percent., by weight, of Glyceryl Trinitrate [$C_3H_5(O.NO_2)_3 = 225.44$]. Spirit of Nitroglycerin should be kept and transported in well-stoppered tin cans, and should be stored in a cool place, remote from lights or fire.

Great care should be exercised in dispensing, handling, packing, transporting, and storing the Spirit, since a dangerous explosion may result if any considerable quantity of it be spilled, and the alcohol be partly or wholly lost by evaporation. If, through accident, it be spilled, a solution of potassium hydroxide should be at once poured over it, to effect decomposition.

A clear, colorless liquid, having the odor and taste of alcohol. *Caution should be exercised in tasting it,* since even a small quantity of it is liable to produce a violent headache. The same effect is produced when it is freely applied to the skin.

It is neutral to litmus paper.

Specific gravity : 0.814 to 0.820 at 25° C. (77° F.).

On diluting 10 Cc. of the Spirit with 15 Cc. of water—both liquids, as well as the mixture, being brought to 15° C. (59° F.)—the liquid will exhibit at most a faint cloudiness, but the addition of a further portion of 5 Cc. of water should produce a white turbidity.

If the specific gravity of the Spirit be higher than 0.830 at 25° C. (77° F.), or if 10 Cc. of it be rendered turbid by less than 10 Cc. of water, the Spirit should be rejected.

Average dose.— 1 minim (0.05 Cc.).

SPIRITUS JUNIPERI. U.S. Spirit of Juniper

	Metric	Old form
***Oil of Juniper**	50 Cc.	1 fl. oz.
Alcohol	950 Cc.	19 fl. oz.
To make	1000 Cc.	20 fl. oz.

Mix them.

Average dose.— 30 minims (2 Cc.).

SPIRITUS JUNIPERI COMPOSITUS. U. S. Compound Spirit of Juniper

	Metric	Old form
***Oil of Juniper**	8 Cc.	30 minims
Oil of Caraway	1 Cc.	4 minims
Oil of Fennel	1 Cc.	4 minims
Alcohol	1400 Cc.	11 fl. oz.
Water, a sufficient quantity,		
To make	2000 Cc.	1 pint

Dissolve the Oils in the Alcohol, and gradually add enough Water to make the product measure 2000 Cc. [old form 1 pint].

Average dose.— 2 fluidrachms (8 Cc.).

SPIRITUS LAVANDULÆ. U.S. Spirit of Lavender

	Metric	Old form
***Oil of Lavender Flowers**	50 Cc.	1 fl. oz.
Alcohol	950 Cc.	19 fl. oz.
To make	1000 Cc.	20 fl. oz.

Mix them.

Average dose.— 30 minims (2 Cc.).

SPIRITUS MENTHÆ PIPERITÆ. U.S. Spirit of Peppermint

	Metric	Old form
***Oil of Peppermint**	100 Cc.	3 fl. oz. 96 min.
Peppermint, bruised	10 Gm.	146 grains
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Oil of Peppermint in 900 Cc. [old form 29 fl. oz.] of Alcohol, add the Peppermint, and allow it to macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure 1000 Cc. [old form 2 pints].

Average dose.— 30 minims (2 Cc.).

SPIRITUS MENTHÆ VIRIDIS. U.S. Spirit of Spearmint

	Metric	Old form
***Oil of Spearmint**	100 Cc.	3 fl. oz. 96 min.
Spearmint, bruised	10 Gm.	146 grains
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Oil of Spearmint in 900 Cc. [old form 29 fl. oz.] of Alcohol, add the Spearmint, and allow it to macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure 1000 Cc. [old form 2 pints].

Average dose.— 30 minims (2 Cc.).

SPIRITUS VINI GALLICI. U.S. Brandy

An alcoholic liquid obtained by the distillation of the fermented, unmodified juice of fresh grapes.

(For tests and comments, see Part IV.)

Elixiria *Elixirs*

Elixirs are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. Although they are largely employed throughout the United States, but *three* have been made official,—Adjuvant Elixir, Aromatic Elixir, and Elixir of the Phosphates of Iron, Quinine and Strychnine. Two are intended as vehicles for the administration of active remedies in small doses. There will be found in the Appendix a number of formulas of unofficial elixirs.

Official Elixirs

Name	Proportions
Elixir Adjuvans	120 Cc. Fluidextract of Glycyrrhiza; 880 Cc. Aromatic Elixir
Aromaticum	12 Cc. Compound Spirit of Orange; 375 Cc. Syrup; 30 Gm. Purified Talc; 238 Cc. Alcohol; with sufficient Distilled Water to make 1000 Cc.
Ferri, Quininæ et Strychninæ Phosphatum	17.5 Gm. Soluble Ferric Phosphate; 8.75 Gm. Quinine; 0.275 Gm. Strychnine; 2 Cc. Phosphoric Acid; 9 Gm. Ammonium Carbonate; 60 Cc. Alcohol; 28.65 Gm. Acetic Acid; Ammonia Water to neutralize; with Distilled Water and Aromatic Elixir to make 1000 Cc.

Unofficial Elixir

Name	Ingredients	Method of Preparation
Elixir Phosphori. U.S. P. 1890	210 Cc. Spirit of Phosphorus; 2 Cc. Oil of Anise; 550 Cc. Glycerin; Aromatic Elixir to make 1000 Cc.	Mix the Spirit of Phosphorus, Oil of Anise, and Glycerin by repeatedly inverting the bottle in which they are contained, and, when they have formed a clear liquid, add Aromatic Elixir to make 1000 Cc. Keep in well-stoppered bottles in a dark place

ELIXIR ADJUVANS. U.S. Adjuvant Elixir

	Metric	Old form
* **Fluidextract of Glycyrrhiza**	120 Cc.	3 fl. oz. 7 fl. dr.
Aromatic Elixir	880 Cc.	28 fl. oz. 1 fl. dr.
To make	1000 Cc.	2 pints

Mix, and filter if necessary.

ELIXIR AROMATICUM. U.S. Aromatic Elixir

[SIMPLE ELIXIR]

	Metric	Old form
***Compound Spirit of Orange**	12 Cc.	184 minims
Syrup	375 Cc.	12 fl. oz.
Purified Talc	30 Gm.	1 oz. av.
Alcohol,		
Distilled Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

To the Compound Spirit of Orange, add enough Alcohol to make 250 Cc. [old form 8 fl. oz.]. To this solution, add the Syrup in several portions, agitating after each addition, and afterwards add, in the same manner, 375 Cc. [old form 12 fl. oz.] of Distilled Water. Mix the Purified Talc intimately with the liquid, and then filter through a wetted filter, returning the first portions of the filtrate until a transparent liquid is obtained. Lastly, wash the filter with a mixture of *1 volume* of Alcohol and *3 volumes* of Distilled Water, until the product measures 1000 Cc. [old form 2 pints].

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Elixir of the Phosphates of Iron, Quinine and Strychnine

	Metric	Old form
***Soluble Ferric Phosphate**	17.500 Gm.	255 grains
Quinine	8.750 Gm.	127 grains
Strychnine	0.275 Gm.	4 grains
Phosphoric Acid	2.000 Cc.	31 minims
Ammonium Carbonate, in translucent pieces	9.000 Gm.	131 grains
Alcohol	60.000 Cc.	1 fl. oz. 7½ fl. dr.
Acetic Acid	28.650 Gm.	418 grains
Ammonia Water,		
Distilled Water,		
Aromatic Elixir, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Quinine and Strychnine in the Alcohol, then add the Phosphoric Acid and 350 Cc. [old form 11 fl. oz. 1 fl. dr.] of Aromatic Elixir. Add the Acetic Acid to the Ammonium Carbonate, contained in a suitable vessel, and when solution is complete, neutralize with Ammonia Water and add enough Distilled Water to make the product measure 50 Cc. [old form 1 fl. oz. 288 min.]. Mix the solution of Ammonium Acetate with the solution of the alkaloids, and add enough Aromatic Elixir to make the liquid measure 880 Cc. [28 fl. oz. 1 fl. dr.]. Dissolve the Ferric Phosphate in 30 Cc. [old form 7½ fl. dr.] of Distilled Water, by the aid of a gentle heat, and if the solution be acid to litmus paper, neutralize exactly with Ammonia Water, and add enough Aromatic Elixir to make the product measure 120 Cc. [old form 3 fl. oz. 7 fl. dr.]. Finally, mix the two solutions and filter if necessary.

Average dose.— 1 fluidrachm (4 Cc.).

CHAPTER XXIV

ETHEREAL SOLUTIONS

Collodia *Collodions*

Collodions are liquid preparations intended for external use, having for their base a solution of pyroxylin, or gun-cotton, in a mixture of ether and alcohol. (For a description of the properties of pyroxylin and collodions, see Part V.) Collodions are applied to the skin by means of a soft brush, and when the ether and alcohol evaporate, a film is left on the surface, which either acts as a protection or brings a medicating agent in contact with the epidermis. *Four* collodions are official.

Official Collodions

Name	Proportions
Collodium	40 Gm. Pyroxylin; 750 Cc. Ether; 250 Cc. Alcohol. Decant the clear Collodion from the sediment
Cantharidatum	60 Gm. Cantharides, No. 60 powder; 85 Gm. Flexible Collodion; Chloroform sufficient to exhaust the Cantharides; after distillation of the Chloroform, the residue is dissolved in the Flexible Collodion. Decant the clear Cantharidal Collodion from the sediment
Flexile	920 Gm. Collodion; 50 Gm. Canada Turpentine; 30 Gm. Castor Oil
Stypticum	20 Gm. Tannic Acid; 5 Cc. Alcohol; 25 Cc. Ether; Collodion to make 100 Cc.

COLLODIUM. U.S. Collodion

	Metric	Old form
* **Pyroxylin**	40 Gm.	1 oz. av. 147 gr.
Ether	750 Cc.	24 fl. oz.
Alcohol	250 Cc.	8 fl. oz.
To make about	1000 Cc.	2 pints

To the Pyroxylin, contained in a suitable bottle, add the Ether, and allow it to stand for fifteen minutes; then add the Alcohol, and shake the bottle until the Pyroxylin is dissolved. Cork the bottle well, and set it aside until the liquid has become clear. Finally, decant the clear portion from any sediment which may have deposited, and transfer it to bottles, which should be well corked and sealed.

Keep the Collodion in a cool place, remote from lights or fire.

COLLODIUM CANTHARIDATUM. U.S. Cantharidal Collodion

[Blistering Collodion]

	Metric	Old form
* **Cantharides,** in No. 60 powder	60 Gm.	2 oz. av. 50 gr.
Flexible Collodion	85 Gm.	3 oz. av.
Chloroform, a sufficient quantity,		
To make	100 Gm.	3 oz. av. 230 gr.

Pack the Cantharides firmly in a cylindrical percolator and gradually pour Chloroform upon it until the powder is exhausted. Recover the Chloroform by distillation from a water-bath and evaporate the residue in a tared evaporating dish on a water-bath, until it weighs 15 Gm. [old form 230 grains]. Dissolve this in the Flexible Collodion, and set it aside in a securely corked bottle, and in a cool place, to become clear by settling. Finally, pour off the clear portion from any sediment which may have deposited, and transfer it to bottles, which should be well corked and sealed.

Keep the Cantharidal Collodion in a cool place, remote from lights or fire.

COLLODIUM FLEXILE. U. S. Flexible Collodion

	Metric	Old form
***Collodion**	920 Gm.	8 oz. av.
Canada Turpentine	50 Gm.	190 grains
Castor Oil	30 Gm.	115 grains
To make	1000 Gm.	about 9 oz. av.

Weigh the ingredients, successively, into a tared bottle, and mix them thoroughly.

Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire.

COLLODIUM STYPTICUM. U.S. Styptic Collodion

	Metric	Old form
***Tannic Acid**	20 Gm.	365 grains
Alcohol	5 Cc.	96 minims
Ether	25 Cc.	1 fl. oz.
Collodion, a sufficient quantity,		
To make	100 Cc.	4 fl. oz.

Introduce the Tannic Acid, Alcohol, and Ether into a graduated bottle, agitate the mixture until the Tannic Acid is thoroughly incorporated and partially dissolved, then add enough Collodion to make up the volume to 100 Cc. [old form 4 fl. oz.], and shake occasionally, until the Tannic Acid is completely dissolved.

Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire.

CHAPTER XXV

OLEAGINOUS SOLUTIONS OR EXTERNAL APPLICATIONS

Linimenta *Liniments*

THESE are solutions or mixtures of various substances in oily or alcoholic liquids, intended for external application, and usually applied with friction and rubbing of the skin. There are *eight* official liniments, of which *three* are made with a fixed oil as the base, *four* with alcohol as the principal liquid, and *one* contains oil of turpentine. They are classified as follows:

Official Liniments

Name	Base	Proportions
Linimentum Ammoniæ	Oil	350 Cc. Ammonia Water; 50 Cc. Alcohol; 570 Cc. Cotton Seed Oil; 30 Cc. Oleic Acid
Calcis	Oil	Equal volumes Lime Water and Linseed Oil
Camphoræ	Oil	200 Gm. Camphor; 800 Gm. Cotton Seed Oil
Belladonnæ	Alcohol	50 Gm. Camphor; Fluidextract of Belladonna to make 1000 Cc.
Chloroformi	Alcohol	300 Cc. Chloroform; 700 Cc. Soap Liniment
Saponis	Alcohol	60 Gm. Granulated Soap; 45 Gm. Camphor; 10 Cc. Oil of Rosemary; 725 Cc. Alcohol; Water to make 1000 Cc.
Saponis Mollis	Alcohol	650 Gm. Soft Soap; 20 Cc. Oil of Lavender Flowers; Alcohol to make 1000 Cc.
Terebinthinæ	Oil of Turpentine	650 Gm. Rosin Cerate; 350 Gm. Oil of Turpentine

Unofficial Liniments

Name	Ingredients	Method of Preparation
Linimentum Aconiti. Br.	500 Gm. Aconite Root, No. 40 powder; 25 Gm. Camphor; Alcohol to make 750 Cc.	Percolate the Aconite Root, after three days maceration, with enough Alcohol to make the liquid, after the Camphor has been dissolved, measure 750 Cc.
Camphoræ Ammoniatum. Br.	50 Gm. Camphor; 2.5 Cc. Oil of Lavender; 100 Cc. Strong Solution of Ammonia (32.5 percent.); Alcohol to make 400 Cc.	Dissolve the Camphor and the Oil of Lavender in 240 Cc. of Alcohol, add the Strong Solution of Ammonia gradually and Alcohol to make 400 Cc., and shake until a clear solution is formed
Crotonis. Br.	20 Cc. Croton Oil; 70 Cc. Oil of Cajuput; 70 Cc. Alcohol	Mix them
Hydrargyri. Br.	30 Gm. Ointment of Mercury; 10 Cc. Strong Solution of Ammonia (32.5 percent); Liniment of Camphor, a sufficient quantity	Add the Strong Solution of Ammonia to enough Liniment of Camphor to make 45 Cc.; triturate the Ointment of Mercury with enough Liniment of Camphor to make 45 Cc. Mix the two liquids
Opii. Br.	50 Cc. Tincture of Opium; 50 Cc. Liniment of Soap	Mix, set aside for a few days, and filter
Potassii Iodidi cum Sapone. Br.	40 Gm. Curd Soap; 30 Gm. Potassium Iodide; 20 Cc. Glycerin; 2.5 Cc. Oil of Lemon; 200 Cc. Distilled Water	Dissolve the Soap, with the aid of a gentle heat, in the Glycerin and Water; add the solution to the powdered Potassium Iodide in a mortar and triturate until cold, set aside for an hour, and then incorporate the Oil of Lemon

Unofficial Liniments—*Continued*

Name	Ingredients	Method of Preparation
Linimentum Sinapis Compositum. U. S. P. 1890	30 Cc. Volatile Oil of Mustard; 200 Cc. Fluidextract of Mezereum; 60 Gm. Camphor; 150 Cc. Castor Oil; Alcohol to make 1000 Cc.	Dissolve the Camphor in 500 Cc. of Alcohol, add successively the Fluidextract, the Oil of Mustard, and the Castor Oil, and finally Alcohol to make 1000 Cc.
Terebinthinæ Aceticum. Br.	100 Cc. Oil of Turpentine; 25 Gm. Glacial Acetic Acid; 100 Cc. Liniment of Camphor	Mix them

LINIMENTUM AMMONIÆ. U.S. Ammonia Liniment

[VOLATILE LINIMENT]

	Metric	Old form
* **Ammonia Water**	350 Cc.	11 fl. oz. 1 fl. dr.
Alcohol	50 Cc.	1 fl. oz. 5 fl. dr.
Cotton Seed Oil	570 Cc.	18 fl. oz. 2 fl. dr.
Oleic Acid	30 Cc.	1 fl. oz.
To make	1000 Cc.	2 pints

Mix them by agitation in a bottle, which should be well stoppered. This Liniment should be freshly prepared when wanted.

LINIMENTUM BELLADONNÆ. U.S. Belladonna Liniment

	Metric	Old form
* **Camphor**	50 Gm.	180 grains
Fluidextract of Belladonna Root, a sufficient quantity,		
To make	1000 Cc.	8 fl. oz.

Dissolve the Camphor in about 800 Cc. [old form 25½ fl. oz.] of the Fluidextract, and then add enough of the latter to make the product measure 1000 Cc. [old form 2 pints]. Mix thoroughly.

LINIMENTUM CALCIS. U.S. Lime Liniment

[CARRON OIL]

	Metric	Old form
* **Lime Water**	500 Cc.	1 pint
Linseed Oil	500 Cc.	1 pint
To make	1000 Cc.	2 pints

Mix them by agitation.

LINIMENTUM CAMPHORÆ. U.S. Camphor Liniment

	Metric	Old form
* **Camphor,** in coarse powder	200 Gm.	2 oz. av.
Cotton Seed Oil	800 Gm.	8 oz. av.
To make	1000 Gm.	10 oz. av.

Introduce the Camphor and the Cotton Seed Oil into a suitable flask, and apply a gentle heat, by means of a water-bath, loosely stoppering the flask during the operation. Agitate the flask occasionally, until the Camphor is dissolved.

LINIMENTUM CHLOROFORMI. U.S. Chloroform Liniment

	Metric	Old form
* **Chloroform**	300 Cc.	9½ fl. oz.
Soap Liniment	700 Cc.	22½ fl. oz.
To make	1000 Cc.	2 pints

Mix them by agitation.

LINIMENTUM SAPONIS. U.S. Soap Liniment

	Metric	Old form
* **Soap,** dried and granulated	60 Gm.	2 oz. av.
Camphor, in small pieces	45 Gm.	1 oz. av. 220 gr.
Oil of Rosemary	10 Cc.	154 minims
Alcohol	725 Cc.	23 fl. oz. 1 fl. dr.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Add the Soap to 200 Cc. [old form 6½ fl. oz.] of boiling Water, heat the mixture on a water-bath until a clear gelatinous mass results. Mix this, while yet warm, with 500 Cc. [old form 1 pint] of Alcohol, and stir it until solution is effected. Dissolve the Camphor and Oil of Rosemary in 225 Cc. [old form 7 fl. oz. 1 fl. dr.] of the Alcohol by agitation in a bottle ; add this solution to the warm Soap mixture ; mix thoroughly, and, if necessary, add enough Water to make the product measure 1000 Cc. [old form 2 pints]. Set it aside in a cool place for twenty-four hours, then filter.

LINIMENTUM SAPONIS MOLLIS. U.S. Liniment of Soft Soap

[TINCTURE OF GREEN SOAP]

	Metric	Old form
* **Soft Soap**	650 Gm.	21½ oz. av.
Oil of Lavender Flowers	20 Cc.	5 fl. dr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Oil of Lavender Flowers with 300 Cc. [old form 9½ fl. oz.] of Alcohol, dissolve in this the Soft Soap by stirring or agitation, and set the solution aside for twenty-four hours. Then filter it through paper, adding sufficient Alcohol to make the product measure 1000 Cc. [old form 2 pints].

LINIMENTUM TEREBINTHINÆ. U.S. Turpentine Liniment

	Metric	Old form
* **Rosin Cerate**	650 Gm.	13 oz. av.
Oil of Turpentine	350 Gm.	7 oz. av.
To make	1000 Gm.	20 oz. av.

Dissolve the Rosin Cerate, previously melted in a dish on a water-bath, in the Oil of Turpentine, and mix them thoroughly.

Oleata *Oleates*

The official oleates are liquid preparations made by dissolving metallic salts or alkaloids in oleic acid. The term oleate is also used commercially to designate solid preparations which are supposed to be chemical compounds of oleic acid with various bases. (See Part

V.) The official oleates are not assumed to be definite chemical compounds. The proportion of oleic acid is excessive, and they must be regarded as solutions of the medicating agent in oleic acid, the latter having special advantages as a basis for administering external remedies, being more readily absorbed than most of the fatty substances used in making ointments. *Five* oleates are official.

Official Oleates

Name	Proportions
Oleatum Atropinæ	2 Gm. Atropine; 2 Cc. Alcohol; 50 Gm. Oleic Acid; Olive Oil to make 100 Gm.
Cocainæ	5 Gm. Cocaine; 5 Cc. Alcohol; 50 Gm. Oleic Acid; Olive Oil to make 100 Gm.
Hydrargyri	25 Gm. Yellow Mercuric Oxide; 25 Cc. Distilled Water; Oleic Acid to make 100 Gm.
Quininæ	25 Gm. Quinine; 75 Gm. Oleic Acid
Veratrinæ	2 Gm. Veratrine; 50 Gm. Oleic Acid; Olive Oil to make 100 Gm.

Unofficial Oleate

Name	Ingredients	Method of Preparation
Oleatum Zinci. U. S. P. 1890	50 Gm. Zinc Oxide; 950 Gm. Oleic Acid	Incorporate the Zinc Oxide with the Oleic Acid contained in a porcelain dish, set aside for three hours, and then heat on a water-bath, frequently stirring, until dissolved

OLEATUM ATROPINÆ. U.S. Oleate of Atropine

	Metric	Old form
* **Atropine**	**2 Gm.**	35 grains
Alcohol	**2 Cc.**	35 minims
Oleic Acid	**50 Gm.**	2 oz. av.
Olive Oil, a sufficient quantity,		
To make	**100 Gm.**	4 oz. av.

Triturate the Atropine in a tared mortar with the Alcohol, then add about an equal volume of the Oleic Acid, and, after warming the mortar, stir until the Alcohol has evaporated, add the remainder of the Oleic Acid, and continue stirring until the Atropine is dissolved; then add sufficient Olive Oil to make the product weigh 100 Gm. [old form 4 oz. av.].

OLEATUM COCAINÆ. U.S. Oleate of Cocaine

	Metric	Old form
* **Cocaine**	**5 Gm.**	87½ grains
Alcohol	**5 Cc.**	90 minims
Oleic Acid	**50 Gm.**	2 oz. av.
Olive Oil, a sufficient quantity,		
To make	**100 Gm.**	4 oz. av.

Triturate the Cocaine, in a tared mortar, with the Alcohol, then add about an equal volume of the Oleic Acid, and, after warming the mortar, stir until the Alcohol has evaporated, add the remainder of the Oleic Acid, and continue stirring until the Cocaine is dissolved; then add sufficient Olive Oil to make the product weigh 100 Gm. [old form 4 oz. av.].

OLEATUM HYDRARGYRI. U.S. Oleate of Mercury

	Metric	Old form
* **Yellow Mercuric Oxide,** in very fine powder	25 Gm.	1 oz. av.
Distilled Water	25 Cc.	1 fl. oz.
Oleic Acid, a sufficient quantity,		
To make	100 Gm.	4 oz. av.

Triturate the Yellow Mercuric Oxide with the Distilled Water in a tared mortar; add 70 Gm. [old form 2½ oz. av.] of Oleic Acid, and mix thoroughly; warm the mortar to a temperature not exceeding 50° C. [122° F.], stir occasionally until the water has evaporated, then add, if necessary, Oleic Acid to make 100 Gm. [old form 4 oz. av.], and mix thoroughly. Avoid contact with metallic utensils; preserve the Oleate in tightly stoppered bottles.

OLEATUM QUININÆ. U.S. Oleate of Quinine

	Metric	Old form
* **Quinine**	25 Gm.	1 oz. av.
Oleic Acid	75 Gm.	3 oz. av.
To make	100 Gm.	4 oz. av.

Triturate the Quinine, in a warm mortar, with a small quantity of the Oleic Acid to a smooth paste. Then add the remainder of the Oleic Acid, previously warmed, and stir frequently, until the Quinine is dissolved.

OLEATUM VERATRINÆ. U.S. Oleate of Veratrine

	Metric	Old form
* **Veratrine**	2 Gm.	35 grains
Oleic Acid	50 Gm.	2 oz. av.
Olive Oil, a sufficient quantity,		
To make	100 Gm.	4 oz. av.

Triturate the Veratrine in a tared mortar with about 5 Cc. [old form 1½ fl. dr.] of Olive Oil, and, after warming the mortar, add the Oleic Acid, and continue stirring until the Veratrine is dissolved; then add sufficient Olive Oil to make the product weigh 100 Gm. [old form 4 oz. av.].

CHAPTER XXVI

AQUEOUS LIQUIDS MADE BY PERCOLATION OR MACERATION

Infusa *Infusions*

INFUSIONS are liquid preparations made by treating vegetable substances with either hot or cold water. *The drug is not subjected to the boiling process,* although it is common to pour boiling water over it; the whole is allowed to stand in a close vessel until cold. While the use of hot water has the advantage of saving time in some cases, it is often objectionable because the *inert* principles in the drug are dissolved by the hot water, and as the infusion cools, they are precipitated out in such a very finely divided condition that they cannot be readily separated by colation or filtration. Cold water should be selected as the menstruum when the drug contains a valuable volatile principle, when the active agent is injured by heat, or when the desirable principles are readily soluble in water of ordinary temperature. The time required to make the infusion must be considered, for in warm weather it is quite possible for an infusion to ferment or decompose before it is finished.

Pure water should be used in making infusions, and large quantities should not be made at one time unless demanded for immediate use, as, without special precautions to preserve them, they soon become decomposed.

Of the inert principles found in plants, starch is extracted by hot water and albumen by cold water, whilst gum, sugar, and extractive are dissolved by both.

In making infusions the drug is usually coarsely comminuted, sliced, or bruised. Fine powders should be avoided whenever possible, because it is difficult to separate the fine particles from the infusion; and if percolation is resorted to, so much time is consumed in the operation, owing to the swelling of the powder, that decomposition may set in before the preparation is finished. The number of official infusions is *three.* Infusions are usually made in four ways: 1. By maceration. 2. By digestion. 3. By percolation. 4. By diluting fluidextracts.

1. **By Maceration.**—This is the process which is most frequently used. The general formula of the U. S. Pharmacopœia, which is here appended, furnishes a model.

General Official Formula for Infusions

An ordinary Infusion, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula:

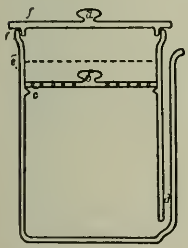
Take of	Metric	Old form
***The Substance,** coarsely comminuted	**50 Gm.**	365 grains
Boiling Water	**1000 Cc.**	1 pint
Water, a sufficient quantity,		
To make	**1000 Cc.**	1 pint

Introduce the Substance into a suitable vessel provided with a cover, pour upon it the Boiling Water, cover the vessel tightly, and let it stand for half an hour in a warm place. Then strain with expression, and pass enough Water through the strainer to make the Infusion measure 1000 Cc. [old form 1 pint].

Caution.—The strength of Infusions of energetic or powerful substances should be specially prescribed by the physician.

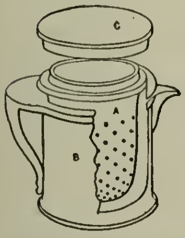
It will be found most convenient to provide special apparatus for making infusions by maceration. One of the oldest forms is known as *Alsop's Infusion Jar.* This presents a very neat and effectual method of making the hot infusions. It consists of an earthen-ware mug, represented in Fig. 430, with a spout, *d*, proceeding from the bottom, and placed closely to the side of the vessel to prevent fracture; a perforated plate or diaphragm, *b*, supported on a ledge, *c*, at about one-quarter or one-third of the height of the vessel from the top; and a lid, *a*, which may be fastened on by a string through holes *f f.* The material to be submitted to infusion is placed on the perforated plate, and the hot water poured in so as to cover it, the vessel having been previously warmed, so as not to chill the liquid. As the water becomes impregnated, it acquires an increased specific gravity, and sinks to the bottom, its place being supplied by the unsaturated portion; and this circulation goes on until the whole of the soluble matter is extracted. In order to maintain a due warmth, the vessel may be placed upon a stove, or upon an iron plate near the fire. The advantage of the process is that the material is subjected to the solvent power of the least impregnated portion of the menstruum. In order that the vessel may be adapted for the preparation of different quantities of infusions, it would be an advantage to have ledges arranged within, at different heights, so that the diaphragm may be supported at any desired point. The surface of the liquid,

Fig. 430



Alsop's infusion jar

Fig. 431



Squire's infusion mug

Fig. 432

Infusion pitcher

Fig. 433

Infusion mug (home-made)

e, should, of course, always be above the medicinal substance. Tinned iron or metallic vessels are unsuited for infusions; they are particularly objectionable when the drug used for making the preparation contains tannin, gallic acid, or an astringent substance. The liability of iron vessels to rust constitutes another objection.

Squire's Infusion Mug differs from the preceding in having a colander of queen's-ware, which is closely covered with a lid, and descends into the jar so as to form a diaphragm for the support of the substance to be infused. It has the advantage that the material, after having been exhausted, may be lifted out without disturbing the infusion. Fig. 431 shows the mug. It is made of queen's-ware, of the capacity of one pint, B; into it a thimble shaped colander, A, descends, supported on the rim of the mug by a projecting ledge, with a carefully fitted cover, C, which closes the whole. The substance to be submitted to infusion is introduced into the colander either before or after it has been fitted to the mug; the water, hot or cold, as the case may be, is then poured in so as to fill the lower vessel and cover the materials in the upper; and, the cover having been applied, the vessel is set aside for the length of time required. The colander is then to be lifted out, and the infusion, without having to strain it, is ready for use.

Fig. 432 represents an earthenware infusion pitcher, which may be used for making a gallon of infusion; it is useful where there is a large demand. Its principle of action is similar to that of Squire's infusion mug. A still better and cheaper apparatus may be made by the pharmacist himself, by selecting a queen's-ware or porcelain tea- or coffee-pot, A, as in Fig. 433, and if a hole is bored with the broken end of a small file through the top, close to the handle, a copper wire may be passed through the hole and around the handle, and made to terminate in a hook. The material to be infused is loosely tied up in a square piece of cheese cloth (coarse, thin muslin) and suspended from the hook; the hot water soon penetrates all parts of the drug and dissolves out the soluble principles by circulatory displacement. This method has the great advantage that no further straining is needed, as the bag retains the solid undissolved portion; the bag may be pressed and the contents then thrown away.

Official Infusions made by Maceration

Name	Ingredients	Use and Dose
Infusum Digitalis	15 Gm. Digitalis; 150 Cc. Cinnamon Water: 100 Cc. Alcohol; 500 Cc. Boiling Water; Cold Water to make 1000 Cc.	Diuretic, cardiac stimulant, fʒii (8 Cc.)
Sennæ Compositum	60 Gm. Senna; 120 Gm. Manna; 120 Gm. Magnesium Sulphate; 20 Gm. Fennel: 800 Cc. Boiling Water; Cold Water to make 1000 Cc.	Purgative, f℥ii to f℥iv (60 Cc. to 120 Cc.)

2. **By Digestion.**—The process of *digestion* consists in subjecting the substance to the continued action of moderate heat below the boiling temperature. In making infusions digestion is often very useful, although it may not be directed in the formula. It generally suffices to place the infusion vessel (see Fig. 433) upon a moderately

hot portion of the stove plate, or upon the floor near the stove or source of heat.

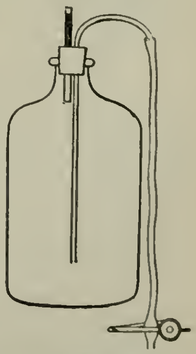
3. **By Percolation.**—This method of making infusions is by far the most satisfactory, and should be used whenever possible. It should be selected when the desirable principles are easily dissolved in water, and when the amount of menstruum is amply sufficient to exhaust the drug thoroughly. Percolation presents the advantages of furnishing a finished preparation, straining being unnecessary. Again, precipitation from the deposition of inert principles after the infusion has been strained, due to the principles being soluble in hot water but insoluble in cold water, is avoided. The chief drawback to the adoption of percolation in making infusions is the length of time it takes to exhaust the drug with water. Infusions are generally extemporaneous preparations, and they are frequently desired quickly; hence the process of maceration is often selected in preference.

Official Infusion made by Percolation

Name	Ingredients	Use and Dose
Infusum Pruni Virginianæ	40 Gm. Wild Cherry; 50 Cc. Glycerin; Water to make 1000 Cc.	Tonic, f℥ii (60 Cc.)

Preservation of Infusions.—The difficulty in preserving infusions arises from the decomposition of the principles which are extracted by water and retained in the preparation. If sufficient alcohol is added to prevent decomposition, the therapeutic action of the infusion is usually interfered with, owing to the comparatively large proportion of spirit contained in the dose. Alcohol is successfully used in preparations like infusion of gentian, orange peel, etc., or simple tonics. If an antiseptic, like boric acid, salicylic acid, sodium benzoate, or phenol, is used, the same objection exists,—the interference due to the therapeutic action of the antiseptic.

Fig. 434



Infusion bottle

It has been proved that infusions may be preserved for a long time if they are protected from the microscopic organisms which float in the air. A simple method is to heat the infusion contained in the bottle gradually to the boiling point, in order to destroy any of the spores that may be present, and then to transfer it at once to small bottles, which are filled to the brim, the corks forced in and tied over, and the cork, lip, and neck of each bottle dipped into hot sealing wax. A useful modification of Almen's method consists in heating to the boiling point the infusion contained in a bottle in a water bath. The rubber cork of the bottle is perforated so as to admit a long bent tube and a short tube; the short tube is loosely filled with cotton, the long limb of the bent tube is passed through the cork, and a rubber tube with a pinchcock attached, as shown in Fig. 434. The cotton permits the admission of air into the bottle, but excludes spores and dust. The infusion may be drawn as wanted from the bottle by the rubber tube and syphon, the flow being controlled by the pinchcock and started by suction.

Infusions from Fluidextracts.—The habit of making infusions from concentrated alcoholic tinctures or fluidextracts is improper and unjustifiable, except in those few cases in which the active and desirable principles of the drug are equally soluble in alcohol and in water, or in the menstrua used for both fluidextract and infusion. This is well illustrated in those preparations in which the activity of the drug is due to resinous bodies. Alcoholic menstrua here are necessary to dissolve the resins, and if such a fluidextract is added to water, precipitation takes place and the filtered infusion is worthless. If the precipitate is inert or does not carry down with it any portion of the active principle, and is readily separated, the only objection to the infusion is the presence of the alcohol, which may or may not seriously interfere with the therapeutic action, according as the quantity present is large or small. The saving in time and labor by making infusions in this way is the cause of the frequent employment of this method, but it should never be used if the therapeutic action of the drug is weakened thereby. The substitution of a fluidextract infusion in a prescription for one directed to be made by the official process is very reprehensible.

The introduction into the British Pharmacopœia (1898) of concentrated infusions made by percolation usually with 20 percent. alcohol (see Table on p. 281) has provoked some criticism on account of their instability through precipitation.

Infusa *Infusions*

General Official Formula.—An ordinary infusion, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula :

Take of	Metric	Old form
* **The Substance,** coarsely comminuted	50 Gm.	365 grains
Boiling Water	1000 Cc.	1 pint
Water, a sufficient quantity,		
To make	1000 Cc.	1 pint

Introduce the substance into a suitable vessel provided with a cover, pour upon it the Boiling Water, cover the vessel tightly, and let it stand for half an hour in a warm place. Then strain with expression, and pass enough Water through the strainer to make the Infusion measure 1000 Cc. [old form 1 pint].

Caution.—The strength of Infusions of energetic or powerful substances should be specially prescribed by the physician.

INFUSUM DIGITALIS. U.S. Infusion of Digitalis

	Metric	Old form
* **Digitalis,** bruised	15 Gm.	½ oz. av.
Alcohol	100 Cc.	3¼ fl. oz.
Cinnamon Water	150 Cc.	5 fl. oz.
Boiling Water	500 Cc.	1 pint
Cold Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Upon the Digitalis, contained in a suitable vessel, pour the Boiling Water, and allow it to macerate for one hour. Then strain, add the Alcohol and Cinnamon Water to the strained liquid, and pass enough Cold Water through the residue on the strainer to make the product measure 1000 Cc. [old form 2 pints]. Mix well.

Average dose.— 2 fluidrachms (8 Cc.).

INFUSUM PRUNI VIRGINIANÆ. U.S. Infusion of Wild Cherry

	Metric	Old form
* **Wild Cherry,** in No. 20 powder	40 Gm.	1 oz. av. 147 gr.
Glycerin	50 Cc.	1½ fl. oz.
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the powder with 60 Cc. [old form 2 fl. oz.] of Water, and allow it to macerate for one hour; then pack it firmly in a conical glass percolator, and, having placed the Glycerin in the receiving bottle, gradually pour Water upon the powder and continue percolation until the Infusion measures 1000 Cc. [old form 2 pints]. Mix well.

Average dose.— 2 fluidounces (60 Cc.).

INFUSUM SENNÆ COMPOSITUM. U.S. Compound Infusion of Senna

	Metric	Old form
* **Senna**	60 Gm.	2 oz. av.
Manna	120 Gm.	4 oz. av.
Magnesium Sulphate	120 Gm.	4 oz. av.
Fennel, bruised	20 Gm.	292 grains
Boiling Water	800 Cc.	25½ fl. oz.
Cold Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Upon the Senna, Manna, and Fennel, contained in a suitable vessel, pour the Boiling Water, and allow it to macerate for half an hour. Then strain with expression, dissolve the Magnesium Sulphate in the Infusion, and again strain. Lastly, add enough Cold Water through the strainer to make the Infusion measure 1000 Cc. [old form 2 pints].

Average dose.— 4 fluidounces (120 Cc.).

Unofficial Infusions

Name	Ingredients	Method of Preparation
Infusum Aurantii. Br.	50 Gm. Dried Bitter Orange Peel; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Aurantii Compositum. Br.	25 Gm. Dried Bitter Orange Peel; 12.5 Gm. Fresh Lemon Peel; 6.25 Gm. Cloves, bruised; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Buchu. Br.	50 Gm. Buchu Leaves; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Calumbæ. Br.	50 Gm. Columba Root; 1000 Cc. boiling Distilled Water	Infuse for half an hour; strain
Caryophylli. Br.	25 Gm. Cloves, bruised; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Cascarillæ. Br.	50 Gm. Cascarilla; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Chiratæ. Br.	50 Gm. Chiretta; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Cinchonæ. U.S. P. 1890	60 Gm. Cinchona; 10 Cc. Aromatic Sulphuric Acid; Water to make 1000 Cc.	Percolate the Cinchona with Water, to which the Acid has been added, to make 1000 Cc. of Infusion

Unofficial Infusions—*Continued*

Name	Ingredients	Method of Preparation
Infusum Cuspariæ. Br.	50 Gm. Cusparia Bark; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Ergotæ. Br.	50 Gm. Ergot, freshly crushed; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Gentianæ Compositum. Br.	12.5 Gm. Gentian Root, sliced; 12.5 Gm. Dried Bitter Orange Peel; 25 Gm. Fresh Lemon Peel; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Krameriæ. Br.	50 Gm. Krameria Root, bruised; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Lupuli. Br.	50 Gm. Hops; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Quassiæ. Br.	10 Gm. Quassia Wood, rasped; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Rhei. Br.	50 Gm. Rhubarb Root, sliced; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Rosæ Acidum. Br.	25 Gm. dried Red-Rose Petals; 12.5 Cc. Diluted Sulphuric Acid; 1000 Cc. boiling Distilled Water	Infuse the Red-Rose Petals in the Water, to which the Acid has been added, in a closed vessel during fifteen minutes; strain
Scoparii. Br.	100 Gm. Broom Tops, bruised; 1000 boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Senegæ. Br.	50 Gm. Senega Root, No. 10 powder; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for half an hour; strain
Sennæ. Br.	100 Gm. Senna; 6.25 Gm. Ginger, sliced; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Serpentariæ. Br.	50 Gm. Serpentary Rhizome, No. 10 powder; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain
Uvæ Ursi. Br.	50 Gm. Bearberry Leaves, bruised; 1000 Cc. boiling Distilled Water	Infuse in a covered vessel for fifteen minutes; strain

NOTE.—Processes for some largely used unofficial infusions are appended.

INFUSUM GENTIANÆ COMPOSITUM. U. S. 1870. Compound Infusion of Gentian

	Metric	U. S. 1870
Gentian, in moderately coarse powder	16 Gm.	½ troy oz.
Bitter Orange Peel, in moderately coarse powder	4 Gm.	60 grains
Coriander, in moderately coarse powder	4 Gm.	60 grains
Alcohol	60 Cc.	2 fl. oz.
Water, a sufficient quantity		

Mix the Alcohol with fourteen fluidounces of Water (435 Cc. metric), and, having moistened the mixed powders with three fluidrachms (12 Cc. metric) of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them, first, the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint (500 Cc. metric).

Average dose.—4 fluidrachms (16 Cc.).

INFUSUM GENTIANÆ COMPOSITUM FORTIUS. Concentrated Compound Infusion of Gentian (quadruple strength)

	Metric	
Gentian, in moderately coarse powder	64 Gm.	2 troy oz.
Bitter Orange Peel, in moderately coarse powder	16 Gm.	½ troy oz.
Coriander, in moderately coarse powder	16 Gm.	½ troy oz.
Alcohol	60 Cc.	2 fl. oz.
Water	435 Cc.	14 fl. oz.

Mix the Alcohol with the Water, and, having moistened the mixed powders with one fluidounce (30 Cc. metric) of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them, first, the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint (500 Cc. metric). This preparation keeps well, is four times the strength of the U. S. P. 1870 infusion, and may be diluted with Water containing Alcohol in the same proportion (1 Alcohol. 7 Water) when Compound Infusion of Gentian is prescribed. If water alone is used to dilute it, a precipitate is apt to occur.

INFUSUM ROSÆ COMPOSITUM. U.S. 1870. Compound Infusion of Rose

	Metric	U. S. 1870
Red Rose, dried petals	16 Gm.	½ troy oz.
Diluted Sulphuric Acid	12 Cc.	3 fl. dr.
Sugar, in coarse powder	48 Gm.	1½ troy oz.
Boiling Water	1250 Cc.	2½ pints

Pour the Water upon the Rose, in a covered glass or porcelain vessel; add the Acid, and macerate for half an hour. Lastly, dissolve the Sugar in the liquid, and strain.

INFUSUM SALVIÆ. U.S. 1870. Infusion of Sage

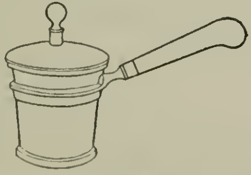
	Metric	U. S. 1870
Sage	16 Gm.	½ troy oz.
Boiling Water	500 Cc.	1 pint

Macerate for half an hour in a covered vessel, and strain.

Decocta *Decoctions*

Decoctions are liquid preparations made by *boiling* vegetable substances with water. The object sought in preparing decoctions is to secure, in aqueous solution, the soluble active principles of drugs which are not injured by heat. It is obvious that very few drugs are suited to this form of administration; and decoctions are rapidly declining in favor. Hot infusion will generally afford a means of obtaining all the benefits that are derived from boiling the drug with water, while the prolonged action of boiling water generally exercises a dissociating effect upon the active principles. The disadvantages of hot infusions are possessed in a more marked degree by decoctions (see page 326). In compound decoctions the ingredients are preferably added at different periods of the opera-

FIG. 435



Block tin decoction vessel

FIG. 436

Brass water bath

tion, the hard, ligneous drugs being added first, and the aromatics, or those containing volatile oils, at the close of the process, so that loss of activity of the latter may not ensue.

The earthenware or porcelain vessels used in preparing infusions are preferred for decoctions (see page 327), as they will bear the heat of boiling water, if heated gradually. Fig. 435 shows a block-tin vessel employed for preparing decoctions, used largely in Germany, and to some extent here. It is preferably used in connection with the brass water bath, R (see Fig. 436). The rim, F, is somewhat flexible, while a small aperture permits the escape of steam. The empyreumatic odor which many decoctions possess when made over a naked fire, and caused by particles adhering to the bottom of the vessel and becoming charred, is avoided by the use of the water bath.

Iron vessels are not used advantageously, because of the discoloration which is caused by the tannin of astringent drugs reacting with the iron.

A general formula for decoctions will be found in the U. S. P. (8th Rev.), but special formulas were not introduced (see below).

DECOCTA. U.S. Decoctions

General Formula U. S. P.—An ordinary Decoction, the strength of which is not directed by the physician, shall be prepared by the following formula:

Take of	Metric	Old form
***The Substance,** coarsely comminuted	50 Gm.	365 grains
Water, a sufficient quantity,		
To make	1000 Cc.	1 pint

Introduce the Substance into a suitable vessel provided with a cover, pour upon it 1000 Cc. [old form 1 pint] of cold Water, cover it well, and boil for fifteen minutes. Then allow it to cool to about 40° C. (104° F.), express, strain the expressed liquid, and pass enough cold Water through the strainer to make the product measure 1000 Cc. [old form 1 pint].

Caution.—The strength of Decoctions of energetic or powerful substances should be specially prescribed by the physician.

NOTE.—Processes for two largely used unofficial decoctions are appended.

DECOCTUM SARSAPARILLÆ COMPOSITUM FORTIUS. P.G. Zittmann's Decoction (Stronger)

	Metric	Old form
Sarsaparilla, cut	20 Gm.	2 oz. av.
Water	520 Cc.	50 fl. oz.

Digest for twenty-four hours, and, having added

	Metric	Old form
Sugar	1 Gm.	44 grains
Alum	1 Gm.	44 grains

expose them in a covered vessel, with occasional stirring, for three hours, to the heat of boiling water; then add to the mixture

	Metric	Old form
Anise, bruised	1 Gm.	44 grains
Fennel, bruised	1 Gm.	44 grains
Senna, cut	5 Gm.	½ oz. av.
Liquorice Root, cut	2 Gm.	88 grains

Digest for a quarter of an hour, and strain the liquid with expression. Allow the Decoction to settle; then pour off the liquid, and, by the addition of water, bring it to 500 Cc. [or 3 pints].

DECOCTUM SARSAPARILLÆ COMPOSITUM MITIUS. P. G. Zittmann's Decoction (Milder)

	Metric	Old form
Sarsaparilla, cut	10 Gm.	1 oz. av.
Water	480 Cc.	46 fl. oz.

Digest for twenty-four hours, and expose in a covered vessel, with occasional stirring, for three hours, to the heat of boiling water on a water bath. Then add to the decoction:

	Metric	Old form
Lemon Peel, cut	1 Gm.	44 grains
Cinnamon, bruised	1 Gm.	44 grains
Cardamom, bruised	1 Gm.	44 grains
Liquorice Root, cut	1 Gm.	44 grains

Digest for a quarter of an hour, and strain the liquid with expression. Allow the Decoction to settle; then pour off the liquid, and, by the addition of water, bring it to 500 Cc. [or 3 pints].

Unofficial Decoctions

Name	Ingredients	Method of Preparation
Decoctum Aloes Compositum. Br.	10 Gm. Extract Barbadoes Aloes; 5 Gm. each of Myrrh, Saffron, and Potassium Carbonate; 40 Gm. Extract Liquorice; 300 Cc. Compound Tincture of Cardamoms; Distilled Water to make 1000 Cc.	Coarsely powder the Extract of Aloes and Myrrh and boil them with the Potassium Carbonate and Extract of Liquorice, in 400 Cc. of Water, for five minutes, then add the Saffron and when cold the Compound Tincture of Cardamoms. Set aside for two hours, strain, and add Distilled Water to make 1000 Cc.
Cetrariæ. U. S. P. 1890	50 Gm. Cetraria; Water to make 1000 Cc.	Infuse the Cetraria, during half an hour, with 400 Cc. Cold Water, express, and throw the liquid away. Boil the residue with 1000 Cc. of Water for thirty minutes, strain, and add Water to make 1000 Cc.
Granati Corticis. Br.	200 Gm. Pomegranate Bark, No. 10 powder; Distilled Water to make 1000 Cc.	Boil the Pomegranate Bark with 1200 Cc. of Water for ten minutes, strain and add Water to make 1000 Cc.
Hæmatoxyli. Br.	50 Gm. Logwood, in chips; 8 Gm. Cinnamon Bark, bruised; Distilled Water to make 1000 Cc.	Boil the Logwood with 1200 Cc. of Water for ten minutes, adding the Cinnamon Bark toward the end of the time, strain, and add Water to make 1000 Cc.
Sarsaparillæ Compositum. U.S.P. 1890	100 Gm. Sarsaparilla, bruised; 20 Gm. Sassafras, No. 20 powder; 20 Gm. rasped Guaiacum Wood; 20 Gm. bruised Glycyrrhiza; 10 Gm. bruised Mezereum; Water to make 1000 Cc.	Boil the Sarsaparilla and Guaiacum Wood for thirty minutes with 1000 Cc. of Water, add the Sassafras, Glycyrrhiza, and Mezereum, cover and macerate for two hours. Finally, strain and add Cold Water to make 1000 Cc.

CHAPTER XXVII

ALCOHOLIC LIQUIDS MADE BY PERCOLATION OR MACERATION

Tincturæ *Tinctures*

TINCTURES are alcoholic solutions of medicinal substances. They differ from spirits in being made from *non-volatile* bodies, there being but one official exception to this rule.[1] They are made by percolation, maceration, solution, or dilution, and the menstrua employed in the official tinctures are alcohol, diluted alcohol of various strengths, aromatic spirit of ammonia, or mixtures of alcohol, water, and glycerin. The official tinctures are *sixty-four* in number. In some unofficial tinctures, ether, spirit of ether, ammoniated alcohol, and spirit of nitrous ether are used. The use of alcohol as a solvent for the active or useful principles in drugs has been practised for many years, but it has required a long time and much experience to determine the proper proportion of water to dilute the alcohol so that the menstrua should thoroughly exhaust the drugs without extracting the inert principles, and yet contain sufficient alcohol to secure permanent preparations that will not deposit in time a portion of their active constituents. The advantages of alcohol as a menstruum have been proved so thoroughly, that the use of aqueous preparations has greatly declined in this country; and yet there are some instances, particularly in the case of the weak tinctures and those requiring a large dose, in which the therapeutic action of the menstruum almost equals that of the drug. In these cases, however, the physician may prefer the fluidextract when he does not desire the stimulating action of the alcohol in the tincture.

In selecting the menstrua the proportion of water in each case was made as great as possible without endangering the permanency of the preparation, one especial advantage being that such tinctures may be added in small proportions to aqueous preparations without serious precipitation. In this respect tinctures have usually a great advantage over fluidextracts, and weaker alcoholic menstrua are often used successfully for tinctures when such would be entirely unsuitable for fluidextracts, because the tincture, on account of its comparative weakness, having a much larger proportion of menstruum than the fluidextract with which to exhaust the drug, may have the excess over the proportion of alcohol used in the fluidextract made up with water. It has been proved that a pint of diluted alcohol will extract by percolation a larger proportion of the soluble principles of a drug than half a pint of alcohol and half a pint of water percolated separately through the drug. The properties of *alcohol* are considered under another head (Part IV.), yet it seems desirable to notice here the solvent properties of this valuable preservative. It mixes freely with

---

[1] Tincture of Iodine.

water, ether, acetic acid, a number of volatile oils, and castor oil; it dissolves resins, camphor, tannin, benzoic acid, chlorophyl, the alkaloids, balsams, iodine, ferric chloride, ammonium carbonate, etc. *Diluted alcohol* extracts from drugs, gum, extractive, chlorophyl, albumen, coloring matter, resins, volatile oils, alkaloids, sugar, tannin, etc. *Glycerin* is used in tinctures to prevent precipitation by retaining in solution principles which would otherwise in time be deposited.

Preparation.—Tinctures are officially made in three ways: 1. By percolation. 2. By maceration. 3. By solution or dilution.

1. **By Percolation.**—This is the best method for making tinctures, and it is always directed by the Pharmacopœia when practicable. Tinctures are made in this way from all drugs which are capable of being readily comminuted and displaced. The special advantages of percolation over maceration and expression are seen in the saving of time and labor, and in the greater efficiency of the product if the process has been carefully and skilfully performed. The introduction of metric measures into the U. S. Pharmacopœia of 1890 has greatly simplified the working formulas, there being now no calculations necessary to determine the end product; the employment of metric receiving bottles in percolating operations secures accuracy within reasonable limits, and their convenience will always be a recommendation. The use of parts by weight for tinctures proved unsatisfactory. If the drugs from which the tinctures are directed to be made could be standardized so that they would always contain a definite and uniform weight of the active principles, there might be an advantage in bringing the end product to a weight which would bear a simple relation to the proportion of active principles selected as a standard; but the Pharmacopœia, for obvious reasons, has not fixed a limit for even the amount of moisture in the air dried drugs, and to assay all of them and to fix a maximum and minimum limit of each active principle present in each drug would be impracticable, and in most cases impossible. Now, the variation in the amount of moisture and in the proportion of active principles in commercial drugs is far greater than is generally supposed; and so long as this ever present bar to uniformity is not overcome, it is useless to regard the trifling advantage supposed to exist in favor of accuracy and convenience in weighing liquids; practically, the question of accuracy resolves itself into one of personal error, for a careful operator will make more accurate tinctures by using measures than a careless one will by using weights, and *vice versa.*

2. **By Maceration.**—This method of making tinctures is officially used in the case of resins, balsams, gums, soap, etc., where the practical difficulties likely to be encountered in percolation would offset any advantages that the latter process might possess (see page 242).

3. **By Solution or Dilution.**—A few tinctures are made in this way, such as tincture of iodine by dissolving iodine in alcohol, and tincture of ferric chloride by diluting the solution of ferric chloride with alcohol.

The proportion of the drug to the finished product varies in the class of tinctures, but at the last revision of the U. S. Pharmacopœia an attempt was made to bring about some degree of uniformity by making the majority of them of two strengths,—10 percent. if made from potent drugs, 20 percent. if made from drugs which are not classed as powerful in their action. The selection of 10 percent. as the strength for potent tinctures was made by the International Conference held at Brussels in 1902, and as it is most desirable to promote uniformity in the strength of potent remedies throughout the world, the U. S. Pharmacopœia (8th Rev.) adopted the proposition, and in consequence there has been a reduction of strength of many of the strong tinctures, the most important changes being that of tincture of aconite from 35 percent. to 10 percent. and of tincture of veratrum from 40 percent. to 10 percent. A number of assay processes for tinctures containing alkaloids have been introduced in the U. S. P. (8th Rev.), and these will serve to bring about reliability and uniformity in strength.

The following tables exhibit the official tinctures, classified, so as to show their relative strength both as to weight and volume, the variations in menstrua, and other useful data :

Official Tinctures arranged in the Order of their Relative Strength, and other Data

Number of Grammes of most Active Agent or Drug represented by 100 Cc.	Number of Grains of most Active Ingredients represented by a Fluidrachm	Official Name	Fineness of Powder	Menstruum	Ingredients in 1000 Cc.
1.6	0.91	Tinctura Opii Camphorata	. . . .	Dil. Alcohol, 96 ; Glycerin, 4	4 Gm. Powdered Opium : 4 Gm. Benzoic Acid ; 4 Gm. Camphor ; 4 Cc. Oil of Anise
Ext. 2	1.14	Nucis Vomicæ	. . . .	Alc. 75 ; Wat. 25	20 Gm. Dried Extract
4.5	2.56	Lavandulæ Composita	. . . .	Alc. 75 ; Wat. 25	8 Cc. Oil of Lavender Flowers ; 2 Cc. Oil of Rosemary ; 20 Gm. Saigon Cinnamon ; 5 Gm. Cloves ; 10 Gm. Myristica ; 10 Gm. Red Saunders
5	2.85	Gambir Composita	50	Dil. Alcohol	50 Gm. Gambir ; 25 Gm. Saigon Cinnamon
5	2.85	Kino	. . . .	Alc. 65 ; Wat. 20 ; Glycerin, 15	50 Gm. Kino
5	2.85	Moschi	. . . .	Alc. 50 ; Wat. 50	50 Gm. Musk
6.2	3.53	Cardamomi Composita	. . . .	Dil. Alcohol, 95 ; Glycerin, 5	25 Gm. Cardamom ; 25 Gm. Saigon Cinnamon, 12 Gm. Caraway ; 5 Gm. Cochineal
7	3.99	Iodi	. . . .	Alcohol	70 Gm. Iodine ; 50 Gm. Potassium Iodide
10	5.70	Aconiti	60	Alc. 70 ; Wat. 30	100 Gm. Aconite. Assayed
10	5.70	Aloes	40	Dil. Alcohol	100 Gm. Purified Aloes ; 200 Gm. Glycyrrhiza
10	5.70	Belladonnæ Foliorum	60	Dil. Alcohol	100 Gm. Belladonna Leaves. Assayed
10	5.70	Cannabis Indicæ	40	Alcohol	100 Gm. Indian Cannabis
10	5.70	Cantharidis	60	Alcohol	100 Gm. Cantharides
10	5.70	Capsici	50	Alc. 95 ; Wat. 5	100 Gm. Capsicum
10	5.70	Colchici Seminis	50	Alc. 60 ; Wat. 40	100 Gm. Colchicum Seed. Assayed
10	5.70	Digitalis	60	Dil. Alcohol	100 Gm. Digitalis
10	5.70	Gelsemii	60	Alc. 65 ; Wat. 35	100 Gm. Gelsemium
10	5.70	Gentianæ Composita	. . . .	Alc. 60 ; Wat. 40	100 Gm. Gentian ; 40 Gm. Bitter Orange Peel ; 10 Gm. Cardamom

Tinctures, U. S. P.—*Continued*

Number of Grammes of most Active Agent or Drug represented by 100 Cc.	Number of Grains of most Active Ingredients represented by a Fluidrachm.	Official Name	Fineness of Powder	Menstruum	Ingredients in 1000 Cc.
10	5.70	Tinctura Hyoscyami	60	Dil. Alcohol	100 Gm. Hyoscyamus. Assay
10	5.70	Lobeliæ	50	Dil. Alcohol	100 Gm. Lobelia
10	5.70	Opii	. . . .	Alc. 50; Wat. 50	100 Gm. Granulated Opium. Assayed
10	5.70	Opii Deodorati	. . . .	Alc. 20; Wat. 80	100 Gm. Granulated Opium. Assayed
10	5.70	Physostigmatis	50	Alcohol	100 Gm. Physostigma. Assay
10	5.70	Sanguinariæ	60	Alc. 60; Wat. 40; Acetic Acid, 2	100 Gm. Sanguinaria
10	5.70	Scillæ	20	Alc. 75; Wat. 25	100 Gm. Squill
10	5.70	Stramonii	60	Dil. Alcohol	100 Gm. Stramonium. Assayed
10	5.70	Strophanthi	60	Alc. 65; Wat. 35	100 Gm. Strophanthus
10	5.70	Vanillæ	Cut and bruised	Alc. 65; Wat. 35	100 Gm. Vanilla; 200 Gm. Sugar
10	5.70	Veratri	60	Alcohol	100 Gm. Veratrum
13.3	7.57	Ferri Chloridi	. . . .	Alc. 75; Wat. 25	350 Cc. Solution of Ferric Chloride
20	11.40	Aloes et Myrrhæ	40	Alc. 75; Wat. 25	100 Gm. Aloes; 100 Gm. Myrrh; 100 Gm. Glycyrrhiza
20	11.40	Arnicæ	20	Dil. Alcohol	200 Gm. Arnica
20	11.40	Asafœtidæ	Bruised	Alcohol	200 Gm. Asafetida
20	11.40	Aurantii Amari	40	Alc. 60; Wat. 40	200 Gm. Bitter Orange Peel
20	11.40	Benzoini	40	Alcohol	200 Gm. Benzoin
20	11.40	Calendulæ	20	Alcohol	200 Gm. Calendula
20	11.40	Calumbæ	20	Alc. 60; Wat. 40	200 Gm. Calumba
20	11.40	Cardamomi	30	Dil. Alcohol	200 Gm. Cardamom
20	11.40	Cimicifugæ	40	Alcohol	200 Gm. Cimicifuga
20	11.40	Cinchonæ	60	Alc. 67.5; Wat. 25; Glycerin, 7.5	200 Gm. Cinchona. Assayed
20	11.40	Cinchonæ Composita	. . . .	Alc. 67.5; Wat. 25; Glycerin, 7.5	100 Gm. Red Cinchona; 80 Gm. Bitter Orange Peel; 20 Gm. Serpentaria
20	11.40	Cinnamomi	50	Alc. 67.5; Wat. 25; Glycerin, 7.5	200 Gm. Saigon Cinnamon
20	11.40	Gallæ	40	Alcohol, 90; Glycerin, 10	200 Gm. Nutgall
20	11.40	Guaiaci	40	Alcohol	200 Gm. Guaiac
20	11.40	Guaiaci Ammoniata	40	Aromatic Spirit of Ammonia	200 Gm. Guaiac
20	11.40	Hydrastis	60	Alc. 65; Wat. 35	200 Gm. Hydrastis. Assayed
20	11.40	Ipecacuanhæ et Opii	. . . .	. . . .	1000 Cc. Deodorized Tincture of Opium; evaporate off 100 Cc. and add 100 Cc. Fluidextract of Ipecac
20	11.40	Krameriæ	40	Dil. Alcohol	200 Gm. Krameria
20	11.40	Myrrhæ	Course powder	Alcohol	200 Gm. Myrrh
20	11.40	Pyrethri	50	Alcohol	200 Gm. Pyrethrum
20	11.40	Quassiæ	50	Alc. 35; Wat. 65	200 Gm. Quassia
20	11.40	Quillajæ	20	Alc. 35; Wat. 65	200 Gm. Quillaja
20	11.40	Rhei	. . . .	Alc. 50; Wat. 40; Glycerin, 10	200 Gm. Rhubarb; 40 Gm. Cardamom
20	11.40	Rhei Aromatica	. . . .	Alc. 50; Wat. 40; Glycerin, 10	200 Gm. Rhubarb; 40 Gm. Saigon Cinnamon; 40 Gm. Cloves; 20 Gm. Myristica
20	11.40	Serpentariæ	50	Alc. 65; Wat. 35	200 Gm. Serpentaria

Tinctures, U. S. P.—*Continued*

Number of Grammes of most Active Agent or Drug represented by 100 Cc.	Number of Grains of most Active Ingredients represented by a Fluidrachm	Official Name	Fineness of Powder	Menstruum	Ingredients in 1000 Cc.
20	11.40	Tinctura Tolutana	. . . .	Alcohol	200 Gm. Balsam of Tolu
20	11.40	Valerianæ	60	Alc. 75; Wat. 25	200 Gm. Valerian
20	11.40	Valerianæ Ammoniata	60	Aromatic Spirit of Ammonia	200 Gm. Valerian
20	11.40	Zingiberis	50	Alcohol	200 Gm. Ginger
24	13.68	Benzoini Composita	40	Alcohol	100 Gm. Benzoin; 20 Gm. Purified Aloes; 80 Gm. Storax; 40 Gm. Balsam of Tolu
50	28.50	Aurantii Dulcis	. . . .	Alcohol	500 Gm. Sweet Orange Peel (fresh)
50	28.50	Lactucarii	. . . .	Alcohol, Water, and Glycerin	500 Gm. Lactucarium
50	28.50	Limonis Corticis	. . . .	Alcohol	500 Gm. Lemon Peel (fresh)
50	28.50	Tincturæ Herbarum Recentium	Cut, bruised, or crushed	Alcohol	500 Gm. of the Fresh Herb

Table of Compound Official Tinctures (arranged Alphabetically) with Data showing Total Amount of Ingredients represented by the Tincture

Total number of Grammes of Ingredients represented by 100 Cc.	Total number of Grains of Ingredients represented by one fluidrachm	Official Name	Ingredients in 1000 Cc.
30	17.10	Aloes	100 Gm. Purified Aloes; 200 Gm. Glycyrrhiza
30	17.10	Aloes et Myrrhæ	100 Gm. Purified Aloes; 100 Gm. Myrrh; 100 Gm. Glycyrrhiza
24	13.68	Benzoini Composita	100 Gm. Benzoin; 20 Gm. Purified Aloes; 80 Gm. Storax; 40 Gm. Balsam of Tolu
6.7	3.82	Cardamomi Composita	25 Gm. Cardamom; 25 Gm. Saigon Cinnamon; 12 Gm. Caraway; 5 Gm. Cochineal
20	11.40	Cinchonæ Composita	100 Gm. Red Cinchona; 80 Gm. Bitter Orange Peel; 20 Gm. Serpentaria
7.5	4.27	Gambir Composita	50 Gm. Gambir; 25 Gm. Saigon Cinnamon
15	8.55	Gentianæ Composita	100 Gm. Gentian; 40 Gm. Bitter Orange Peel; 10 Gm. Cardamom
20	11.40	Ipecacuanhæ et Opii	1000 Cc. Tincture of Deodorized Opium, evaporate off 100 Cc. and add 100 Cc. Fluid Extract of Ipecac
5.5	3.13	Lavandulæ Composita	8 Cc. Oil of Lavender Flowers; 2 Cc. Oil of Rosemary; 20 Gm. Saigon Cinnamon; 5 Gm. Cloves; 10 Gm. Myristica; 10 Gm. Red Saunders
1.6	0.91	Opii Camphorata	4 Gm. Powdered Opium; 4 Gm. Benzoic Acid; 4 Gm. Camphor; 4 Cc. Oil of Anise
24	13.68	Rhei	200 Gm. Rhubarb; 40 Gm. Cardamom
30	17.10	Rhei Aromatica	200 Gm. Rhubarb; 40 Gm. Saigon Cinnamon; 40 Gm Cloves; 20 Gm. Myristica
30	17.10	Vanillæ	100 Gm. Vanilla; 200 Gm. Sugar

Unofficial Tinctures

Name	Ingredients	Method of Preparation
Tinctura Arnicæ Radicis. U. S. P. 1890	100 Gm. Arnica Root, No. 40 powder; Alcohol (65 percent.) to make 1000 Cc.	Percolate the drug with the menstruum to make 1000 Cc.
Bryoniæ. U. S. P. 1890.	100 Gm. Bryonia, No. 40 powder; Alcohol to make 1000 Cc.	Percolate the drug with Alcohol, after macerating twenty-four hours, to make 1000 Cc.
Buchu. Br.	200 Gm. Buchu Leaves, No. 20 powder; Alcohol (60 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Cascarillæ. Br.	200 Gm. Cascarilla, No. 40 powder; Alcohol (70 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Chiratæ. Br. U. S. P. 1890	100 Gm. Chirata, No. 40 powder; Alcohol (about 60 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Chloroformi et Morphinæ Composita. Br.	75 Cc. Chloroform; 10 Gm. Morphine Hydrochloride; 50 Cc. Diluted Hydrocyanic Acid; 25 Cc. Tincture of Capsicum; 100 Cc. Tincture of Indian Hemp; 1.5 Cc. Oil of Peppermint; 250 Cc. Glycerin; Alcohol (90 percent.) to make 1000 Cc.	Mix the Chloroform, Tinctures of Capsicum, and Indian Hemp, Oil of Peppermint, and Glycerin with 450 Cc. of Alcohol, dissolve the Morphine Hydrochloride in the mixture, add the Diluted Hydrocyanic Acid and Alcohol to make 1000 Cc.
Cocci. Br.	100 Gm. Cochineal, in powder; Alcohol (45 percent.) 1000 Cc.	Macerate during seven days, frequently agitating, strain, express, and filter liquid if necessary
Conii. Br.	200 Gm. Conium Fruit, No. 40 powder; Alcohol (70 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Croci. U. S. P. 1890	100 Gm. Saffron; Diluted Alcohol to make 1000 Cc.	Percolate the drug with Diluted Alcohol to make 1000 Cc.
Cubebæ. U.S.P. 1890	200 Gm. Cubeb, No. 30 powder; Alcohol to make 1000 Cc.	Percolate the drug with Alcohol, after twenty-four hours maceration, to make 1000 Cc.
Ergotæ Ammoniata. Br.	250 Gm. Ergot, No. 20 powder; 100 Cc. Solution of Ammonia (10 percent.); Alcohol (60 percent.) to make 1000 Cc.	Percolate the drug with 900 Cc. of the 60 percent. Alcohol, to which the Solution of Ammonia has been added, and continue with the Alcohol to make 1000 Cc. Set aside for twenty-four hours, filter if necessary
Hamamelidis. Br.	100 Gm. Hamamelis Bark, No. 20 powder; Alcohol (45 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Humuli. U.S.P. 1890	200 Gm. Hops, No. 20 powder; Diluted Alcohol to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Jaborandi. Br.	200 Gm. Jaborandi Leaves, No. 40 powder; Alcohol (45 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Jalapæ. Br.	200 Gm. Jalap, No. 40 powder; Alcohol (70 percent.), a sufficient quantity	Percolate the drug with the menstruum, to make 600 Cc. of percolate, express the marc, mix the two liquids, then set it aside for twenty-four hours, and filter. Assay for Resin, and add menstruum to make each 100 Cc. contain 1.5 Gm. of Resin
Limonis. Br.	250 Gm. Fresh Lemon Peel, shredded; Alcohol (90 percent.) 1000 Cc.	Macerate during seven days, frequently agitating, strain, express, and filter liquid if necessary
Lobeliæ Ætherea. Br.	200 Gm. Lobelia, No. 40 powder; Spirit of Ether to make 1000 Cc.	Percolate the drug with Spirit of Ether, after macerating for twenty-four hours, to make 1000 Cc.
Matico. U.S.P. 1890	100 Gm. Matico, No. 40 powder; Diluted Alcohol to make 1000 Cc.	Percolate the drug with Diluted Alcohol, after maceration for twenty-four hours, to make 1000 Cc.
Opii Ammoniata. Br.	150 Cc. Tincture of Opium; 20.6 Gm. Benzoic Acid; 6.25 Cc. Oil of Anise; 200 Cc. Solution of Ammonia (10 percent.); Alcohol (90 percent.) to make 1000 Cc.	Dissolve the Oil of Anise and Benzoic Acid in 600 Cc. of Alcohol; add the Tincture of Opium and Solution of Ammonia, mix, filter, and add enough of the Alcohol to make 1000 Cc.

Unofficial Tinctures—*Continued*

Name	Ingredients	Method of Preparation
Tinctura Podophylli. Br.	36.5 Gm. Podophyllum Resin; Alcohol (90 percent.) to make 1000 Cc.	Add the Resin to 900 Cc. of the Alcohol; set aside for twenty-four hours, occasionally agitating; filter, and add enough Alcohol to make 1000 Cc.
Pruni Virginianæ. Br.	200 Gm. Wild Cherry Bark, No. 20 powder; 625 Cc. Alcohol; 375 Cc. Water	Mix the drug with the Water; set aside for twenty-four hours, then add the Alcohol and macerate during seven days, frequently agitating; strain, express, and filter liquid if necessary
Quininæ. Br.	20 Gm. Quinine Hydrochloride; 1000 Cc. Tincture of Orange	Dissolve the Quinine Hydrochloride in the Tincture of Orange
Quininæ Ammoniata. Br.	20 Gm. Quinine Sulphate; 100 Cc. Solution of Ammonia (10 percent.); 900 Cc. Alcohol (60 percent.)	Mix the Solution of Ammonia with the Alcohol, add the Quinine Sulphate, and shake until a clear solution results; set it aside for three days, and filter
Rhei Dulcis. U. S. P. 1890	100 Gm. Rhubarb; 40 Gm. Glycyrrhiza; 40 Gm. Anise; 10 Gm. Cardamom; 100 Cc. Glycerin; Alcohol and Water to make 1000 Cc.	Reduce the Rhubarb, Glycyrrhiza, Anise, and Cardamom to a No. 40 powder; mix the Glycerin with 500 Cc. Alcohol and 400 Cc. Water, and percolate the mixed powders, after twenty-four hours maceration, with this menstruum, finishing with Diluted Alcohol to make 1000 Cc.
Senegæ. Br.	200 Gm. Senega Root, No. 40 powder; Alcohol (60 percent.) to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.
Sennæ Composita. Br.	200 Gm. Senna, broken; 100 Gm. Raisins (seeded); 25 Gm. Caraway Fruit, bruised; 25 Gm. Coriander Fruit, bruised; 1000 Cc. Alcohol (45 percent.)	Macerate the drugs with the 45 percent. Alcohol during seven days, express, and filter liquid if necessary
Stramonii Seminis. U. S. P. 1890	150 Gm. Stramonium Seed, No. 40 powder; Diluted Alcohol to make 1000 Cc.	Percolate the drug with Diluted Alcohol, after macerating twenty-four hours, to make 1000 Cc.
Sumbul. U. S. P. 1890	100 Gm. Sumbul, No. 30 powder; Alcohol, 65, and Water, 35, to make 1000 Cc.	Percolate the drug with the menstruum, after twenty-four hours maceration, to make 1000 Cc.

TINCTURA ACONITI. U. S. Tincture of Aconite

Note.—The strength of this Tincture has been reduced from 35 Gm. of Aconite in 100 Cc. (Pharm. 1890) to 10 Gm. of Aconite in 100 Cc.

	Metric	Old form
* **Aconite,** in No. 60 powder (containing not less than 0.5 percent. of aconitine)	100 Gm.	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix Alcohol and Water in the proportion of 700 Cc. [old form 22½ fl. oz.] of Alcohol to 300 Cc. [old form 9½ fl. oz.] of Water. Moisten the Aconite with 40 Cc. [old form 1½ fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum until 1000 Cc. [old form 2 pints] are obtained.

Tincture of Aconite, when assayed by the process given below, should contain in 100 Cc., 0.045 Gm. of aconitine.

Assay of Tincture of Aconite

Transfer 100 Cc. of Tincture of Aconite to an evaporating dish and evaporate it carefully to dryness at a temperature not exceeding 60° C. (140° F.), and assay the resulting extract by the method given under *Fluidextractum Aconiti*, page 382, using the same details as there directed for 10 Cc. of Fluidextract of Aconite, with the exception that the multiplication of the product by 10 must be omitted; the result will represent the weight in grammes of aconitine contained in 100 Cc. of Tincture of Aconite.

Average dose.— 10 minims (0.6 Cc.).

TINCTURA ALOES. U.S. Tincture of Aloes

	Metric	Old form
* **Purified Aloes,** in No. 40 powder	100 Gm	3 oz. av. 148 gr.
Glycyrrhiza, in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Purified Aloes and Glycyrrhiza in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Diluted Alcohol, for seven days, with occasional agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough Diluted Alcohol through the residue to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA ALOES ET MYRRHÆ. U.S. Tincture of Aloes and Myrrh

	Metric	Old form
* **Purified Aloes,** in No. 40 powder	100 Gm.	3 oz. av. 148 gr.
Myrrh, in No. 40 powder	100 Gm.	3 oz. av. 148 gr.
Glycyrrhiza, in No. 40 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 750 Cc. [old form 24 fl. oz.] of Alcohol with 250 Cc. [old form 8 fl. oz.] of Water. Macerate the Purified Aloes, Myrrh, and Glycyrrhiza in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of the menstruum, for seven days, with occasional agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pass enough menstruum through the residue to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA ARNICÆ. U.S. Tincture of Arnica

[TINCTURA ARNICÆ FLORUM, PHARM. 1890]

	Metric	Old form
* **Arnica,** in No. 20 powder	200 Gm.	6 oz. av. 296 gr.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Arnica with 500 Cc. [old form 1 pint] of Diluted Alcohol in a closed vessel, in a moderately warm place, for three days, with occasional stirring, and express strongly. Repeat this operation twice successively with 250 Cc. [old form 8 fl. oz.] of Diluted Alcohol, macerating for twenty-four hours each time; then, having ascertained the volume of the united expressed liquids, macerate the residual marc for six hours with sufficient menstruum to make approximately 1000 Cc. [old form 2 pints], and express as before. Mix the expressed liquids, filter through paper, and pass sufficient Diluted Alcohol through the filter to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA ASAFŒTIDÆ. U.S. Tincture of Asafetida

	Metric	Old form
* **Asafetida**, well bruised	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Asafetida in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Alcohol, during three days, with frequent agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough Alcohol through the residue to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA AURANTII AMARI. U.S. Tincture of Bitter Orange Peel

	Metric	Old form
* **Bitter Orange Peel**, in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 600 Cc. [old form 19 fl. oz.] of Alcohol with 400 Cc. [old form 13 fl. oz] of Water. Moisten the Bitter Orange Peel with 80 Cc. [old form 2½ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA AURANTII DULCIS. U.S. Tincture of Sweet Orange Peel

	Metric	Old form
* **Sweet Orange Peel**, from the fresh fruit, in thin shavings and cut into narrow shreds	500 Gm.	16 oz. av. 302 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Sweet Orange Peel in a stoppered wide-mouthed container and in a moderately warm place, with 1000 Cc. [old form 2 pints] of Alcohol, during forty-eight hours, with frequent agitation; then filter through purified cotton, and, when the liquid has drained off completely, gradually pass enough menstruum through the residue to make 1000 Cc. [old form 2 pints] of Tincture; finally, filter it through paper.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA BELLADONNÆ FOLIORUM. U.S. Tincture of Belladonna Leaves

	Metric	Old form
* **Belladonna Leaves,** in No. 60 powder (containing not less than 0.3 percent. of alkaloids)	100 Gm.	3 oz. av. 148 gr.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the powder with 40 Cc. [old form 1½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for three hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on Diluted Alcohol until 1000 Cc. [old form 2 pints] of percolate are obtained.

Tincture of Belladonna Leaves, when assayed by the process given below, should contain in 100 Cc., 0.03 Gm. of the alkaloids from Belladonna Leaves.

Assay of Tincture of Belladonna Leaves

Transfer 100 Cc. of Tincture of Belladonna Leaves to an evaporating dish and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 384), using the same details as there directed for 10 Cc. of Fluidextract of Belladonna Root, with the exception that the multiplication of the product by 10 be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of Tincture of Belladonna Leaves.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA BENZOINI. U.S. Tincture of Benzoin

	Metric	Old form
* **Benzoin,** in No. 40 powder.	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Benzoin with 250 Cc. [old form 8 fl. oz.] of Alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of 500 Cc. [old form 1 pint] of Alcohol, and set it aside in a moderately warm place, shaking frequently during three days. Then transfer the mixture to a paper filter, and when the liquid has drained off completely, pour on enough Alcohol to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA BENZOINI COMPOSITA. U. S. Compound Tincture of Benzoin.

	Metric	Old form
* **Benzoin,** in No. 40 powder	100 Gm.	3 oz. av. 148 gr.
Purified Aloes, in No. 40 powder	20 Gm.	292 grains
Storax	80 Gm.	2 oz. av. 293 gr.
Balsam of Tolu	40 Gm.	1 oz. av. 147 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Benzoin and Purified Aloes with 250 Cc. [old form 8 fl. oz.] of Alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of 500 Cc. [old form 1 pint] of Alcohol, add the Storax and Balsam of Tolu, and set the mixture aside in a moderately warm place, shaking it frequently during three days; then transfer it to a paper filter, and, when the liquid has drained off completely, pour on enough Alcohol to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA CALENDULÆ. U. S. Tincture of Calendula

	Metric	Old form
* **Calendula,** in No. 20 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Calendula with 80 Cc. [old form 2½ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

TINCTURA CALUMBÆ. U. S. Tincture of Calumba

	Metric	Old form
* **Calumba,** in No. 20 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 600 Cc. [old form 19 fl. oz.] of Alcohol with 400 Cc. [old form 13 fl. oz.] of Water. Moisten the Calumba with 100 Cc. [old form 3¼ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twenty-four hours; then pack it with moderate pressure, pour on enough menstruum to saturate the powder and leave a stratum above it, and allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CANNABIS INDICÆ. U.S. Tincture of Indian Cannabis

	Metric	Old form
* **Indian Cannabis,** in No. 40 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Indian Cannabis with 50 Cc. [old form $1\frac{3}{4}$ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 10 minims (0.6 Cc.).

TINCTURA CANTHARIDIS. U.S. Tincture of Cantharides

NOTE.—The strength of this tincture has been increased in the U. S. P., 8th Rev., from 5 Gm. in 100 Cc. to 10 Gm. in 100 Cc.

	Metric	Old form
* **Cantharides,** in No. 60 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Cantharides with 35 Cc. [old form $1\frac{1}{4}$ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 5 minims (0.3 Cc.).

TINCTURA CAPSICI. U.S. Tincture of Capsicum

NOTE.—The strength of this tincture has been increased in the U. S. P., 8th Rev., from 5 Gm. in 100 Cc. to 10 Gm. in 100 Cc.

	Metric	Old form
* **Capsicum,** in No. 50 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 950 Cc. [old form 30 fl. oz.] of Alcohol with 50 Cc. [old form 2 fl. oz.] of Water. Moisten the Capsicum with 35 Cc. [old form $1\frac{1}{4}$ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow

the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA CARDAMOMI. U.S. Tincture of Cardamom

	Metric	Old form
* **Cardamom,** in No. 30 powder	200 Gm.	6 oz. av. 296 gr.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Cardamom with 80 Cc. [old form 2½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CARDAMOMI COMPOSITA. U.S. Compound Tincture of Cardamom

	Metric	Old form
* **Cardamom**	25 Gm.	365 grains
Saigon Cinnamon	25 Gm.	365 grains
Caraway	12 Gm.	175 grains
Cochineal	5 Gm.	73 grains
Glycerin	50 Cc.	1½ fl. oz.
Diluted Alchol, a sufficient quanity,		
To make	1000 Cc.	2 pints

Mix the Glycerin with 950 Cc. [old form 30 fl. oz.] of Diluted Alcohol. Reduce the Cardamom, Saigon Cinnamon, Caraway, and Cochineal to a No. 40 powder, and macerate this powder in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of the menstruum during seven days, with occasional agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pour on the residue, first the remainder of the menstruum, and then sufficient Diluted Alcohol to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CIMICIFUGÆ. U.S. Tincture of Cimicifuga

	Metric	Old form
* **Cimicifuga,** in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Cimicifuga with 60 Cc. [old form 2 fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CINCHONÆ. U.S. Tincture of Cinchona

	Metric	Old form
* **Cinchona**, in No. 60 powder (yielding not less than 4 percent. of anhydrous ether-soluble alkaloids) . .	200 Gm.	6 oz. av. 296 gr.
Glycerin	75 Cc.	2½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Glycerin with 675 Cc. [old form 21½ fl. oz.] of Alcohol and 250 Cc. [old form 8 fl. oz.] of Water. Moisten the Cinchona with 80 Cc. [old form 2½ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, until 1000 Cc. [old form 2 pints] of percolate are obtained.

Tincture of Cinchona, when assayed by the process given below, should contain in 100 Cc., 0.75 Gm. of anhydrous ether-soluble alkaloids of Cinchona.

Assay of Tincture of Cinchona

Transfer 50 Cc. of Tincture of Cinchona to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc., transfer the liquid to a bottle having the capacity of about 180 Cc., rinsing the dish with 10 Cc. of diluted alcohol, then assay the resulting liquid by the method given under *Fluidextractum Cinchonæ* (page 389), with the exception that the multiplication of the product should be by 4 instead of 20; the result will represent the weight in grammes of anhydrous ether-soluble alkaloids contained in 100 Cc. of Tincture of Cinchona.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CINCHONÆ COMPOSITA. U.S. Compound Tincture of Cinchona

	Metric	Old form
* **Red Cinchona** (yielding not less than 5 percent. of anhydrous cinchona alkaloids)	100 Gm.	3 oz. av. 148 gr.
Bitter Orange Peel	80 Gm.	2 oz. av. 293 gr.
Serpentaria	20 Gm.	292 grains
Glycerin	75 Cc.	2½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Glycerin with 675 Cc. [old form 21½ fl. oz.] of Alcohol and 250 Cc. [old form 8 fl. oz.] of Water. Reduce the Red Cinchona, Bitter Orange Peel, and Serpentaria to a No. 60 powder, moisten this powder with 80 Cc. [old form 2½ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA CINNAMOMI. U.S. Tincture of Cinnamon

	Metric	Old form
* **Saigon Cinnamon,** in No. 50 powder	**200 Gm.**	6 oz. av. 296 gr.
Glycerin	**75 Cc.**	2½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix the Glycerin with 675 Cc. [old form 21½ fl. oz.] of Alcohol and 250 Cc. [old form 8 fl. oz.] of Water. Moisten the Saigon Cinnamon with 80 Cc. [old form 2½ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA COLCHICI SEMINIS. U.S. Tincture of Colchicum Seed

	Metric	Old form
* **Colchicum Seed,** in No. 50 powder (containing not less than 0.45 percent. of colchicine)	**100 Gm.**	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix 600 Cc. [old form 19 fl. oz.] of Alcohol with 400 Cc. [old form 13 fl. oz.] of Water. Moisten the Colchicum Seed with 40 Cc. [old form 1½ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of percolate.

Tincture of Colchicum Seed, when assayed by the process given below, should contain in 100 Cc., 0.04 Gm. of colchicine.

Assay of Tincture of Colchicum Seed

Transfer 100 Cc. of Tincture of Colchicum Seed to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Colchici Seminis* (page 391), with the exception that the multiplication of the product by 10 be omitted ; the result will represent the weight in grammes of colchicine contained in 100 Cc. of Tincture of Colchicum Seed.

Average dose.— 30 minims (2 Cc.).

TINCTURA DIGITALIS. U.S. Tincture of Digitalis

	Metric	Old form
* **Digitalis,** in No. 60 powder	**100 Gm.**	3 oz. av. 148 gr.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Moisten the Digitalis with 40 Cc. [old form 1½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours ; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA FERRI CHLORIDI. U.S. Tincture of Ferric Chloride

A hydro-alcoholic solution of Ferric Chloride [$FeCl_3 = 161.04$] containing not less than 13.28 percent. of the anhydrous salt, corresponding to 4.6 (4.58) percent. of metallic iron.

	Metric	Old form
* **Solution of Ferric Chloride**	**350 Cc.**	22 fl. oz. 3 fl. dr.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	4 pints

Mix the Solution with enough Alcohol to make 1000 Cc. [old form 4 pints]. Let the Tincture stand, in a closely covered vessel, protected from light, at least three months ; then transfer it to glass-stoppered bottles, and keep it protected from light.

(For tests and comments, see Part III.)

Average dose.— 8 minims (0.5 Cc.).

TINCTURA GALLÆ. U.S. Tincture of Nutgall

	Metric	Old form
* **Nutgall,** in No. 40 powder	**200 Gm.**	6 oz. av. 296 gr.
Glycerin	**100 Cc.**	3¼ fl. oz.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix the Glycerin with 900 Cc. [old form 28¾ fl. oz.] of Alcohol. Introduce the Nutgall, without moistening it, into a glass percolator, shaking down the powder evenly and compactly, and pour on sufficient of the menstruum to saturate it and leave a stratum above it. Allow the percolation to proceed slowly, pouring on the remainder of the menstruum, and then sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA GAMBIR COMPOSITA. U.S. Compound Tincture of Gambir

[To replace Tinctura Catechu Composita, Pharm. 1890]

	Metric	Old form
***Gambir**, in No. 50 powder	50 Gm.	1 oz. av. 293 gr.
Saigon Cinnamon, in No. 50 powder	25 Gm.	365 grains
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Gambir and Saigon Cinnamon in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Diluted Alcohol during forty-eight hours, with frequent agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pass enough menstruum through the residue to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.—1 fluidrachm (4 Cc.).

TINCTURA GELSEMII. U.S. Tincture of Gelsemium

	Metric	Old form
***Gelsemium**, in No. 60 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 650 Cc. [old form 21 fl. oz.] of Alcohol with 350 Cc. [old form 11 fl. oz.] of Water. Moisten the Gelsemium with 35 Cc. [old form 1¼ fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.—8 minims (0.5 Cc.).

TINCTURA GENTIANÆ COMPOSITA. U.S. Compound Tincture of Gentian

	Metric	Old form
***Gentian**	100 Gm.	3 oz. av. 148 gr.
Bitter Orange Peel	40 Gm.	1 oz. av. 147 gr.
Cardamom	10 Gm.	146 grains
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 600 Cc. [old form 19 fl. oz.] of Alcohol with 400 Cc. [old form 13 fl. oz.] of Water. Reduce the Gentian, Bitter Orange Peel, and Cardamom to a No. 40 powder, moisten this powder with 60 Cc. [old form 2 fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twelve hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twelve hours; then

allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA GUAIACI. U.S. Tincture of Guaiac

	Metric	Old form
* **Guaiac,** in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Guaiac in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Alcohol during three days, with frequent agitation; then filter, and when the liquid has drained off, pour on enough Alcohol to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA GUAIACI AMMONIATA. U.S. Ammoniated Tincture of Guaiac

	Metric	Old form
* **Guaiac,** in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Aromatic Spirit of Ammonia, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Guaiac in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Aromatic Spirit of Ammonia during three days, with frequent agitation; then filter, and, when the liquid has drained off, pour on enough Aromatic Spirit of Ammonia to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA HYDRASTIS. U.S. Tincture of Hydrastis

	Metric	Old form
* **Hydrastis,** in No. 60 powder (containing not less than 2.5 percent. of hydrastine)	200 Gm.	6 oz. av. 296 gr.
Alcohol, **Water,** each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix Alcohol and Water in the proportion of 650 Cc. [old form 21 fl. oz.] of Alcohol and 350 Cc. [old form 11 fl. oz.] of Water. Moisten the Hydrastis with 60 Cc. [old form 2 fl. oz.] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding menstruum until 1000 Cc. [old form 2 pints] of percolate are obtained.

Tincture of Hydrastis, when assayed by the process given below, should contain in 100 Cc., 0.4 Gm. of hydrastine.

Assay of Tincture of Hydrastis

Transfer 100 Cc. of Tincture of Hydrastis to an evaporating dish, and evaporate it on a water-bath until the liquid measures about 10 Cc. If any insoluble matter has separated, add sufficient alcohol to dissolve it, and then assay the resulting liquid by the method given under *Fluidextractum Hydrastis* (page 401), using the same details as there directed for 10 Cc. of Fluidextract of Hydrastis, with the exception that the weight of the residual alkaloids must be multiplied by 2 instead of by 20 as there directed, to give the weight in grammes of hydrastine contained in 100 Cc. of Tincture of Hydrastis.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA HYOSCYAMI. U.S. Tincture of Hyoscyamus

	Metric	Old form
* **Hyoscyamus,** in No. 60 powder (containing not less than 0.8 percent. of mydriatic alkaloids)	**100 Gm.**	3 oz. av. 148 gr.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Moisten the Hyoscyamus with 40 Cc. [old form 1½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol until 1000 Cc. [old form 2 pints] are obtained.

Tincture of Hyoscyamus, when assayed by the process given below, should contain in 100 Cc., 0.007 Gm. of mydriatic alkaloids.

Assay of Tincture of Hyoscyamus

Transfer 100 Cc. of Tincture of Hyoscyamus to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 384), using the same details as there directed for 10 Cc. of Fluidextract of Belladonna Root, with the exception that the multiplication by 10 be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of Tincture of Hyoscyamus.

Average dose.— 15 minims (1 Cc.).

TINCTURA IODI. U.S. Tincture of Iodine

	Metric	Old form
* **Iodine**	**70 Gm.**	255 grains
Potassium Iodide	**50 Gm.**	182 grains
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	8 fl. oz.

Triturate the Iodine and Potassium Iodide rapidly, in a mortar, to a coarse powder, and transfer it at once to a graduated bottle. Rinse the mortar with several successive portions of Alcohol, and pour the rinsings into the bottle. Then add Alcohol, shaking occasionally, until the Iodine and Potassium Iodide are dissolved, and the finished Tincture measures 1000 C. [old form 8 fl. oz.]. (If there is no necessity for rapid solution, the unpowdered Iodine and Potassium Iodide may be placed in the bottle containing the Alcohol and allowed to dissolve slowly.)

If 5 Cc. of the Tincture be mixed with about 25 Cc. of water and titrated with tenth-normal sodium thiosulphate V.S., about 27.25 Cc. of tenth-normal sodium thiosulphate V. S. should be required for complete decolorization (corresponding to about 6.86 Gm. of Iodine in 100 Cc.).

Average dose.— 1½ minims (0.1 Cc.).

TINCTURA IPECACUANHÆ ET OPII. U.S. Tincture of Ipecac and Opium

[Fluid Dover's Powder]

	Metric	Old form
* **Tincture of Deodorized Opium**	1000 Cc.	10 fl. oz.
Fluidextract of Ipecac	100 Cc.	1 fl. oz.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	10 fl. oz.

Evaporate the Tincture of Deodorized Opium, in a tared dish, on a water-bath, until it weighs 800 Gm. [old form 8 oz. av.]. When it has become cold, add to it the Fluidextract of Ipecac, filter the mixture, and pass enough Diluted Alcohol through the filter to obtain 1000 Cc. [old form 10 fl. oz.] of Tincture.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA KINO. U. S. Tincture of Kino

Note.—The strength of this tincture has been reduced from 10 Gm. in 100 Cc., U. S. P. 1890, to 5 Gm. in 100 Cc., U. S. P. 8th Rev.

	Metric	Old form
* **Kino**	50 Gm.	182 grains
Purified Talc	10 Gm.	36 grains
Glycerin	150 Cc.	1 fl. oz. 1 fl. dr.
Alcohol	650 Cc.	5 fl. oz. 1 fl. dr.
Water, a sufficient quantity,		
To make	1000 Cc.	8 fl. oz.

Mix the Glycerin with 200 Cc. [old form 1 fl. oz. 6 fl. dr.] of Water, and triturate the Kino and Purified Talc with sufficient of the mixture to produce a thin, smooth magma. Transfer this magma to a flask by the aid of the remainder of the mixture, and, having ascertained the weight of the flask and contents, heat it on a water-bath for about one hour; allow the flask and contents to cool, and restore the original weight by the addition of sufficient Water. Then add the Alcohol, mix, and pass the Tincture through a filter of purified cotton, keeping the funnel well covered. Finally, add sufficient Alcohol through the filter to obtain 1000 Cc. [old form 8 fl. oz.] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA KRAMERIÆ. U. S. Tincture of Krameria

	Metric	Old form
* **Krameria,** in No. 40 powder	200 Gm.	6 oz. av. 296 gr.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Krameria with 80 Cc. [old form 2½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA LACTUCARII. U. S. Tincture of Lactucarium

	Metric	Old form
* **Lactucarium**	**500 Gm.**	16 oz. av. 302 gr.
Glycerin	**250 Cc.**	8 fl. oz.
Alcohol,		
Purified Petroleum Benzin,		
Diluted Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Beat the Lactucarium in an iron mortar, with clean sand, to a coarse powder, and introduce it into a bottle; add 2000 Cc. [old form 4 pints] of Purified Petroleum Benzin, cork the bottle tightly, and set it aside for forty-eight hours, frequently agitating the mixture. Pour the mixture on a double filter, and allow it to drain. Wash the residue by gradually adding 1500 Cc. [old form 3 pints] of Purified Petroleum Benzin, and allow the Lactucarium to dry by exposing it to a current of air. When it is dry and free from the odor of Benzin, reduce it to powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the Glycerin with 200 Cc. [old form 6½ fl. oz.] of Water, and 500 Cc. [old form 1 pint] of Alcohol, and moisten the powder with 500 Cc. [old form 1 pint] of the mixture. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed very slowly, gradually adding, first the remainder of the menstruum, and then diluted Alcohol, until the Lactucarium is exhausted. Reserve the first 750 Cc. [old form 24 fl. oz.] of the percolate, evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to 250 Cc. [old form 8 fl. oz.] and mix this with the reserved portion. Filter, and add enough Diluted Alcohol through the filter to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA LAVANDULÆ COMPOSITA. U. S. Compound Tincture of Lavender

	Metric	Old form
* **Oil of Lavender Flowers**	**8 Cc.**	123 minims
Oil of Rosemary	**2 Cc.**	31 minims
Saigon Cinnamon	**20 Gm.**	292 grains
Cloves	**5 Gm.**	73 grains
Myristica	**10 Gm.**	146 grains
Red Saunders	**10 Gm.**	146 grains
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Reduce the Saigon Cinnamon, Cloves, Myristica, and Red Saunders to a No. 50 powder, and macerate this powder for three days in a mixture of 750 Cc. [old form 24 fl. oz.] of Alcohol and 250 Cc. [old form 8 fl. oz.] of Water, in which liquid the Oils have been dissolved. Then filter, and, when the liquid has drained off completely, pass enough of a mixture of Alcohol and Water, made in the same proportions as before, through the residue on the filter to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA LIMONIS CORTICIS. U. S. Tincture of Lemon Peel

	Metric	Old form
* **Lemon Peel,** from the fresh fruit, in thin shavings and cut into narrow shreds	**500 Gm.**	16 oz. av. 302 gr.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Macerate the Lemon Peel in a stoppered, wide-mouthed container, in a moderately warm place, with 1000 Cc. [old form 2 pints] of Alcohol during forty-eight hours, with frequent agitation; then filter through purified cotton, and, when the liquid has drained off completely, gradually pour on enough Alcohol to make 1000 Cc. [old form 2 pints] of Tincture, and filter.

TINCTURA LOBELIÆ. U. S. Tincture of Lobelia

NOTE.—The strength of this tincture has been reduced from 20 Gm. of Lobelia in 100 Cc. to 10 Gm. of Lobelia in 100 Cc.

	Metric	Old form
* **Lobelia,** in No. 50 powder,	**100 Gm.**	3 oz. av. 148 gr.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Moisten the Lobelia with 40 Cc. [old form 1½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— { Expectorant, 15 minims (1 Cc.).
Emetic, 1 fluidrachm (4 Cc.).

TINCTURA MOSCHI. U. S. Tincture of Musk

	Metric	Old form
* **Musk**	**5 Gm.**	91 grains
Alcohol	**45 Cc.**	1 fl. oz. 6 fl. dr.
Water	**45 Cc.**	1 fl. oz. 6 fl. dr.
Diluted Alcohol, a sufficient quantity,		
To make	**100 Cc.**	4 fl. oz.

Triturate the Musk with the Water, a little at a time, until a smooth mixture is obtained; transfer this mixture to a bottle and allow it to stand twenty-four hours; add the Alcohol and macerate the mixture for six days, occasionally shaking it. Then filter through a plain paper filter, and, when the liquid has drained off completely, pass enough Diluted Alcohol through the filter to make 100 Cc. [old form 4 fl. oz.] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA MYRRHÆ. U.S. Tincture of Myrrh

	Metric	Old form
* **Myrrh,** in moderately coarse powder	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Macerate the Myrrh in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of Alcohol during three days, with frequent agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pour on enough menstruum to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA NUCIS VOMICÆ. U.S. Tincture of Nux Vomica

	Metric	Old form
* **Extract of Nux Vomica** (containing 5 percent. of strychnine)	20 Gm.	292 grains
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Extract of Nux Vomica in a sufficient quantity of a mixture of Alcohol and Water, made in the proportion of 750 Cc. [old form 24 fl. oz.] of Alcohol and 250 Cc. [old form 8 fl. oz.] of water, to make the solution measure 1000 Cc. [old form 2 pints], and filter through a well-covered filter.

Tincture of Nux Vomica, when assayed by the process given below, should contain in 100 Cc., 0.1 Gm. of strychnine.

Assay of Tincture of Nux Vomica

Transfer 100 Cc. of Tincture of Nux Vomica to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under *Extractum Nucis Vomicæ* (page 449), using the same details as there directed for 2 Gm. of Extract of Nux Vomica, with the exception that the multiplication by 50 be omitted; the result will represent the weight in grammes of strychnine contained in 100 Cc. of Tincture of Nux Vomica.

Average dose.— 10 minims (0.6 Cc.).

TINCTURA OPII. U.S. Tincture of Opium. Laudanum

	Metric	Old form
* **Granulated Opium** (containing 12 to 12.5 percent. of crystallizable morphine)	100 Gm.	3 oz. 148 gr.
Alcohol,		
Water,		
Diluted Alcohol, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Heat 400 Cc. [old form 13 fl. oz.] of water to boiling, and pour it on the Granulated Opium contained in a tared vessel, weigh, and stir occasionally during twelve hours; then restore the original weight by the addition of cold Water, add 400 Cc. [old form 13 fl. oz.] of Alcohol, pour the mixture into a bottle, and continue the maceration for forty-eight hours, occasionally shaking. Transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation slowly, pouring on sufficient Diluted Alcohol until 1000 Cc. [old form 2 pints] are obtained.

Tincture of Opium when assayed by the process given below, should contain in 100 Cc. not less than 1.2 nor more than 1.25 Gm. of crystallizable morphine.

Assay of Tincture of Opium

Tincture of Opium	**100.0 Cc.**
Ammonia Water	**3.5 Cc.**
Alcohol,	
Ether,	
Water,	
Lime Water, each, a sufficient quantity	

Transfer 100 Cc. of Tincture of Opium to an evaporating dish and evaporate it on a water-bath to about 20 Cc., add 40 Cc. of Water, mix thoroughly, and set the liquid aside for one hour, occasionally stirring to disintegrate the resinous flakes adhering to the dish. Then filter the liquid and wash the filter and residue with water, until all soluble matter is extracted (indicated by an almost colorless filtrate), and collect the washings separately. First evaporate the washings, in a tared dish, to a small volume, then add the first filtrate and evaporate the whole to a weight of 14 Gm.

Determine the morphine in this extract by the method given under Opium (twenty-first line of the Assay, beginning with the word "Rotate"), using the same details as there directed for 10 Gm. of Opium, with the exception that the final multiplication by 10 be omitted. The result will represent the weight in grammes of crystallized morphine yielded by 100 Cc. of Tincture of Opium.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA OPII CAMPHORATA. U.S. Camphorated Tincture of Opium. Paregoric

	Metric	Old form
* **Powdered Opium**	4 Gm.	58½ grains
Benzoic Acid	4 Gm.	58½ grains
Camphor	4 Gm.	58½ grains
Oil of Anise	4 Cc.	1 fl. dr.
Glycerin	40 Cc.	1¼ fl. oz.
Diluted Alcohol	950 Cc.	30 fl. oz.
To make	1000 Cc.	2 pints

Place all the ingredients in a stoppered container and macerate for three days with frequent agitation; then filter the mixture through a well-covered paper filter, adding sufficient Diluted Alcohol through the filter to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 2 fluidrachms (8 Cc.).

TINCTURA OPII DEODORATI. U.S. Tincture of Deodorized Opium

	Metric	Old form
* **Granulated Opium** (containing 12 to 12.5 per cent. of crystallizable morphine)	100 Gm.	3 oz. av. 148 gr.
Purified Petroleum Benzin	75 Cc.	2½ fl. oz.
Alcohol	200 Cc.	6 fl. oz. 3 fl. dr.
Water,		
To make	1000 Cc.	2 pints

Heat 500 Cc. [old form 1 pint] of Water to boiling, and pour it on the Granulated Opium contained in a suitable vessel, stirring the mixture frequently during twenty-four hours. Then transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation with Water until the Opium is exhausted. Concentrate the percolate by evaporation on a water-bath until it measures 150 Cc. [old form 4¾ fl. oz.], and, when cooled, shake it frequently and vigorously for ten minutes with 65 Cc. [old form 2 fl. oz.] of the Purified Petroleum Benzin. Separate the Benzin, repeat the shaking out for a few minutes with the remainder of the Benzin, and, having carefully and completely separated this second portion of Benzin, evaporate the remaining liquid in a warm place spontaneously, until the odor of Benzin has disappeared, removing the last traces by the heat of a water-bath. Mix the deodorized liquid so obtained with 500 Cc. [old form 19 fl. oz.] of Water, filter the mixture through a paper filter, and, having mixed the Alcohol with the filtrate, wash the filter with sufficient Water to make 1000 Cc. [old form 2 pints] of Tincture.

Assay of Tincture of Deodorized Opium

If 100 Cc. of Tincture of Deodorized Opium be assayed by the process given under *Tinctura Opii* (page 359) it should yield not less than 1.2 nor more than 1.25 Gm. of crystallized morphine.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA PHYSOSTIGMATIS. U.S. Tincture of Physostigma

	Metric	Old form
* **Physostigma,** in No. 50 powder (containing 0.15 percent. of ether-soluble alkaloids)	100 Gm.	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Physostigma with 40 Cc. [old form 1½ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Tincture of Physostigma, when assayed by the process given below, should contain in 100 Cc., 0.014 Gm. of the ether-soluble alkaloids from Physostigma.

Assay of Tincture of Physostigma

Transfer 100 Cc. of Tincture of Physostigma to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under *Extractum Physostigmatis* (page 451), using the same details as there directed for 1 Gm. of Extract of Physostigma, with the exception that the product must be multiplied by 2 instead of 200; the result will represent the weight in grammes of ether-soluble alkaloids from Physostigma contained in 100 Cc. of Tincture of Physostigma.

Average dose.— 15 minims (1 Cc.).

TINCTURA PYRETHRI. U.S. Tincture of Pyrethrum

	Metric	Old form
* **Pyrethrum,** in No. 50 powder	**200 Gm.**	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Moisten the Pyrethrum with 80 Cc. [old form 2½ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

TINCTURA QUASSIÆ. U.S. Tincture of Quassia

	Metric	Old form
* **Quassia,** in No. 50 powder	**200 Gm.**	6 oz. av. 296 gr.
Alcohol,		
Water, each, a sufficient quantity		
To make	**1000 Cc.**	2 pints

Mix 350 Cc. [old form 11 fl. oz.] of Alcohol with 650 Cc. [old form 21 fl. oz.] of Water. Moisten the Quassia with 60 Cc. [old form 2 fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA QUILLAJÆ. U.S. Tincture of Quillaja

	Metric	Old form
* **Quillaja,** in No. 20 powder	**200 Gm.**	6 oz. av. 296 gr.
Alcohol	**350 Cc.**	11 fl. oz.
Water, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Boil the Quillaja in a covered vessel with 800 Cc. [old form 25½ fl. oz.] of Water for fifteen minutes, strain while hot, and wash the residue on the strainer with 200 Cc. [old form 6½ fl. oz.] of Water, previously heated to boiling. Then evaporate the strained liquid to 600 Cc. [old form 19 fl. oz.], allow it to cool, add the Alcohol, and set it aside for twelve hours. Decant the clear liquid, filter it through paper, then pour the residue on the filter, and, when the liquid ceases to drop, wash the filter with sufficient water to make 1000 Cc. [old form 2 pints] of Tincture.

TINCTURA RHEI. U. S. Tincture of Rhubarb

	Metric	Old form
* **Rhubarb**	200 Gm.	6 oz. av. 296 gr.
Cardamom	40 Gm.	1 oz. av. 147 gr.
Glycerin	100 Cc.	3¼ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Glycerin with 500 Cc. [old form 1 pint] of Alcohol, and 400 Cc. [old form 12¾ fl. oz.) of Water. Reduce the Rhubarb and Cardamom to a No. 40 powder, and moisten this powder with 90 Cc. [old form 3 fl. oz.] of this menstruum ; transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twelve hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on, first, the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA RHEI AROMATICA. U. S. Aromatic Tincture of Rhubarb

	Metric	Old form
* **Rhubarb**	200 Gm.	6 oz. av. 296 gr.
Saigon Cinnamon	40 Gm.	1 oz. av. 147 gr.
Cloves	40 Gm.	1 oz. av. 147 gr.
Myristica	20 Gm.	292 grains
Glycerin	100 Cc.	3¼ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix the Glycerin with 500 Cc. [old form 1 pint] of Alcohol and 400 Cc. [old form 12¾ fl. oz.] of Water. Reduce the Rhubarb, Saigon Cinnamon, Cloves, and Myristica to a No. 40 powder, and moisten this powder with 90 Cc. [old form 3 fl. oz.] of this menstruum ; transfer it to a percolator, and, without pressing the powder, allow it to stand for twelve hours ; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on, first, the remainder of the menstruum, and then sufficient of a mixture of

Alcohol and Water, made in the same proportions as before, to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA SANGUINARIÆ. U. S. Tincture of Sanguinaria

	Metric	Old form
* **Sanguinaria,** in No. 60 powder	100 Gm.	3 oz. av. 148 gr.
Acetic Acid	20 Cc.	5 fl. dr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 600 Cc. [old form 19 fl. oz.] of Alcohol with 400 Cc. [old form 13 fl. oz.] of water. Moisten the Sanguinaria with the Acetic Acid and 30 Cc. [old form 1 fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA SCILLÆ. U.S. Tincture of Squill

	Metric	Old form
* **Squill,** in No. 20 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 750 Cc. [old form 24 fl. oz.] of Alcohol with 250 Cc. [old form 8 fl. oz.] of Water. Macerate the Squill with 600 Cc. [old form 19 fl. oz.] of the menstruum, in a closed vessel, in a moderately warm place for three days, occasionally stirring, and express strongly. Repeat this operation with 300 Cc. [old form 9½ fl. oz.] of menstruum, macerating one day before expression; and, finally, macerate the residue for six hours in sufficient menstruum to make the united expressed liquids measure about 1000 Cc. [old form 2 pints]. Express as before, mix the expressed liquids, filter through paper, and pass sufficient menstruum through the filter to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA SERPENTARIÆ. U.S. Tincture of Serpentaria

	Metric	Old form
* **Serpentaria,** in No. 50 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 650 Cc. [old form 21 fl. oz.] of Alcohol with 350 Cc. [old form 11 fl. oz.] of Water. Moisten the Serpentaria with 60 Cc. [old form

2 fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA STRAMONII. U.S. Tincture of Stramonium

	Metric	Old form
* **Stramonium,** in 60 powder (containing not less than 0.25 percent. of mydriatic alkaloids)	**100 Gm.**	3 oz. av. 148 gr.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Moisten the Stramonium with 40 Cc. [old form 1½ fl. oz.] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for three hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on Diluted Alcohol until 1000 Cc. [old form 2 pints] are obtained.

Tincture of Stramonium, when assayed by the process given below, should contain in 100 Cc., 0.025 Gm. of mydriatic alkaloids from Stramonium.

Assay of Tincture of Stramonium

Transfer 100 Cc. of Tincture of Stramonium to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 384), using the same details as there directed for 10 Cc. of Fluidextract of Belladonna Root, with the exception that the multiplication by 10, as there directed, be omitted; the result will represent the weight in grammes of alkaloids contained in 100 Cc. of Tincture of Stramonium.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA STROPHANTHI. U.S. Tincture of Strophanthus

NOTE.—The strength of this tincture has been increased from 5 Gm. of Strophanthus in 100 Cc. to 10 Gm. of Strophanthus in 100 Cc.

	Metric	Old form
* **Strophanthus,** in No. 60 powder	**100 Gm.**	3 oz. av. 148 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix 650 Cc. [old form 21 fl. oz.] of Alcohol with 350 Cc. [old form 11 fl. oz.] of Water. Moisten the Strophanthus with 50 Cc. [old form 1¾ fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to satu-

rate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 8 minims (0.5 Cc.).

TINCTURA TOLUTANA. U.S. Tincture of Tolu.

	Metric	Old form
* **Balsam of Tolu,**	**200 Gm.**	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Macerate the Balsam of Tolu in 800 Cc. [old form 25 fl. oz., 288 min.] of Alcohol, shaking frequently until dissolved; then filter through paper, and wash the filter with sufficient Alcohol to make 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA VALERIANÆ. U.S. Tincture of Valerian

	Metric	Old form
* **Valerian,** in No. 60 powder	**200 Gm.**	6 oz. av. 296 gr.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Mix 750 Cc. [old form 24 fl. oz.] of Alcohol with 250 Cc. [old form 8 fl. oz.] of Water. Moisten the Valerian with 60 Cc. [old form 2 fl. oz.] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 1 fluidrachm (4 Cc.).

TINCTURA VALERIANÆ AMMONIATA. U.S. Ammoniated Tincture of Valerian

	Metric	Old form
* **Valerian,** in No. 60 powder	**200 Gm.**	6 oz. av. 296 gr.
Aromatic Spirit of Ammonia, a sufficient quanity,		
To make	**1000 Cc.**	2 pints

Moisten the Valerian with 60 Cc. [old form 2 fl. oz.] of Aromatic Spirit of Ammonia, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Aromatic Spirit of Ammonia to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Aromatic Spirit of Ammonia to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURA VANILLÆ. U.S. Tincture of Vanilla

	Metric	Old form
* **Vanilla,** cut into small pieces and bruised	100 Gm.	3 oz. av. 148 gr
Sugar, in coarse powder	200 Gm.	6 oz. av. 296 gr.
Alcohol,		
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 650 Cc. [old form 21 fl. oz.] of Alcohol with 350 Cc. [old form 11 fl. oz.] of Water. Macerate the Vanilla in 500 Cc. [old form 1 pint] of the mixture for twelve hours; then drain off the liquid and set it aside. Transfer the Vanilla to a mortar, beat it with the Sugar into a uniform powder, then pack it in a percolator and pour upon it the reserve liquid. When this has disappeared from the surface, continue the percolation by gradually pouring on sufficient menstruum to make 1000 Cc. [old form 2 pints] of Tincture.

TINCTURA VERATRI. U.S. Tincture of Veratrum

[Tinctura Veratri Viridis, Pharm. 1890]

Note.—The strength of this tincture has been reduced from 40 Gm. of Veratrum Viride in 100 Cc. to 10 Gm. of Veratrum in 100 Cc.

	Metric	Old form
* **Veratrum,** in No. 60 powder	100 Gm.	3 oz. av. 148 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Veratrum with 40 Cc. [old form 1½ fl. oz.] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 15 minims (1 Cc.).

TINCTURA ZINGIBERIS. U.S. Tincture of Ginger

	Metric	Old form
* **Ginger,** in No. 50 powder	200 Gm.	6 oz. av. 296 gr.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	2 pints

Moisten the Ginger with 60 Cc. [old form 2 fl. oz] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain 1000 Cc. [old form 2 pints] of Tincture.

Average dose.— 30 minims (2 Cc.).

TINCTURÆ HERBARUM RECENTIUM. U.S. **Tinctures of Fresh Herbs**

Tinctures of Fresh Herbs, when not otherwise directed, are to be prepared according to the following formula:

	Metric	Old form
* **The Fresh Herb,** cut, bruised, or crushed	500 Gm.	16½ oz. av.
Alcohol	1000 Cc.	2 pints

Macerate the Herb with the Alcohol in a closed vessel in a moderately warm place during fourteen days, with occasional stirring; then strongly express the liquid and filter it through paper.

Vina Medicata *Medicated Wines*

These are liquid preparations containing the soluble principles of medicinal substances dissolved in wine. Pharmaceutically they most resemble tinctures, differing from them merely in the character of the menstruum. The fermented juice of the grape, known officially as "Vinum Album," or "White Wine," when brought to a definite alcoholic strength, is the menstruum used as the basis for medicated wines; and wines have the advantage over infusions and decoctions of being much more permanent preparations, on account of the presence of alcohol.

The stability of medicated wines was greatly improved by the requirement of the U. S. P. 1880 that they should be made from stronger white wine, a menstruum containing from 20 to 25 per-cent. of absolute alcohol by weight. The Eighth Decennial Revision of the U. S. P. requires the addition of alcohol or of an alcoholic tincture to every medicated wine. It is apparent that more useful and permanent preparations could be made by substituting a menstruum composed of alcohol and water, and hence tinctures are preferable. Of the *ten* official wines, *two* are not medicated, *seven* are made by solution or admixture, and *one* by maceration.

Official Wines

Name	Definition and Ingredients
Not Medicated	
Vinum Album	An alcoholic liquid, made by fermenting the juice of fresh grapes freed from seeds, stems, and skins
Rubrum	An alcoholic liquid, made by fermenting the juice of fresh, red-colored grapes, in presence of their skins
Made by Solution or Admixture	
Vinum Antimonii	4 Gm. Antimony and Potassium Tartrate; 65 Cc. Boiling Distilled Water; 175 Cc. Alcohol; White Wine to make 1000 Cc.
Cocæ	65 Cc. Fluidextract of Coca; 75 Cc. Alcohol; 65 Gm. Sugar; Red Wine to make 1000 Cc.
Colchici Seminis	100 Cc. Fluidextract of Colchicum Seed; 150 Cc. Alcohol; 750 Cc. White Wine
Ergotæ	200 Cc. Fluidextract of Ergot; 50 Cc. Alcohol; 750 Cc. White Wine
Ferri	40 Gm. Iron and Ammonium Citrate; 60 Cc. Tincture of Sweet Orange Peel; 100 Cc. Syrup; White Wine to make 1000 Cc.
Ferri Amarum	50 Gm. Soluble Iron and Quinine Citrate; 60 Cc. Tincture of Sweet Orange Peel; 300 Cc. Syrup; White Wine to make 1000 Cc.
Ipecacuanhæ	100 Cc. Fluidextract of Ipecac; 100 Cc. Alcohol; 800 Cc. White Wine
Made by Maceration	
Opii	100 Gm. Granulated Opium; 10 Gm. Saigon Cinnamon; 10 Gm. Cloves; Alcohol, White Wine, to make 1000 Cc.

Unofficial Wines

Name	Ingredients	Method of Preparation
Vinum Aurantii. Br.	Wine, containing 10 to 12 per-cent. of ethyl hydroxide and flavored by Bitter-Orange Peel.	Obtained from the fermentation of a saccharine solution to which Fresh Bitter Orange Peel has been added
Colchici Radicis. U. S. P. 1890.	400 Gm. Colchicum Root, No. 30 powder; 150 Cc. Alcohol; White Wine to make 1000 Cc.	Percolate the drug with 850 Cc. of White Wine, to which the Alcohol has been added, finishing with White Wine to make 1000 Cc.
Ferri. Br.	50 Gm. Iron Wire; 1000 Cc. Sherry	Set aside for thirty days in a closed vessel, frequently shaking; filter
Quininæ. Br.	2 Gm. Quinine Hydrochloride; 875 Cc. Orange Wine	Dissolve the Quinine Hydrochloride in the Orange Wine and filter if necessary

VINUM ALBUM. U.S. White Wine

An alcoholic liquid, made by fermenting the juice of fresh grapes, the fruit of *Vitis vinifera* Linné (Fam. *Vitaceæ*), freed from seeds, stems, and skins, and subjected to the usual cellar-treatment for fining and aging.

When White Wine is prescribed without further specification, it is recommended that a dry White Wine of domestic production be employed.

White Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place.

(For tests and comments, see Part IV.)

VINUM ANTIMONII. U.S. Wine of Antimony

	Metric	Old form
***Antimony and Potassium Tartrate**	4 Gm.	58½ grains
Boiling Distilled Water	65 Cc.	2 fl. oz.
Alcohol	175 Cc.	5½ fl. oz.
White Wine, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Antimony and Potassium Tartrate in the Boiling Distilled Water. Add this solution to a mixture of the Alcohol with 725 Cc. [old form 23 fl. oz.] of White Wine; mix well, and allow the mixture to stand until it has cooled. Then filter and add sufficient White Wine through the filter to make the liquid measure 1000 Cc. [old form 2 pints].

Average dose.— 15 minims (1 Cc.).

VINUM COCÆ. U.S. Wine of Coca

	Metric	Old form
***Fluidextract of Coca**	65 Cc.	2 fl. oz. 38 min.
Alcohol	75 Cc.	2½ fl. oz.
Sugar	65 Gm.	2⅓ oz. av.
Red Wine, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the sugar in 500 Cc. [old form 1 pint] of Red Wine, add the Alcohol and Fluidextract of Coca, and enough Red Wine to make the liquid measure 1000 Cc. [old form 2 pints]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 4 fluidrachms (16 Cc.).

VINUM COLCHICI SEMINIS. U. S. Wine of Colchicum Seed

	Metric	Old form
***Fluidextract of Colchicum Seed**	100 Cc.	3 fl. oz. 1 fl. dr.
Alcohol	150 Cc.	4 fl. oz. 7 fl. dr.
White Wine	750 Cc.	24 fl. oz.
To make	1000 Cc.	2 pints

Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 30 minims (2 Cc.).

VINUM ERGOTÆ. U. S. Wine of Ergot

	Metric	Old form
***Fluidextract of Ergot**	200 Cc.	6¼ fl. oz.
Alcohol	50 Cc.	1¾ fl. oz.
White Wine	750 Cc.	24 fl. oz.
To make	1000 Cc.	2 pints

Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 2 fluidrachms (8 Cc.).

VINUM FERRI. U.S. Wine of Iron

[VINUM FERRI CITRATIS PHARM. 1890]

	Metric	Old form
***Iron and Ammonium Citrate**	40 Gm.	1 oz. av. 147 gr.
Tincture of Sweet Orange Peel	60 Cc.	2 fl. oz.
Syrup	100 Cc.	3¼ fl. oz.
White Wine, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Iron and Ammonium Citrate in 700 Cc. [old form 22½ fl. oz.] of White Wine. Add to this the Tincture of Sweet Orange Peel and the Syrup, and, lastly, enough White Wine to make the product measure 1000 Cc. [old form 2 pints]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 2 fluidrachms (8 Cc.).

VINUM FERRI AMARUM. U.S. Bitter Wine of Iron

	Metric	Old form
***Soluble Iron and Quinine Citrate**	50 Gm.	1 oz. av. 293 gr.
Tincture of Sweet Orange Peel	60 Cc.	2 fl. oz.
Syrup	300 Cc.	9½ fl. oz.
White Wine, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Soluble Iron and Quinine Citrate in 500 Cc. [old form 1 pint] of White Wine. Add to this the Tincture of Sweet

Orange Peel and the Syrup, and, lastly, enough White Wine to make the product measure 1000 Cc. [old form 2 pints]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 2 fluidrachms (8 Cc.).

VINUM IPECACUANHÆ. U.S. Wine of Ipecac

	Metric	Old form
* **Fluidextract of Ipecac**	100 Cc.	3 fl. oz. 1 fl. dr.
Alcohol	100 Cc.	3 fl. oz. 1 fl. dr.
White Wine	800 Cc.	25 fl. oz. 6 fl. dr.
To make	1000 Cc.	2 pints

Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel.

Average dose.— 15 minims (1 Cc.).

VINUM OPII. U.S. Wine of Opium

	Metric	Old form
* **Granulated Opium**	100 Gm.	3 oz. av. 148 gr.
Saigon Cinnamon, in No. 60 powder	10 Gm.	146 grains
Cloves, in No. 30 powder	10 Gm.	146 grains
Alcohol, **White Wine,** each, a sufficient quantity,		
To make	1000 Cc.	2 pints

Mix 150 Cc. [old form 5 fl. oz.] of Alcohol and 850 Cc. [old form 27 fl. oz.] of White Wine. Macerate the Opium, Saigon Cinnamon, and Cloves in a stoppered container, in a moderately warm place, with 750 Cc. [old form 24 fl. oz.] of this menstruum, during seven days, with occasional agitation; then filter through purified cotton, in a well-covered funnel, returning the first portions until the filtrate passes perfectly clear, and finally pass enough menstruum through the residue to make the liquid measure 1000 Cc. [old form 2 pints].

For this preparation of Opium the U. S. Pharmacopœia (8th Rev.) does not provide an assay process owing to the presence of extractive matter from the powders; this interferes with the estimation of the morphine.

Average dose.— 8 minims (0.5 Cc.).

VINUM RUBRUM. U.S. Red Wine

An alcoholic liquid, made by fermenting the juice of fresh red-colored grapes, the fruit of *Vitis vinifera* Linné (Fam. *Vitaceæ*), in presence of their skins, and subjected to the usual cellar-treatment for fining and aging.

When Red Wine is prescribed without further specification, it is recommended that a dry Red Wine of domestic production be employed.

Red Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place.

(For tests and comments, see Part IV.)

Fluidextracta *Fluidextracts*

Fluidextracts are liquid alcoholic preparations of uniform and definite strength, made by percolating drugs with menstrua, and concentrating a portion of the percolate so that in each case a cubic centimeter represents the medicinal virtues of one gramme of the drug; they are mostly concentrated tinctures. Fluidextracts were official for the first time in 1850, and the list was then made up of *seven* concentrated preparations, although but *one* of these could be called a fluidextract within the present meaning of the term; of the seven, two were oleoresins, four were concentrated syrups, and but one was a concentrated tincture. Since 1850 the use of fluidextracts has increased to an enormous extent; the Pharmacopœia contains formulas for *eighty-five*, the number being greater than that of any other class of preparations in the work. Fluidextracts may be justly called "American preparations," and the advance made in pharmacy in this country within the last quarter of a century is largely due to the stimulus given by the studies in percolation and the demand for these useful liquids. The striking advantages possessed by fluidextracts are: 1. Permanence. 2. Concentration. 3. The uniform relation existing between the fluidextract and the drug.

In the U. S. P., 8th Revision, one word, "Fluidextractum," was adopted in place of two words, "Extractum Fluidum," formerly used. The object of this change was to avoid the confusion heretofore existing due to the alphabetical arrangement, which compelled Fluidextracts to be printed with the Extracts; thus, "Extractum Rhei" had to be followed by "Extractum Rhei Fluidum." By making the Latin name for fluidextracts "Fluidextractum," these preparations are now under the letter F instead of E. The English name is, of course, "Fluidextract" instead of "Fluid Extract."

Permanence is secured by the use of alcoholic menstrua; formerly, sugar and glycerin were relied upon as preservatives, but continued experience has developed the value of alcohol, so that at present it is most largely used as the solvent.

Concentration enables the physician to decrease the bulk of the dose, diminishing the volume of the preparation so that portability is secured. It also aids greatly in securing permanence.

The uniform relation existing between the fluidextract and the drug is of great assistance to the physician in fixing the dose, because, as one cubic centimeter is represented by one gramme, the dose of the fluidextract must be practically the same as that of the drug. It has also obvious advantages in the arrangement of the formulas and in working from them. The present strength of fluidextracts renders them five percent. weaker than the fluidextracts of U. S. P. 1870; this is practically of no significance, so long as the drugs themselves are not brought to a standard limiting the amount of moisture or active principles present, for there would be more variation than five percent. between different lots of the same drug, in these particulars; indeed, the proposition to make fluidextracts just half their present strength has met with favor from many able pharmacists, the principal arguments being that more thorough exhaustion can be secured by the ordinary operator upon the small scale, and that the fluidextracts can be made to represent the drug more accurately and honestly when *one hundred* parts by measure are made from *fifty* parts by weight of the drug than when one hundred parts by measure are made from one hundred parts by weight of the drug. The standard of strength of the official fluidextracts is based upon the theory that from a given weight of drug an amount of fluidextract shall be made equal in measure to the bulk of the same weight of distilled water; in other words, the relation is that of gramme to cubic centimeter.

Fluidextracts may be standardized whenever made from a drug capable of being assayed. *Fourteen* official fluidextracts are standardized, they are as follows: Aconite, belladonna root, cinchona, coca, colchicum seed, conium, guarana, hydrastis, hyoscyamus, ipecac, nux vomica, pilocarpus, scopola, stramonium.

Preparation.—Fluidextracts are made in several ways. The manufacturer generally adopts a different process from that directed by the Pharmacopœia, because upon the large scale some practical modifications are necessary; the finished preparation is, however, generally brought to the official standard. The processes at present in use may be classified as follows: 1. Percolation with partial evaporation (official). 2. Percolation with incomplete exhaustion. 3. Repercolation. 4. Continuous percolation. 5. Vacuum maceration with percolation.

1. **Percolation with Partial Evaporation.**—This process can be best described by selecting from the official formulas a type which will serve as an example.

Typical Formula for an Official Fluidextract

1000 Gm. of the powdered drug is moistened with a certain quantity of menstruum, packed in a suitable percolator, and enough menstruum added to saturate the powder and leave a stratum above it; the lower orifice of the percolator is closed when the liquid begins to drop, and the percolator is closely covered to prevent evaporation and permit maceration for a specified time; additional menstruum is poured on and percolation continued slowly until the drug is exhausted. Usually about 800 Cc. of the first portion of the percolate is reserved, and the remainder evaporated at a temperature not exceeding 50° C. (122° F.) to a soft extract; this is to be dissolved in the reserved portion, and enough menstruum added to make the fluidextract measure 1000 Cc. In the case of standardized fluidextracts, 10 Cc. of the reserved percolate is assayed and the finished fluidextract brought to the standard strength by the addition of the proper quantity of menstruum. The precipitation experienced heretofore when the evaporated weak percolate was added to the reserved portion is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluidextracts, was due to the volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this residue was added to the strongly alcoholic reserved portion, a precipitation of resinous and frequently of active matter took place, which necessitated the storing of the fluidextract until precipitation ceased, and subsequent filtration. This is almost altogether avoided by evaporating to a soft extract, and the loss of activity through precipitation thus greatly diminished.

The argument is frequently advanced that the application of heat is detrimental to solutions of organic principles, that it dissociates some, and always proves injurious to the desirable constituents, *and that no heat whatever should be used in making fluidextracts;* these views are undoubtedly correct, when considered in connection with a few special cases, but do not apply with any practical force to the moderate use of heat recommended by the official processes upon that portion of the percolate which represents the least active and least desirable constituents of the drug, for from seven-tenths to nine-tenths of the whole amount of percolate (frequently representing ninety-five percent. of the activity of the drug) is reserved and is not subjected to heat at all.

2. **Percolation with Incomplete Exhaustion.**—This process consists in percolating a given weight of a drug with the proper menstruum in the usual manner, and stopping the percolation when an amount of percolate has been received which is equal to about three-fourths of the weight of the drug. To illustrate: 1000 grammes, or 16 ounces, of drug is percolated with the menstruum until 750 Cc. or 12 fluidounces of percolate has been received; this is the complete process, and the residue containing absorbed menstruum is sacrificed. This method has the merit of saving time and labor, and avoiding evaporation with the necessary contact of heat. It is based on the assumption that when percolation is properly conducted, the first seventy-five percent. of percolate received contains at least seventy-five percent. of the soluble and desirable principles of the drug, and that the wastage of alcohol comes chiefly from the effort to obtain the last twenty-five percent. or less of soluble principles. In addition, this smaller amount of extractive matter in the weak percolate is said to be lessened in activity by the effects of the heat during the evaporation to recover the alcohol from it; hence the argument that in carefully conducted operations the active matter left after receiving the percolate representing seventy-five percent. of the drug, does not represent twenty-five percent. of activity, but oftentimes less than ten percent. The principal disadvantage of this method is that the *strength* of the finished fluidextract depends *entirely* upon the *skill* and *care* of the operator. If careful, in one operation he may obtain seventy-five percent. of the active principles in the first seventy-five percent. of percolate; in another case, circumstances may prevent his obtaining more than fifty percent. of the active principles in the first seventy-five percent. of percolate. By this method of making fluidextracts he cannot invariably secure uniformity, while in making fluidextracts by the official process a valuable check always exists,—*i.e., that percolation proceeds until exhaustion is reached, the weak percolate is evaporated at a limited temperature, and the soft extract is incorporated with the reserved portion*, so that imperfect percolation happening in the first part of the process is compensated for in the latter part, the only difference being that the weak percolate in this case contains a larger proportion of activity than if the operation had been thoroughly conducted from the first.

3. **Repercolation.**—This process, already considered under the head of percolation (see page 269), is an improvement upon the method just noticed, because the drug is percolated to exhaustion,

and evaporation obviated by storing away the weak percolate until the next operation upon the same drug, when it is used in the place of fresh menstruum. This process may be best explained by selecting a typical fluidextract and noting the details.

Fluidextract of Cinchona by Repercolation (Squibb).—Take of Yellow Cinchona, in powder No. 50, 32 parts; Alcohol, 2 parts; Glycerin, 1 part; Water, 2 parts, or a sufficient quantity.

Weigh the Alcohol, Glycerin, and Water in succession, in any convenient quantity at a time, into a tared bottle, and mix them thoroughly for a menstruum.

Moisten 8 parts of the Cinchona with 8 parts of the menstruum, by thoroughly mixing them, and allow the mixture to stand eight hours in a closely covered vessel. Then pass the moist powder through a No. 8 sieve, and pack it firmly in a percolator. Pour menstruum on top until the mass is filled with liquid and a stratum remains on top unabsorbed; cover the percolator closely, and macerate for forty-eight hours. Then arrange the percolator for an automatic supply of menstruum, and start the percolation at such a rate as to give 1 part of percolate in about four hours. Reserve the first 6 parts of percolate, and continue the percolation until the Cinchona is exhausted, separating the percolate received after the reserved portion into fractions of about 8 parts each.

Moisten a second portion of 8 parts of the Cinchona with 8 parts of the weak percolate,—the first portion that was obtained next after the reserved percolate,—and allow the moist powder to stand for eight hours in a vessel closely covered. Then pack it moderately in a percolator, and supply the percolator automatically with the remaining fractions of the weak percolate in the order in which they were received, and finally with fresh menstruum, until the Cinchona is exhausted. Percolate in the same manner and at the same rate as with the first portion of Cinchona, and, reserving 8 parts of the first percolate, separate the weaker percolate into fractions of about 8 parts each.

Percolate the third and fourth portions of 8 parts each of the Cinchona in the same way as the second portion.

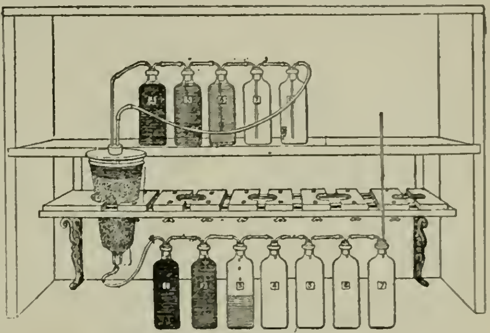
Finally, mix the four reserved percolates together to make 30 parts of finished fluidextract; and, having corked, labelled, and numbered the bottles containing the fractions of weak percolate, set them away until the process for Cinchona is to be resumed.

When this fluidextract is to be again made, repeat the process as with the second portion, and reserve 8 parts of the first percolate as finished fluidextract from each 8 parts of Cinchona from that time forward so long as the fractions of weak percolate are carried forward with which to commence each operation.

4. **Continuous Percolation.**—Robert W. Beck has devised a modification of Dr. Squibb's method of repercolation with a view of rendering the process more suitable for the smaller operations carried on by retail pharmacists. The storing away of the last weak percolates, and particularly the necessity for collecting the fractions of percolates, have operated to prevent repercolation from being used in small operations to the extent that it would be otherwise. Mr. Beck has sought to remove some of these disadvantages, and the illustration shown in Fig. 437 serves to render the explanations which follow

more easily understood. His process and apparatus effect a saving in time and attention, and the difficulty of keeping the percolators containing the drugs supplied with the proper menstruum at the time when the portion previously added has just disappeared has been overcome ; the watchfulness necessary to see that each receiving vessel does not overflow, or get more than its due proportion of the weaker percolate or menstruum, is reduced to a minimum, and the constant changing of receiving bottles is no longer required. The continuous method is based on the principle of *connecting* the receiving bottles containing the weaker percolates or menstruum, and after this to join the series to the percolator containing the drug by a syphon tube so that the menstruum will flow slowly and regularly, and that each portion will be delivered on the upper surface of the drug in its proper order.

FIG. 437



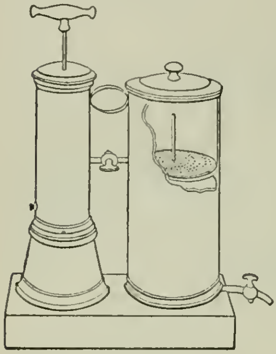
Beck's continuous percolation method

The percolate is carried from one receiving bottle, when full, to the next one by tubes inserted in the corks from the neck of one bottle to the neck of the other. Very little diffusion occurs, owing to the fact that the heavier liquids are drawn off first, and in each case a lighter liquid is deposited slowly (by drops) upon a denser one ; as the same principle is employed in receiving the percolates, the bottle nearest the percolator is filled with very dense percolate, and when the bottle is as full as desired, the tube connecting with the next bottle draws off the light liquid as it is deposited on top, and practically no intermixture occurs. Of course, the same action takes place in the remaining bottles of the series. If desired, the reserve or strongest percolate or finished fluidextract contained in the first bottles of the series can be removed, their place being supplied by empty bottles, so that even the slight risk of diffusion would apply only to weak percolates. In Fig. 437 the percolator is connected with No. 1 bottle by a rubber tube having a pinchcock to regulate the flow ; the remaining bottles are all connected in proper order by means of glass tubes and rubber tubing, as shown, the ends of the glass tubes being adjusted so as to be on the same level. When No. 1 bottle is full of dense percolate No. 2 bottle begins to fill with weaker percolate, then No. 3 with still weaker percolate, and so on. From the top of the last bottle on the upper shelf (No. 8) a piece of rubber tubing is connected with a glass tube having an inside diameter of $\frac{1}{4}$ inch, which passes through the cover of the percolator, the lower end about $\frac{1}{8}$ inch above the surface of the drug. This device makes an automatic supply of menstruum, the latter ceasing to flow when the liquid rises in the percolator above the end of the supply tube.

5. **Vacuum Maceration followed by Percolation.**—This method

of making fluidextracts was proposed in 1869 by S. P. Duffield. His original process was to introduce the drug, ground to the requisite fineness, into a strong cylinder connected with an airpump. The air was exhausted by the pump, and through a syphon tube the requisite amount of menstruum was sucked into the vacuum chamber. The air enclosed in the interstices and pores of the drug was thus expelled, and, the menstruum being brought immediately in contact with the soluble constituents, maceration was facilitated. The same process was suggested by Needles many years ago. Fig. 438 is an illustration of his original apparatus, the vessel upon the right hand being the percolator and receiver, the pump for exhausting the receiver being connected by a short tube carrying a stopcock. The most effective apparatus known to the author for using this principle upon the large scale is that devised by Wm. M. Thomson, of Philadelphia, and illustrated in the *American Journal of Pharmacy*, page 237, 1882. The percolators are egg shaped, and made of tinned copper; they are capable of being tightly covered, and communicate with a very efficient double-acting airpump by means of stopcocks above and below, and iron and stout rubber tubing. The moistened powder is packed tightly in the percolator, and the cover securely bolted on. The stopcock in the cover, communicating with the airpump, is opened, and a partial vacuum created in the space above the moistened drug; it is then closed, and another stopcock in the cover opened, which communicates by a tube with the reservoir containing the menstruum. The menstruum quickly penetrates the powder, taking the place of the interstitial air, and when the powder is saturated it is permitted to macerate *in vacuo* a sufficient length of time. To start percolation, a receiver is connected with the beak of the percolator, and the air exhausted from it. When the flow slackens, air may be forced by the pump into the space above the powder, and the receiver again exhausted below. In this way entire control of these powerful physical forces may be secured. The advantages are apparent in preventing the loss of alcohol and protecting from chemical change caused by exposure to the air. It is quite possible to make an official fluidextract without recourse to the subsequent evaporation of weak percolate.

Fig. 438



Needles's vacuum percolator

Preservation of Fluidextracts.—Very little trouble is experienced in keeping fluidextracts which have been properly made. They should be placed in glass vessels and stored in rooms of uniform temperature; precipitation to a greater or less extent will certainly take place. This is often especially noticeable in fluidextracts made during warm weather, and is due to the greater solvent action of the menstruum at higher temperatures. Precipitation is also caused by the variation in the strength of different portions of the menstruum in an alcoholic fluidextract; the first part of the percolate which is received contains the displaced water which was present as moisture in the powder, and the mixture of this with the strong alcoholic percolate which follows causes precipitation in time. The character of the precipitates should be ascertained; if active, they should be incorporated by shaking with the fluidextract; if inert, they should be filtered out.

Acetic Fluidextracts, or Fluidacetracts.—These were proposed by C. F. Squibb, and consist of preparations made like fluidextracts of definite strength (gramme for cubic centimeter), but made with acetic acid or diluted acetic acid of various strengths. The advantages claimed for them are cheapness, permanence, and miscibility with aqueous liquids. The disadvantages which have been urged against their use are the presence of acetic acid, which is not always desirable, and the loading of the finished preparation with inert constituents for which acetic acid is a good solvent. It is obvious that this class of preparations is of value, but it is also clear that acetic acid is suited, on account of its great solvent and penetrating power, for extracting the soluble principles from certain drugs, but for others alcohol is to be preferred. The ideal menstruum for any drug is one which will extract the desirable principles and leave in the marc those which are not needed. In the Pharmacopœia of 1870 glycerin entered as a menstruum into nearly every fluidextract; experience showed, however, that it was unsuited for this purpose, because the fluidextract was loaded heavily with inert and useless principles which were dissolved in the glycerin. For oleoresinous drugs and those containing resinous active principles the acetic acid used as a menstruum should range in strength from 36 percent. to 90 percent., while for drugs which do not contain these principles the acetic acid need not be stronger than from 6 to 10 percent.

The antiseptic powers of acetic acid are well known, and where it is desirable to avoid the use of alcohol, fluidacetracts would supply an excellent substitute.

The fears which have been frequently expressed about the action of acetic acid when taken into the stomach have not been borne out by considerable experience with their use, because it must be remembered that the quantity of acetic acid entering the stomach in the small dose in which these concentrated preparations are administered would not be more than the quantity frequently used by patients with their food. At the present time sufficient experience has not been had with them to justify the admission of more than three to the United States Pharmacopœia, 8th Revision.

Fluidextracts from Green Drugs.—This class of preparations has been used to some extent, and they may be made by crushing the drug, obtaining the liquid by pressure, and adding alcohol or diluted alcohol, according to the nature of the drug, repressing, and making the final product represent one gramme in a cubic centimeter. Owing to the varying proportion of water found in green drugs, it is evident that each preparation must be made from a special formula, and the quantity of alcohol to be added must depend upon the amount of water present in the drug; for drugs containing principles which are volatile or easily dissociated, this method produces good preparations, but unusual care must be exercised to secure uniformity.

Official Fluidextracts arranged in Classes according to the Alcoholic Strength of their Menstrua, with Manipulative Notes

Name	Number of Cc. used to moisten	Menstruum	Number of Cc. of Reserve	Process and Remarks
Class 1		**Alcohol**		
Fluidextractum Aromaticum	350	“	850	From Aromatic Powder
Cannabis Indicæ	300	“	900	
Capsici	500	“	900	Having moistened the powder, exhaust with the menstruum, reserve the number of Cc. directed, and distil or evaporate the remainder to a soft extract; add this to the reserved portion and sufficient menstruum to make the whole measure 1000 Cc.
Cimicifugæ	250	“	900

Opii Liquidum. Br.	. .	. . . .	. .	. .	18.75 Gm. Extract of Opium; 400 Cc. Distilled Water; 100 Cc. 90 percent. Alcohol. Rub the extract with the water, stir frequently during an hour, add the Alcohol, set aside for twenty-four hours, and then filter
Rumicis Fluidum. U. S. P. 1890	350	Diluted Alcohol	800	40	General process (see below)
Sanguinariæ. U. S. P. 1890	300	Alc. 75; Wat. 25	850	60	50 Cc. Acetic Acid included in the 300 Cc. used to moisten drug
Scillæ. U. S. P. 1890	200	Alc. 75; Wat. 25	750	20	General process (see below)
Scoparii. U. S. P. 1890	350	Diluted Alcohol	850	60	“ “ “ “
Stramonii Seminis. U. S. P. 1890	200	Alc. 75; Wat. 25	900	60	“ “ “ “

General Process for Fluidextracts.—Having moistened the powder, macerate for forty-eight hours, then exhaust with the menstruum, reserving the number of Cc. directed and distilling or evaporating the remainder to a soft extract: add this to the reserved portion and sufficient menstruum to make the whole measure 1000 Cc.

FLUIDEXTRACTUM ACONITI. U.S. Fluidextract of Aconite

[EXTRACTUM ACONITI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Aconite,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	**1000 Cc.**	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Aconite is exhausted. Reserve the first 800 Cc. [old form $38\frac{1}{2}$ fl. oz.] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserve portion, mixing thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of aconitine in the remainder of the liquid, add to this enough menstruum to make each 100 Cc. of the finished fluidextract contain 0.4 Gm. of aconitine.

Assay of Fluidextract of Aconite

Fluidextract of Aconite	**10 Cc.**
Ether,	
Distilled Water,	
Ammonia Water,	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V.S.,	
Cochineal T.S., each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Aconite by means of a graduated pipette to a porcelain dish, and evaporate it carefully to dryness on a water-bath at a temperature not exceeding 60° C. (140° F.). Add 5 Cc. of tenth-normal sulphuric acid V.S. and 25 Cc. of distilled water. When the extract is dissolved, filter the liquid into a separator, washing the dish and filter, with about 25 Cc. of distilled water; when this has passed through, add 25 Cc. of ether and 2 Cc. of ammonia water to the separator, and agitate for one minute. Draw off the lower layer into a flask and filter the ether-solution into a beaker. Return the contents of the flask to the separator, add 15 Cc. of ether, and agitate for one minute. Draw off the lower layer into the flask and filter the ether-solution into the beaker. Repeat, with two other portions of 10 Cc. each of ether. Evaporate the ether-solution to dryness, and dissolve the residue in 3 Cc. of tenth-normal sulphuric acid V.S. diluted with 20 Cc. of distilled water. Add to the solution 5 drops of cochineal T.S., and then carefully run in fiftieth-normal potassium hydroxide V.S. until a pink color is produced. Divide the number of Cc. of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 3 (the 3 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.064, and this product by 10, which will give the weight in grammes of aconitine contained in 100 Cc. of the Fluidextract of Aconite.

Average dose.—1 minim (0.05 Cc.).

FLUIDEXTRACTUM APOCYNI. U.S. **Fluidextract of Apocynum**

[Extractum Apocyni Fluidum, Pharm. 1890]

	Metric	Old form
* **Apocynum,** in No. 60 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Alcohol, **Water,** each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 600 Cc. [old form 29 fl. oz.] of Alcohol and 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of 600 Cc. [old form 29 fl. oz.] of Alcohol to 400 Cc. [old form 19 fl. oz.] of Water, until the Apocynum is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. [122° F.], to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM AROMATICUM. U.S. **Aromatic Fluidextract**

[Extractum Aromaticum Fluidum, Pharm. 1890]

	Metric	Old form
* **Aromatic Powder**	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Aromatic Powder is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM AURANTII AMARI. U.S. **Fluidextract of Bitter Orange Peel**

[Extractum Aurantii Amari Fluidum, Pharm. 1890]

	Metric	Old form
* **Bitter Orange Peel,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol, **Water,** each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it moderately in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Bitter Orange Peel is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM BELLADONNÆ RADICIS. U.S. Fluidextract of Belladonna Root

[Extractum Belladonnæ Radicis Fluidum, Pharm. 1890]

	Metric	Old form
* **Belladonna Root,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	**1000 Cc.**	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Belladonna Root is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract, dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 0.4 Gm. of mydriatic alkaloids from Belladonna Root.

Assay of Fluidextract of Belladonna Root

Fluidextract of Belladonna Root	**10 Cc.**
Distilled Water,	
Ammonia Water,	
Chloroform,	
Normal Sulphuric Acid V.S.,	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V.S.,	
Cochineal T.S. or Iodeosin T.S., each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Belladonna Root by means of a graduated pipette to a separator, add 10 Cc. of distilled water, 20 Cc. of chloroform, and 2 Cc. of ammonia water. Shake the separator well for one minute, and draw off the lower chloroformic layer into a second separator. Repeat the extraction with two portions of 10 Cc. each of chloroform, and draw the chloroformic solution into the second separator. To the latter add 8 Cc. of normal sulphuric acid V.S. and 20 Cc. of distilled water, shaking well for one minute. When perfectly separated draw off and reject the lower chloroformic layer, and filter the acid aqueous layer into a clean separator. Wash the separator and filter with 10 Cc. of distilled water, adding this to the clean separator. To the latter add 20 Cc. of chloroform and 4 Cc. of ammonia water, and shake well for several minutes. Draw off the lower chloroformic layer into a beaker, and repeat the extraction with two portions of 10 Cc. each of chloroform, adding the chloroformic solution to the beaker. Allow the chloroform in the beaker to evaporate on a water-bath, containing warm water, until the residue is perfectly dry. To the alkaloidal residue add 5 Cc. of tenth-normal sulphuric acid V.S., and when the residual alkaloids have all dissolved, titrate the solution with fiftieth-normal potassium hydroxide V.S., using 5 drops of cochineal or iodeosin T.S. as an indicator. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0287, and this product by 10, to obtain the weight in grammes of mydriatic alkaloids contained in 100 Cc. of the Fluidextract of Belladonna Root.

Average dose.— 1 minim (0.05 Cc.).

FLUIDEXTRACTUM BERBERIDIS. U.S. Fluidextract of Berberis

	Metric	Old form
* **Berberis,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol until the Berberis is exhausted. Reserve the first 700 Cc. [old form 33½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM BUCHU. U.S. Fluidextract of Buchu

[Extractum Buchu Fluidum, Pharm. 1890]

	Metric	Old form
* **Buchu,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the

percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Buchu is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM CALAMI. U.S. Fluidextract of Calamus

[Extractum Calami Fluidum, Pharm. 1890]

	Metric	Old form
* **Calamus,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Calamus is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM CALUMBÆ. U.S. Fluidextract of Calumba

[Extractum Calumbæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Calumba,** in 20 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 700 Cc. [old form 33½ fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Calumba is exhausted. Reserve the first 700 Cc. [old form 33½

fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure, 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM CANNABIS INDICÆ. U.S. Fluidextract of Indian Cannabis

[Extractum Cannabis Indicæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Indian Cannabis,** in No. 30 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Indian Cannabis is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 1 minim (0.5 Cc.).

FLUIDEXTRACTUM CAPSICI. U.S. Fluidextract of Capsicum

[Extractum Capsici Fluidum, Pharm. 1890]

	Metric	Old form
* **Capsicum,** in No. 50 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 500 Cc. [old form 24 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Capsicum is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 1 minim (0.05 Cc.).

FLUIDEXTRACTUM CHIMAPHILÆ. U.S. Fluidextract of Chimaphila

[Extractum Chimaphilæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Chimaphila,** in No. 30 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Chimaphila is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM CHIRATÆ. U.S. Fluidextract of Chirata

[Extractum Chiratæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Chirata,** in No. 30 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Chirata is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM CIMICIFUGÆ. U.S. Fluidextract of Cimicifuga

[Extractum Cimicifugæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Cimicifuga,** in No. 60 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 250 Cc. [old form 12 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Cimicifuga is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM CINCHONÆ. U.S. Fluidextract of Cinchona

[EXTRACTUM CINCHONÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
***Cinchona**, in No. 60 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix the Glycerin with 800 Cc. [old form 38½ fl. oz.] of Alcohol and 100 Cc. [old form 4 fl. oz. 384 min.] of Water. Moisten the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, and, when the liquid in the percolator has disappeared from the surface, gradually pour on a mixture of Alcohol and Water, made in the proportion of 800 Cc. [old form 38½ fl. oz.] of Alcohol to 200 Cc. [old form 9½ fl. oz.] of Water, and continue the percolation slowly until the Cinchona is exhausted. Reserve the first 700 Cc. [old form 33½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of anhydrous ether-soluble alkaloids in the remainder of the liquid, and add to this enough of a mixture of Alcohol and Water, using the same proportions as before, to make each 100 Cc. of the Fluidextract contain 4 Gm. of anhydrous ether-soluble alkaloids from Cinchona.

Assay of Fluidextract of Cinchona

Fluidextract of Cinchona	10 Cc.
Ether, sp. gr. not above 0.720 at 25° C. (77° F.),	
Normal Sulphuric Acid V.S.,	
Ammonia Water,	
Chloroform, each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Cinchona by means of a graduated pipette to an Erlenmeyer flask of 200 Cc. capacity, and add a mixture of 100 Cc. of ether, 25 Cc. of chloroform, and 10 Cc. of ammonia water. Insert the stopper securely, and shake the flask vigorously, at intervals, during ten minutes. Allow the liquids to separate, decant into a measuring cylinder exactly 66 Cc. of the supernatant liquid (representing 5 Cc. of the Fluidextract), and transfer this to a separator, rinsing the cylinder with 5 Cc. of ether and adding this to the separator. Add to the latter about 10 Cc. of normal sulphuric acid V.S., or enough to make the solution distinctly acid, and shake the separator vigorously for several minutes, and when the liquids have completely separated, draw off the lower layer into a second separator. To the first separator add 5 Cc. more of normal sulphuric acid V.S., and 5 Cc. of distilled water, shake it for several minutes, and when the liquids have separated, draw off the lower layer into the second separator. Now add 5 Cc. of distilled water to the first separator, shake it, separate as before, and then draw off the lower aqueous layer into the second separator. To the second separator add 25 Cc. of ether, a small piece of red litmus paper, and then, gradually, ammonia water, keeping the temperature of the liquids below 25° C. (77° F.), until the reaction is alkaline. Then shake the separator vigorously for two minutes, and allow the liquids to stand for ten minutes at a temperature below 15° C. (59° F.). Draw off and reject the lower aqueous layer,

and then transfer the ether-layer into a tared beaker. Add 5 Cc. more of ether to the separator, rinse carefully, and add the rinsings to the tared beaker, and entirely evaporate the ether at a moderate heat on a water-bath. Then dry the beaker in an air-bath at 110° C. (230° F.) for half an hour, cool, and weigh. Replace the beaker in the air-bath, and heat again at the same temperature for half an hour, cool, and weigh, repeating until the weight is constant. Multiply the weight of the residue by 20, to obtain the weight in grammes of anhydrous ether-soluble alkaloids contained in 100 Cc. of the Fluidextract of Cinchona.

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM COCÆ. U.S. Fluidextract of Coca

[EXTRACTUM COCÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Coca,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make about	**1000 Cc.**	3 pints

Moisten the powder with 450 Cc. [old form 21½ fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Coca is exhausted. Reserve the first 700 Cc. [old form 33½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of ether-soluble alkaloids in the remainder of the liquid, and add to this enough Diluted Alcohol to make each 100 Cc. of the Fluidextract contain 0.5 Gm. of ether-soluble alkaloids from Coca.

Assay of Fluidextract of Coca

Fluidextract of Coca	**10 Cc.**
Ammonia Water,	
Ether,	
Distilled Water,	
Normal Sulphuric Acid V.S.,	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V. S.,	
Cochineal T. S. or Iodeosin T. S., each, a sufficient quantity.	

Transfer 10 Cc. of Fluidextract of Coca by means of a graduated pipette to a separator, add 25 Cc. of ether, and then 2 Cc. of ammonia water, shaking together for one minute. When the liquids have completely separated, draw off the lower aqueous layer into a second separator, and to this add 20 Cc. more of ether, and repeat the shaking for one minute. Draw off and reject the lower aqueous layer from the second separator, and add the ether-layer to the first separator. To this separator now add 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, and shake it well for one or two minutes. After the liquids have separated, draw off the lower aqueous layer into the other separator, and repeat the extraction in the first separator with 9 Cc. of distilled water and 1 Cc. of normal sulphuric acid V.S., shaking the liquids for one minute, and separating as before. Add the aqueous solution to the other separator, and reject the ether. Now add to the combined acid liquids 20 Cc. of ether, a small piece of red litmus paper, and sufficient ammonia water to render the mixture distinctly alkaline, and shake the

liquids for one or two minutes. Draw off the separated aqueous layer into the other separator and the ether-layer into a beaker. Repeat the extraction of the aqueous layer in the other separator with two portions (15 Cc. each) of ether, and add the resulting ether-solutions to the beaker. Now evaporate the ether from the beaker, and, when dry, add to it 5 Cc. of tenth-normal sulphuric acid V.S., and stir until the alkaloidal residue is dissolved. Then add 5 drops of cochineal T.S. or iodeosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken, and multiply the remainder by 0.03, and this product by 10, to obtain the weight in grammes of ether-soluble alkaloids contained in 100 Cc. of the Fluidextract of Coca.

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM COLCHICI SEMINIS. U. S. Fluidextract of Colchicum Seed

[EXTRACTUM COLCHICI SEMINIS FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Colchicum Seed,** in No. 50 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Colchicum Seed is exhausted. Reserve the first 750 Cc. [old form 36 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of colchicine in the remainder of the liquid, and add to this enough menstruum to make each 100 Cc. of the Fluidextract contain 0.4 Gm. of colchicine.

Assay of Fluidextract of Colchicum Seed

Fluidextract of Colchicum Seed	10 Cc.
Ether,	
Chloroform,	
Alcohol,	
Ammonia Water,	
Distilled Water, each, a sufficient quantity	

Measure into a separator 10 Cc. of Fluidextract of Colchicum Seed, add 1 Cc. of ammonia water, and shake out the alkaloid with three successive portions, 15, 15, and 10 Cc., of chloroform. Collect the chloroformic solutions in a beaker or dish, and evaporate it nearly to dryness by applying a very gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether is evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in the beaker or dish. Redissolve the residue in a little ether, add 5 Cc. of water, and proceed as before. Wash the container and filter with a little water, and shake the aqueous solution well for one minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a tared flask, and again shake out the aqueous liquid, successively, with three portions of 10 Cc. each of chloroform, collecting these solutions in the tared flask. Evaporate the chloroform completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve it in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.) until the weight, after cooling in a desiccator, remains constant. Multiply the weight of the residue by 10, to obtain the weight in grammes of colchicine contained in 100 Cc. of the Fluidextract of Colchicum Seed.

Average dose.—3 minims (0.2 Cc.).

FLUIDEXTRACTUM CONII. U. S. Fluidextract of Conium

[Extractum Conii Fluidum, Pharm. 1890]

	Metric	Old form
* **Conium,** in No. 40 powder	1000 Gm.	50 oz. av.
Acetic Acid	20 Cc.	1 fl. oz.
Diluted Alcohol, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix the Acetic Acid with 980 Cc. [old form 47 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until the Conium is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of coniine in the remainder of the liquid, and add to this enough Diluted Alcohol to make each 100 Cc. of the Fluidextract contain 0.45 Gm. of coniine.

Assay of Fluidextract of Conium

Fluidextract of Conium	10 Cc.
Ether,	
Alcohol,	
Absolute Alcohol,	
Ammonia Water,	
Normal Sulphuric Acid V.S.,	
Sodium Carbonate T.S.,	
Hydrochloric Acid Solution (5 percent. HCl),	
Distilled Water, each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Conium by means of a graduated pipette to an evaporating dish containing a little clean sand, and evaporate it to dryness at a gentle heat. Mix the sand uniformly with the extract and transfer it to an Erlenmeyer flask of about 200 Cc. capacity, rinse the dish with 100 Cc. of a mixture of ether 100 Cc., alcohol 7 Cc., and ammonia water 3 Cc., added in portions, and transfer the rinsings to the flask. Insert the stopper securely and shake the flask at intervals during one hour. Decant 50 Cc. of the liquid (representing 5 Cc. of the Fluidextract of Conium) into a beaker, and add sufficient normal sulphuric acid V.S. to produce a distinctly acid reaction. Evaporate the ether at a gentle heat by the aid of a water-bath; then add 15 Cc. of absolute alcohol, and set the

beaker aside in a cool place for two hours to allow the ammonium sulphate to deposit. Filter the liquid; wash the residue and filter with a little absolute alcohol, and add the washings to the filtrate; neutralize any excessive amount of acid with sodium carbonate T.S., being careful to retain a slight acidity. Concentrate the liquid to 3 Cc. by the aid of a gentle heat on a water-bath, add 3 Cc. of distilled water and 2 drops of normal sulphuric acid V.S. Add 15 Cc. of ether to remove traces of fatty matter, pour off the ether-solution, and repeat the washing. Then transfer the acid liquid to a separator, introduce a small piece of red litmus paper, and add sufficient sodium carbonate T.S. to render the liquid slightly alkaline; then shake out with successive portions of 15, 10, and 10 Cc. of ether. To the combined ether-solutions in a tared beaker add, drop by drop, sufficient hydrochloric acid solution (5 percent.) to insure an excess of acid, and then evaporate the ether by a gentle heat on a water-bath. Remove the excess of hydrochloric acid by adding to the residue 3 Cc. of alcohol and heating gently to evaporate the liquid, repeat this operation once, and dry the residue at a temperature not exceeding 60° C. (140° F.) until the weight, after cooling in a desiccator, remains constant. Multiply the weight of the residue by 0.777, and the product by 20, to obtain the weight in grammes of coniine contained in 100 Cc. of the Fluidextract of Conium.

Average dose.— 3 minims (0.2 Cc.).

FLUIDEXTRACTUM CONVALLARIÆ. U.S. Fluidextract of Convallaria

[EXTRACTUM CONVALLARIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Convallaria,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 650 Cc. [old form 31 fl. oz.] of Alcohol with 350 Cc. [old form 17 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Convallaria is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—8 minims (0.5 Cc.).

FLUIDEXTRACTUM CUBEBÆ. U.S. Fluidextract of Cubeb

[EXTRACTUM CUBEBÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Cubeb,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 200 Cc. [old form 9½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Cubeb is exhausted. Reserve the first 900

Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM CYPRIPEDII. U.S. Fluidextract of Cypripedium

[EXTRACTUM CYPRIPEDII FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Cypripedium,** in No. 60 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Cypripedium is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM DIGITALIS. U.S. Fluidextract of Digitalis

[EXTRACTUM DIGITALIS FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Digitalis,** in No. 60 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Digitalis is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—1 minim (0.05 Cc.).

FLUIDEXTRACTUM ERGOTÆ. U.S. Fluidextract of Ergot

[EXTRACTUM ERGOTÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Ergot,** recently ground and in No. 60 powder	1000 Gm.	50 oz. av.
Acetic Acid	20 Cc.	1 fl. oz.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Acetic Acid with 980 Cc. [old form 47 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until the Ergot is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM ERIODICTYI. U.S. Fluidextract of Eriodictyon

[EXTRACTUM ERIODICTYI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Eriodictyon,** in No. 60 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eriodictyon is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM EUCALYPTI. U.S. Fluidextract of Eucalyptus

[EXTRACTUM EUCALYPTI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Eucalyptus,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to

drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eucalyptus is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM EUONYMI. U.S. Fluidextract of Euonymus

	Metric	Old form
* **Euonymus,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Euonymus is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 8 minims (0.5 Cc.).

FLUIDEXTRACTUM EUPATORII. U.S. Fluidextract of Eupatorium

[Extractum Eupatorii Fluidum, Pharm. 1890]

	Metric	Old form
* **Eupatorium,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Eupatorium is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM FRANGULÆ. U.S. Fluidextract of Frangula

[Extractum Frangulæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Frangula,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 500 Cc. [old form 24 fl. oz.] of Alcohol with 800 Cc. [old form 38½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Frangula is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM GELSEMII. U.S. Fluidextract of Gelsemium

[Extractum Gelsemii Fluidum, Pharm. 1890]

	Metric	Old form
* **Gelsemium,** in No. 60 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Gelsemium is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—1 minim (0.05 Cc.).

FLUIDEXTRACTUM GENTIANÆ. U.S. Fluidextract of Gentian

[Extractum Gentianæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Gentian,** in No. 30 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Gentian is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM GERANII. U.S. Fluidextract of Geranium

[EXTRACTUM GERANII FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Geranium,** in No. 30 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 600 Cc. [old form 29 fl. oz.] of Alcohol, and 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of 600 Cc. [old form 29 fl. oz.] of Alcohol to 400 Cc. [old form 19 fl. oz.] of Water, until the Geranium is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.)

FLUIDEXTRACTUM GLYCYRRHIZÆ. U.S. Fluidextract of Glycyrrhiza

[EXTRACTUM GLYCYRRHIZÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Glycyrrhiza,** in No. 20 powder	1000 Gm.	50 oz. av.
Glycerin	250 Cc.	12 fl. oz.
Ammonia Water	50 Cc.	2½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Pour 400 Cc. [old form 19 fl. oz.] of boiling Water upon the Glycyrrhiza, contained in a suitable vessel, and allow it to stand for one hour. Pack the moistened powder loosely in a metallic percolator, pour boiling Water upon it, and allow the percolation to proceed, supplying boiling Water until the Glycyrrhiza is exhausted. Evaporate the percolate at a moderate heat, until it measures 450 Cc. [old

form 21½ fl. oz.], and, when cool, add 450 Cc. [old form 21½ fl. oz.] of Alcohol, mix well and set aside for three days. After filtering the liquid, distil it until 500 Cc. [old form 21½ fl. oz.] of distillate have been obtained; transfer the liquid in the still to a suitable container, add the Glycerin, Ammonia Water, and 200 Cc. [old form 9½ fl. oz.] of Alcohol. Finally, add sufficient Water to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM GRANATI. U.S. **Fluidextract of Pomegranate**

	Metric	Old form
* **Granatum**, in No. 30 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 900 Cc. [old form 43 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Pomegranate is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM GRINDELIÆ. U.S. **Fluidextract of Grindelia**

[EXTRACTUM GRINDELIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Grindelia**, in No. 30 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.) of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Grindelia is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM GUARANÆ. U.S. Fluidextract of Guarana

[Extractum Guaranæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Guarana,** in No. 60 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Moisten the powder with 200 Cc. [old form 9½ fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Guarana is exhausted. Reserve the first 700 Cc. [old form 33½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 5 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloids contained in the reminder of the liquid; add to this enough Diluted Alcohol to make each 100 Cc. of the finished Fluidextract contain 3.5 Gm. of the alkaloids from Guarana.

Assay of Fluidextract of Guarana

Fluidextract of Guarana	5 Cc.
Chloroform,	
Ether,	
Ammonia Water,	
Normal Sulphuric Acid V.S.,	
Distilled Water, each, a sufficient quantity	

Transfer to a separator 5 Cc. of Fluidextract of Guarana, add 15 Cc. of chloroform and 1 Cc. of ammonia water. Shake well and allow the liquid to separate completely. Draw off the chloroform into a beaker. Shake out the fluid remaining in the separator with two additional portions of chloroform of 10 Cc. each, evaporate the combined chloroformic solutions carefully to dryness. Dissolve the alkaloidal residue in a mixture of 2 Cc. of normal sulphuric acid V.S. and 20 Cc. of warm distilled water. Allow it to cool, and filter the solution into a separator, rinse the flask and filter with distilled water, adding the rinsings to the separator, then add 20 Cc. of chloroform and 2 Cc. of ammonia water and shake the separator for one minute. Draw off the chloroform into a tared flask, and repeat the extraction with two portions of 10 C. each of chloroform, adding this to the tared flask. Distil off the chloroform, and, when dry, add 2 Cc. of ether, and evaporate this very carefully with the aid of a water-bath (to avoid decrepitation). Dry the residue to a constant weight on the water-bath. Multiply the weight by 20, which will give the weight in grammes of alkaloids contained in 100 Cc. of Fluidextract of Guarana.

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM HAMAMELIDIS FOLIORUM. U.S. Fluidextract of Hamamelis Leaves

[Extractum Hamamelidis Fluidum, Pharm. 1890]

	Metric	Old form
* **Hamamelis Leaves,** in No. 40 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 300 Cc. [old form 14½ fl. oz.] of Alcohol and 600 Cc. [old form 29 fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of 300 Cc. [old form 14½ fl. oz.] of Alcohol to 600 Cc. [old form 29 fl. oz.] of Water, until the Hamamelis Leaves are exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM HYDRASTIS. U.S. Fluidextract of Hydrastis

[EXTRACTUM HYDRASTIS FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Hydrastis,** in No. 60 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix the Glycerin with 600 Cc. [old form 29 fl. oz.] of Alcohol and 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of 600 Cc. [old form 29 fl. oz.] of Alcohol to 300 Cc. [old form 14½ fl. oz.] of Water, until the Hydrastis is exhausted. Reserve the first 750 Cc. [old form 36 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of hydrastine in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 2 Gm. of hydrastine.

Assay of Fluidextract of Hydrastis

Fluidextract of Hydrastis	10 Cc.
Distilled Water,	
Potassium Iodide,	
Ammonia Water,	
Ether, each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Hydrastis by means of a graduated pipette to a 100 Cc. measuring flask, add 85 Cc. of distilled water in which 2 Gm. of potas-

sium iodide have been previously dissolved, and sufficient water to make 100 Cc., and shake the liquid for several minutes. Then filter 50 Cc. of the liquid into a measuring cylinder and transfer it to a separator. Render the liquid alkaline with ammonia water, add 30 Cc. of ether, and shake the separator at intervals during several minutes. When separated, draw off the aqueous layer into a beaker, and the ether-solution into a tared beaker. Return the aqueous solution to the separator, and shake it with 20 Cc. more of ether for one minute. Draw off and reject the aqueous layer, and run the ether-solution into the tared beaker. Allow the combined ether-solutions to evaporate at a gentle heat, and dry the residue in the beaker to a constant weight on a water-bath. Multiply the weight by 20, which will give the weight in grammes of hydrastine contained in 100 Cc. of Fluidextract of Hydrastine.

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM HYOSCYAMI. U.S. Fluidextract of Hyoscyamus

[EXTRACTUM HYOSCYAMI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Hyoscyamus**, in No. 60 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about . . . . :	1000 Cc.	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Hyoscyamus is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 50 Cc. of this liquid, as directed below; from the results thus obtained, ascertain by calculation the amount of the alkaloids in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 0.075 Gm. of the alkaloids from Hyoscyamus.

Assay of Fluidextract of Hyoscyamus

The method to be employed is identical with that given on page 384, using 50 Cc. of Fluidextract of Hyoscyamus, instead of the quantity of Fluidextract of Belladonna Root there directed, and multiplying the product by 2 instead of 10.

Average dose.— 3 minims (0.2 Cc.).

FLUIDEXTRACTUM IPECACUANHÆ. U.S. Fluidextract of Ipecac

[EXTRACTUM IPECACUANHÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Ipecac**, in No. 80 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 350 Cc.

[old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Ipecac is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of the alkaloids in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 1.5 Gm. of the alkaloids from Ipecac.

Assay of Fluidextract of Ipecac

Fluidextract of Ipecac . . . . **10 Cc.**
Ammonia Water,
Ether,
Normal Sulphuric Acid V.S.,
Tenth-normal Sulphuric Acid V.S.,
Fiftieth-normal Potassium Hydroxide V.S.,
Cochineal T.S., each, a sufficient quantity

Transfer 10 Cc. of Fluidextract of Ipecac by means of a graduated pipette to a porcelain evaporating dish. Evaporate off the alcohol with the aid of a water-bath, and, when almost cool, add 5 Cc. of normal sulphuric acid V.S. and 20 Cc. of distilled water, and stir the liquid at intervals for three minutes. Filter the liquid into a separator, rinse the dish, and wash the filter successively with 10 Cc. and 5 Cc. of distilled water, and add these liquids to the separator. To the separator add 20 Cc. of ether and a small piece of red litmus paper; render the liquid alkaline with ammonia water and shake the separator for one minute. Draw off the aqueous layer into a beaker, and the ether-layer into another beaker. Return the aqueous solution to the separator, add 10 Cc. more of ether and shake the liquid, adding the ether-solution to that already in the beaker, and returning the aqueous solution to the separator; repeat the extraction with 10 Cc. more of ether, and then add the ether-layer to that already in the beaker. Allow the combined ether-solutions to evaporate, either spontaneously or with the aid of a water-bath containing warm water, and then add 10 Cc. of tenth-normal sulphuric acid V.S. Stir the liquid carefully with a glass rod to facilitate the solution of the alkaloids, and when these have all dissolved, add 5 drops of cochineal T.S. From a graduated burette, add sufficient fiftieth-normal potassium hydroxide V.S. until a pink color is produced. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 10 (the 10 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0238, and this product by 10, which will give the weight in grammes of alkaloids contained in each 100 Cc. of Fluidextract of Ipecac.

Average dose.— { Emetic, 15 minims (1 Cc.).
{ Expectorant, 1 minim (0.05 Cc.).

FLUIDEXTRACTUM KRAMERIÆ. U.S. Fluidextract of Krameria

[EXTRACTUM KRAMERIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Krameria,** in No. 40 Powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical glass percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Krameria is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM LAPPÆ. U.S. **Fluidextract of Lappa**

[Extractum Lappæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Lappa,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Lappa is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM LEPTANDRÆ. U.S. **Fluidextract of Leptandra**

[Extractum Leptandræ Fluidum, Pharm. 1890]

	Metric	Old form
* **Leptandra,** in No. 60 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Leptandra is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dis-

solve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM LOBELIÆ. U.S. Fluidextract of Lobelia

	Metric	Old form
* **Lobelia,** in No. 50 powder	1000 Gm.	50 oz. av.
Acetic Acid,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 275 Cc. [old form 13 fl. oz.] of Acetic Acid with 725 Cc. [old form 35 fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Acetic Acid and Water as before, until the Lobelia is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50 C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to made the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 8 minims (0.5 Cc.).

FLUIDEXTRACTUM LUPULINI. U.S. Fluidextract of Lupulin

[Extractum Lupulini Fluidum, Pharm. 1890]

	Metric	Old form
* **Lupulin**	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Pack the Lupulin firmly in a cylindrical percolator; then add enough Alcohol to saturate the Lupulin and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Lupulin is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 8 minims (0.5 Cc.).

FLUIDEXTRACTUM MATICO. U.S. Fluidextract of Matico

[Extractum Matico Fluidum, Pharm. 1890]

	Metric	Old form
* **Matico,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Matico is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 1 fluidrachm (4 Cc.).

FLUIDEXTRACTUM MEZEREI. U.S. Fluidextract of Mezereum

[EXTRACTUM MEZEREI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Mezereum,** in No. 30 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Mezereum is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

FLUIDEXTRACTUM NUCIS VOMICÆ. U.S. Fluidextract of Nux Vomica

[EXTRACTUM NUCIS VOMICÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Nux Vomica,** in No. 40 powder	1000 Gm.	50 oz. av.
Acetic Acid	50 Cc.	2½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix Alcohol and Water in the proportion of 750 Cc. [old form 36 fl. oz.] of Alcohol and 250 Cc. [old form 12 fl. oz.] of Water. Moisten the powder with 1000 Cc. [old form 3 pints] of the mixture, to which the Acetic Acid had previously been added, and let it digest, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it in a cylindrical glass percolator, gradually pour menstruum upon it, and allow the percolation to proceed slowly until the Nux Vomica is practically exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of strychnine in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 1 Gm. of strychnine.

Assay of Fluidextract of Nux Vomica

Fluidextract of Nux Vomica	10 Cc.
Ammonia Water,	
Ether,	
Chloroform,	
Distilled Water,	
Normal Sulphuric Acid V.S.,	
Sulphuric Acid Solution (3 percent. H_2SO_4),	
Sodium Hydroxide Solution (1 in 10),	
Nitric Acid (sp. gr. 1.42),	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V.S.,	
Iodeosin T.S., each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Nux Vomica by means of a graduated pipette to a porcelain dish, evaporate it to dryness with the aid of a water-bath, and dissolve the residue, while warm, in a mixture of 16 Cc. of ether, 5 Cc. of chloroform, and 4 Cc. of ammonia water, and transfer the solution to a separator, rinsing the dish with a little chloroform, which is to be added to the separator, and shake the separator carefully for a few minutes. When the fluids have separated, draw off the aqueous layer into another separator, wash the chloroform-ether liquid and separator with a little water, and add this to the second separator. Then shake the aqueous liquid with two successive portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a small portion of the liquid left in the second separator still shows, after acidifying, a reaction with mercuric potassium iodide T.S., repeat the shaking out with 10 Cc. more of chloroform. Now shake the combined liquids in the first separator with three successive portions, respectively, of 15, 10, and 10 Cc. of normal sulphuric acid V.S., and collect the combined acid solutions in another separator. To this acid solution add a small piece of red litmus paper, and sufficient ammonia water to render it alkaline, then shake out successively with three portions, respectively, of 25, 10, and 10 Cc. of chloroform, and collect the chloroform solutions in a beaker. Evaporate the chloroform with the aid of a water-bath, dissolve the alkaloidal residue in 15 Cc. of 3 percent. sulphuric acid solution, by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cooled mixture of equal volumes of nitric acid (specific gravity 1.42) and distilled water, and, after rotating the liquid a few times, set it aside for exactly ten minutes, stirring it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10), wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not quite turbid, add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a flask. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the flask, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue, add 10 Cc. of tenth-normal sulphuric acid V.S., 5 drops of iodeosin T.S., about 80 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the

excess of acid with fiftieth-normal potassium hydroxide V.S., until the aqueous liquid just turns pink. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. taken, by 5, subtract this number from 10 (the 10 Cc. of tenth-normal sulphuric acid V.S taken), multiply the remainder by 0.0332, and this product by 10, which will give the weight in grammes of strychnine contained in 100 Cc. of the Fluidextract of Nux Vomica.

Average dose.— 1 minim (0.05 Cc.).

FLUIDEXTRACTUM PAREIRÆ. U. S. Fluidextract of Pareira

[Extractum Pareiræ Fluidum, Pharm. 1890]

	Metric	Old form
* **Pareira,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Glycerin	**100 Cc.**	4 fl. oz. 384 min.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix the Glycerin with 600 Cc. [old form 29 fl. oz.] of Alcohol and 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of 600 Cc. [old form 29 fl. oz.] of Alcohol to 400 Cc. [old form 19 fl. oz.] of Water, until the Pareira is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM PHYTOLACCÆ. U. S. Fluidextract of Phytolacca

[Extractum Phytolaccæ Radicis Fluidum, Pharm. 1890]

	Metric	Old form
* **Phytolacca,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Phytolacca is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— { Emetic, 15 minims (1 Cc.).
{ Alterative, 1½ minims (0.1 Cc.).

FLUIDEXTRACTUM PILOCARPI. U. S. **Fluidextract of Pilocarpus**

[EXTRACTUM PILOCARPI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Pilocarpus,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make about	**1000 Cc.**	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Pilocarpus is exhausted. Reserve the first 750 Cc. [old form 36 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloid in the remainder of the liquid; add to this enough menstruum to make each 100 Cc. of Fluidextract contain 0.4 Gm. of the alkaloids from Pilocarpus.

Assay of Fluidextract of Pilocarpus

Fluidextract of Pilocarpus	**10 Cc.**
Chloroform,	
Ammonia Water,	
Normal Sulphuric Acid V.S.,	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V.S.,	
Cochineal T.S. or **Iodeosin T.S.,** each, a sufficient quantity	

Transfer 10 Cc. of Fluidextract of Pilocarpus by means of a graduated pipette to a porcelain dish containing a little clean sand, and evaporate it to dryness with the aid of a water-bath. Mix the sand uniformly with the extract and transfer the mixture to an Erlenmeyer flask of about 100 Cc. capacity, rinsing the dish with a mixture of 25 Cc. of chloroform and 2.5 Cc. of ammonia water. Transfer the rinsings to the flask, cork it securely, and shake it well at intervals during one hour. Decant the liquid, transfer to a separator, wash the sand with several portions of chloroform, draw off and filter the chloroformic liquid into another separator. Then shake out the chloroform solution with 15 Cc. of normal sulphuric acid V. S., transferring the acid aqueous solution to another separator. Repeat the shaking out with a mixture of 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, collecting the acid solutions in the second separator. Again repeat the shaking out with 10 Cc. of distilled water, and add the aqueous liquid to the second separator. Introduce into the second separator a small piece of red litmus paper, add enough ammonia water to render the liquid alkaline, and shake out the liquid with 20 Cc. of chloroform, drawing off the chloroformic solution into a beaker. Repeat the shaking out with two portions of 15 and 10 Cc. of chloroform, and add the chloroformic solutions to the beaker. Evaporate the chloroform by means of a water-bath, and dissolve the alkaloidal residue in 8 Cc. of tenth-normal sulphuric acid V.S. Add 5 drops of cochineal T.S. or iodeosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 8 (the 8 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.02, and this product by 10, to obtain the

weight in grammes of alkaloids contained in 100 Cc. of the Fluidextract of Pilocarpus.

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM PODOPHYLLI. U. S. Fluidextract of Podophyllum

[Extractum Podophylli Fluidum, Pharm. 1890]

	Metric	Old form
* **Podophyllum,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator ; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Podophyllum is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract ; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 8 minims (0.5 Cc.).

FLUIDEXTRACTUM PRUNI VIRGINIANÆ. U.S. Fluidextract of Wild Cherry

[Extractum Pruni Virginianæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Wild Cherry,** in No. 30 powder	**1000 Gm.**	50 oz. av.
Glycerin	**200 Cc.**	9½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix the Glycerin with 200 Cc. [old form 9½ fl. oz.] of Alcohol and 600 Cc. [old form 29 fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical glass percolator ; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours ; then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of 200 Cc. [old form 9½ fl. oz.] of Alcohol to 800 Cc. [old form 38½ fl. oz.] of Water, and allow the percolation to proceed very slowly, until the Fluidextract measures 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM QUASSIÆ. U.S. Fluidextract of Quassia

[Extractum Quassiæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Quassia**, in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 300 Cc. [old form 14½ fl. oz.] of Alcohol with 600 Cc. [old form 29 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Quassia is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 8 minims (0.5 Cc.).

FLUIDEXTRACTUM QUERCUS. U.S. Fluidextract of Quercus

	Metric	Old form
* **Quercus**, in No. 40 powder	1000 Gm.	50 oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 900 Cc. [old form 43 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Quercus is exhausted. Reserve the first 700 Cc. [old form 33½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM QUILLAJÆ. U.S. Fluidextract of Quillaja

	Metric	Old form
* **Quillaja**, in No. 40 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Quillaja is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fuidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 3 minims (0.2 Cc.).

FLUIDEXTRACTUM RHAMNI PURSHIANÆ. U.S. Fluidextract of Cascara Sagrada

[EXTRACTUM RHAMNI PURSHIANÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Cascara Sagrada,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 400 Cc. [old form 19 fl. oz.] of Alcohol with 600 Cc. [old form 29 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Cascara Sagrada is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM RHAMNI PURSHIANÆ AROMATICUM. U.S. Aromatic Fluidextract of Cascara Sagrada

	Metric	Old form
* **Cascara Sagrada,** in No. 40 powder	1000 Gm.	50 oz. av.
Glycyrrhiza, in No. 30 powder	100 Gm.	5 oz. av.
Magnesium Oxide	125 Gm.	6¼ oz. av.
Glycerin	250 Cc.	12 fl. oz.
Compound Spirit of Orange	10 Cc.	½ fl. oz.
Alcohol,		
Diluted Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Cascara Sagrada, Glycyrrhiza, and Magnesium Oxide thoroughly, and, having added 2000 Cc. [old form 6 pints] of Water, allow the mixture to macerate for twelve hours, and then dry it at a gentle heat. Mix the Glycerin with 500 Cc. [old form 21 fl. oz.] of Alcohol and 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the powder is exhausted. Reserve the first 800 Cc. [old form $38\frac{1}{2}$ fl. oz.] of the percolate, and evaporate the remainder to a soft extract ; dissolve this in the reserved portion, add the Compound Spirit of Orange and enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM RHEI. U.S. Fluidextract of Rhubarb

[EXTRACTUM RHEI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Rhubarb,** in No. 30 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 800 Cc. [old form $38\frac{1}{2}$ fl. oz.] of Alcohol with 200 Cc. [old form $9\frac{1}{2}$ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a conical percolator ; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Rhubarb is exhausted. Reserve the first 750 Cc. [old form 36 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 70° C. (158° F.), to a soft extract ; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM RHOIS GLABRÆ. U.S. Fluidextract of Rhus Glabra

[EXTRACTUM RHOIS GLABRÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Rhus Glabra,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Glycerin	**100 Cc.**	4 fl. oz. 384 min.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix the Glycerin with 900 Cc. [old form 43 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator ; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Rhus Glabra is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM ROSÆ. U.S. Fluidextract of Rose

[EXTRACTUM ROSÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Red Rose,** in No. 20 powder	**1000 Gm.**	50 oz. av.
Glycerin	**100 Cc.**	4 fl. oz. 384 min.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix the Glycerin with 900 Cc. [old form 43 fl. oz.] of Diluted Alcohol, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Red Rose is exhausted. Reserve the first 750 Cc. [old form 36 fl. oz.] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM RUBI. U.S. Fluidextract of Rubus

[EXTRACTUM RUBI FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Rubus,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Rubus is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM SABINÆ. U.S. Fluidextract of Savin

[Extractum Sabinæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Savin,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 250 Cc. [old form 12 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Savin is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—5 minims (0.3 Cc.).

FLUIDEXTRACTUM SANGUINARIÆ. U.S. Fluidextract of Sanguinaria

	Metric	Old form
* **Sanguinaria,** in No. 30 powder	1000 Gm.	50 oz. av.
Acetic Acid,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 275 Cc. [old form 13 fl. oz.] of Acetic Acid with 725 Cc. [old form 35 fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, allow it to macerate, in a well-covered vessel, during forty-eight hours. Then pack it firmly in a cylindrical glass percolator, gradually pour menstruum upon it, using the same proportions of Acetic Acid and Water as before, and allow the percolation to proceed slowly, until the Sanguinaria is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—1½ minims (0.1 Cc.).

FLUIDEXTRACTUM SARSAPARILLÆ. U.S. Fluidextract of Sarsaparilla

[Extractum Sarsaparillæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Sarsaparilla,** in No. 30 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 300 Cc. [old form 14½ fl. oz.] of Alcohol with 600 Cc. [old form 29 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop

from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Sarsaparilla is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM SARSAPARILLÆ COMPOSITUM. U. S. Compound Fluidextract of Sarsaparilla

[Extractum Sarsaparillæ Fluidum Compositum, Pharm. 1890]

	Metric	Old form
* **Sarsaparilla,** in No. 30 powder	750 Gm.	37½ oz. av.
Glycyrrhiza, in No. 30 powder	120 Gm.	6 oz. av.
Sassafras, in No. 30 powder	100 Gm.	5 oz. av.
Mezereum, in No. 30 powder	30 Gm.	1½ oz. av.
Glycerin	100 Cc.	4 fl. oz. 384 min.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the Glycerin with 900 Cc. [old form 43 fl. oz.] of Diluted Alcohol, and, having moistened the mixed powders with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding first the remainder of the menstruum and then Diluted Alcohol, until the powder is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM SCILLÆ. U. S. Fluidextract of Squill

	Metric	Old form
* **Squill,** in No. 20 powder	1000 Gm.	50 oz. av.
Acetic Acid,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 275 Cc. [old form 13 fl. oz.] of Acetic Acid with 725 Cc. [old form 35 fl. oz.] of Water, and, having added 800 Cc. [old form 38½ fl. oz.] of the mixture to the powder, allow it to macerate, in a well-covered glass or porcelain vessel, during forty-eight hours, then transfer it to a conical glass percolator, and allow the percolation to proceed slowly, adding menstruum gradually, using the same proportions of Acetic Acid and Water as before, until the Fluidextract measures 1000 Cc. [old form 3 pints].

Average dose.—1½ minims (0.1 Cc.).

FLUIDEXTRACTUM SCOPOLÆ. U. S. Fluidextract of Scopola

	Metric	Old form
* **Scopola,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	1000 Cc.	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 350 Cc. [old form 17 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Scopola is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid as directed below; from the results thus obtained, ascertain by calculation the amount of mydriatic alkaloids in the remainder of the liquid and add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 0.5 Gm. of the mydriatic alkaloids from Scopola.

Assay of Fluidextract of Scopola

The method to be employed is identical with that given for Fluidextract of Belladonna Root on page 384, using 10 Cc. of Fluidextract of Scopola.

Average dose.— 1 minim (0.05 Cc).

FLUIDEXTRACTUM SCUTELLARIÆ. U.S. Fluidextract of Scutellaria

[Extractum Scutellariæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Scutellaria,** in No. 40 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Scutellaria is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM SENEGÆ. U.S. **Fluidextract of Senega**

[Extractum Senegæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Senega,** in No. 40 powder	1000 Gm.	50 oz. av.
Solution of Potassium Hydroxide	30 Cc.	1½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix the solution of Potassium Hydroxide with 600 Cc. [old form 29 fl. oz.] of Alcohol and 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 450 Cc. [old form 21½ fl. oz.] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of 600 Cc. [old form 29 fl. oz.] of Alcohol to 300 Cc. [old form 14½ fl. oz.] of Water until the Senega is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, in a porcelain dish, to a soft extract; dissolve this in the reserved portion, and add enough of the last-mentioned mixture of Alcohol and Water to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

FLUIDEXTRACTUM SENNÆ. U.S. **Fluidextract of Senna**

[Extractum Sennæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Senna,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Diluted Alcohol, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 350 Cc. [old form 17 fl. oz.] of Alcohol, pack it firmly in a cylindrical percolator, and percolate it with Alcohol until the Senna is exhausted. The alcoholic percolate thus obtained is to be rejected. Remove the powder from the percolator, dry it, and, having moistened it with 400 Cc. [old form 19 fl. oz.] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Senna is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM SERPENTARIÆ. U.S. **Fluidextract of Serpentaria**

[EXTRACTUM SERPENTARIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Serpentaria,** in No. 50 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Serpentaria is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—15 minims (1 Cc.).

FLUIDEXTRACTUM SPIGELIÆ. U.S. **Fluidextract of Spigelia**

[EXTRACTUM SPIGELIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Spigelia,** in No. 40 powder	1000 Gm.	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Spigelia is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—1 fluidrachm (4 Cc.).

FLUIDEXTRACTUM STAPHISAGRIÆ. U.S. **Fluidextract of Staphisagria**

	Metric	Old form
* **Staphisagria,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 800 Cc. [old form 38½ fl. oz.] of Alcohol with 200 Cc. [old form 9½ fl. oz.] of Water, and, having moistened the powder with

300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Staphisagria is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—1 minim (0.05 Cc.).

FLUIDEXTRACTUM STILLINGIÆ. U.S. Fluidextract of Stillingia

[EXTRACTUM STILLINGIÆ FLUIDUM, PHARM. 1890]

	Metric	Old form
* **Stillingia,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Diluted Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Stillingia is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.—30 minims (2 Cc.).

FLUIDEXTRACTUM STRAMONII. U.S. Fluidextract of Stramonium

	Metric	Old form
* **Stramonium,** in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make about	**1000 Cc.**	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz. of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Stramonium is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.], of the percolate, and evaporate the remainder, at a temperature not exceed-

ing 50° C. (122° F.], to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay 10 Cc. of this liquid, as directed below; from the results thus obtained, ascertain by calculation the amount of mydriatic alkaloids in the remainder of the liquid, and add to this enough menstruum to make each 100 Cc. of the finished Fluidextract contain 0.25 Gm. of the mydriatic alkaloids from Stramonium.

Assay of Fluidextract of Stramonium

The method to be employed is identical with that given for Fluidextract of Belladonna Root on page 384, using 10 Cc. of Fluidextract of Stramonium.

Average dose.— 1 minim (0.05 Cc.).

FLUIDEXTRACTUM SUMBUL. U.S. Fluidextract of Sumbul

	Metric	Old form
* **Sumbul,** in No. 30 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Sumbul is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM TARAXACI. U.S. Fluidextract of Taraxacum

[Extractum Taraxaci Fluidum, Pharm. 1890]

	Metric	Old form
* **Taraxacum,** in No. 30 powder	1000 Gm.	50 oz. av.
Solution of Sodium Hydroxide	50 Cc.	2½ fl. oz.
Diluted Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Taraxacum is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, add the Solution of Sodium Hydroxide, and enough Diluted Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 2 fluidrachms (8 Cc.).

FLUIDEXTRACTUM TRITICI. U.S. **Fluidextract of Triticum**

[Extractum Tritici Fluidum, Pharm. 1890]

	Metric	Old form
* **Triticum,** finely cut	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Pack the Triticum in a cylindrical metallic percolator, pour boiling Water upon it, and allow the percolation to proceed, supplying boiling water, as required, until the Triticum is exhausted. Evaporate the percolate to 750 Cc. [old form 36 fl. oz.] and, having added to it 250 Cc. [old form 12 fl. oz.] of Alcohol, mix well and set it aside for forty-eight hours. Then filter the liquid and add to the filtrate enough of a mixture of Alcohol and Water made in the proportion of *one volume* of Alcohol to *three volumes* of Water to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 2 fluidrachms (8 Cc.).

FLUIDEXTRACTUM UVÆ URSI. U.S. **Fluidextract of Uva Ursi**

[Extractum Uvæ Ursi Fluidum, Pharm. 1890]

	Metric	Old form
* **Uva Ursi,** in No. 30 powder	**1000 Gm.**	50 oz. av.
Glycerin	**300 Cc.**	14½ fl. oz.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix the Glycerin with 200 Cc. [old form 9½ fl. oz.] of Alcohol and 500 Cc. [old form 24 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 19 fl. oz.] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of 200 Cc. [old form 9½ fl. oz.] of Alcohol to 500 Cc. [old form 24 fl. oz.] of Water, until the Uva Ursi is exhausted. Reserve the first 800 Cc. [old form 38½ fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of Alcohol and Water to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM VALERIANÆ. U.S. Fluidextract of Valerian

[Extractum Valerianæ Fluidum, Pharm. 1890]

	Metric	Old form
* **Valerian,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Valerian is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM VERATRI. U. S. Fluidextract of Veratrum

[Extractum Veratri Viridis Fluidum, Pharm. 1890]

	Metric	Old form
* **Veratrum,** in No. 60 powder	1000 Gm.	50 oz. av.
Alcohol, a sufficient quantity,		
To make	1000 Cc.	3 pints

Moisten the powder with 300 Cc. [old form 14½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Veratrum is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 1½ minims (0.1 Cc.).

FLUIDEXTRACTUM VIBURNI OPULI. U.S. Fluidextract of Viburnum Opulus

[Extractum Viburni Opuli Fluidum, Pharm. 1890]

	Metric	Old form
* **Viburnum Opulus,** in No. 40 powder	1000 Gm.	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	1000 Cc.	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Viburnum Opulus is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM VIBURNI PRUNIFOLII. U.S. Fluidextract of Viburnum Prunifolium

[Extractum Viburni Prunifolii Fluidum, Pharm. 1890]

	Metric	Old form
* **Viburnum Prunifolium**, in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, each, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 600 Cc. [old form 29 fl. oz.] of Alcohol with 300 Cc. [old form 14½ fl. oz.] of Water, and, having moistened the powder with 300 Cc. [old form 14½ fl. oz.] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Viburnum Prunifolium is exhausted. Reserve the first 850 Cc. [old form 41 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM XANTHOXYLI. U.S. Fluidextract of Xanthoxylum

[Extractum Xanthoxyli Fluidum, Pharm. 1890]

	Metric	Old form
* **Xanthoxylum**, in No. 40 powder	**1000 Gm.**	50 oz. av.
Alcohol,		
Water, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Mix 750 Cc. [old form 36 fl. oz.] of Alcohol with 250 Cc. [old form 12 fl. oz.] of Water, and, having moistened the powder with 250 Cc. [old form 12 fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to

drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Xanthoxylum is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 30 minims (2 Cc.).

FLUIDEXTRACTUM ZINGIBERIS. U.S. Fluidextract of Ginger

[Extractum Zingiberis Fluidum, Pharm. 1890]

	Metric	Old form
* **Ginger,** in No. 50 powder	**1000 Gm.**	50 oz. av.
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	3 pints

Moisten the powder with 250 Cc. [old form 12 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Ginger is exhausted. Reserve the first 900 Cc. [old form 43 fl. oz.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure 1000 Cc. [old form 3 pints].

Average dose.— 15 minims (1 Cc.).

CHAPTER XXVIII

OLEORESINOUS LIQUIDS MADE BY PERCOLATION

Oleoresinæ *Oleoresins*

THE oleoresins are official liquid preparations, consisting principally of natural oils and resins extracted from vegetable substances by percolation with acetone; ether was formerly used as the menstruum, but it was replaced by acetone in the U. S. Pharmacopœia (8th Rev.), because the latter is less inflammable and not so expensive, the oleoresin of cubeb is the exception in this class, its menstruum being alcohol. The oleoresins were formerly classed with fluidextracts, but they differ essentially from the latter: 1. They do not bear the uniform relation to the drug that the fluidextracts do, of gramme to cubic centimeter,—the yield of oleoresin obtained from the drug varying according to the proportion of oil and resin naturally present. 2. The menstruum (acetone) extracts principles which are often insoluble in alcohol, diluted alcohol or water. 3. They are without exception the most concentrated liquid preparations of the drugs that are produced.

FIG. 439

Percolator for volatile liquids

Oleoresins are prepared by percolating the powdered drug contained in a cylindrical percolator provided with a cover and receptacle suitable for volatile liquids, with acetone or alcohol, until exhausted, recovering the greater part of the liquid by distillation, and exposing the residue in a capsule to spontaneous evaporation until the remaining liquid has evaporated. Fig. 439 shows a convenient percolator for making oleoresins. The powder should not be packed too tightly in the narrow percolator; the exit tube affords a means of easily regulating the flow. A *continuous extraction apparatus* can be made of this percolator by enclosing the upper part in a suitable case and passing cold water between, arranging the apparatus like a Liebig's condenser (see page 149). A glass tube is connected with the top of the percolator and the mouth of the bottle by rubber tube connections, and if the receiving bottle is placed in a water-bath and the water gently heated, the acetone will evaporate from the percolate, the vapors rising in the tube and condensing in the upper part of the percolator.

Oleoresins which have not been evaporated sufficiently are frequently found in commerce; they have a decided odor of the menstruum, sometimes of benzin, showing in the latter case that a menstruum which is an inferior solvent has been substituted for the one authorized by the Pharmacopœia. *Six* oleoresins are official.

Table of Official Oleoresins

Name	Yield	Dose
Oleoresina Aspidii	10 to 15 percent.	fʒss to fʒi (2 Cc. to 4 Cc.)
Capsici	5 percent.	♏¼ to ♏i (0.01 Cc. to 0.05 Cc.)
Cubebæ	18 to 25 percent.	♏v to ♏xxx (0.3 Cc. to 2 Cc.)
Lupulini	50 percent.	♏ii to ♏v (0.15 Cc. to 0.3 Cc.)
Piperis	5 percent.	♏¼ to ♏i (0.01 Cc. to 0.05 Cc.)
Zingiberis	6 to 8 percent.	♏i (0.05 Cc.)

OLEORESINA ASPIDII. U.S. Oleoresin of Aspidium

	Metric	Old form
* **Aspidium,** recently reduced to No. 40 powder	**500 Gm.**	16 oz. av.
Acetone, a sufficient quantity		

Introduce the Aspidium into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Aspidium is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. (The product is usually about 60 Gm.) [old form 2 fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

NOTE.—Oleoresin of Aspidium usually deposits, on standing, a granular, crystalline substance (filicic acid). This should be thoroughly mixed with the liquid portion before use.

Average dose.— 30 grains (2 Gm.).

OLEORESINA CAPSICI. U.S. Oleoresin of Capsicum

	Metric	Old form
* **Capsicum,** in No. 40 powder	**500 Gm.**	32 oz. av.
Acetone, a sufficient quantity		

Introduce the Capsicum into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until 800 Cc. [old form 3 pints] of percolate have been obtained. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. Then pour off the liquid portion, transfer the remainder to a glass funnel provided with a pledget of cotton, and, when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. (The product is usually about 25 Gm.) [old form 1½ fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

Average dose.— ½ grain (0.030 Gm.).

OLEORESINA CUBEBÆ. U.S. Oleoresin of Cubeb

	Metric	Old form
* **Cubeb,** in No. 30 powder	**500 Gm.**	16 oz. av.
Alcohol, a sufficient quantity		

Introduce the Cubeb into a cylindrical glass percolator, pack the powder firmly, and percolate slowly with Alcohol, added in successive portions until the Cubeb is exhausted. Recover the greater part of the Alcohol from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Alcohol to evaporate, with constant stirring, in a warm place. (The product is usually about 125 Gm.) [old form 4 fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

NOTE.—Oleoresin of Cubeb deposits, after standing for some time, a waxy and crystalline matter, which should be rejected, the liquid portion only being used.

Average dose.— 7½ grains (0.500 Gm.).

OLEORESINA LUPULINI. U.S. Oleoresin of Lupulin

	Metric	Old form
* **Lupulin**	**500 Gm.**	16 oz. av.
Acetone, a sufficient quantity		

Introduce the Lupulin into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and a receptacle suitable for volatile liquids. Press the powder very lightly, and percolate slowly with Acetone, added in successive portions, until the Lupulin is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and having transferred the residue, to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. (The product is usually about 250 Gm.) [old form 8 fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

Average dose.—3 grains (0.200 Gm.).

OLEORESINA PIPERIS. U.S. Oleoresin of Pepper

	Metric	Old form
* **Pepper,** in No. 40 powder	**500 Gm.**	32 oz. av.
Acetone, a sufficient quantity		

Introduce the Pepper into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and a receptacle for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Pepper is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, set this aside in a warm place until the remaining Acetone has evaporated, and the deposition of crystals of piperine has ceased. Lastly, separate the Oleoresin from the piperine by straining through purified cotton. (The product is usually about 25 Gm.) [old form 1½ fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

Average dose.—½ grain (0.030 Gm.).

OLEORESINA ZINGIBERIS. U.S. Oleoresin of Ginger

	Metric	Old form
* **Ginger,** in No. 60 powder	**500 Gm.**	16 oz. av.
Acetone, a sufficient quantity		

Introduce the Ginger into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Ginger is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. (The product is usually about 30 Gm.) [old form 1 fl. oz.]. Keep the Oleoresin in a well-stoppered bottle.

Average dose.— $\frac{1}{2}$ grain (0.030 Gm.).

CHAPTER XXIX

ACETOUS LIQUIDS MADE BY PERCOLATION

Aceta *Vinegars*

THIS class of preparations is an old one, having been in use since the days of Hippocrates. Medicated vinegars are solutions of the active principles of drugs in diluted acetic acid, the latter being chosen as a menstruum because acetic acid is not only a good solvent but also possesses antiseptic properties.

Diluted acetic acid replaces the menstrua formerly used, wine and cider vinegar having been discarded on account of their variable quality. Acetic acid may be obtained in all parts of the country very cheaply and of unexceptionable quality, and by simple admixture with about five times its weight of water the menstruum is produced. The properties of acetic acid are noticed in Part IV of this work.

Two vinegars are official at present; one is made from a drug which owes its activity to alkaloids. The advantage of using acidulous menstruum is apparent in forming soluble salts with most of the active principles of drugs, and experience has proved the value of diluted acetic acid as a solvent in exhausting drugs. The medicated vinegars should not be made in larger quantities than can be used within a reasonable time, for, although possessed of most of the characters of permanent preparations, they are liable to deposit upon standing.

The official vinegars are now uniform in strength (10 percent.), each containing the soluble principles from the drug. They are both made by maceration.

Official Vinegars

Name	Ingredients
Acetum Opii	100 Gm. Powdered Opium; 30 Gm. Powdered Myristica; 200 Gm. Sugar, with sufficient Diluted Acetic Acid to make 1000 Cc.
Scillæ	100 Gm. Squill, No. 20 powder, with sufficient Diluted Acetic Acid to make 1000 Cc.

Unofficial Vinegars

Name	Ingredients	Method of Preparing
Acetum Cantharidis. Br.	100 Gm. Cantharides, bruised; Glacial Acetic Acid and Water, of each, to make 1000 Cc.	Macerate the Cantharides in 900 Cc. equal parts Glacial Acetic Acid and Water for twenty-four hours, then transfer to a percolator, and add enough menstruum to make 1000 Cc.
Ipecacuanhæ. Br.	50 Cc. Fluidextract of Ipecac; 100 Cc. Alcohol; 850 Cc. Diluted Acetic Acid (4.27 percent.)	Mix, filter and add Diluted Acetic Acid to make 1000 Cc.

ACETUM OPII. U.S. **Vinegar of Opium**

	Metric	Old form
* **Powdered Opium**	**100 Gm.**	365 grains
Myristica, in No. 30 powder	**30 Gm.**	109 grains
Sugar	**200 Gm.**	1 oz. av. 182 gr.
Diluted Acetic Acid, a sufficient quantity,		
To make	**1000 Cc.**	8 fl. oz.

Macerate the Opium and Myristica in 500 Cc. [old form 4 fl. oz.] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin of close texture, and express the liquid. Mix the residue with 200 Cc. [old form 1½ fl. oz.] of Diluted Acetic Acid until a uniform magma is produced, then strain and express again. Mix and filter the strained liquids, dissolve the Sugar in the filtrate, and pass enough Diluted Acetic Acid through the filter to make the product measure 1000 Cc. [old form 8 fl. oz.]

Average dose.— 8 minims (0.5 Cc.).

ACETUM SCILLÆ. U.S. **Vinegar of Squill**

	Metric	Old form
* **Squill,** in No. 20 powder	**100 Gm.**	3 oz. av. 148 gr.
Diluted Acetic Acid, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Macerate the Squill with 900 Cc. [old form 29 fl. oz.] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin, and wash the mass on the strainer with enough Diluted Acetic Acid to make the strained liquid measure nearly 1000 Cc. [old form 2 pints]. Heat this liquid to boiling, filter while hot, and when cooled add sufficient Diluted Acetic Acid to make the product measure 1000 Cc. [old form 2 pints.]

Average dose.— 15 minims (1 Cc.).

CHAPTER XXX

SOLID PREPARATIONS MADE BY PERCOLATION

Extracta *Extracts*

EXTRACTS are solid or semi-solid preparations produced by evaporating solutions of vegetable principles. The solutions may be made by percolating the drug with water, alcohol, diluted alcohol of various strengths, ether, diluted acetic acid, or diluted solution of ammonia, and the extracts made from such percolates are termed respectively *aqueous*, *alcoholic*, *hydro-alcoholic*, *ethereal*, *acetic*, or *ammoniated* extracts. In addition to this, the juices of fresh plants extracted by contusion and expression are evaporated, and such extracts are frequently called *Succi spissati*, or *inspissated juices.*

Preparation of Inspissated Juices.—The variation in the amount of extractive matter afforded by expressing fresh plants is so great that the quality of this class of extracts is necessarily very uncertain. Although alcoholic extracts are also subject to variations, experience has shown that they are much more reliable, when properly made, than extracts prepared from expressed juices. For this reason inspissated juices were not recognized in the U. S. Pharmacopœia (8th Rev.). The inspissated juices most largely consumed in America are made in Great Britain, and the general formula of the British Pharmacopœia is appended:

Bruise the fresh plant in a mortar, press out the juice, and heat it gradually to 130° F., and separate the green colouring matter by a calico filter. Heat the strained liquid to 200° F. (to coagulate the albumen) and filter again. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; add to it the green colouring matter previously separated and passed through a hair-sieve, stir the whole together, and evaporate at a temperature not exceeding 140° F. to the consistence of a soft extract. Four extracts from fresh plants or parts of plants are official in the British Pharmacopœia as follows: green extract of belladonna, green extract of hyoscyamus, extract of colchicum, and extract of taraxacum.

Prof. Herrara has proposed a plan of making extracts without the use of much heat,—*by freezing the juices.* He finds that by compressing the frozen juice the expressed liquid, or mother-liquor, is greatly strengthened, the water being largely removed as ice, which remains in the press-cloth, and the concentrated juice is then dried by exposure on plates to the sun.

The percolates, or expressed juices of drugs, contain, in addition to the active principles, certain inert substances, which exist in the liquids in varying quantities. The amount of inert matter found in the extract depends largely upon the manipulation, but the composition of extracts also varies with the nature of the drug, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant, with as little of the inert matter, as possible; though sometimes it may be desirable to separate two active ingredients from each other, when their effects upon the system are materially different; this may be partially accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are *gum*, *sugar*, *starch*, *tannin*, *extractive*, *chlorophyl*, *coloring-matter*, *salts*, and the *peculiar principles of plants;* to which, when a spiritous solvent is employed, may usually be added *resinous substances*, *fatty matter*, and frequently more or less *volatile oil*, gum and starch being excluded when the menstruum is strong alcohol. Inert fixed oil or fat is often removed from powdered drugs by previous percolation with ether or petroleum benzin; these liquids do not, as a rule, extract the active principles, and thus a dry powdered extract can be made.

Extractive.—It has long been known that in most vegetable bodies there is a substance, soluble both in water and in alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first, a greenish, then a yellowish-brown, and ultimately a deep brown color, and becoming itself insoluble. This substance has received the appropriate name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence as depending upon the mutual reaction of other principles. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect; and Berzelius long ago proposed to substitute for it that of *apothem*, synonymous with deposit. According to Berzelius, apothem is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into apothem may be injurious by causing a precipitation of a portion of the active principle; and in practical pharmaceutical operations this change should always, if possible, be avoided.

Variable Quality of Extracts.—*It is evident that there must be great variation in the quality of extracts of pilular consistence as found in commerce*, for, whether made by any of the processes commonly employed, or by a special patented process, the lack of a fixed standard to determine the amount of moisture which is to remain in the extracts renders them very variable in strength. The Pharmacopœia is necessarily compelled to avoid specifying an exact limit in this respect, and the approximate standard of "*pilular consistence*" has been adopted. The powdered extracts are more stable and the preparations considered in another place, called *abstracts*, have a great advantage over extracts in this respect. It should be said in addition that the variation in the strength of extracts of pilular consistence does not cease even after their manufacture. The exposure to the air to which they are subjected in dispensing, particularly if kept in the customary open queen's-ware jars, causes loss of moisture, and they become hard, and consequently stronger, in proportion to the quantity of moisture that is thus lost; this loss may in some cases amount to as much as 25 percent. In moist climates, however, some extracts absorb moisture and become thinner. One of the advantages of powdered extracts is that they may be kept in tightly corked vials, and thus protected from moisture. The greatest variation in the commercial extracts, however, arises from the difference in the alcoholic strength of the menstruum employed. This may be best illustrated by taking the case of extract of jalap. Alcohol always dissolves the active principles, while water is the best solvent for those that are inert. If a manufacturer in making extract of jalap uses equal parts of alcohol and water, he will obtain twice as much extract as the manufacturer who simply uses alcohol; but the alcoholic extract or resin has twice the strength of the hydro-alcoholic extract, and is worth double the price, because it has been shown by actual experiment that the aqueous extract of jalap is absolutely inert even in doses of two hundred and forty grains. The difference between the relative merits of alcoholic and aqueous extracts does not so clearly appear in many of the extracts as in the instance just noted, but it is shown in such important extracts as those from belladonna, hyoscyamus, digitalis, etc., for here the strength depends largely upon the menstrua used in exhausting them, water removing the inert principles, starch, gum, albumen, sugar, salt, etc. The relative value of commercial extracts must depend upon the amount of *active* principles present; and as the manufacturer never states upon the label the menstruum that he has employed in making the extract, nor the yield of the extract from the drug from which it is prepared, and as each manufacturer often uses the menstruum that he thinks best, the pharmacist and physician have no means of knowing the dose of the extract, nor can they usually form any correct judgment of its value without a therapeutical experiment or analytical assay. It will be seen, therefore, from the foregoing considerations that extracts are among the most *unreliable* of all classes of preparations. It is greatly to be regretted that manufacturers do not *strictly adhere* to the menstrua directed in the Pharmacopœia, for the sake of securing uniformity, if for no other reason.

Preparation of Extracts.—The manipulations necessary to produce extracts have been considered under the various heads of Maceration, Expression, Percolation, Decoction, Infusion, Evaporation, Use of Steam Heat, Vacuum Apparatus, etc. The special precautions necessary for each extract will be noticed in the official working formulas which follow. The details of the formulas vary so much that a general formula is of little value, except to serve as a type for the alcoholic extracts, which resemble one another more closely than do any of the others.

Preservation of Extracts.—The general practice is to take no especial care in the preservation of soft extracts. This arises from the incorrect impression that they are permanent preparations and do not need it. The manufacturers seal the jars or bottles which contain them, because experience has compelled them to be very careful about this, to avoid loss in transportation,—in the case of soft extracts, through inversion of the jar. The loosely fitting covers to the jars permit the exposure which causes the variation above noticed, and it is impracticable for the pharmacist on every occasion to seal the jar immediately after he has used a portion of the extract. Several expedients have been suggested to overcome these difficulties. It is good practice to enclose the jar in a tightly fitting tin can, or to put the extract in a jar with a screw-cap cover which has a thin cork disk in the top to aid in making a tight joint.

Powdered Extracts.—These extracts are largely superseding soft extracts for reasons given in a preceding paragraph; the difficulty of making them arises from the injurious influence of heat upon concentrated percolates of organic substances, but by the use of vacuum apparatus, suitable absorptive diluents and care they can be made successfully.

General Formula for Powdered Extracts.—Evaporate the Fluidextract of the drug at a temperature not exceeding 70° C. (158° F.) with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered glycyrrhiza to make the finished extract weigh —— Gm. Mix thoroughly. Permission is given by the U. S. P. (8th Rev.) to use instead of powdered glycyrrhiza the dried and powdered marc from the same drug.

Powdered extracts should be kept in tightly closed vials and in a cool place.

General Formula for Alcoholic Extracts.—Percolate the powdered drug with the menstruum directed, until it is exhausted; reserve the first third of the percolate, evaporate the remainder at a temperature not exceeding 50° C. (122° F.) until it weighs 10 per cent. of the weight of the drug. Mix this with the reserved portion, and evaporate both at the above temperature to a pilular consistence. Or, instead of reserving a part of the percolate, the whole quantity is distilled until the alcohol is recovered, and the residue evaporated to a pilular consistence. In the case of those extracts which are apt to become hard, 10 percent. of glycerin may be added to enable them to retain their consistence.

Official Extracts.—The official extracts are *twenty-eight* in number. Of these, *seventeen* are directed to be made with alcoholic menstrua of various strengths,—viz., Extracts of Belladonna Leaves, Cannabis Indica, Cascara Sagrada, Cimicifuga, Colocynth, Compound Colocynth, Digitalis, Ergot, Euonymus, Hyoscyamus, Leptandra, Physostigma, Rhubarb, Scopola, Stramonium, Sumbul, and Taraxacum.

Nine official extracts are made with aqueous menstrua,—viz., Extracts of Aloes, Hæmatoxylon, Gentian, Opium, Krameria, Malt, Quassia, Glycyrrhiza, and Pure Extract of Glycyrrhiza. Of these,

One extract is percolated with water containing 5 percent. of ammonia water,—*i.e.*, Pure Extract of Glycyrrhiza.

Two extracts are made with a menstruum composed of water containing official acetic acid,—*i.e.*, Extract of Colchicum Corm and Extract of Nux Vomica.

Nine extracts are made by evaporating fluidextracts,—*i.e*, Extracts of Cimicifuga, Digitalis, Euonymus, Hyoscyamus, Leptandra, Rhubarb, Scopola, Stramonium, and Sumbul.

One extract is made by mixing extracts with aromatics, etc,—*i.e.*, Compound Extract of Colocynth.

Ten powdered extracts are official in the U. S. Pharmacopœia (8th Revision).

Official Extracts arranged according to the Strength of their Menstrua, with Manipulative Notes

Name and Menstruum	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Process and Notes
Alcoholic				
Extractum Cannabis Indicæ	20	300	. . .	Percolate to exhaustion, after forty-eight hours maceration, distil off the alcohol, and evaporate to a pilular consistence
Cimicifugæ	60	250	900	Made by evaporating 100 Cc. of Fluidextract of Cimicifuga, with constant stirring, to dryness, at a temperature not exceeding 70° C. (158° F.), powdering the product, adding enough powdered Glycyrrhiza to make the Extract weigh 25 Gm., and mixing
Physostigmatis	80	400	900	Percolate 1000 Gm. of drug to exhaustion, after forty-eight hours maceration, reserve 900 Cc. of percolate, evaporate the remainder to 100 Cc., mix with reserved portion, and evaporate the mixed liquids to a pilular consistence, at a temperature not exceeding 50° C. (122° F.). Assay and add sufficient sugar of milk, if necessary, to reduce it to the standard of 2 percent. of ether-soluble alkaloids
Alcohol, 4; Water, 1				
Extractum Euonymi	40	350	800	Made by evaporating 100 Cc. of Fluidextract of Euonymus, with constant stirring, to dryness, at a temperature not exceeding 70° C. (158° F.), powdering the product, adding enough powdered Glycyrrhiza to make the Extract weigh 25 Gm., and mixing

Official Extracts—*Continued*

Name and Menstruum	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Process and Notes
Extractum Rhei	30	400	750	Made by evaporating 100 Cc. of Fluidextract of Rhubarb, with constant stirring, to a pilular consistence, at a temperature not exceeding 50° C. (122° F.)
Scopolæ	40	350	800	Made by evaporating 100 Cc. of Fluidextract of Scopola, with constant stirring, to a pilular consistence, at a temperature not exceeding 50° C. (122° F.), assaying and adding sufficient sugar of milk, if necessary, to reduce it to the standard of 2 percent. of mydriatic alkaloids
Alcohol, 3 ; Water, 1				
Extractum Leptandræ	40	400	850	Made by evaporating 100 Cc. of Fluidextract of Leptandra, with constant stirring, to dryness, at a temperature not exceeding 70° C. (158° F.), powdering the product, adding enough powdered Glycyrrhiza to make the Extract weigh 25 Gm., and mixing
Sumbul	30	400	850	Made by evaporating 100 Cc. of Fluidextract of Sumbul, with constant stirring, to a pilular consistence, at a temperature not exceeding 70° C. (158° F.)
Alcohol, 5 ; Water, 2				
Extractum Ergotæ	40	500	. . .	Percolate 1000 Gm. of drug to exhaustion, after forty-eight hours maceration, evaporate the liquid to 250 Gm., at a temperature not exceeding 50° C. (122° F.), and add 250 Cc. of Water. When cold, add 50 Cc. of Diluted Hydrochloric Acid and set aside for twenty-four hours, then filter, add 8.5 Gm. of Monohydrated Sodium Carbonate, evaporate the liquid at the above-named temperature to 150 Gm., add 12.5 Gm. of Glycerin, and continue evaporation until the Extract is reduced to 125 Gm.
Alcohol, 2 ; Water, 1				
Extractum Belladonnæ Foliorum	60	400	900	Percolate 1000 Gm. of drug to exhaustion, after forty-eight hours maceration, reserve 900 Cc. of percolate, evaporate the remainder to 100 Cc., mix with reserved portion and evaporate the mixed liquids to a pilular consistence at a temperature not exceeding 50° C. (122° F.). Assay and add sufficient sugar of milk, if necessary, to reduce it to the standard of 1.4 percent. of mydriatic alkaloids
Hyoscyami	60	400	800	Made by evaporating 100 Cc. of Fluidextract of Hyoscyamus, with constant stirring, to a pilular consistence, at a temperature not exceeding 50° C. (122° F.), assaying and adding sufficient sugar of milk, if necessary, to reduce it to the standard of 0.3 percent. of mydriatic alkaloids
Stramonii	40	400	800	Made by evaporating 100 Cc. of Fluidextract of Stramonium, with constant stirring, to a pilular consistence, at a temperature not exceeding 50° C. (122° F.), assaying and adding sufficient sugar of milk, if necessary, to reduce it to the standard of 1.4 percent. of mydriatic alkaloids
Diluted Alcohol				
Extractum Digitalis	60	400	850	Made by evaporating 100 Cc. of Fluidextract of Digitalis, with constant stirring, to a pilular consistence, at a temperature not exceeding 50° C. (122° F.)

Official Extracts—*Continued*

Name and Menstruum	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Process and Notes
Extractum Colocynthidis (freed from seeds)	Coarse powder	. . .	. . .	Macerate for four days, express and strain the tincture through flannel, percolate the residue, distil the mixed tinctures to recover the alcohol, evaporate the residue to dryness, and make it into a powdered Extract
Alcohol, 1 ; Water, 7				
Extractum Rhamni Purshianæ	60	400	850	Percolate 1000 Gm. of drug to exhaustion, after forty-eight hours maceration, reserve the number of cubic centimeters directed, evaporate the remainder to the consistence of syrup, add the reserved portion, and continue the evaportion to dryness, at a temperature not exceeding 70° C. (158° F.). Finally, powder the product, adding enough powdered Glycyrrhiza to make the Extract weigh 250 Gm., and mix
Taraxaci	30	250	. . .	Percolate to exhaustion, after twenty-four hours maceration, and evaporate the liquid, on a water-bath, to a pilular consistence
Acetic Acid, Water				
Extractum Colchici Cormi	60	500	. . .	Percolate to exhaustion with 17.8 *percent. of official Acetic Acid,* after forty-eight hours maceration, and evaporate the liquid to a pilular consistence, at a temperature not exceeding 80° C. (176° F.). Assay and add sufficient sugar of milk, if necessary, to reduce it to the standard of 1.4 percent. of colchicine
Nucis Vomicæ	20	400	750	Percolate 1000 Gm. of drug to exhaustion with 27.7 *percent. of official Acetic Acid,* after forty-eight hours maceration, reserve the number of cubic centimeters directed, evaporate the remainder to a soft extract, add this to the reserved portion, and sufficient water to make the liquid measure 900 Cc. Add 3000 Cc. of Alcohol, shake and set aside for twenty-four hours with occasional agitation ; then filter and evaporate, on a water-bath, to dryness. Assay and add sufficient sugar of milk, if necessary, to reduce it to the standard of 5 percent. of strychnine. Finally, powder and mix
Water				Maceration
Extractum Aloes	. . .	. . .	. . .	*Macerate* in boiling water, with stirring, allow mixture to stand for twelve hours, decant the liquid, and evaporate to dryness
Hæmatoxyli	Rasped	. . .	. . .	*Macerate,* with cold water for forty-eight hours, then boil (avoiding the use of metallic vessels) until one-half the water has evaporated, strain the decoction while hot, and evaporate to dryness
Malti	12	. . .	. . .	*Macerate* 1000 Gm. of Malt with 1000 Cc. of water for six hours, then add 4000 Cc. of warm water, digest for one hour at a temperature not exceeding 55° C. (131° F.). Strain with strong expression and evaporate the liquid at a temperature not exceeding 55° C. (131° F.) to the consistence of thick honey
Opii	. . .	. . .	. . .	*Macerate,* with occasional agitation, in cold water during twelve hours, filter, evaporate the filtrate on a water-bath, assay, and add sufficient sugar of milk, if necessary, to reduce it to the standard of 20 percent. of morphine. Finally, powder and mix

Official Extracts—*Continued*

Name and Menstruum	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Process and Notes
Extractum Gentianæ	20	400	. . .	Percolate to exhaustion, after twenty-four hours maceration, boil the liquid until reduced to three-fourths of its weight, strain, and evaporate, on a water-bath, to a pilular consistence
Glycyrrhizæ Purum	20	1000	. . .	Percolate to exhaustion, after twenty-four hours maceration with water, containing about *5 percent. of Ammonia Water,* to dissolve the Glycyrrhizin, evaporate the liquid to a pilular consistence, and add 5 percent. of its weight of Glycerin
Krameriæ	40	300	. . .	Percolate to exhaustion, heat the liquid to the boiling point, strain, and evaporate to dryness, at a temperature not above 70° C. (158° F.)
Quassiæ	20	400	. . .	Percolate to exhaustion, reduce the liquid to three-fourths of its weight by boiling, strain, and evaporate to dryness, on a water-bath, and add sufficient sugar of milk to make the Extract weigh 100 Gm. for every 1000 Gm. of drug taken. Mix and reduce to fine powder
Glycyrrhizæ	. . .	. . .	. . .	*Commercial Extract* in rolls: not less than 60 percent. of it should be soluble in cold water
Colocynthidis Compositum	**Compound Extract** Extract of Colocynth, 160 Gm.; Purified Aloes, 500 Gm.; Cardamom, No. 60 powder, 60 Gm.; Resin of Scammony, in fine powder, 140 Gm.; Soap, dried and in coarse powder, 140 Gm.; Alcohol, 100 Cc.			Melt the Aloes with the aid of heat, add the Alcohol, Soap, Extract of Colocynth, and Resin of Scammony, maintain a temperature not exceeding 120° C. (248° F.) until homogeneous, withdraw the heat and add the Cardamom; when cold, *reduce the product to a fine powder*

Extracts (*of pilular consistence*)

Extractum Belladonnæ Foliorum
- Cannabis Indicæ
- Colchici Cormi
- Digitalis
- Ergotæ
- Gentianæ
- Glycyrrhizæ Purum

Extractum Hyoscyami
- Malti (thick honey)
- Rhei
- Scopolæ
- Stramonii
- Sumbul
- Taraxaci

Extracts (*solid*)

Extractum Aloes
- Glycyrrhizæ

Extractum Hæmatoxyli
- Krameriæ

Extracts (*powdered*)

Extractum Cimicifugæ
- Colocynthidis
- Colocynthidis Compositum
- Euonymi
- Leptandræ

Extractum Nucis Vomicæ
- Opii
- Physostigmatis
- Quassiæ
- Rhamni Purshianæ

Unofficial Extracts

Name	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Menstruum	Process
Extractum Aconiti. U. S. P. 1890	60	400	900	Alcohol	Percolate 1000 Gm. of Aconite to exhaustion, after forty-eight hours maceration, reserve 900 Cc. of percolate, evaporate the remainder to 100 Cc., mix with the reserved portion and evaporate the mixed liquids to a pilular consistence at a temperature not exceeding 50° C. (122° F.)
Aloes Barbadensis. Br.	. .	. . .	. . .	Boiling Water	Add 1000 Gm. of Barbadoes Aloes to 10 liters of boiling Water and mix thoroughly; set it aside for twenty-four hours, decant, strain, and evaporate the liquid to dryness at a temperature not exceeding 60° C. (140° F.)
Anthemidis. Br.	. .	. . .	. . .	Water	Boil 1000 Gm. of Chamomile Flowers with 10 liters of Water until reduced to about 5 liters, strain, press, filter the liquid, and then evaporate to a soft extract. Finally, add 2 Cc. Oil of Chamomile and mix
Arnicæ Radicis. U. S. P. 1890	60	400	900	Diluted Alcohol	Percolate 1000 Gm. of Arnica Root and continue the operation as directed under Extractum Aconiti
Belladonnæ Viride. Br.	. .	. . .	. . .	. . . . . .	Bruise the fresh leaves and young branches of Belladonna in a mortar, press out the juice and heat to 54.4° C. (130° F.). Separate the green coloring matter by straining, and evaporate the strained liquid, after heating to 93.3° C. (200° F.) and filtering, to a thin syrupy consistence. Then add the green coloring matter and evaporate the whole, at a temperature not exceeding 60° C. (140° F.), to a soft extract
Cinchonæ. U. S. P. 1890	60	350	. . .	Alcohol, 75; Water, 25; finishing with Diluted Alcohol	Percolate 1000 Gm. of Cinchona to exhaustion, after forty-eight hours maceration, using first, 4000 Cc. of menstruum made from Alcohol, 3; Water, 1, and finishing with Diluted Alcohol. Distil the Alcohol, and evaporate the residue on a water-bath to a pilular consistence
Colchici. Br.	. .	. . .	. . .	. . . . . .	Crush fresh Colchicum Corms, deprived of their coats; press, set the liquid aside, decant clear portion, heat to 100° C. (212° F.), strain and evaporate to a soft extract at a temperature not exceeding 71.1° C. (160° F.)
Conii. U. S. P. 1890	40	300	900	Diluted Alcohol	Add 2 percent of Acetic Acid (36 percent.) to the first 1000 Cc. of menstruum used, percolate 1000 Gm. of Conium, and continue the operation as directed under Extractum Aconiti
Iridis. U. S. P. 1890	60	400	. . .	Alcohol	Percolate 1000 Gm. of Iris to exhaustion, after forty-eight hours maceration, distil the Alcohol from the tincture, and evaporate the residue, on a water bath, to a pilular consistence

Unofficial Extracts—*Continued*

Name	Fineness of Powder	Quantity to moisten 1000 Gm. of Drug	Quantity of Percolate reserved for 1000 Gm. of Drug	Menstruum	Process
Extractum, Jalapæ. U.S.P. 1890	60	350	900	Alcohol	Percolate 1000 Gm. of Jalap and continue the operation as directed under Extractum Aconiti
Juglandis. U. S. P. 1890	30	400	. . .	Diluted Alcohol	Percolate 1000 Gm. of Juglans and continue the operation as directed under Extractum Iridis
Podophylli. U. S. P. 1890	60	300	. . .	Alcohol, 80 ; Water, 20	Percolate 1000 Gm. of Podophyllum and continue the operation as directed under Extractum Iridis
Stramonii Seminis. U. S. P. 1890	60	300	900	Diluted Alcohol	Percolate 1000 Gm. of Stramonium Seed and continue the operation as directed under Extractum Aconiti
Strophanthi. Br.	30	. . .	. . .	Alcohol	Exhaust 25 Gm. of Strophanthus Seeds with Purified Ether, dry the marc, and again percolate with Alcohol, after forty-eight hours maceration, to make 250 Cc. Evaporate the liquid until it thickens, and add sufficient powdered Sugar of Milk to make the product weigh 50 Gm. Powder
Uvæ Ursi. U. S. P. 1890	30	400	900	Alcohol, 20 ; Water, 50	Percolate 1000 Gm. of Uva Ursi and continue the operation as directed under Extractum Aconiti

EXTRACTUM ALOES. U.S. Extract of Aloes

	Metric	Old form
* **Aloes**	**100 Gm.**	32 oz. av.
Boiling Water	**1000 Cc.**	20 pints

Mix the Aloes with the Boiling Water in a suitable vessel, stirring constantly until the particles of Aloes are thoroughly disintegrated, and allow the mixture to stand for twelve hours ; then pour off the clear liquid, strain the residue, and evaporate the mixed liquids to dryness with the aid of a water-bath or steam-bath.

Average dose.— 2 grains (0.125 Gm.).

EXTRACTUM BELLADONNÆ FOLIORUM. U. S. Extract of Belladonna Leaves

[Extractum Belladonnæ Foliorum Alcoholicum, Pharm. 1890]

	Metric	Old form
* **Belladonna Leaves,** in No. 60 powder	**1000 Gm.**	32 oz. av.
Alcohol,		
Water, each, a sufficient quantity		

Mix 2000 Cc. [old form 4 pints] of Alcohol with 1000 Cc. [old form 2 pints] of Water, and, having moistened the powder with 400 Cc. [old form 12½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator ; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until 3000 Cc. [old form 6 pints] of tincture are obtained, or the Belladonna Leaves are exhausted. Reserve the first 900 Cc. [old form 28½ fl. oz.] of the percolate, evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 100 Cc. [old form 3 fl. oz.], mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence.

When assayed by the process given below, Extract of Belladonna Leaves should contain 1.4 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 percent.

Assay of Extract of Belladonna Leaves

Extract of Belladonna Leaves . . . . **5 Gm.**
Alcohol,
Ammonia Water,
Distilled Water,
Chloroform,
Normal Sulphuric Acid V.S.,
Tenth-normal Sulphuric Acid V.S.,
Fiftieth-Normal Potassium Hydroxide V.S.,
Cochineal T.S. or **Iodeosin T.S.,** each, a sufficient quantity

Introduce the Extract of Belladonna Leaves into a small beaker and dissolve it in a mixture consisting of alcohol 5 Cc., distilled water 10 Cc., ammonia water 2 Cc., and chloroform 20 Cc. When dissolved, transfer it to a separator, rinsing the beaker with a little alcohol and adding the rinsings to the separator. Insert the stopper securely and shake the separator for half a minute. Draw off the chloroformic layer into a second separator, and add to the first separator 10 Cc. more of chloroform. Shake it for half a minute, allow to separate, and again draw off the chloroformic layer into the second separator. Repeat this with 10 Cc. more of chloroform. To the united chloroformic liquids in the second separator, add 5 Cc. of normal sulphuric acid V.S. and 10 Cc. of distilled water, and shake it for half a minute. Draw off the chloroformic layer, after the liquids have separated, into the first separator, after cleaning it thoroughly, and the aqueous layer into a beaker, and repeat the process by adding to the first separator, 10 Cc. of distilled water and 1 Cc. of normal sulphuric acid V.S. Draw off the chloroformic layer, rejecting the same, and then run the acid aqueous layer into the beaker. Pass the combined acid aqueous solutions through a pledget of purified cotton into the first separator, after cleaning it thoroughly, rinsing the second separator, the beaker, and the funnel with about 10 Cc. of distilled water. To the first separator, add 15 Cc. of chloroform, a small piece of red litmus paper, and enough ammonia water to produce a distinctly alkaline reaction. Shake the separator for half a minute, and when the liquids have separated, draw off the chloroformic layer into a beaker. Repeat this process with two portions of 10 Cc. each of chloroform, and evaporate the combined chloroformic liquids in the beaker to dryness on a water-bath containing warm water; dissolve the residue in 3 Cc. of ether and allow the latter to evaporate completely. To the alkaloidal residue add 5 Cc. of tenth-normal sulphuric acid V.S. and 5 drops of cochineal T.S. (or iodeosin T.S.), then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0287, and this product by 20, to obtain the percentage of mydriatic alkaloids contained in the Extract of Belladonna Leaves. The figure 0.0287 represents the weight in grammes of mydriatic alkaloids (mainly atropine) required to neutralize 1 Cc. of tenth-normal sulphuric acid V.S.

Average dose.—⅙ grain (0.010 Gm.).

EXTRACTUM CANNABIS INDICÆ. U.S. Extract of Indian Cannabis

	Metric	Old form
* **Indian Cannabis,** in No. 20 powder	1000 Gm.	32 oz. av.
Alcohol, a sufficient quantity		

Moisten the powder with 300 Cc. [old form 9½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol until the Indian Cannabis is exhausted. Distil off the Alcohol from the percolate by means of a water-bath, and evaporate the residue, in a porcelain dish, on a water-bath, to a pilular consistence.

Average dose.—⅕ grain (0.010 Gm.).

EXTRACTUM CIMICIFUGÆ. U.S. Extract of Cimicifuga

	Metric	Old form
* **Fluid Extract of Cimicifuga**	100 Cc.	3¾ fl. oz.
Glycyrrhiza (peeled, Russian), in No. 80 powder, a sufficient quantity,		
To make	25 Gm.	1 oz. av.

Evaporate the Fluidextract of Cimicifuga in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered Glycyrrhiza to make the finished Extract weigh 25 Gm. [old form 1 oz. av.]. Mix thoroughly.

Average dose.—4 grains (0.250 Gm.).

EXTRACTUM COLCHICI CORMI. U.S. Extract of Colchicum Corm

[EXTRACTUM COLCHICI RADICIS, PHARM. 1890]

	Metric	Old form
* **Colchicum Corm,** in No. 60 powder	1000 Gm.	35 oz. av.
Acetic Acid	350 Cc.	11 fl. oz.
Water, a sufficient quantity		

Mix the Acetic Acid with 1500 Cc. [old form 3 pints] of Water, and, having moistened the powder with 500 Cc. [old form 1 pint] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Water, until the Colchicum Corm is exhausted. Evaporate the percolate in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence.

When assayed by the process given below, Extract of Colchicum Corm should contain 1.4 percent. of colchicine. If the Extract should be found by assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 percent.

Assay of Extract of Colchicum Corm

Extract of Colchicum Corm	4 Gm.
Chloroform,	
Alcohol,	
Ether,	
Distilled Water,	
Ammonia Water, each, a sufficient quantity	

Dissolve the Extract of Colchicum Corm in 20 Cc. of distilled water, carefully transfer the solution to a graduated flask, and add sufficient alcohol to make the liquid measure 100 Cc. Shake the flask well, allow it to stand for five minutes, filter, and collect 50 Cc. of the filtrate (representing 2 Gm. of the Extract), and evaporate it to dryness in a porcelain dish by means of a water-bath. Add to the residue 10 Cc. of ether and 5 Cc. of distilled water, stir the mixture well and heat it gently until the ether is evaporated. After cooling, pour off the aqueous solution, filtering it into a separator, retaining as much of the insoluble matter in the dish as possible. Again treat the residue with 10 Cc. of ether, and 5 Cc. of water, and proceed as before; rinse the dish and filter with a little water and collect all of the aqueous liquids in the separator. Introduce a small piece of red litmus paper into the separator, add enough ammonia water to render the liquid alkaline, and then shake it out with three successive portions of chloroform, of 20, 15, and 10 Cc., respectively. Collect the combined chloroformic solutions in an Erlenmeyer flask, evaporate the chloroform, and add to the alkaloidal residue two successive small portions of alcohol, evaporating the alcohol each time. Now add to the residue a mixture of 5 Cc. of distilled water and 10 Cc. of ether, agitate the liquid gently and evaporate the ether; after cooling, filter the aqueous liquid into a separator. Rinse the flask with distilled water, pass the rinsings through the filter into the separator, and shake out the aqueous solutions with three successive portions of chloroform, 20, 15, and 10 Cc., respectively. Collect the combined chloroformic solutions in a tared Erlenmeyer flask, evaporate the chloroform, and treat the alkaloidal residue with two successive small portions of alcohol, evaporating the alcohol each time, and dry the residue at 100° C. (212° F.), to a constant weight. The weight multiplied by 50 will give the percentage of colchicine in the Extract of Colchicum Corm.

Average dose.— 1 grain (0.065 Gm.).

EXTRACTUM COLOCYNTHIDIS. U.S. Extract of Colocynth

	Metric	Old form
***Colocynth,** freed from the seeds	1000 Gm.	32 oz. av.
Diluted Alcohol, a sufficient quantity.		

Reduce the Colocynth to a coarse powder by grinding or bruising, and macerate it in 3500 Cc. [old form 7 pints] of Diluted Alcohol for four days, with occasional stirring; then express strongly and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour Diluted Alcohol upon it until the tincture and expressed liquid, mixed together, measure 5000 Cc. [old form 10 pints]. Distil off the Alcohol from the mixture by means of a water-bath, evaporate the residue to dryness, and reduce the dry mass to powder.

Extract of Colocynth should be kept in well-stoppered bottles.

Average dose.— $\frac{1}{2}$ grain (0.030 Gm.).

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U.S. Compound Extract of Colocynth

	Metric	Old form
***Extract of Colocynth**	160 Gm.	16 oz. av.
Purified Aloes	500 Gm.	50 oz. av.
Cardamom, in No. 60 powder	60 Gm.	6 oz. av.
Resin of Scammony, in fine powder	140 Gm.	14 oz. av.
Soap, dried, and in coarse powder	140 Gm.	14 oz. av.
Alcohol	100 Cc.	12 fl. oz.

Heat the Purified Aloes, contained in a suitable vessel, on a water-bath, until it is completely melted; then add the Alcohol, Soap, Extract of Colocynth, and Resin of Scammony, and heat the mixture at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous, and a thread taken from the mass becomes brittle when cool. Then withdraw the heat, thoroughly incorporate the Cardamom with the mixture, and cover the vessel until the contents are cold. Finally, reduce the product to a fine powder.

Compound Extract of Colocynth should be kept in well-stoppered bottles.

Average dose.— 8 grains (0.500 Gm.).

EXTRACTUM DIGITALIS. U.S. Extract of Digitalis

	Metric	Old form
***Fluidextract of Digitalis**	**100 Cc.**	3 fl. oz.

Evaporate the Fluidextract of Digitalis in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, until it is reduced to a pilular consistence.

Average dose.— $\frac{1}{5}$ grain (0.010 Gm.).

EXTRACTUM ERGOTÆ. U.S. Extract of Ergot

	Metric	Old form
***Ergot,** in No. 40 powder	**1000.0 Gm.**	32 oz. av.
Diluted Hydrochloric Acid	**50.0 Gm.**	1 oz. av. 263 gr.
Monohydrated Sodium Carbonate	**8.5 Gm.**	119 grains
Glycerin	**12.5 Gm.**	175 grains
Alcohol,		
Water, each, a sufficient quantity,		
To make	**125 Gm.**	4 oz. av.

Mix 1000 Cc. [old form 2 pints] of Alcohol with 400 Cc. [old form 12½ fl. oz.] of Water, and, having moistened the powder with 500 Cc. [old form 1 pint] of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Ergot is exhausted. Evaporate the percolate in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), to 250 Gm. [old form 8 oz. av.]; add 250 Cc. [old form 8 fl. oz.] of Water, and stir; filter when cold, rinse the dish with a little Water, and add this to the filter. Add the Diluted Hydrochloric Acid to the filtrate; then set it aside for twenty-four hours; filter, wash the contents of the filter with Water until the washings no longer have an acid reaction, and add the washings to the filtrate. To this, add gradually the Monohydrated Sodium Carbonate, and, when the evolution of carbon dioxide has ceased, evaporate the liquid in a tared dish until it weighs 150 Gm. [old form 4$\frac{4}{5}$ oz. av.]; add the Glycerin, and continue the evaporation, at the above-named temperature, until the weight of the Extract is reduced to 125 Gm. [old form 4 oz. av.].

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM EUONYMI. U.S. Extract of Euonymus

	Metric.	Old form
* **Fluid Extract of Eunonymus**	100 Cc.	3¾ fl. oz.
Glycyrrhiza (peeled, Russian), in No. 80 powder, a sufficient quantity,		
To make	25 Gm.	1 oz. av.

Evaporate the Fluidextract of Euonymus in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring to complete dryness. Reduce the product to a fine powder, and add enough powdered Glycyrrhiza to make the finished extract weigh 25 Gm. [old form 1 oz. av.]. Mix thoroughly.

Average dose.— 2 grains (0.125 Gm.).

EXTRACTUM GENTIANÆ. U.S. Extract of Gentian

	Metric	Old form
* **Gentian,** in No 20 powder	1000 Gm.	32 oz. av.
Water, a sufficient quantity		

Moisten the powder with 400 Cc. [old form 12½ fl. oz.] of Water, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slighly imbued with the properties of Gentian. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then, by means of a water-bath, evaporate to a pilular consistence.

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM GLYCYRRHIZÆ. U.S. Extract of Glycyrrhiza

The commercial extract of the root of *Glycyrrhiza glabra* Linné, or of *Glycyrrhiza glandulifera* Waldstein and Kitaibel (Fam. *Leguminosæ*).

In flattened cylindrical rolls, from 15 to 18 Cm. long, and from 15 to 30 Mm. thick; of a glossy black color. It breaks with a sharp, conchoidal, shining fracture, and has a very sweet, peculiar taste. Not less than 60 percent. of it should be soluble in cold water.

Average dose.— 15 grains (1 Gm.).

EXTRACTUM GLYCYRRHIZÆ PURUM. U.S. Pure Extract of Glycyrrhiza

	Metric	Old form
* **Glycyrrhiza,** peeled, in No. 20 powder	1000 Gm.	32 oz. av.
Ammonia Water	150 Cc.	4½ fl. oz.
Glycerin,		
Water, a sufficient quantity		

Mix the Ammonia Water with 3000 Cc. [old form 6 pints] of Water, and, having moistened the powder with 1000 Cc. [old form 2 pints] of the mixture, allow it to macerate in a closed vessel for twenty-four hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first the remainder of the menstruum, and then Water, until the Glycyrrhiza is exhausted. Lastly, evaporate the liquid in a tared porcelain dish, by means of a water-bath, to a pilular consistence, and while the mass is still warm, incorporate with it 5 percent. of its weight of Glycerin.

Average dose.— 15 grains (1 Gm.).

EXTRACTUM HÆMATOXYLI. U.S. Extract of Hematoxylon

	Metric	Old form
* **Hematoxylon,** rasped	1000 Gm.	32 oz. av.
Water	10000 Cc.	20 pints

Macerate the Hematoxylon with the Water for forty-eight hours. Then boil (avoiding the use of metallic vessels) until one-half of the Water has evaporated ; strain the decoction, while hot, and evaporate it to dryness.

Average dose.— 15 grains (1 Gm.).

EXTRACTUM HYOSCYAMI. U.S. Extract of Hyoscyamus

	Metric	Old form
* **Fluidextract of Hyoscyamus**	100 Cc.	4 fl. oz.

Evaporate the Fluidextract of Hyoscyamus in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.

When assayed as directed below, Extract of Hyoscyamus should contain 0.3 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 0.3 percent.

Assay of Extract of Hyoscyamus

The method to be employed is identical with that given on page 442, using 10 Gm. of Extract of Hyoscyamus instead of the quantity of Extract of Belladonna Leaves there directed, and multiplying the product by 10 instead of 20.

Average dose.— 1 grain (0.065 Gm.).

EXTRACTUM KRAMERIÆ. U.S. Extract of Krameria

	Metric	Old form
* **Krameria,** in No. 40 powder	1000 Gm.	32 oz. av.
Water, a sufficient quantity		

Moisten the powder with 300 Cc. [old form 9½ fl. oz.] of Water, pack it in a conical glass percolator, and gradually pour Water upon it, until the infusion passes but slightly imbued with the astringency of the Krameria. Heat the liquid to the boiling point, strain, and evaporate the strained liquid, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to dryness.

Average dose.— 8 grains (0.500 Gm.).

EXTRACTUM LEPTANDRÆ. U.S. Extract of Leptandra

	Metric	Old form
* **Fluidextract of Leptandra**	100 Cc.	3¾ fl. oz.
Glycyrrhiza, peeled, Russian, in No. 80 powder, a sufficient quantity,		
To make	25 Gm.	1 oz. av.

Evaporate the Fluidextract of Leptandra in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered Glycyrrhiza to make the finished Extract weigh 25 Gm. [old form 1 oz. av.]. Mix thoroughly.

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM MALTI. U.S. Extract of Malt

	Metric	Old form
* **Malt**, in coarse powder, not finer than No. 12	1000 Gm.	32 oz. av.
Water, a sufficient quantity		

Upon the powder, contained in a suitable vessel, pour 1000 Cc. [old form 2 pints] of Water, and macerate for six hours. Then add 4000 Cc. [old form 8 pints] of Water, heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceeding 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath, or vacuum apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid rapidly to the consistence of thick honey.

Extract of Malt should be kept in well-closed vessels, in a cool place.

Average dose.— 4 fluidrachms (16 Cc.).

EXTRACTUM NUCIS VOMICÆ. U.S. Extract of Nux Vomica

	Metric	Old form
* **Nux Vomica**, in No. 20 powder	1000 Gm.	32 oz. av.
Acetic Acid,		
Water,		
Alcohol,		
Sugar of Milk, dried and in fine powder, each a sufficient quantity		

Mix 500 Cc. [old form 1 pint] of Acetic Acid with 1300 Cc. [old form 2 pints, 9½ fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 12½ fl. oz.] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then Water, until the percolate passes but faintly imbued with bitterness, and the Nux Vomica is exhausted. Reserve the first 750 Cc. [old form 1½ pints] of the percolate, and, having heated the remainder to boiling, filter, and evaporate the filtrate to a soft extract; dissolve this in the reserved portion, and add enough Water to make the liquid measure 900 Cc. [old form 28½ fl. oz.]. To the liquid thus obtained, add 3000 Cc. [old form 6 pints] of Alcohol, shake the mixture well, and set it aside for twenty-four hours, with occasional agitation. Filter the liquid through paper, and wash the residue in the filter with a mixture of Alcohol three volumes, and Water one volume, until the washings are only faintly bitter. Evaporate the filtrate and washings in a porcelain dish, on a water-bath, to dryness. Determine, by the method given below, the percentage of strychnine in the dry Extract; ascertain, by calculation, the amount of strychnine in the remainder of the Extract; add to this enough well-dried Sugar of Milk to bring the quantity of strychnine in the final dry extract of Nux Vomica to 5 percent. of the total weight; and, when thoroughly powdered and mixed, transfer the Extract to small, well-stoppered vials.

Extract of Nux Vomica, when assayed by the following process, should be found to contain 5 percent. of strychnine.

Assay of Extract of Nux Vomica

Extract of Nux Vomica . . . . 2 Gm.
Distilled Water,
Ether,
Chloroform,
Ammonia Water,
Sulphuric Acid Solution (3 percent. H_2SO_4),
Nitric Acid (sp. gr. 1.42),
Sodium Hydroxide Solution (1 in 10),
Tenth-normal Sulphuric Acid V.S.,
Fiftieth-normal Potassium Hydroxide V.S.,
Iodeosin T.S., each a sufficient quantity

Introduce the Extract of Nux Vomica into a beaker, and dissolve it in 25 Cc. of a mixture of 16 Cc. of ether, 5 Cc. of Chloroform, and 4 Cc. of ammonia water. When dissolved, transfer it to a separator, rinsing the beaker with a little Chloroform, and adding the rinsings to the separator. Insert the stopper securely and shake the separator carefully for a few minutes. Draw off the aqueous layer into another separator, washing the ether-solution and separator with a little water, and adding this to the second separator. Then shake out the aqueous liquid with two portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a few drops of the liquid left in the second separator still give a reaction with mercuric potassium iodide T.S. after acidulating, repeat the shaking out with 10 Cc. more of chloroform. Now shake out the chloroformic solution in the first separator with three portions of 15, 10, and 10 Cc. of sulphuric acid solution (3 percent.), and collect the combined acid solutions in another separator. Introduce a small piece of red litmus paper, add enough ammonia water to render the liquid alkaline, and extract the mixture with three portions, respectively, of 15, 10, and 10 Cc. of chloroform. Draw off the chloroformic solutions into a beaker, and evaporate the chloroform with the aid of a water-bath. Dissolve the alkaloidal residue in the beaker in 15 Cc. of 3 percent. sulphuric acid solution by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cool mixture of equal volumes of nitric acid (specific gravity 1.42) and distilled water, and after rotating the liquid a few times, set it aside for exactly ten minutes, stirring it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10), and wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not quite turbid, add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a flask. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the flask, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue, add 10 Cc. of tenth-normal sulphuric acid V.S., 5 drops of iodeosin T.S., about 90 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. until the aqueous liquid just turns pink. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 10 (the 10 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.0332, and this product by 50, which will give the percentage of strychnine contained in the Extract of Nux Vomica.

Average dose.— $\frac{1}{4}$ grain (0.015 Gm.).

EXTRACTUM OPII. U.S. Extract of Opium

	Metric	Old form
* **Powdered Opium**	**100 Gm.**	3 oz. av. 231 gr.
Sugar of Milk, recently dried and in fine powder,		
Water, each, a sufficient quantity		

Rub the Powdered Opium, in a mortar, into a smooth paste with 250 Cc. [old form 8 fl. oz.] of Water; then transfer to a bottle of the capacity of 1000 Cc. [old form 2 pints], wash the mortar with 750 Cc. [old form 1½ pints] of water in successive portions, and add the washings to the contents of the bottle. Cork the bottle and shake it vigorously once every two hours during twelve hours. Then filter through a rapidly acting, double filter, and pour water on the magma slowly, until the filtrate passes nearly colorless and only faintly bitter.

Concentrate the filtrate and washings in a tared dish, on a water-bath, until the contents weigh about 200 Gm. [old form 7 oz. av.], and allow the Extract to become cold. Then weigh it accurately, transfer 12 Gm. to an Erlenmeyer flask having a capacity of about 100 Cc., and determine in this portion the amount of morphine by the process of assay given below, using the same quantities of liquids as there directed for 4 Gm. of the dry Extract. In another portion of 5 Gm. determine the amount of water by drying it in a flat-bottomed dish, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained, ascertain by calculation the amount of morphine and of water contained in the remainder of the Extract, add to this enough well-dried Sugar of Milk to bring the quantity of morphine in the final dry Extract to 20 percent., then evaporate the whole to dryness, reduce it to powder, and transfer it to small, well-stoppered vials.

Assay of Extract of Opium

Extract of Opium, dried at 100° C. (212 F.)	4.0 Gm.
Ammonia Water	2.2 Cc.
Alcohol,	
Ether,	
Water,	
Lime Water, each, a sufficient quantity	

Dissolve the Extract of Opium in 30 Cc. of water, filter the solution through a small filter, and wash the filter and residue with water, until all soluble matters are extracted, collecting the washings separately. Evaporate, in a tared dish, on a water-bath, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 10 Gm. Rotate the concentrated solution in the dish, until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the dish with a few drops of water at a time, until the entire solution weighs 15 Gm. Add 7 Gm. (or 8.5 Cc.) of alcohol, shake the flask well, then add 20 Cc. of ether, and repeat the shaking. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night.

Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ether-solution as completely as possible upon the inner filter. Add 15 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 15 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when the liquid has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-liquor, and afterwards wash them with alcohol (previously saturated with powdered morphine), added drop by drop from a pipette. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc., or more if necessary. Allow the

the filter to dry in a moderately warm place at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals of morphine to a tared watch-glass and weigh them.

Transfer the crystals (which are not quite pure) to an Erlenmeyer flask, add lime water in the proportion of 10 Cc. for each 0.1 Gm. of morphine, and shake the flask at intervals for twenty-five minutes. Pass the liquid through two counterpoised, rapidly acting, plainly folded filters, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), and rinse the flask with additional lime water, passing the washings through the filter until the filtrate, after acidulation, no longer yields a precipitate with mercuric potassium iodide T.S. Then press the filters between bibulous paper, dry them to a constant weight, and weigh the contents of the inner filter, using the outer as a counterpoise. Subtract the weight of the insoluble matter, on the filter, from the weight of the impure morphine previously found, and the difference, multiplied by 25, will be the percentage of pure crystalline morphine contained in the Extract of Opium.

Average dose.—½ grain (0.030 Gm.).

EXTRACTUM PHYSOSTIGMATIS. U.S. Extract of Physostigma

	Metric	Old form
* **Physostigma,** in No. 80 powder	1000 Gm.	32 oz. av.
Alcohol,		
Glycyrrhiza (peeled, Russian), in No. 80 powder, each, a sufficient quantity		

Moisten the Physostigma with 400 Cc. [old form 12½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until 3000 Cc. [old form 6 pints] of percolate are obtained, or the Physostigma is exhausted. Reserve the first 900 Cc. [old form 28½ fl. oz.] of the percolate and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to 100 Cc. [old form 3 fl. oz.]; mix this with the reserved portion, and evaporate, at or below the above-mentioned temperature, on a water-bath, to dryness. Remove 1 Gm. of the Extract, and assay this by the process given below; from the results thus obtained, ascertain by calculation the amount of ether-soluble alkaloids contained in the remainder of the Extract, add to this enough powdered Glycyrrhiza to bring the quantity of the alkaloids in the finished powdered Extract to 2 percent., reduce to powder, mix thoroughly, and transfer it at once to well-stoppered, amber-colored vials.

Extract of Physostigma, when assayed by the following process, should be found to contain 2 percent. of ether-soluble alkaloids.

Assay of Extract of Physostigma

Extract of Physostigma	1 Gm.
Alcohol,	
Diluted Alcohol,	
Ether,	
Sodium Bicarbonate,	
Normal Sulphuric Acid V.S.,	
Distilled Water,	
Tenth-normal Sulphuric Acid V.S.,	
Fiftieth-normal Potassium Hydroxide V.S.,	
Iodeosin T.S., each, a sufficient quantity	

Transfer the Extract of Physostigma to a small porcelain dish, add 5 Cc. of diluted alcohol, and digest for five minutes in a water-bath below boiling temperature; then add about 5 Gm. of very clean, fine quartz sand, and evaporate to dryness on a water-bath, triturating thoroughly with a pestle to secure uniform admixture. When dry, carefully transfer the contents of the dish to an Erlenmeyer flask, add a little more sand to the dish and, by rubbing, remove any adherent extract, which transfer to the flask, add 100 Cc. of ether, and shake the flask. Then add 10 Cc. of an aqueous solution of sodium bicarbonate (1 in 20), and shake the contents vigorously at intervals for one hour. Allow the mixture to stand, and, when settled, decant 50 Cc. of the ether-solution into a separator, to which add a small piece of blue litmus paper, sufficient normal sulphuric acid V.S. to render the liquid acid, and 10 Cc. of distilled water. Shake the separator well for one minute, and draw off the aqueous layer into another separator. Repeat the shaking-out process, using 2 Cc. of normal sulphuric acid V.S. and 8 Cc. of distilled water, and add the acid aqueous layer to the second separator; again repeat the extraction, using 1 Cc. of normal sulphuric acid V.S. and 9 Cc. of distilled water, and add this to the second separator. To the combined acid liquids in the second separator, add 25 Cc. of ether, a small piece of red litmus paper, and sufficient sodium bicarbonate solution (1 in 20) to render it alkaline. Shake the separator for one minute, allow the liquids to separate, and draw off the ether into a beaker. Repeat the shaking-out process with 20 Cc. and again with 15 Cc. of ether added to the separator; shake each time for one minute, allow the liquids to separate, and draw off the ether into the beaker. Carefully evaporate the ether from the combined solutions by means of a water-bath, and, when dry, dissolve the residue in 2 Cc. of tenth-normal sulphuric acid V.S.; rinse the solution carefully into a 200 Cc. flask with distilled water, add enough distilled water to bring the volume to about 90 Cc., add 25 Cc. of ether, and having shaken the flask, add 5 drops of iodeosin T.S., then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., until, after shaking, the aqueous liquid just acquires a pink color. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 2 (the 2 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0273, and this product by 200; the result will be the percentage of ether-soluble alkaloids contained in the Extract of Physostigma.

Average dose.— $\frac{1}{8}$ grain (0.008 Gm.).

EXTRACTUM QUASSIÆ. U.S. Extract of Quassia

	Metric	Old form
* **Quassia**, in No. 20 powder	1000 Gm.	32 oz. av.
Water,		
Sugar of Milk, recently dried and in fine powder, each, a sufficient quantity,		
To make	100 Gm.	3 oz. av. 231 gr.

Moisten the Quassia with 400 Cc. [old form 12½ fl. oz.] of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly imbued with bitterness. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then evaporate, by means of a water-bath, to dryness and add enough Sugar of Milk to make the Extract weigh 100 Gm. [old form 3 oz. av. 231 gr.]. Mix thoroughly, reduce to fine powder, and transfer to well-stoppered bottles.

Average dose.— 1 grain (0.065 Gm.).

EXTRACTUM RHAMNI PURSHIANÆ. U.S. Extract of Cascara Sagrada

	Metric	Old form
* **Cascara Sagrada**, in No. 60 powder	1000 Gm.	32 oz. av.
Alcohol,		
Water,		
Glycyrrhiza (peeled, Russian), in No. 80 powder, each, a sufficient quantity,		
To make	250 Gm.	8 oz. av.

Mix 125 Cc. [old form 4 fl. oz.] of Alcohol with 875 Cc. [old form 28 fl. oz.] of Water, and, having moistened the powder with 400 Cc. [old form 12½ fl. oz.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the drug is exhausted. Reserve the first 850 Cc. [old form 27 fl. oz.] of the percolate, and evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to the consistence of syrup. Mix this with the reserved portion, and continue the evaporation, at or below the above-mentioned temperature, to dryness. Reduce the Extract to fine powder, and add enough powdered Glycyrrhiza to make the product weigh 250 Gm. [old form 8 oz. av.]. Mix thoroughly.

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM RHEI. U.S. Extract of Rhubarb

	Metric	Old form
* Fluidextract of Rhubarb	100 Cc.	4 fl. oz.

Evaporate the Fluidextract of Rhubarb in a porcelain dish, by means of a water-bath, with constant stirring, at a temperature not exceeding 50° C. (122° F.), to a pilular consistence.

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM SCOPOLÆ. U.S. Extract of Scopola

	Metric	Old form
* Fluidextract of Scopola	100 Cc.	4 fl. oz.

Evaporate the Fluidextract of Scopola in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, to a pilular consistence.

When assayed as directed below, Extract of Scopola should contain 2 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 2 percent.

Assay of Extract of Scopola

The method to be employed is identical with that given on page 442, using 2 Gm. of Extract of Scopola instead of the quantity of Extract of Belladonna Leaves there directed. The product must be multiplied by 50 instead of 20.

Average dose.— ⅕ grain (0.010 Gm.).

EXTRACTUM STRAMONII. U.S. Extract of Stramonium

	Metric	Old form
* Fluidextract of Stramonium	100 Cc.	4 fl. oz.

Evaporate the Fluidextract of Stramonium in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, to a pilular consistence.

When assayed as directed below, Extract of Stramonium should contain 1.0 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.0 percent.

Assay of Extract of Stramonium

The method to be employed is identical with that given for Extract of Belladonna Leaves, on page 442, using 5 Gm. of Extract of Stramonium.

Average dose.— $\frac{1}{5}$ grain (0.010 Gm.).

EXTRACTUM SUMBUL. U.S. Extract of Sumbul

	Metric	Old form
* **Fluidextract of Sumbul**	100 Cc.	4 fl. oz.

Evaporate the Fluidextract of Sumbul in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to a pilular consistence.

Average dose.— 4 grains (0.250 Gm.).

EXTRACTUM TARAXACI. U.S. Extract of Taraxacum

	Metric	Old form
* **Taraxacum,** in No. 30 powder	1000 Gm.	32 oz. av.
Alcohol,		
Water, each, a sufficient quantity		

Mix 125 Cc. [old form 4 fl. oz.] of Alcohol with 875 Cc. [old form 28 fl. oz.] of Water, and, having moistened the powder with 250 Cc. [old form 8 fl. oz.] of the mixture, pack it in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Taraxacum is exhausted. Evaporate the percolate, by means of a water-bath, to a pilular consistence.

Average dose.— 15 grains (1 Gm.).

Abstracta U. S. 1880 *Abstracts*

Abstracts are solid powdered preparations containing the soluble constituents of the drugs from which they are made, and bearing a definite and uniform relation to the drug. These preparations were first introduced into the U. S. Pharmacopœia of 1880, and have many advantages over ordinary extracts. They are prepared by evaporating an alcoholic tincture of a drug spontaneously or at a low temperature, mixing it with a sufficient quantity of dried sugar of milk to make the final product when dry weigh one-half the weight of the drug, and then powdering it. The following general formula exhibits the typical process. Abstracts are not official in the U. S. P. 8th Rev., not having been used sufficiently during 1880–1900 by physicians to justify their reintroduction. One of their disadvantages is that they are not as concentrated as extracts. The present official powdered extracts closely resemble abstracts.

General Formula

Drug, in No. 60 powder, *two hundred parts* [or four ounces av.]; Sugar of Milk, recently dried and in fine powder, Alcohol, each, *a* *sufficient quantity*, To make *one hundred parts* [or two ounces av.]. Moisten the drug with *eighty parts* [or one and three-quarter fluidounces] of Alcohol, and pack firmly in a cylindrical glass percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the drug is exhausted. Reserve the first *one hundred and seventy parts* [or three and one-half fluidounces] of the percolate, evaporate the remainder to *thirty parts* [or half a fluidounce], at a temperatnre not exceeding 50° C. (122° F.), and mix with the reserved portion. Place the mixture in an evaporating dish, and, having added *fifty parts* [or one ounce av.] of Sugar of Milk, cover it with a piece of thin muslin gauze, and set aside in a warm place, where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough Sugar of Milk to make the mixture weigh *one hundred parts* [or two ounces av.], reduce it to a fine, uniform powder. Preserve the powder in a well-stoppered bottle.

The advantages possessed by abstracts may be briefly stated as follows:

1. Each abstract represents twice the strength of the drug or fluidextract from which it is prepared.
2. They are dry powders, if properly made, and thus are permanent and portable; not subject to precipitation as fluidextracts are; not liable to become hard, tough, and variable in strength, as is the case with extracts.
3. Injurious exposure to heat is entirely avoided, and the official process of 1880 requires no apparatus but such as either is at hand in the pharmacy, or can be easily obtained by a pharmacist operating upon the small scale.
4. The final thorough trituration of the dry powder reduces the soluble and active constituents of the drug to a pulverulent condition, the diluent is soluble, and the fine state of division of abstracts is the most favorable condition that a powder can possess to secure efficient medication.

The improvement suggested for the processes for abstracts is that the temperature 50° Ce. (122° F.), which is lower than need be, for abstracts of aconite, belladonna, digitalis, hyoscyamus, ignatia, jalap, nux vomica, podophyllum, and senega, be increased to 80° C. (176° F.).

Conium and valerian require a very low temperature, but the temperature of 80° C. (176° F.) is not injurious to those first mentioned if the evaporation of the fluidextract is quickly and carefully effected. An alcoholic fluidextract may be used in preparing an abstract, if the menstruum used in making it is not too aqueous, and if it is free from glycerin. Dr. Squibb's modification for making abstracts from fluidextracts, as shown in the case of fluidextract of aconite, is as follows: "Put the fluidextract (a weighed quantity) upon a flat-bottomed dinner-plate and allow it to evaporate spontaneously, without heating, for twenty-four or thirty-six hours. At the end of that time there will remain upon the plate a thin layer of solid extract.

Add to this extract about double its weight of powdered sugar of milk, warm the plate and contents until it can be just comfortably held in the hand, and incorporate the melted extract and powder by means of a stiff spatula. When thoroughly incorporated and cold, remove the mixture from the plate, weigh it, and add enough powdered sugar of milk to make the whole weigh one-half the original weight of the fluidextract. Finally, rub it to a fine, uniform powder, sifting it through a No. 60 sieve." Abstracts are *not* well made when the dry powdered solid extract is simply rubbed up with dry powdered sugar of milk, as suggested by some writers, because such mixtures of dry powder invariably *stratify* in time. This fault may be easily discovered on close examination, a darker layer of powdered extract being succeeded by a lighter one containing variable proportions of sugar of milk ; this arrangement of the particles is largely owing to the vibration to which the bottles containing them are continually subjected on the shelves of the dispensing counter and by use elsewhere. If the U. S. 1880 process is employed, this fault does not exist, because the particles of sugar of milk become thoroughly saturated with the concentrated liquid extract when mixed together, and when the alcohol evaporates the solid extract is thoroughly diffused among, and is closely adherent to, the particles of sugar of milk ; hence a dose taken from the portion at the top or at the middle of the bottle would have the same medicinal effect as one taken from the portion at the bottom.

Preservation and Administration.—Abstracts should be carefully protected from exposure to moist air. They should be kept in small bottles with mouths wide enough to admit the end of a spatula. Corks of the best quality should be used, and the bottles should not be kept near a hot flue, but in as cool a place as possible.

The following table exhibits the *eleven* U. S. 1880 abstracts in a form convenient for study :

Abstracta U. S. 1880 *Abstracts*

Name	Fineness of Powder	Menstruum	To moisten 200 Parts	Quantity reserved	Name and additions
Abstractum Aconiti	60	Alcohol	80	170	2 per cent. Tartaric Acid added to menstruum to exhaust Aconite Root
Belladonnæ	60	"	80	170	From Belladonna Root
Conii	40	"	80	170	6 per cent. Hydrochloric Acid added to menstruum to exhaust Conium Fruit
Digitalis	60	"	80	170	
Hyoscyami	60	"	80	170	
Jalapæ	40	"	100	170	
Podophylli	60	"	80	170	
Senegæ	60	"	80	170	
Valerianæ	60	"	80	170	
Ignatiæ	60	Alcohol, 8 Water, 1	100	170	
Nucis Vomicæ	60	Alcohol, 8 Water, 1	100	170	

Resinæ U. S. *Resins*

The official resins are solid preparations consisting principally of the resinous principles from vegetable bodies. The officially prepared resins differ from alcoholic extracts in the fact that the latter contain all the principles in the drug which alcohol is capable of dissolving, while the resins contain only those principles which are soluble in alcohol and are insoluble in water. It is obvious that the resins prepared from those drugs which owe their activity exclusively to resinous principles, which are insoluble in water, are stronger preparations than the alcoholic extracts from such drugs. *Four* resins are official :

Official Resins

Name	Preparation
Resina	By-product, the residue left after distilling Oil of Turpentine
Jalapæ	Percolate Jalap, in No. 60 powder, with Alcohol until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, and add the concentrated tincture to water, collect, wash, drain, and dry the precipitate
Podophylli	Percolate Podophyllum, in No. 60 powder, with Alcohol until the tincture ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, and add the concentrated tincture to cold water, acidulated with 1 percent. of Hydrochloric Acid, collect, wash, drain, and dry the precipitate
Scammonii	Digest Scammony with boiling Alcohol until exhausted, mix the tinctures, distil off the alcohol, add the concentrated tincture to water, wash, and dry the precipitate

RESINA. U.S. **Rosin**

The residue left after distilling off the volatile oil from turpentine.

Usually in sharp, angular fragments, translucent, amber-colored, usually covered with a yellowish dust ; at ordinary temperatures brittle, pulverizable ; fracture shiny and shallow-conchoidal ; odor and taste faintly terebinthinate.

The specific gravity of Rosin is 1.070 to 1.080 ; it is easily fusible, and burns with a dense yellowish smoke, yielding no appreciable ash ; soluble in alcohol, ether, benzene, carbon disulphide, acetic acid, fixed or volatile oils, and in solutions of potassium or sodium hydroxide ; acid number not less than 150. (See U. S. P. Test No. 98, Chap. LXII.)

Average dose.— 4 grains (0.250 Gm.).

RESINÆ JALAPÆ. U.S. **Resin of Jalap**

	Metric	Old form
* **Jalap,** in No. 60 powder	1000 Gm.	32 oz. av.
Alcohol,		
Water, a sufficient quantity		

Moisten the powder with 300 Cc. [old form 9½ fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator ; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until 2500 Cc. [old form 5 pints] of percolate are obtained, or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the percolate is reduced in weight to 250 Gm. [old form 8 oz. av.], and add the latter slowly, with constant stirring, to 3000 Cc. [old form 6 pints] of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of hot water. After having drained off all the liquid, transfer the Resin to a porcelain dish and heat it to dryness on a water-bath.

Yellow to brown masses or fragments, breaking with a resinous, glossy fracture, translucent at the edges, or a yellowish-gray to yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. Permanent in the air. Soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, and fixed or volatile oils. Its alcoholic solution has a faintly acid reaction to blue litmus paper. Not more than 15 percent. of Resin of Jalap should be soluble in ether, and not more than 35 percent. in chloroform.

Slowly but completely soluble in 5 times its weight of ammonia water; when this solution is acidified with hydrochloric acid, only a slight turbidity should appear (absence of *rosin, guaiac*, and *other resins*).

Resin of Jalap should not suffer any material loss of weight when heated at 100° C. (212° F.) (absence of *water*). Anhydrous Resin of Jalap melts at about 150° C. (302° F.).

Water triturated with Resin of Jalap should neither become colored nor dissolve any portion of it (absence of *soluble impurities*).

No greenish-blue color should be produced on adding a few drops of ferric chloride T.S. to some of the powder moistened with alcohol (absence of *guaiac*).

One Gm. of Resin of Jalap when dissolved in 50 Cc. of alcohol containing 1 Cc. of phenolphthalein T.S. should require not more than 0.5 Cc. of half-normal alcoholic potassium hydroxide V.S. to produce a red color (limit of *acid resins*).

If to 1 Gm. of Resin of Jalap, dissolved in 50 Cc. of alcohol in a flask, 25 Cc. of half-normal alcoholic potassium hydroxide V.S. be added, and the mixture be heated on a water-bath for one hour, and if the excess of alkali be titrated with half-normal sulphuric acid V.S., using 5 drops of phenolphthalein T.S. as indicator, at least 20 Cc. of half-normal sulphuric acid V.S. should be required (limit of *saponifiable substances*).

Average dose.— 2 grains (0.125 Gm.).

RESINA PODOPHYLLI. U.S. Resin of Podophyllum

	Metric	Old form
* **Podophyllum,** in No. 60 powder	**1000 Gm.**	32 oz. av.
Hydrochloric Acid	**10 Cc.**	150 minims
Alcohol,		
Water, each, a sufficient quantity		

Moisten the powder with 480 Cc. [old form 15 fl. oz.] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until 1600 Cc. [old form 3¼ pints] of percolate are obtained, or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the percolate is reduced to the consistence of a thin syrup, and pour it slowly, with constant stirring, into 1000 Cc. [old form 2 pints] of water previously cooled to a temperature below 10° C. (50° F.), and mixed with the Hydrochloric Acid. When the precipitate has subsided, decant the supernatant liquid and wash the precipitate twice, by decantation, with fresh portions of cold Water.

Spread it in a thin layer, upon a strainer, and dry the Resin by exposure to the air, in a cool place, protected from the light. Should it coalesce during the drying, or aggregate into lumps, having a varnish-like surface, it should be removed, broken in pieces, and rubbed in a mortar.

It should be kept in amber-colored, well-stoppered vials.

An amorphous powder, varying in color from grayish-white to pale greenish-yellow, turning darker when subjected to a heat exceeding 35° C. (95° F.) or when exposed to light. It has a slight, peculiar odor and a faintly bitter taste; very irritating to the mucous membrane, especially to that of the eyes.

Soluble in alcohol in all proportions; not less than 75 percent. of Resin of Podophyllum should be soluble in ether, not less than 65 percent. in chloroform, and not more than 25 percent. in boiling water. A hot aqueous solution deposits most of its contents on cooling, and if the cool liquid be filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride T.S. Soluble in potassium or sodium hydroxide T.S., forming a deep yellow liquid, which gradually becomes darker on standing, and from which the resin is reprecipitated by acids.

Not less than 99 percent. of Resin of Podophyllum should be soluble in alcohol; the solution should be clear or, at most, slightly opalescent, and should have a faintly acid reaction.

Upon incineration, Resin of Podophyllum should yield not more than 1 per cent. of ash.

Average dose.— Purgative, $\frac{1}{4}$ grain (0.015 Gm.).
Laxative, $\frac{1}{10}$ grain (0.005 Gm.).

RESINA SCAMMONII. U.S. Resin of Scammony

	Metric	Old form
* **Scammony,** in No. 60 powder	**1000 Gm.**	32 oz. av.
Alcohol,		
Water, each, a sufficient quantity		

Digest the Scammony with successive portions of boiling Alcohol until it is exhausted. Mix the liquids, filter, and reduce the mixture to a syrupy consistence by distilling off the Alcohol. Then add the residue in a thin stream, with active stirring, to 2500 Cc. [old form 5 pints] of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it at a gentle heat.

Yellowish-brown or brownish-yellow masses or fragments, breaking with a glossy resinous fracture, translucent at the edges; or a yellowish-white or grayish-white powder, having a faint, characteristic odor, and a slight, peculiar taste.

Soluble in alcohol in all proportions, completely soluble in oil of turpentine, and almost completely soluble in ether and chloroform. Ammonia water and solutions of alkalies dissolve it with the aid of a gentle heat, and from these solutions the Resin is not reprecipitated by acids.

When incinerated it should not yield more than 1 percent. of ash.

Average dose.— 3 grains (0.200 Gm.).

Unofficial Resin

Name	Description	Tests
Resina Copaibæ. U. S. P. 1890	The residue left after distilling off the volatile oil from copaiba	A yellowish or brownish-yellow brittle resin, having a slight odor and taste of copaiba. Soluble in alcohol, ether, chloroform, carbon disulphide, benzene, or amylic alcohol

CHAPTER XXXI

SOLID OFFICIAL PREPARATIONS MADE WITHOUT PERCOLATION

It is not the intention in this chapter to consider *in detail* the classes of solid official preparations included in the above title, because their manufacture either belongs to the domain of magistral pharmacy or is intimately connected with it. They are more appropriately treated in the final chapters of the work, because their preparation generally demands a higher degree of skill, and a more intimate knowledge of the physical properties of medicinal substances, than are necessary in making those which have been heretofore considered. For these reasons it has been the author's custom, in lecturing upon the subjects treated of in this work, to reserve the consideration of the solid official preparations made without percolation, and those which are embraced under the general term "extemporaneous," until after the student has studied the physical and chemical properties of the various substances which compose the materia medica. It is well for the student to have sufficient knowledge of these preparations to be able to define each class, so that when they are incidentally mentioned in Parts III. and IV. he may be able to describe the use and appearance of a powder, troche, plaster, pill, etc. If it is considered desirable to deviate from this plan, the chapters on these subjects are so constructed that the student may easily turn to them and study them out of the order given here. They will be found in Part V.

It will be well, however, in this place, in order to keep the classification in view, to enumerate them briefly. They are Pills, Troches, Masses, Confections, Powders, Triturations, Suppositories, Cerates, Ointments, Plasters, and Papers. Among those intended for internal administration pills and troches are largely used, and, because their preparation requires the drugs to be in the form of powder, the classes termed powders and triturations, which are dispensed extemporaneously, are grouped with them. Masses and confections are, of course, considered in connection with pills, because they are used in their preparation. Suppositories stand alone as a class, while cerates, ointments, plasters, and papers form a natural group, being preparations that are used externally.

PART III

INORGANIC SUBSTANCES

INTRODUCTORY

THE various operations and processes which are used in the practice of pharmacy having been treated of in their general relations to one another in the preceding chapters, it is now necessary to consider in detail the physical and chemical properties of the substances that enter into the preparations which are used in medicine.

The plan which will be followed presupposes on the part of the student a knowledge of elementary chemistry, and hence chemical physics, nomenclature, the theoretical construction of formulæ, etc., will not be entered into. The great number of valuable text-books on chemistry, now accessible to every student, renders the introduction of even brief articles on these subjects unnecessary, and the space will be reserved for the consideration of the chemical substances of the materia medica from a pharmaceutical standpoint. For reasons which need not be entered into here, the latest (and to some extent conflicting) views of modern chemists upon the classification of these substances are not adopted, but a method is employed which, while it does not do violence to the accepted theories, is simple and practical. The substances are grouped together according to their physical or therapeutical properties, while their supposed chemical analogies have not been entirely overlooked. This plan has the merit of giving the student a different view of the chemical substances from that to which he is accustomed in his study of chemistry, and will, perhaps, enhance the interest and impress the points of difference in the substances more forcibly upon the mind.

As an illustration, the chemical properties of such non-metallic elements as Hydrogen, Oxygen, and Nitrogen will not be noticed at length; they are not recognized articles of the materia medica in their free state; but the acids, bases, and salts containing them are largely used, and they form substances which can be advantageously grouped together for profitable study by the pharmacist.

The table which follows gives the symbols and atomic weights of the elements; those which are of special interest from a pharmaceutical point of view are distinguished from the rest by being printed in heavier type.

TABLE OF ATOMIC WEIGHTS. U. S.

Adopted by the International Committee on Atomic Weights (1904)

H = 1.000

Name	Symbol	Atomic Weight	Name	Symbol	Atomic Weight
Aluminum	Al	26.9	Neodymium	Nd	142.5
Antimony	Sb	119.3	Neon	Ne	19.9
Argon	Ar	39.6	Nickel	Ni	58.3
Arsenic	As	74.4	**Nitrogen**	N	13.93
Barium	Ba	136.4	Osmium	Os	189.6
Bismuth	Bi	206.9	**Oxygen**	O	15.88
Boron	B	10.9	Palladium	Pd	105.7
Bromine	Br	79.36	**Phosphorus**	P	30.77
Cadmium	Cd	111.6	Platinum	Pt	193.3
Cæsium	Cs	131.9	**Potassium**	K	38.86
Calcium	Ca	39.8	Praseodymium	Pr	139.4
Carbon	C	11.91	Radium	Ra	223
Cerium	Ce	139.2	Rhodium	Rh	102.2
Chlorine	Cl	35.18	Rubidium	Rb	84.8
Chromium	Cr	51.7	Ruthenium	Ru	100.9
Cobalt	Co	58.56	Samarium	Sm	148.9
Columbium	Cb	93.3	Scandium	Sc	43.8
Copper	Cu	63.1	Selenium	Se	78.6
Erbium	Er	164.8	**Silicon**	Si	28.2
Fluorine	F	18.9	**Silver**	Ag	107.12
Gadolinium	Gd	155	**Sodium**	Na	22.88
Gallium	Ga	69.5	**Strontium**	Sr	86.94
Germanium	Ge	71.9	**Sulphur**	S	31.83
Glucinum	Gl	9.03	Tantalum	Ta	181.6
Gold	Au	195.7	Tellurium	Te	126.6
Helium	He	4	Terbium	Tb	158.8
Hydrogen	H	1.000	Thallium	Tl	202.6
Indium	In	113.1	Thorium	Th	230.8
Iodine	I	125.90	Thulium	Tu	169.7
Iridium	Ir	191.5	Tin	Sn	118.1
Iron	Fe	55.5	Titanium	Ti	47.7
Krypton	Kr	81.2	Tungsten	W	182.6
Lanthanum	La	137.9	Uranium	U	236.7
Lead	Pb	205.35	Vanadium	V	50.8
Lithium	Li	6.98	Xenon	Xe	127
Magnesium	Mg	24.18	Ytterbium	Yb	171.7
Manganese	Mn	54.6	Yttrium	Yt	88.3
Mercury	Hg	198.5	**Zinc**	Zn	64.9
Molybdenum	Mo	95.3	Zirconium	Zr	89.9

CHAPTER XXXII

HYDROGEN, OXYGEN, AND WATER

H ; 1. O ; 15.88. H_2O ; 17.88

Hydrogen is a colorless, inodorous, and combustible gas ; it is the lightest of all substances. Chemically, it is one of the most important and interesting of the elements, the atomic weights of all usually being referred to it as unity. Pharmaceutically, in its uncombined state, it is of very little importance, and the reader is referred, for further information, to the chemical text-books.

Oxygen, as usually seen, is a colorless, inodorous gas which aids combustion; it is the most abundant of the elements, forming about one-fifth of the total weight of our atmosphere. Water contains nearly ninety percent. by weight of oxygen, and it is present in varying quantities in most vegetable and animal substances. The compounds which it forms with other bodies are termed oxides : these are of great pharmaceutical interest, and they will be considered hereafter under their appropriate heads. Oxygen in its free, gaseous condition is frequently used medicinally, and is supplied by manufacturers, compressed and in cylinders.

AQUA. U.S. Water

$H_2O = 17.88$

Potable Water in its purest obtainable state.

Water is the most important and useful compound known to the pharmacist : its molecule, H_2O, is composed of two parts of hydrogen and one part of oxygen.

The purity of water is specified in the official description, which is as follows :

Official Description.—A colorless, limpid liquid.

Odor, Taste, and Reaction.—Without odor or taste at ordinary temperatures ; odorless when heated ; perfectly neutral reaction.

Impurities and Tests for Impurities.—*Heavy metals.* 1000 Cc., when concentrated by evaporation to 20 Cc., should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of soluble salts. On evaporating 1000 Cc. of Water on a water-bath, it should not leave a residue weighing more than 0.5 Gm.

This residue, when ignited, should not carbonize, nor evolve *ammoniacal* or *acid* vapors.

Limit of sulphates. If 200 Cc. of Water be acidulated with hydrochloric acid, heated to boiling, and 0.5 Cc. of barium chloride T.S. be added, the liquid, when cooled and filtered, should give no further precipitate on the addition of a few drops of barium chloride T.S., even on standing.

Limit of chlorides. If 200 Cc. of Water be acidulated with nitric acid, heated to boiling, and 0.5 Cc. of tenth-normal silver nitrate V.S. be added, the liquid, when cooled and filtered, should not be affected by the subsequent addition of a few drops of silver nitrate T.S.

Limit of nitrates. If 10 Cc. of Water mixed with a few drops of diphenylamine T.S. be carefully poured upon about 3 Cc. of sulphuric acid, free from nitrous compounds, contained in a test-tube, so as to form a separate layer, no blue color should be formed at the line of contact of the two liquids.

Limit of nitrites. If to 50 Cc. of Water contained in a glass cylinder 2 Cc. each of sulphanilic acid T.S. and naphthylamine acetate T.S. are added, and the solution well mixed, no distinct pink coloration should appear within five minutes, if the cylinder be placed upon a white surface and viewed from above.

Limit of ammonia. If to 50 Cc. of Water contained in a glass cylinder 2 Cc. of alkaline mercuric potassium iodide T.S. (Nessler's Reagent) be added and thoroughly mixed, no yellow or brownish tint should be produced immediately; the cylinder should be placed upon a white surface and viewed from above.

Limit of organic or other oxidizable substances. On heating to boiling 100 Cc. of Water, acidulated with 10 Cc. of diluted sulphuric acid, and subsequently adding 0.4 Cc. of tenth-normal potassium permanganate V.S., the pink color of the liquid should not be completely destroyed after it has been boiled for ten minutes.

Uses.—The powers and uses of water as a solvent have been already noticed in the previous chapters. The United States Pharmacopœia directs water, under the name of Aqua, or distilled water, under the name of Aqua Destillata, to be used in the various processes according to the necessities of the occasion. Ordinary water always contains solid matter and traces of various salts in solution or suspension; these do not unfit it for drinking purposes, but would often seriously interfere with the purity of many chemical substances if such water were used in their preparation. The official processes err on the safe side, and direct distilled water in all cases where the use of ordinary water might be injurious or of doubtful propriety. In some sections of the country the drinking water might be pure enough for the processes, or at least not contain serious impurities; in other sections the water would be totally unfit for the preparations. The purity of official distilled water is beyond question, and its use therefore removes all doubts.

AQUA DESTILLATA. U.S. Distilled Water

For process, see page 277. The official tests for the purity of distilled water are, of course, much more exacting than those for water (see below).

Official Description.—A colorless, limpid liquid.

Odor, Taste, and Reaction.—Without odor or taste, and perfectly neutral to litmus paper.

Impurities and Tests for Impurities.—*Heavy metals.* Distilled Water should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXVII).

Sulphates. Nor should the slightest turbidity result upon the addition to separate portions of barium chloride T.S., or

Chlorides. Silver nitrate T.S., or

Calcium. Ammonium oxalate T.S.

Carbonic acid. Nor should its transparency be affected when mixed with twice its volume of calcium hydroxide T.S.

Nitrates, nitrites, or ammonia. It should give no reaction for nitrates, nitrites, or ammonia when tested as described under *Aqua.*

Residue. When 1000 Cc. of Distilled Water are evaporated on a water-bath to dryness, not more than 0.050 Gm. of *residue* should remain.

Organic or other oxidizable substances. On heating to boiling 100 Cc. of Distilled Water, acidulated with 10 Cc. of diluted sulphuric acid, and subsequently adding 0.1 Cc. of tenth-normal potassium permanganate V.S., the color of the liquid should not be completely destroyed by boiling for ten minutes, nor should it wholly disappear if the vessel be afterwards set aside in a dark place, covered, for ten hours.

Uses.—Distilled water is used in pharmacy principally as a solvent for delicate chemical salts, and for purposes for which ordinary water is unfitted (see page 464).

AQUA HYDROGENII DIOXIDI. U.S. Solution of Hydrogen Dioxide

[SOLUTION OF HYDROGEN PEROXIDE]

A slightly acid, aqueous solution of Hydrogen Dioxide [$H_2O_2 = 33.76$], which should contain, when freshly prepared, about 3 percent., by weight, of absolute Hydrogen Dioxide, corresponding to about 10 volumes of available oxygen. It should be kept in a cool place. Upon removing the stopper from the bottle not more than a slight pressure should be observed.

Solution of Hydrogen Dioxide is made commercially now on a large scale. The former official method of preparation consisted of decomposing barium dioxide with phosphoric acid.

$$BaO_2 + 2H_3PO_4 = Ba(H_2PO_4)_2 + H_2O_2$$

Any trace of barium salt in the solution of hydrogen dioxide remaining after the decomposition is removed by the cautious addition of sulphuric acid, which precipitates an insoluble barium sulphate.

Other methods are, however, in use. Phosphoric acid has been replaced by hydrochloric acid or hydrofluoric acid. Oxalic acid in small amount is sometimes added to the solution by manufacturers, thus fraudulently raising its indicated strength when assayed.

Official Description.—A colorless liquid, liable to deteriorate upon keeping or protracted agitation. If the stopper in the bottle be replaced by a pledget of cotton, deterioration is retarded.

Odor and Taste.—Without odor, slightly acidulous to the taste, and producing a peculiar sensation and soapy froth in the mouth.

Tests for Identity.—When exposed to the air at the ordinary temperature, or when heated on a water-bath at a temperature not exceeding 60° C. (140° F.), the solution loses chiefly water. When rapidly heated, it frequently decomposes suddenly.

On adding to 10 Cc. of water in a test-tube, 1 drop of potassium chromate T.S., then 10 drops of diluted sulphuric acid, and pouring a few Cc. of ether on top, the subsequent addition of a few drops of Solution of Hydrogen Dioxide, even when considerably diluted, will cause a blue color to appear at the zone of contact of the two liquids. After shaking, the ether-layer will separate with a blue color.

Impurities and Tests for Impurities.—*Limit of free acids.* If to 25 Cc. of the Solution, 5 Cc. of tenth-normal potassium hydroxide V.S. be added, and the mixture be evaporated to about 10 Cc., and 3 drops of phenolphthalein T.S. added, not less than 2.5 Cc. of tenth-normal sulphuric acid V.S. should be required to discharge the red color of the solution after continued boiling.

Limit of total solids. If 20 Cc. of the Solution be evaporated to dryness upon a water-bath, and the drying completed at 120° C. (248° F.), not more than 0.03 Gm. of solid residue should remain.

Arsenic. If to 1 Cc. of the Solution, 1 Cc. of ammonia water be added, and the liquid evaporated to dryness upon a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Heavy metals. If 1 Cc. of the Solution, be evaporated to dryness upon a water-bath, the residue, when dissolved in 10 Cc. of distilled water containing 1 Cc. of diluted hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Hydrofluoric acid. On evaporating to dryness, upon a water-bath, 50 Cc. of the Solution, previously rendered alkaline by sodium hydroxide T.S., transferring the dry residue to a watch-glass, moistening it with sulphuric acid, and setting the glass in a moderately warm place for a few hours, the surface of the glass, after being washed, should exhibit no sign of corrosion.

Barium. The addition of a few drops of diluted sulphuric acid to 10 Cc. of the Solution should produce no turbidity or precipitate.

Assay.—Dilute 10 Cc. of the solution with sufficient distilled water to measure 100 Cc. Transfer 16.9 Cc. of this liquid (containing 1.69 Cc. of the Solution) to a beaker, add 5 Cc. of diluted sulphuric acid, and then, from a burette, slowly add, with constant stirring, tenth-normal potassium permanganate V.S. until the liquid just retains a faint pink tint. Each Cc. of tenth-normal potassium permanganate V.S. consumed corresponds to 0.1 percent. of absolute Hydrogen Dioxide, or 0.329 volumes of oxygen. If the Solution be of full strength, 30 Cc. of tenth-normal potassium permanganate V.S. will be required.

Uses.—Solution of hydrogen dioxide (or peroxide, as it is usually termed) is an energetic antiseptic and disinfectant; it is oxygenated water, another atom of oxygen being chemically combined; as found in commerce it is designated as a 15 vol., 10 vol., 8 vol. solution, etc., by which is meant a solution of the hydrogen dioxide which will yield 15 volumes, 10 volumes, or 8 volumes of active oxygen when used. Diluted solutions are employed as local applications and in inflammations of mucous membranes. It is probably free from poisonous properties. *Great care must be exercised to prevent decomposition; the bottles containing the solution must be kept in a cool place, and the stopper may be advantageously replaced by a pledget of cotton.*

CHAPTER XXXIII

THE INORGANIC ACIDS

THE official inorganic acids form one of the most important classes of compounds used in pharmacy. They are distinguished from other bodies by the following properties: 1. They all contain hydrógen, and are sometimes called hydrogen salts. The hydrogen is capable of being replaced by metals. 2. They have a characteristic sour taste and corrosive action. 3. They act on litmus and other vegetable substances, changing their color.

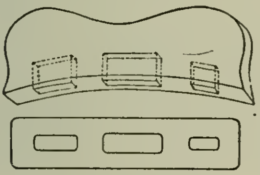
The official inorganic acids will be considered in the following order: 1. those which do not contain oxygen or *hydracids*, and which are derived from non-metallic elements,—viz., Hydrochloric, Hydriodic, and Hydrobromic Acids. 2. The non-metallic oxygen acids,—Nitric, Nitrohydrochloric, Sulphuric, Sulphurous, Hypophosphorous, and Phosphoric Acids. 3. Arsenic Trioxide and Chromium Trioxide (formerly known as Arsenous and Chromic Acids) and the weak acid obtained from Boron, will not be treated as acids, but will be described under the headings of the elements from which they are formed.

The name of the acids which contain oxygen vary in their terminations like the salts of certain metals,—the suffixes *ous* and *ic* being used, the former to denote the lower proportion of oxygen, the latter the higher. Thus sulphur*ous* acid, H_2SO_3, contains less oxygen than sulphur*ic* acid H_2SO_4; nitr*ous* acid, HNO_2, less than nitr*ic* acid, HNO_3, etc.

Practical Points in handling Strong Acids.—The strong inorganic acids are never made by the pharmacist for commercial purposes, as they can be manufactured much more economically upon a large scale. They are corrosive in their action, and must be handled very cautiously to avoid personal injury. They are usually sent out by manufacturers in one pound, or in five pint, glass-stoppered bottles, or in carboys holding about ten gallons. One of the common annoyances is the liability of the glass stopper to become so tightly fastened in the neck of the bottle that it is extracted with difficulty. As this always happens with bottles which have well-fitting and hence most valuable stoppers, it becomes an object to extract the stopper without injury. This may frequently be done by grasping the bottle firmly, and, after cleaning off the lute, carefully tapping the stopper *gently* with the *wooden* handle of a pestle or spatula. If very moderate measures do not succeed, the stopper wrench (see Fig. 440) should be used. This is made of hard wood, of the shape shown in the cut, the lower cut giving the end view and showing the relative sizes of three holes in the wrench. These should be made somewhat larger than the stoppers of the bottles for which the wrench is likely to be used. The upper cut gives the side view of the wrench, which is shaped to fit the hand, and shows the relative depths of the holes. The refractory stopper is placed in the hole, and the operator grasps the wrench with the right hand and endeavors to twist the stopper out. If it does not yield to moderate treatment, the neck of the bottle may be cautiously heated by wrapping it in a cloth wet with hot water, or by means of a spirit-lamp or Bunsen burner with a low flame, passing the flame quickly around it several times so that it shall be uniformly heated. This will cause expansion of the neck, and if the right moment be seized, which is just before the outer surface of the stopper becomes correspondingly heated, the stopper may be easily extracted, the principle of action depending upon unequal expansion. If these means do not succeed, the bottle should be inverted in a vessel of warm water to a depth sufficient to cover the neck and allowed to remain several hours ; if the wrench is then used, success is generally assured. Corks should not be used as stoppers for the strong acids, because of the corrosive action of the latter on them,—a portion of the cork almost invariably contaminating and discoloring the acid.

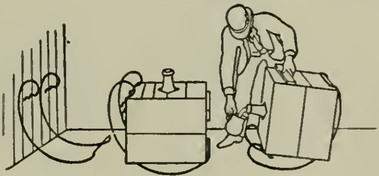
The handling of carboys containing strong acids is sometimes attended with difficulty and danger. The simplest method known to the author is by the use of Stevenson's carboy rocker (see Fig. 441).

FIG. 440



Stopper wrench

FIG. 441



Use of carboy rocker

This consists of a solid elastic steel rod bent into the shape shown in the cut. To place it in position, the carboy is tilted until it rests on a bottom corner; the closed end of the rocker is then pushed into place on the bottom edge, and the springs adjust themselves to the upper edge of the carboy. The latter can then be tilted easily and without spilling the contents. The last drop can be poured out readily.

Quality of Commercial Acids.—Two grades of acids are found in commerce. The first is designated as C. P. (chemically pure), and this is the quality indicated by the U. S. Pharmacopœia to be used in making preparations and for tests, etc. The lower grade is sometimes known as medicinally pure, and is intended to be employed in the arts and for common uses.

Too much importance cannot be attached to the duty of securing pure and strong acids. The introduction of full and reliable tests in the Eighth Decennial Revision of the Pharmacopœia leaves the pharmacist without excuse if he neglects their careful examination. They are used in many of the qualitative and quantitative official tests. If the reagent used for testing is impure itself, the substance which is suspected and is being tested will fall under condemnation when it may be absolutely faultless. Then, again, loss and annoyance in making many preparations, like the iron salts and solutions, will surely follow the use of acids deficient in strength and purity.

Strength of the Official Acids.—The official inorganic acids are mostly solutions of gaseous acids in water, and no uniformity is to be found among them in the amount of water contained in the strong acids. For instance, hydrochloric acid contains 31.9 percent. of gaseous hydrochloric acid; nitric acid contains 68 percent. of gaseous nitric acid; and sulphuric acid contains 92.5 percent. of absolute sulphuric acid. On the other hand, the *diluted* acids are intended to be uniform,—diluted hydriodic, hydrobromic, hydrochloric, hypophosphorous, nitric, phosphoric, and sulphuric acids each containing 10 percent. of absolute acid.

Medical Properties.—The inorganic acids are generally tonic and refrigerant when administered in a diluted condition; externally, if applied undiluted, they are caustic and corrosive, and should be used with the greatest care. Brushes made of spun glass are sometimes employed to apply strong acids externally to ulcers. Test bottles with elongated stoppers, or the bottle shown in Fig. 442, are also advantageously used. One of the principal difficulties attendant upon the internal administration of acids is their injurious action upon the teeth. To avoid the destructive contact with the enamel, the diluted acid should be sucked through a narrow glass tube.

Fig. 442

Acid-dropper

Antidotes.—The strong acids are sometimes accidentally taken internally in poisonous doses; their corrosive action is rapidly manifested, and dangerous results may be justly apprehended. *Mild* alkalies in large doses should at once be administered in connection with some bland fixed oil. Lime liniment is usually upon the shelf already prepared, and valuable time may often be saved by at once giving it to the patient in large doses. Soap or sodium bicarbonate in dilute solution also may be given.

Official Inorganic Acids

Official Name	Sp. Gr. at 25° C. (77° F.)	Composition
Hydracids		
Acidum Hydriodicum Dilutum	1.106	10 percent. HI
Hydrobromicum Dilutum	1.076	10 percent. HBr
Hydrochloricum	1.158	31.9 percent. HCl
Hydrochloricum Dilutum	1.049	10 percent. HCl
Oxyacids		
Acidum Hypophosphorosum	1.130	30 percent. HPH_2O_2
Hypophosphorosum Dilutum	1.042	10 percent. HPH_2O_2
Nitricum	1.403	68 percent. HNO_3
Nitricum Dilutum	1.054	10 percent. HNO_3
Nitrohydrochloricum	. . . . .	180 Cc. Nitric Acid 820 Cc. Hydrochloric Acid
Nitrohydrochloricum Dilutum	. . . . .	40 Cc. Nitric Acid 182 Cc. Hydrochloric Acid 778 Cc. Distilled Water
Phosphoricum	1.707	85 percent. H_3PO_4
Phosphoricum Dilutum	1.057	10 percent. H_3PO_4
Sulphuricum	1.826	92.5 percent. H_2SO_4
Sulphuricum Aromaticum	0.933	111 Cc. Sulphuric Acid 50 Cc. Tincture of Ginger 1 Cc. Oil of Cinnamon 838 Cc. Alcohol
Sulphuricum Dilutum	1.067	10 percent. H_2SO_4
Sulphurosum	1.028	6 percent. SO_2

ACIDUM HYDROCHLORICUM. U.S. Hydrochloric Acid

A liquid composed of 31.9 percent., by weight, of absolute Hydrochloric Acid [$HCl = 36.18$], and 68.1 percent. of water. It should be kept in glass-stoppered bottles.

Preparation.—Hydrochloric acid, the only known compound of chlorine and hydrogen, is made on a very large scale both abroad and in this country. It is obtained most cheaply as a by-product resulting from the manufacture of soda-ash, by decomposing common salt heated to a high temperature with sulphuric acid. Sodium sulphate is formed, and gaseous hydrochloric acid is liberated. The latter is conducted into a tall tower filled with coke, called a coke scrubber; the ascending gas is met by a descending flow of water, which trickles from a reservoir near the top. The gas readily dissolves in the water, and the relative quantities are so arranged that a strong solution passes out at the bottom of the tower. A purer product is formed by selecting the sodium chloride and sulphuric acid and using a series of stoneware jars shaped like Woulfe's bottles. About 120 parts of the salt require 100 parts of strong sulphuric acid. Two steps in the process are recognized. In the first reaction but one-half of the sodium chloride is decomposed, the decomposition of the remainder being effected at a temperature of 220° C. (428° F.) or over. The reaction is thus shown:

$$\underset{\substack{\text{Sodium}\\\text{Chloride}}}{2NaCl} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{HCl} + \underset{\substack{\text{Sodium}\\\text{Chloride}}}{NaCl} + \underset{\substack{\text{Acid Sodium}\\\text{Sulphate}}}{NaHSO_4}$$

and the residue, when heated, yields the rest of the hydrochloric acid, as follows:

$$\underset{\substack{\text{Sodium}\\\text{Chloride}}}{NaCl} + \underset{\substack{\text{Acid Sodium}\\\text{Sulphate}}}{NaHSO_4} = \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{HCl} + \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4}$$

Hydrochloric acid, or, more properly, solution of hydrochloric acid, is used in pharmacy to make the official preparations of the diluted hydrochloric acid, nitrohydrochloric acid, and diluted nitrohydrochloric acid, in the preparation of chlorine water, chlorides, and many other compounds. The yellow color of the common acid (*muriatic acid*,) is generally due to organic substances or a trace of iron; the white fumes produced when the acid is exposed to the air are caused by the gaseous acid combining with the moisture in the air, and also with a trace of ammonia usually present, forming ammonium chloride. The official description and tests are as follows:

Official Description.—A colorless, fuming liquid.

Odor, Taste, and Reaction.—Pungent odor; intensely acid taste; the fumes and odor disappear on diluting the Acid with 2 volumes of water. Intensely acid reaction.

Specific Gravity.—About 1.158 at 25° C. (77° F.).

Solubility.—*Water.* Miscible in all proportions.

Alcohol. Miscible in all proportions.

Tests for Identity.—On distilling it, at first a stronger acid passes over, until at 110° C. (230° F.), a liquid containing 20.13 percent. of the absolute acid remains (specific gravity about 1.098 at 25° C.), which distils unchanged, leaving no residue.

Heated with manganese dioxide it evolves chlorine.

With silver nitrate T.S. it yields a white, curdy precipitate, insoluble in nitric acid, but readily soluble in ammonia water.

Impurities and Tests for Impurities.—*Limit of non-volatile impurities.* If 10 Cc. of the Acid be evaporated from a platinum or porcelain dish, and dried at 110° C. (230° F.), no appreciable residue should remain.

Bromine or iodine. If to 5 Cc. of Hydrochloric Acid diluted with an equal volume of water, 1 Cc. of chloroform be added, and if chlorine water which has been diluted with an equal volume of water be then cautiously added, a drop at a time, with constant agitation, the chloroform should remain free from any yellow, orange, or violet color.

Free chlorine or bromine. If 1 Cc. of the Acid be diluted with 5 Cc. of water, and if 1 Cc. of potassium iodide T.S. with 1 Cc. of chloroform be added, and the mixture agitated, the chloroform should be free from any violet coloration.

Arsenic. Five Cc. of diluted Hydrochloric Acid (1 in 10), should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Sulphuric acid or sulphates. If 1 Cc. of the Acid be diluted with 5 Cc. of water, and a few drops of barium chloride T.S. be added, no precipitate or turbidity should appear within one hour.

Sulphurous Acid. Nor should the addition to this mixture of a few drops of tenth-normal iodine V.S. produce any turbidity.

Heavy metals. Hydrochloric Acid when diluted with distilled water (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—Introduce into a stoppered weighing bottle 3 Cc. of Hydrochloric Acid and weigh accurately. Dilute the Acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 3.618, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Hydrochloric Acid in the latter.

Uses.—Hydrochloric acid is largely used in making chlorides and other preparations. Medicinally it is usually prescribed in a diluted form. The dose is five to ten minims (0.3 to 0.6 Cc.).

ACIDUM HYDROCHLORICUM DILUTUM. U.S. Diluted Hydrochloric Acid

Diluted Hydrochloric Acid should contain 10 percent., by weight, of absolute Hydrochloric Acid [$HCl = 36.18$], and 90 percent. of water. It should be kept in glass-stoppered bottles.

	Metric	Old form
* **Hydrochloric Acid**	**100 Gm.**	4½ fl. oz.
Distilled Water	**219 Gm.**	11½ fl. oz.
To make	**319 Gm.**	16 fl. oz.

Mix them.

Official Specific Gravity.—About 1.049 at 25° C. (77° F.).

Tests for Identity.—It does not fume in the air and is without odor, but otherwise it should conform to the reactions and tests given under *Acidum Hydrochloricum.*

Quantitative Test.—If to 3.62 Gm. of Diluted Hydrochloric Acid there be added about 20 Cc. of water, it should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Hydrochloric Acid), methyl-orange T.S. being used as indicator.

Uses.—Diluted hydrochloric acid is used as a refrigerant and tonic in doses of fifteen to thirty minims (1 to 2 Cc.), largely diluted with water. It should be sucked through a glass tube or straw, to avoid injury to the teeth.

ACIDUM HYDROBROMICUM DILUTUM. U.S. Diluted Hydrobromic Acid

A liquid composed of not less than 10 percent., by weight, of absolute Hydrobromic Acid [$HBr = 80.36$], and about 90 percent. of water. It should be kept in amber-colored, glass-stoppered bottles, protected from light.

Preparation.—Two methods are generally used for making this preparation,—one by distillation, the other by double decomposition and precipitation. The former method yields the purer product, the latter is the more convenient. For other methods of preparation, see U. S. Dispensatory.

Diluted Hydrobromic Acid (*Distillation Process*).—Take of Potassium Bromide and Sulphuric Acid, each, 150 parts (by weight), Distilled Water, a sufficient quantity. Add the Sulphuric Acid to

25 parts of Distilled Water, and cool the mixture. Then dissolve the Potassium Bromide in 150 parts of water by the aid of heat, supplying the loss of water by evaporation during the heating. Carefully pour the diluted Sulphuric Acid into the hot solution with constant stirring, and set the mixture aside for twenty-four hours, in order that the Acid Potassium Sulphate may crystallize. Pour off the liquid into a retort, break up the crystalline mass, transfer it to a funnel, and, having drained the crystals, drop slowly upon them 50 parts of cold Distilled Water so as to wash out the acid liquid. Add this liquid to that in the retort, and distil nearly to dryness at a moderate heat. If red fumes of bromine are given off during any stage of the distillation, change the receiver until such fumes cease to appear. Finally, determine in the distillate the amount of absolute Hydrobromic Acid (10 Gm. of the diluted acid should require 12.4 Cc. normal potassium hydroxide V.S. for neutralization), and add to the remaining weighed distillate such an amount of cold Distilled Water as shall cause the finished acid to contain 10 percent. by weight of absolute Hydrobromic Acid.

This process is based upon that proposed by Dr. E. R. Squibb, the acid preferred by him having, however, the strength of 34 percent. instead of 10 percent.

$$\underset{\substack{\text{Potassium}\\ \text{Bromide}}}{KBr} + \underset{\substack{\text{Sulphuric}\\ \text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Acid Potassium}\\ \text{Sulphate}}}{KHSO_4} + \underset{\substack{\text{Hydrobromic}\\ \text{Acid}}}{HBr}$$

Diluted Hydrobromic Acid (*Precipitation Process*).—Dissolve 340 grains of Potassium Bromide in 4 fluidounces of Water, add 430 grains of Tartaric Acid to the solution, cool the mixture to 40° F., allowing it to stand without agitation as long as possible before pouring off the clear solution from the precipitated acid potassium tartrate. If it can be kept in a cool place for several weeks before it is used, it will be improved ; it will contain about 10 percent. of absolute Hydrobromic Acid. This method is a modification of Wade's and Fothergill's processes, and has the advantage of separating the acid potassium tartrate more effectually. The crystals which form upon the bottom and sides of the bottle act as nuclei, and in time serve to abstract all of the acid tartrate from the liquid.

Official Description.—A clear, colorless liquid.
Odor, Taste, and Reaction.—Odorless ; strongly acid taste and reaction.
Specific Gravity.—About 1.076 at 25° C. (77° F.).
Solubility.—*Water.* Miscible in all proportions.
Alcohol. Miscible in all proportions.

Tests for Identity.—On distilling it, water and weak acid first pass over ; when the temperature of 126° C. (258.8° F.) is reached, an acid of 48 percent. remains, which may be distilled unchanged.

Silver nitrate T.S. causes a yellowish-white precipitate, which is insoluble in diluted nitric acid, but slowly soluble in an excess of stronger ammonia water, and readily soluble in solutions of sodium thiosulphate or potassium cyanide.

If copper sulphate T.S. be added to the Acid, a deep red color is produced upon the addition of sulphuric acid.

The Acid should not become colored on keeping.

Impurities and Tests for Impurities.—*Limit of sulphuric acid.* Ten Cc. of the Acid should not be rendered more than slightly cloudy by the addition of 1 Cc. of barium chloride T. S.

Barium. Ten Cc. of the Acid should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Limit of non-volatile impurities. If 10 Cc. of Diluted Hydrobromic Acid be evaporated to dryness, and heated to 110° C. (230° F.), no appreciable residue should remain.

Heavy metals. Ten Cc. of the Diluted Acid without further acidulation, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Free bromine. If 10 Cc. of the Acid be shaken with 2 Cc. of chloroform, no color should be imparted to the latter.

Iodine. Upon subsequently adding chlorine water, which has been previously diluted with an equal volume of water, drop by drop, with shaking, the chloroform should be colored orange, with no trace of violet.

Arsenic. Five Cc. of Diluted Hydrobromic Acid should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of hydrochloric acid and chlorides. If 0.5 Cc. of Diluted Hydrobromic Acid be mixed with 10 Cc. of water, and 8 Cc. of silver nitrate T.S. with 6 Cc. of ammonium carbonate T.S., be added, and if the mixture, after digesting for ten minutes on a bath of boiling water, be cooled and filtered, the filtrate, on supersaturating with nitric acid, should not become more than slightly opalescent.

Quantitative Test.—If 10 Gm. of Diluted Hydrobromic Acid be diluted with sufficient distilled water to measure 100 Cc., and if to 8.04 Cc. of this solution, after exact neutralization with diluted ammonia water (litmus T.S. being used as indicator), there be added 3 drops of potassium chromate T.S., then not less than 10 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red tint (each Cc. corresponding to 1 percent. of absolute Hydrobromic Acid).

Uses.—Diluted hydrobromic acid is used as a nervine and hypnotic, in doses of two fluidrachms (8 Cc.).

ACIDUM HYDRIODICUM DILUTUM. U.S. Diluted Hydriodic Acid

A solution of Hydriodic Acid [HI = 126.9], containing not less than 10 percent., by weight, of the absolute Acid, and about 90 percent. of water. It should be kept in amber-colored, glass-stoppered bottles, protected from the light.

	Metric	Old form
* **Potassium Iodide**	135.0 Gm.	4 oz. av. 431 gr.
Potassium Hypophosphite	10.0 Gm.	161 grains
Tartaric Acid	136.5 Gm.	5 oz. av. 16 gr.
Distilled Water,		
Diluted Alcohol, each, a sufficient quantity,		
To make	1000 Gm.	2 pints

Dissolve the Potassium Salts in 250 Cc. [old form 8 fl. oz.] of Distilled Water with the aid of heat, and the Tartaric Acid in 400 Cc. [old form 12 fl. oz.] of Diluted Alcohol. Having poured the solution of Tartaric Acid into a bottle of about 1000 Cc. [old form 2 pints] capacity, add the solution of the Potassium Salts and shake the mixture briskly. Place the bottle in a bath of ice-water for several hours and, having inserted a pledget of cotton tightly in the throat of a funnel, transfer the contents of the bottle to the funnel. When all the liquid has passed through, wash the bottle and crystalline precipitate with Diluted Alcohol in successive small portions until 1000 Gm. [old form 2 pints] of clear solution have been obtained. Evaporate the liquid at a moderate temperature, on a water-bath, until all of the Alcohol has been dissipated, and add sufficient Distilled Water to make the product weigh 1000 Gm. [or measure 2 pints].

Diluted Hydriodic Acid was introduced into the U. S. Pharmacopœia (8th Revision) for the purpose of quickly preparing syrup of hydriodic acid (see page 290). The process is similar to that for preparing diluted hydrobromic acid (see page 470), potassium iodide being decomposed by tartaric acid, acid potassium tartrate crystallizing out; the use of diluted alcohol and the cooling of the liquid are depended upon to assist in separating the crystals.

$$\underset{\text{Potassium Iodide}}{KI} + \underset{\text{Tartaric Acid}}{H_2C_4H_4O_6} = \underset{\text{Hydriodic Acid}}{HI} + \underset{\text{Acid Potassium Tartrate}}{KHC_4H_4O_6}$$

The object of adding potassium hypophosphite is to protect the diluted acid from discoloration through the possible liberation of iodine, hypophosphorous acid, an oxidizing agent being produced by the action of the tartaric acid on potassium hypophosphite; the phosphoric acid and hydriodic acid produced by the action of the hypophosphorous acid on the iodine are colorless.

$$\underset{\text{Hypophosphorous Acid}}{H_3PO_2} + \underset{\text{Iodine}}{2I_2} + \underset{\text{Water}}{2H_2O} = \underset{\text{Hydriodic Acid}}{4HI} + \underset{\text{Phosphoric Acid}}{H_3PO_4}$$

Traces of potassium iodide, acid potassium tartrate, or hypophosphorous acid will not affect the medicinal action of the finished product.

Official Description.—A clear, colorless liquid.

Odor, Taste, and Reaction.—Odorless; acid taste; strongly acid reaction.

Specific Gravity.—About 1.106 at 25° C. (77° F.).

Solubility.—*Water.* Miscible in all proportions.

Alcohol.—Miscible in all proportions.

Tests for Identity.—On distilling Diluted Hydriodic Acid, water with some weak acid first passes over; at the temperature of 127° C. (260.6° F.), an acid of the strength of 57.5 percent. distils over unchanged.

Silver nitrate T.S. produces a yellow, curdy precipitate, insoluble in nitric acid, almost insoluble in ammonia water, but soluble in solutions of sodium thiosulphate and potassium cyanide.

If a few drops of ferric chloride T.S. or chlorine water be added to the Acid, diluted with twice its volume of water, iodine will be liberated and impart to the solution a reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color.

The Acid should not become colored on keeping.

Diluted Hydriodic Acid, when evaporated to dryness on a bath of boiling water, and then heated to 115° C. (239° F.), should not leave more than 8.3 percent. of residue.

Impurities and Tests for Impurities—*Limit of sulphuric acid.* Ten Cc. of the Acid should not be rendered more than slightly cloudy by the addition of 1 Cc. of barium chloride T.S.

Barium. The Acid should not be rendered turbid by the addition of potassium sulphate T.S.

Heavy metals. Ten Cc. of the Diluted Acid, without further acidulation, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. If 5 Cc. of Diluted Hydriodic Acid be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and then evaporated to dryness on a bath of boiling water, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Quantitative Test.—Into a flask provided with a well fitting stopper, introduce 2.54 Gm. of Diluted Hydriodic Acid, diluted with 50 Cc. of distilled water, followed by 25 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of ferric ammonium sulphate T.S., and 3 to 4 Cc. of nitric acid (free from nitrous compounds); then securely stopper the flask, and shake it well. Not more than 5 Cc. of tenth-normal potassium sulphocyanate V.S. should then be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 0.5 percent. of absolute Hydriodic Acid).

Uses.—Although this liquid is used mainly for dilution with syrup (see Syrupus Acidi Hydriodici, page 290), it is sometimes given internally in doses of five to ten minims (0.3 to 0.6 Cc.)

ACIDUM NITRICUM. U.S. Nitric Acid

A liquid composed of 68 percent., by weight, of absolute Nitric Acid [HNO_3 or $NO_2.OH = 62.57$], and 32 percent. of water. It should be kept in glass-stoppered bottles.

Preparation.—Nitric acid is prepared from N_2O_5, one of the five compounds of nitrogen and oxygen; these are nitrogen monoxide, or hyponitrous oxide (laughing gas), N_2O; nitrogen dioxide, N_2O_2 or $(NO)_2$; nitrous oxide, N_2O_3; nitrogen tetroxide or peroxide, N_2O_4; and nitric oxide, N_2O_5. From this latter, by the addition of water, nitric acid is formed, $N_2O_5 + H_2O = (HNO_3)_2$. Nitric acid is prepared commercially by reacting on sodium nitrate or *Chili saltpetre* with sulphuric acid. Sodium nitrate is preferred as the source, because it is cheaper than potassium nitrate, and, in addition, it affords a larger yield of nitric acid. If two molecules of the sodium salt and one of sulphuric acid be taken, the reactions will be as follows:

$$\underset{\substack{\text{Sodium}\\\text{Nitrate}}}{NaNO_3} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Acid Sodium}\\\text{Sulphate}}}{NaHSO_4} + \underset{\substack{\text{Nitric}\\\text{Acid}}}{HNO_3}$$

Then, by raising the heat, the acid sodium sulphate acts upon the second molecule of sodium nitrate:

$$\underset{\substack{\text{Sodium}\\\text{Nitrate}}}{NaNO_3} + \underset{\substack{\text{Acid Sodium}\\\text{Sulphate}}}{NaHSO_4} = \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4} + \underset{\substack{\text{Nitric}\\\text{Acid}}}{HNO_3}$$

Nitric acid has been made from atmospheric nitrogen, and an economical process may yet be devised.

The specific gravity of the official acid, or, as it is technically termed, 43° acid, is 1.403 at 25° C. (77° F.). That which is usually furnished in commerce is not so strong as this, but has the specific gravity of 1.355, and is known as 38° acid. Care should always be observed to specify, in ordering from the manufacturing chemist or dealer, the specific gravity of the acid desired, for if preparations are to be made, like the official solutions of iron, success cannot be expected if acids of official strength are not used. The reddish acid, called *nitrous acid*, is nitric acid containing more or less nitrogen tetroxide (N_2O_4). The same acid may be formed by passing nitrogen dioxide (N_2O_2) into nitric acid.

Official Description.—A colorless, fuming liquid, very caustic and corrosive.

Odor and Reaction.—Peculiar, somewhat suffocating odor; acid reaction.

Specific Gravity.—About 1.403 at 25° C. (77° F.).

Tests for Identity.—It boils and is completely volatilized at 120.5° C. (248.9° F.).

It dissolves copper, mercury, silver, and other metals with evolution of red fumes, and stains woollen fabrics and animal tissues a bright yellow.

Heated with indigo T.S., it discharges the blue color of the reagent.

Impurities and Tests for Impurities.—*Limit of non-volatile impurities.* If 10 Cc. of the Acid be evaporated to dryness and further heated to 110° C. (230° F.), no appreciable residue should remain.

Arsenic. Five Cc. of diluted Nitric Acid (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Sulphuric acid. Other portions of this dilution should not yield a precipitate upon the addition of barium chloride T.S., or

Hydrochloric acid. Silver nitrate T.S.

Heavy metals. Nitric Acid when neutralized with ammonia water and diluted with distilled water (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Iodine or bromine. If the diluted Acid (1 in 3) be shaken with a few drops of chloroform, the latter should remain colorless.

Iodic or bromic acid. The above solution should remain colorless, even after the introduction of a small piece of metallic tin.

Quantitative Test.—Introduce into a stoppered weighing bottle 3 Cc. of Nitric Acid and weigh accurately. Dilute the Acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 6.257, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Nitric Acid in the latter.

Uses.—Nitric acid, sometimes called *aqua fortis*, is used in pharmaceutical operations to form nitrates and as an oxidizing agent. Free nitric acid, however, will evolve oxygen at a red heat, according to the following reaction:

$$\underset{\text{Nitric Acid}}{4HNO_3} = \underset{\substack{\text{Nitrogen}\\\text{Tetroxide}}}{2N_2O_4} + \underset{\text{Oxygen}}{O_2} + \underset{\text{Water}}{2H_2O}$$

It oxidizes sulphur and phosphorus (giving rise to sulphuric and phosphoric acids) and all the metals, with a few exceptions. It combines with salifiable bases and forms nitrates. Medicinally, nitric acid, when taken internally in doses of five to ten minims (0.3 to 0.6 Cc.), largely diluted, is tonic, antiseptic, and astringent; when applied to the skin it is escharotic, producing a yellow stain, due to the formation of *xanthoproteic acid.*

ACIDUM NITRICUM DILUTUM. U.S. Diluted Nitric Acid

Diluted Nitric Acid should contain 10 percent., by weight, of absolute Nitric Acid [HNO_3 or $NO_2.OH = 62.57$], and 90 percent. of water.

	Metric	Old form
* **Nitric Acid**	**100 Gm.**	1¾ fl. oz.
Distilled Water	**580 Gm.**	14¼ fl. oz.
To make	**680 Gm.**	16 fl. oz.

Mix them. Keep the product in dark amber-colored, glass-stoppered bottles.

Diluted nitric acid contains about 14.7 percent. of official nitric acid, corresponding to 10 percent. of absolute nitric acid.

Official Specific Gravity.—About 1.054 at 25° C. (77° F.).
Tests for Identity.—It should respond to the reactions and tests given under *Acidum Nitricum.*
Quantitative Test.—To neutralize 6.26 Gm. (6.257 Gm.) of Diluted Nitric Acid should require 10 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 1 percent. of absolute Nitric Acid), methyl-orange T.S. being used as indicator.

Uses.—It is used medicinally for the same purposes as the strong nitric acid; when taken internally, the dose is fifteen to twenty minims (0.9 to 1.3 Cc.).

ACIDUM NITROHYDROCHLORICUM. U.S. Nitrohydrochloric Acid

[NITROMURIATIC ACID]

	Metric	Old form
* **Nitric Acid**	**180 Cc.**	1 fl. oz.
Hydrochloric Acid	**820 Cc.**	4½ fl. oz.
To make about	**1000 Cc.**	5½ fl. oz.

Mix the Acids in a capacious glass vessel, and, when effervescence has ceased, pour the product into dark amber-colored, glass-stoppered bottles, which should not be more than half filled, and which should be kept in a cool place.

When nitric acid is mixed with hydrochloric acid, mutual decomposition takes place, according to the reaction

$$\underset{\text{Nitric Acid}}{HNO_3} + \underset{\substack{\text{Hydrochloric}\\ \text{Acid}}}{3HCl} = \underset{\substack{\text{Nitrosyl}\\ \text{Chloride}}}{NOCl} + \underset{\text{Chlorine}}{Cl_2} + \underset{\text{Water}}{2H_2O}$$

and a liquid is formed, capable of dissolving gold, called *aqua regia.*

The value of this acid depends upon the completion of the above reaction and the production of nitrosyl chloride and free chlorine. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have its chlorine converted into hydrochloric acid by the action of light and the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be kept on hand very long; care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper or cause the bottle to explode violently.

Official Description.—A golden-yellow, fuming, and very corrosive liquid.
Odor.—Strong odor of chlorine.
Tests for Identity.—Completely volatilized by heat. It readily dissolves gold leaf, and a drop of it, when added to potassium iodide T.S., liberates iodine.

Uses.—Nitrohydrochloric acid, or, as it is still called, nitromuriatic acid, is given internally in hepatic affections, in doses of three minims (0.2 Cc.) and upward, well diluted with water. Great care should be taken in dispensing this acid, particularly if directed in combination with infusions, tinctures, etc. ; the reaction occurring upon mixing should be permitted to cease entirely before dispensing, to avoid the possibility of an explosion taking place when the preparation is in the patient's hands.

ACIDUM NITROHYDROCHLORICUM DILUTUM. U. S. Diluted Nitrohydrochloric Acid

[DILUTED NITROMURIATIC ACID]

	Metric	Old form
* **Nitric Acid**	40 Cc.	1 fl. oz.
Hydrochloric Acid	182 Cc.	4½ fl. oz.
Distilled Water	778 Cc.	19½ fl. oz.
To make about	1000 Cc.	25 fl. oz.

Mix the Acids in a capacious glass vessel, and, when effervescence has ceased, add the Distilled Water. Diluted Nitrohydrochloric Acid should be kept in dark amber-colored, glass-stoppered bottles, in a cool place. It should not be dispensed unless recently prepared.

It should be made strictly according to the official directions. The acids must be mixed while concentrated, otherwise the nitrosyl chloride and chlorine are not produced. Hence the "rapid method," so frequently used, of mixing the acids and immediately diluting with water, does not produce an official preparation, and is reprehensible in practice.

Official Description.—A colorless or pale yellowish liquid.
Odor and Taste.—Faint odor of chlorine; very acid taste.
Tests for Identity.—It is completely volatilized by heat. When it is added to potassium iodide T.S., iodide is liberated.

Uses.—Diluted nitrohydrochloric acid is given in doses of fifteen minims (1 Cc.), properly diluted, as a tonic and stimulant to the liver.

ACIDUM SULPHURICUM. U. S. Sulphuric Acid

A liquid composed of not less than 92.5 percent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $SO_2(OH_2) = 97.35$], and about 7.5 percent. of water. It should be kept in glass-stoppered bottles.

Preparation.—Sulphuric acid is obtained by burning sulphur or iron pyrites, FeS_2, and allowing the product of combustion, sulphur dioxide SO_2, to mix with nitrous fumes obtained from the decomposition of sodium nitrate, which change SO_2 into sulphur trioxide SO_3, and this uniting with steam yields sulphuric acid H_2SO_4. If the sulphur were burned by itself, the product would be sulphur dioxide, which contains only two-thirds as much oxygen as sulphur trioxide. The object of the sodium nitrate is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to remember that several of the oxides of nitrogen have oxidizing power. The reactions are thus expressed :

$$\underset{\substack{\text{Sulphur}\\ \text{Dioxide}}}{2SO_2} + \underset{\substack{\text{Nitrogen}\\ \text{Tetroxide}}}{N_2O_4} = \underset{\substack{\text{Sulphur}\\ \text{Trioxide}}}{2SO_3} + \underset{\substack{\text{Nitrogen}\\ \text{Dioxide}}}{N_2O_2} ;$$

then

$$\underset{\substack{\text{Nitrogen}\\ \text{Dioxide}}}{N_2O_2} + \underset{\text{Oxygen}}{O_2} = \underset{\substack{\text{Nitrogen}\\ \text{Tetroxide}}}{N_2O_4} ;$$

then

$$\underset{\substack{\text{Sulphur}\\ \text{Trioxide}}}{SO_3} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Sulphuric}\\ \text{Acid}}}{H_2SO_4} ;$$

in which the sulphur dioxide, from the burning pyrites or sulphur, is oxidized to sulphur trioxide by the nitrogen tetroxide, which readily parts with two atoms of oxygen to such bodies as sulphur dioxide, and then takes two atoms of oxygen again from the atmosphere, regenerating the original tetroxide. The nitrogen tetroxide thus acts simply as a carrier of atmospheric oxygen, whereby the SO_2 is changed into SO_3. This latter compound then unites with steam to form H_2SO_4, the final product.

This acid is made on an immense scale, the reactions taking place in leaden chambers. Sulphur is used most largely in the United States as the source of production, while pyrites is used almost exclusively abroad. As the latter nearly always contains arsenical compounds, the foreign commercial product is contaminated with them.

Sulphuric Acid is now made by the "contact method," in which the nitrogen tetroxide, used as a carrier of oxygen in the above process, is replaced by a "solid" contact, which by its catalytic action changes sulphur dioxide to sulphur trioxide. This process promises to revolutionize the older methods.

Official Description.—A colorless liquid, of oily consistence, and very caustic and corrosive.

Odor, Taste, and Reaction.—Inodorous; acid reaction.

Specific Gravity.—Not below 1.826 at 25° C. (77° F.).

Solubility.—Miscible, in all proportions, with water or alcohol, with evolution of much heat; the Acid should be added with great caution to the diluent.

Tests for Identity.—It boils at 338° C. (640.4° F.). When heated on platinum foil, it is vaporized, with the evolution of dense fumes, without leaving a residue.

If Sulphuric Acid be dropped upon cane-sugar or wood, it chars them.

Diluted with 20 volumes of water, it yields with barium chloride T.S. a copious white precipitate, insoluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Lead.* On mixing the Acid carefully with 4 or 5 volumes of alcohol, no precipitate should be formed within one hour.

Limit of nitric or nitrous acid. If there be carefully poured upon it, in a test-tube, a layer of ferrous sulphate T.S., and the liquid cooled, the zone of contact should not assume a brown or reddish color.

Hydrochloric acid. Sulphuric Acid, diluted with 20 volumes of water, should yield no precipitate upon the addition of silver nitrate T.S.

Heavy metals. Nor should the solution respond to the Time Limit Test for *heavy metal* (see U. S. P. Test No. 121, Chap. LXII).

Non-volatile impurities. Nor upon supersaturating with ammonia water should the solution leave any appreciable fixed residue on evaporation and ignition.

Limit of sulphurous or nitrous acid. One Cc. of Sulphuric Acid, diluted with 5 Cc. of water and cooled, should not at once discharge the color of 0.1 Cc. of tenth-normal potassium permanganate V. S.

Arsenic. If Sulphuric Acid be diluted with water (1 in 10), 5 Cc. should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of selenium. If 2 Cc. of hydrochloric acid in which a fragment of sodium sulphite has been dissolved be carefully poured upon 2 Cc. of Sulphuric Acid contained in a test-tube, the zone of contact should not assume a pink or red color upon standing, nor should a precipitate form after heating.

Quantitative Tests.—Introduce into a stoppered weighing bottle 3 Cc. of Sulphuric Acid and weigh accurately. Dilute the acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 4.8675, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Sulphuric Acid in the latter.

Uses.—Sulphuric acid is the most powerful of the official inorganic acids. It is employed in making many preparations, mostly on account of its energetic action in decomposing salts, and the large use made of its compounds with metals, alkaloids, and other bodies. It is rarely used in the pure state as an escharotic, owing to its tendency to spread. When accidentally dropped upon the skin, a quick and profuse application of magnesia will prove effective. Unless the quantity of acid is very small, care should be used in applying water, except when a very large quantity can be applied at once, as the amount of heat produced when water is mixed with sulphuric acid would increase the pain. Internally, sulphuric acid is administered either in its diluted form or as aromatic sulphuric acid.

ACIDUM SULPHURICUM AROMATICUM. U.S. Aromatic Sulphuric Acid

Aromatic Sulphuric Acid should contain not less than 20 percent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $SO_2(OH)_2 = 97.35$], partly in the form of ethyl-sulphuric acid.

	Metric	Old form
* **Sulphuric Acid**	**111 Cc.**	3 fl. oz. 265 min.
Tincture of Ginger	**50 Cc.**	1 fl. oz. 288 min.
Oil of Cinnamon	**1 Cc.**	15 minims
Alcohol, a sufficient quantity,		
To make	**1000 Cc.**	2 pints

Add the Sulphuric Acid gradually, and with great caution, to 700 Cc. [old form 22½ fl. oz.] of Alcohol, and allow the mixture to cool. Then add to it the Tincture of Ginger and the Oil of Cinnamon, and afterwards enough Alcohol to make the whole measure 1000 Cc. [old form 2 pints]. Keep the product in glass-stoppered bottles.

Official Specific Gravity.—About 0.933 at 25° C. (77° F.).

Quantitative Test.—If 10 Gm. of Aromatic Sulphuric Acid be mixed in a small flask with 30 Cc. of water and be boiled for four hours, cooled and diluted with water to measure 100 Cc., then 48.68 Cc. of this solution, to which exactly 25 Cc. of normal potassium hydroxide V.S. have been added, should require not more than 5 Cc. of normal sulphuric acid V.S. for complete neutralization (each Cc. of the normal potassium hydroxide V.S. consumed corresponding to 1 percent. of absolute Sulphuric Acid), methyl-orange T.S. being used as indicator.

Uses.—This preparation, known as *elixir of vitriol*, and largely used, is employed principally as a remedy in the night-sweats of phthisis. It is used somewhat as an excipient for quinine pills, to reduce their size and render them more soluble. The introduction of the acid sulphate of quinine has diminished this use. The dose is from ten to thirty minims (0.6 to 2 Cc.).

ACIDUM SULPHURICUM DILUTUM. U.S. Diluted Sulphuric Acid

Diluted Sulphuric Acid should contain not less than 10 percent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $SO_2(OH)_2 = 97.35$], and about 90 percent. of water.

	Metric	Old form
***Sulphuric Acid**	100 Gm.	1 fl. oz.
Distilled Water	825 Gm.	15 fl. oz.
To make	925 Gm.	16 fl. oz.

Pour the Acid gradually, with constant stirring, into the Distilled Water. Keep the product in glass-stoppered bottles.

The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of a glass vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is lead sulphate, and from which the diluted acid should be poured off.

The formation of this precipitate does not occur if official or chemically pure sulphuric acid is used. The lead salt is present only in sulphuric acid which has not been purified.

Specific Gravity.—About 1.067 at 25° C. (77° F.).
Tests for Identity.—It should respond to the reactions and tests given under *Acidum Sulphuricum.*
Quantitative Tests.—To neutralize 4.868 Gm. of Diluted Sulphuric Acid not less than 10 Cc. of normal potassium hydroxide V.S. should be required (each Cc. corresponding to 1 percent. of absolute Sulphuric Acid), methyl-orange T.S. being used as indicator.

Uses.—Diluted sulphuric acid has the same properties as the acid from which it is made, except those which are dependent upon the strength of the latter. It is given internally, properly diluted, in doses of ten to thirty minims (0.6 to 2 Cc.).

ACIDUM SULPHUROSUM. U.S. Sulphurous Acid

An aqueous solution containing not less than 6 percent., by weight, of sulphur dioxide [$SO_2 = 63.59$], and about 94 percent. of water.

	Metric	Old form
***Sulphuric Acid**	60 Cc.	2 fl. oz. 14 min.
Charcoal, in coarse powder	20 Gm.	309 grains.
Distilled Water	500 Cc.	16 fl. oz. 435 min.

Introduce the Charcoal into a glass flask having a capacity of about 500 Cc. [old form 1 pint], add the Acid, and mix them well. Connect the flask by means of bent glass tubing, about 50 Cm. [old form about 20 inches] in length, with a wash bottle having a capacity of about 200 Cc. [old form 6½ fl. oz.] containing about 50 Cc. [old form 1½ fl. oz.] of water so that the end of the inlet tube shall be below the surface of the water. Through the triply perforated rubber stopper of the wash bottle pass a safety tube, which should reach nearly to the bottom of the bottle, and connect the latter by means of glass tubing, with a bottle provided with a doubly perforated rubber stopper, having a capacity of about 1000 Cc. [old form 2 pints], and containing 500 Cc. [old form 1 pint] of well-cooled Distilled Water. The inlet tube should dip about 25 Mm. [old form about 1 inch] below the surface of the Distilled Water. By means of a second tube connect this bottle with another containing water, the end of the tube extending 5 Cm. [old form about 2 inches] below the surface. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the Sulphuric Acid and Charcoal, until the evolution of gas has nearly ceased, and, during the passage of the gas, keep the bottle containing the Distilled Water at or below 10° C. (50° F.), by surrounding it with cold water or ice. Assay a small portion of the Sulphurous Acid by the method given below. Then add to the remainder sufficient Distilled water to bring the product to the strength of 6.4 percent., by weight, of sulphur dioxide. Finally pour the Sulphurous Acid into dark amber-colored, glass-stoppered bottles, which should be completely filled, and kept in a cool place, protected from light.

Owing to its rapid deterioration, Sulphurous Acid should be frequently assayed, and none should be dispensed, if it fails to conform to the assay given below.

The reactions which take place are simple. When the sulphuric acid (H_2SO_4) and charcoal are heated together, two molecules of the former each give up an atom of oxygen to the latter, and there are thus produced sulphur dioxide and carbon dioxide which, having been first passed through a wash bottle containing a little water to absorb impurities, are received into the distilled water, where the sulphur dioxide is absorbed, while the greater part of the carbonic acid gas escapes.

$$\underset{\substack{\text{Sulphuric}\\ \text{Acid}}}{4H_2SO_4} + \underset{\text{Carbon}}{C_2} = \underset{\substack{\text{Sulphur}\\ \text{Dioxide}}}{4SO_2} + \underset{\substack{\text{Carbon}\\ \text{Dioxide}}}{2CO_2} + \underset{\text{Water}}{4H_2O}$$

The mounted flask figured on page 141 is well adapted for preparing sulphurous acid (the thermometer may be omitted). The wash-bottle illustrated upon page 197 can be used in lieu of the bottle directed in the official formula; as the generation of the gas progresses, the liquid in the wash bottle accumulates. Care must be observed in making sulphurous acid to disconnect the wash bottle from the tube leading to the flask the instant the gas ceases to come over, otherwise a portion of the liquid in the wash bottle will be sucked into the flask by the partial vacuum produced, almost certainly involving fracture of the flask.

Official Description.—A colorless liquid.

Odor, Taste, and Reaction.—Characteristic odor of burning sulphur; acid sulphurous taste. Blue litmus paper moistened with the Acid is first reddened and afterwards bleached.

Specific Gravity.—Not less than 1.028 at 25° C. (77° F.).

Tests for Identity.—By heat it is completely volatilized.

On gently heating a few Cc. of the Acid in a test-tube, the gas evolved will blacken a strip of paper moistened with mercurous nitrate T.S., but will not affect one moistened with lead acetate T.S.

On mixing, in a test-tube, 1 Cc. of Sulphurous Acid with 5 Cc. of diluted hydrochloric acid, and adding a small piece of pure zinc, hydrogen sulphide gas will be evolved, which will blacken a strip of paper moistened with lead acetate T.S.

Impurity and Test.—*Limit of sulphuric acid.* If 1 Cc. of Sulphurous Acid be diluted with 99 Cc. of water and there be added 1 Cc. of diluted hydrochloric acid, and afterwards 1 Cc. of barium chloride T.S., not more than a slight turbidity should be at once produced.

Assay.—Introduce into a stoppered weighing bottle 2 Cc. of Sulphurous Acid and weigh accurately. To this add 50 Cc. of tenth-normal iodine V.S., and allow it to stand for five minutes, then slowly add tenth-normal sodium thiosulphate V.S. until the mixture is just decolorized. Subtract the number of cubic centimeters of the tenth-normal sodium thiosulphate V.S. used, from 50, and multiply the difference by 0.318, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Sulphurous Acid in the latter. Dilute the Sulphurous Acid with distilled water, as directed in the process above, so that it shall have the strength of 6.4 percent. of sulphur dioxide.

Uses.—Sulphurous acid is principally used to prevent the growth of the microscopic organisms which induce fermentation. Internally, it is rarely administered, its salts, the sulphites, being preferred. The dose is from three minims to one fluidrachm (0.2 to 4 Cc.) diluted with water.

ACIDUM PHOSPHORICUM. U.S. Phosphoric Acid

A liquid composed of 85 percent., by weight, of absolute Orthophosphoric Acid [H_3PO_4 or $PO(OH)_3 = 97.29$], and 15 percent. of water. It should be kept in glass-stoppered bottles.

The above-mentioned percentage (85) is that used for Phosphoric Acid in the formulas of pharmacopœial preparations. It is sometimes termed *syrupy phosphoric acid* on account of its consistence.

The process for making phosphoric acid was abandoned by the U. S. P. 1890 on account of the danger usually attending the operation, and because it can be made much more profitably on the large scale.

A modification of this process, which obviates any likelihood of danger, is as follows: Pour 12 fluidounces of distilled water, mixed with 11 fluidounces of nitric acid, into a two-pint flask. Add 40 grains of bromine, and shake it gently until it is dissolved. Now add two ounces of phosphorus, and set the flask aside, where the nitrous vapors may be carried off without injury. In winter-time, or if the acid is needed at once, it will be necessary to aid the reaction by a gentle heat; but if sufficient time can be allowed, the phosphorus will disappear gradually at the ordinary temperature, and no particular attention will be needed until the phosphorus is oxidized. The nearly colorless liquid remaining in the flask is then evaporated, tested for impurities by the official method, and diluted to the proper strength.

The most dangerous impurity likely to be found in the finished preparation is arsenic,—its presence being traced to the sulphuric acid made from pyrites, which is often used in making the phosphorus.

Official Description.—A colorless liquid of a syrupy consistence.

Odor, Taste, and Reaction.—Without odor; strongly acid taste; acid reaction.

Specific Gravity.—About 1.707 at 25° C. (77° F).

Solubility.—*Water.* Miscible in all proportions.

Alcohol. Miscible in all proportions.

Tests for Identity.—When heated the liquid loses water; at 200° C. (392° F.), it gradually begins to change to pyrophosphoric acid. At a still higher temperature it is converted into metaphosphoric acid, which volatilizes in dense fumes, or, on cooling, forms a transparent mass of glacial phosphoric acid.

If a small portion of Phosphoric Acid be supersaturated with ammonia water, the addition of magnesium sulphate T.S. (or of magnesia mixture) produces a white, crystalline precipitate. If this precipitate be collected, washed, and dissolved in diluted acetic acid, the solution yields a yellow precipitate with silver nitrate T.S. (distinction from *metaphosphoric* or *pyrophosphoric acid*).

Impurities and Tests for Impurities.—*Nitric acid.* If a crystal of ferrous sulphate be dropped into a cooled mixture of 1 Cc., each, of Phosphoric Acid, sulphuric acid, and water, no brown or brownish-black color should appear around the crystal.

Phosphorous acid. If 1 Cc. of Phosphoric Acid be diluted with 5 Cc. of water, and the liquid gently warmed, it should not be blackened upon the addition of a few drops of silver nitrate T.S., or rendered turbid by mercuric chloride T.S.

Arsenic. If Phosphoric Acid be diluted with water (1 in 10), 5 Cc. should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Phosphates. Upon adding to 1 Cc. of Phosphoric Acid a mixture of 3 Cc. of alcohol and 1 Cc. of ether, no turbidity should appear.

Heavy metals. If Phosphoric Acid be diluted with water (1 in 20), 10 Cc. should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Hydrochloric acid. After diluting a portion of the Acid with 5 volumes of water, no precipitate should be produced, in separate portions of the liquid, by silver nitrate T.S., or

Metaphosphoric acid. When dropped into albumin T.S.

Pyrophosphoric and metaphosphoric acids. Nor should any precipitate be formed, even after several hours, by the addition of an equal volume of official tincture of ferric chloride.

Limit of sulphuric acid.—If 0.1 Cc. of the Acid be diluted with water to 7 Cc. and 1 Cc. of barium chloride T.S. be added, no cloudiness or precipitate should appear within 30 seconds.

Quantitative Test.—If 10 Gm. of Phosphoric Acid be diluted to measure 100 Cc., then 9.73 Cc. of this solution, when diluted with a cold saturated aqueous solution containing 5 Gm. of sodium chloride, should require 17 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 5 percent. of absolute Phosphoric Acid), phenolphthalein T.S. being used as indicator.

Uses.—Phosphoric acid is used to make diluted phosphoric acid.

ACIDUM PHOSPHORICUM DILUTUM. U. S. Diluted Phosphoric Acid

Diluted Phosphoric Acid should contain 10 percent., by weight, of absolute Orthophosphoric Acid [H_3PO_4 or $PO(OH)_3 = 97.29$], and 90 percent of water.

	Metric	Old form
***Phosphoric Acid**	**100 Gm.**	**1¼ fl. oz.**
Distilled Water	**750 Gm.**	**16 fl. oz.**
To make	**850 Gm.**	**17¼ fl. oz.**

Mix them. Keep the product in glass-stoppered bottles.

The precipitation which sometimes occurs when this acid is mixed with tincture of ferric chloride is generally due to the presence of pyrophosphoric acid. Ferric pyrophosphate is precipitated in the form of an insoluble gelatinous precipitate.

Official Specific Gravity.—About 1.057 at 25° C. (77° F.).

Tests for Identity.—It corresponds in chemical properties and should conform to the reactions and tests given under *Acidum Phosphoricum.*

Quantitative Test.—If 4.87 Gm. of Diluted Phosphoric Acid be diluted with 5 Cc. of a cold saturated solution of sodium chloride, it should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Phosphoric Acid), phenolphthalein T.S. being used as indicator.

Uses.—Diluted phosphoric acid is tonic and refrigerant in doses of thirty minims (2 Cc.).

ACIDUM HYPOPHOSPHOROSUM. U.S. Hypophosphorous Acid

A liquid composed of 30 percent., by weight, of absolute Hypophosphorous Acid [$PO.H_2(OH) = 65.53$], and 70 percent. of water. It should be kept in glass-stoppered bottles.

Preparation.—Hypophosphorous Acid may be made in several ways, but probably the most satisfactory method is that of carefully decomposing barium hypophosphite with diluted sulphuric acid.

Official Description.—A colorless liquid.

Odor, Taste, and Reaction.—Without odor, and having an acid taste; acid reaction.

Specific Gravity.—About 1.130 at 25° C. (77° F.).

Solubility.—*Water.* Miscible in all proportions.

Tests for Identity.—When heated in a porcelain dish, water evaporates, and the acid becomes more concentrated. On further heating between 130° and 140° C. (266° and 284° F.), it decomposes, forming hydrogen phosphide, which ignites, and phosphorous acid; the latter between 160° and 170° C. (320° and 338° F.) decomposes into hydrogen phosphide and phosphoric acid; the pasty residue finally reddens, ignites, and the last portions of unoxidized phosphorus burn out at a higher temperature.

The addition of silver nitrate T.S. to Hypophosphorous Acid, diluted with an equal volume of water, produces a black precipitate of metallic silver; the addition of mercuric chloride T.S., a white precipitate of mercurous chloride.

When the Acid is gently heated with copper sulphate T.S., a yellow precipitate forms, which rapidly assumes a reddish-brown color.

Impurities and Tests for Impurities.—*Limit of barium.* If 10 Cc. of the Acid be neutralized with ammonia water, not more than a slight precipitate should result, and after filtering, the filtrate should not become turbid upon the addition of potassium sulphate T.S.

Heavy metals. Ten Cc. of the Acid should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of potassium. Neither platinic chloride T.S. nor sodium cobaltic nitrite T.S. should produce more than a slight yellow turbidity in the diluted Acid.

Arsenic. If 2 Cc. of Hypophosphorous Acid be measured into a beaker containing 3 Cc. of nitric acid, which has been previously diluted with about 10 Cc. of water, and the whole evaporated to dryness on a bath of boiling water, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Quantitative Test.—If 10 Gm. of Hypophosphorous Acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require 30 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent of absolute Hypophosphorous Acid), methyl-orange T.S. being used as indicator.

Uses.—This acid is used solely to prepare diluted hypophosphorous acid.

ACIDUM HYPOPHOSPHOROSUM DILUTUM. U. S. Diluted Hypophosphorous Acid

A liquid composed of 10 percent., by weight, of absolute Hypophosphorous Acid [$PO.H_2(OH) = 65.53$], and 90 percent. of water.

	Metric	Old form
* **Hypophosphorous Acid**	200 Gm.	5 fl. oz.
Distilled Water	400 Gm.	11½ fl. oz.
To make	600 Gm.	16½ fl. oz.

Mix them. Keep the product in well-stoppered bottles.

Diluted hypophosphorous acid, although directed to be made by diluting hypophosphorous acid (see above), may be made in various ways; the process of the National Formulary (see Part VI.), consists of decomposing potassium hypophosphite with tartaric acid. The trace of acid potassium tartrate left in the solution is insufficient to be considered objectionable when used medicinally, but the present official method is preferable.

Specific Gravity.—About 1.042 at 25° C. (77° F.).

Tests for Identity.—It should respond to the reactions and tests given under *Acidum Hypophosphorosum.*

Quantitative Test.—If 10 Gm. of Diluted Hypophosphorous Acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent of absolute Hypophosphorous Acid), methyl-orange T.S. being used as indicator.

Uses.—This acid was introduced into the U. S. P. 1890 for the purpose of acting as a reducing agent when added to solutions of various iodides which are liable to be decomposed by the action of light and air, as in syrup of ferrous iodide, or to aid in dissolving hypophosphites in the official syrups; calcium hypophosphite frequently requiring such an addition.

CHAPTER XXXIV

PREPARATIONS OF THE HALOGENS

Chlorine, Bromine, and Iodine

Cl; 35.18. Br; 79.46. I; 125.90

FOUR elements, *chlorine, bromine, iodine,* and *fluorine,* are termed halogens (salt-producers). Fluorine is of so little interest in pharmacy that it will not be noticed; the other three are of great interest both to medicine and to pharmacy.

Chlorine Cl; 35.18

Chlorine is a greenish-yellow, gaseous body, having a very suffocating odor; its specific gravity is 2.45 (when liquefied 1.38). Its most useful and characteristic property is that of bleaching organic coloring principles; the presence of water is necessary to effect this object. Chlorine is one of the most reliable disinfectants; it is principally used in combination with lime as bleaching powder, the official name being Calx Chlorinata. Chlorine in its free state is used officially in Chlorine Water (Liquor Chlori Compositus).

Chlorine combines with hydrogen and the metals, but has very little attraction for oxygen; its principal hydrogen compound is hydrochloric acid, HCl (see Acidum Hydrochloricum). The compounds of chlorine with metals and bases are termed chlorides; they will be considered under the heads of their respective bases.

Chlorine combines indirectly with oxygen, and the compounds produced by the union of the oxyacid, chloric acid, $HClO_3$, with metals or bases are termed chlorates. Perchlorates are also known.

Tests for Chlorides and Chlorates

Chlorides in solution, or hydrochloric acid, may be recognized by the addition of a solution of silver nitrate; a curdy white precipitate is produced, which is soluble in ammonia water, but insoluble in nitric acid.

Chlorates are recognized by the evolution of oxygen when heated, and by the reaction of the residue corresponding with that of chlorides.

Chlorine, Bromine, and Iodine and their Official Preparations

Chlorine.—Made by the action of heat upon hydrochloric acid and manganese dioxide, or produced by the action of hydrochloric acid upon potassium chlorate.

Liquor Chlori Compositus.—An aqueous solution, containing 0.4 percent. of Chlorine with oxides of chlorine and potassium chloride.

Chlorine loosely combined

Calx Chlorinata.—Made by subjecting calcium hydroxide to the action of chlorine.

Liquor Sodæ Chlorinatæ.—Made by decomposing solution of chlorinated lime with monohydrated sodium carbonate.

Bromum (Bromine).—Made by decomposing crude magnesium bromide with chlorine.
Iodum (Iodine).—Made by decomposing crude sodium iodide with manganese dioxide and sulphuric acid and subliming.
Tinctura Iodi.—An alcoholic solution of iodine containing 7 Gm. of iodine and 5 Gm. of potassium iodide in 100 Cc.
Liquor Iodi Compositus.—A 5 percent. aqueous solution of iodine, made soluble by the addition of 10 percent. of potassium iodide.
Unguentum Iodi.—Four percent. iodine; 4 percent. potassium iodide; 12 percent. glycerin, with benzoinated lard.

Iodine loosely combined

Acidum Hydriodicum Dilutum.—Ten percent. absolute hydriodic acid.
Syrupus Acidi Hydriodici.—One percent. absolute hydriodic acid.

Unofficial Preparations of Chlorine, Bromine, and Iodine

Acidum Hypochlorosum, $HClO$ Hypochlorous Acid	Agitate chlorine water with precipitated mercuric oxide. Distil the liquid to remove mercuric chloride, and collect the distillate
Acidum Chloricum, $HClO_3$ Chloric Acid	Decompose barium chlorate with an equivalent amount of pure diluted sulphuric acid; pour off the clear solution of chloric acid, and evaporate carefully *in vacuo* over strong sulphuric acid
Acidum Perchloricum, $HClO_4$ Perchloric Acid	Distil pure dry potassium perchlorate with four times its weight of concentrated (previously boiled) sulphuric acid. Collect the yellow distillate
Bromi Chloridum Bromine Chloride	Pass chlorine gas over bromine
Acidum Bromicum Bromic Acid	Decompose barium bromate with an equivalent amount of diluted sulphuric acid, filter, and evaporate
Acidum Iodicum, HIO_3 Iodic Acid	Heat 1 part iodine with 10 parts nitric acid in a retort until the iodine is dissolved and fumes cease to be evolved. Evaporate the solution, and heat the residue to 200° F. until all trace of acid is removed. Collect the white powder
Acidum Periodicum, HIO_4 Periodic Acid	Add 1 part iodine to a solution of 7 parts sodium carbonate in 100 parts water, and pass chlorine into the heated liquid until a precipitate ceases to form. Dissolve this precipitate in pure nitric acid, then add silver nitrate, and dissolve the resulting precipitate in hot diluted nitric acid. Then concentrate to crystallize. Treat the crystals with water, filter, and evaporate
Amylum Iodatum Iodized Starch	Five parts iodine moistened with water and triturated with 90 parts starch. It has been asserted by Bondonneau, Payen, Fritzsche, and others that iodine forms with starch a definite compound, and the formulas $(C_6H_{10}O_5)_5I$ and $(C_6H_{10}O_5)_{10}I$ have been assigned to it. The existence of these compounds is regarded as doubtful, however, and the U. S. P. 1880 terms the mixture iodized starch Iodized starch is a convenient preparation for administering iodine internally, the principal advantage being that starch forms an admirable diluent and the iodine is freed from irritant properties. The dose is two to four drachms (8 to 16 Gm.)

LIQUOR CHLORI COMPOSITUS. U. S. Compound Solution of Chlorine, Chlorine Water

[To replace Aqua Chlori, Pharm. 1890]

An aqueous solution, containing, when freshly prepared, about 0.4 percent. of Chlorine [Cl = 35.18], with some oxides of chlorine and potassium chloride.

	Metric	Old form
* **Potassium Chlorate,** granulated	5 Gm.	73 grains
Hydrochloric Acid	18 Cc.	276 minims
Distilled Water, a sufficient quantity,		
To make about	1000 Cc.	2 pints

Add the Hydrochloric Acid, diluted with 20 Cc. [old form 5 fl. dr.] of Distilled Water, to the Potassium Chlorate contained in a flask of the capacity of about 2000 Cc. [old form 4 pints].

Insert in the flask a stopper perforated to admit a funnel of the capacity of about 100 Cc. [old form 3¼ fl. oz.] containing about 10 Gm. [old form 2½ dr.] of purified cotton well wetted with cold water; place the flask on a water-bath containing boiling water, for a period of from two to three minutes; when the flask is completely filled with a greenish-yellow gas, remove it from the bath and add cold Distilled Water through the cotton in the funnel, in two separate portions of 500 Cc. [old form 1 pint] each. After the addition of each separate portion of cold Distilled Water, stopper the flask securely, invert, and thoroughly agitate the contents.

This solution should be freshly made when wanted.

Chlorine water was directed to be prepared in the U. S. P. 1890 by heating 35 Cc. of hydrochloric acid with 10 Gm. of manganese dioxide and conducting the generated chlorine into 400 Cc. of distilled water until a saturated solution is produced. The reactions are shown below:

$$\underset{\text{Manganese Dioxide}}{MnO_2} + \underset{\text{Hydrochloric Acid}}{4HCl} = \underset{\text{Manganese Chloride}}{MnCl_2} + \underset{\text{Chlorine}}{Cl_2} + \underset{\text{Water}}{2H_2O}$$

The chlorine water must be kept secluded from the light, to prevent its partial conversion into hydrochloric acid through the decomposition of the water by the union of the chlorine with its hydrogen.

The little apparatus shown in Fig. 265 is well adapted for making small quantities of chlorine water rapidly. The process adopted by the U. S. P. (8th Rev.) is practical and efficient; the slight traces of potassium chloride and oxides of chlorine may be disregarded, for they do not interfere with medicinal and pharmaceutical uses.

Uses.—Compound solution of chlorine, or chlorine water, is antiseptic and stimulant; it is given in doses of from thirty to sixty minims (2 to 4 Cc.) diluted with water; it is used as a gargle in scarlet fever, diphtheria, and similar diseases. Chlorine in the gaseous state is largely used as a disinfectant. A convenient way of generating it is by the well-known *chlorine saucer disinfectant;* this is made by pouring half a fluidounce of equal measures of sulphuric acid and water upon two hundred grains of a finely ground mixture of equal parts of black manganese oxide and common salt, contained in a saucer. Chlorine is gradually evolved from this mixture for several days.

CALX CHLORINATA. U.S. Chlorinated Lime Chlorinated Calcium Oxide

[CALX CHLORATA, PHARM. 1890 CHLORIDE OF LIME]

A compound resulting from the action of chlorine upon calcium hydroxide, and containing not less than 30 percent. of available chlorine. It is often improperly called "Chloride of Lime." It should be kept in well-closed vessels, in a cool and dry place.

Preparation.—Chlorinated lime is made by exposing finely powdered calcium hydroxide, which is placed on trays in a suitable chamber, to the action of chlorine. The gas is absorbed by the lime, and a chemical compound is formed, which is represented by the formula $CaOCl_2$. Various views have been held by chemists as to its exact composition, but the weight of opinion is now in favor of considering it to be a *calcium chloro-hypochlorite*, and yielding, by decomposition with water, calcium hypochlorite and calcium chloride. The value of chlorinated lime, whether used for bleaching purposes or in medicine, depends upon the amount of chlorine which can be liberated; for, whatever view is accepted as to its composition, it is admitted that the chlorine is very loosely combined.

A very excellent method of preservation is now in vogue in which the dry chlorinated lime is hermetically sealed in metallic zinc boxes. When exposed to the air it soon becomes moist, on account of the hygroscopic character of the calcium chloride present.

Official Description.—A white, or grayish-white, granular powder, becoming moist and gradually decomposing on exposure to air.

Odor, Taste, and Reaction.—Exhaling the odor of hypochlorous acid; repulsive, saline taste. An aqueous solution first colors red litmus paper blue, and then bleaches it.

Solubility.—*Water.* Partially.
Alcohol. Partially.

Tests for Identity.—If Chlorinated Lime be dissolved in diluted acetic acid, an abundance of chlorine gas will be evolved, and only a trifling residue remain undissolved.

From this solution ammonium oxalate T.S. throws down a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid.

Quantitative Test.—Introduce into a stoppered weighing bottle between 3 and 4 Gm. of Chlorinated Lime and weigh accurately; triturate this thoroughly with 50 Cc. of water, transfer the mixture to a graduated vessel, together with the rinsings, and add sufficient water to make 1000 Cc. After thoroughly shaking, add to 100 Cc. of the mixture 1 Gm. of potassium iodide, 5 Cc. of diluted hydrochloric acid, and sufficient tenth-normal sodium thiosulphate V.S. for complete decolorization. Multiply the number of Cc. of tenth-normal sodium thiosulphate V.S. consumed, by 0.3518, and divide this product by one-tenth of the weight of the Chlorinated Lime taken; the quotient represents the percentage of available chlorine present.

Uses.—Chlorinated lime is used in the preparation of solution of chlorinated soda, but most largely as a disinfectant, through its power of arresting animal and vegetable putrefaction. It is rarely given internally, but is sometimes used as a stimulant and alterative, in doses of three to six grains (0.2 to 0.38 Gm.). Externally, it is used in solution as an application to ulcers, burns, etc.

LIQUOR SODÆ CHLORINATÆ. U.S. Solution of Chlorinated Soda

[Liquor Sodæ Chloratæ, Pharm. 1890 Labarraque's Solution]

An aqueous solution of several chlorine compounds of sodium, containing at least 2.4 percent., by weight, of available chlorine.

	Metric	Old form
* **Monohydrated Sodium Carbonate**	65 Gm.	9 oz. av. 47 gr.
Chlorinated Lime	90 Gm.	12 oz. av. 262 gr.
Water, a sufficient quantity,		
To make	1000 Gm.	8 pints

Triturate the Chlorinated Lime (which should contain not less than 30 percent. of available chlorine) with 200 Cc. [old form 25½ fl. oz.] of Water, gradually added, until a uniform mixture results. Allow the heavier particles to subside, and transfer the thinner, supernatant portion to a filter. Then triturate the residue again with 200 Cc. [old form 25½ fl. oz.] of Water, transfer the whole to the filter, and, when the liquid has drained off, wash the filter and contents with 100 Cc. [old form 13 fl. oz.] of Water. Dissolve the Monohydrated Sodium Carbonate in 300 Cc. [old form 38 fl. oz.] of hot Water, and add this solution to the previously obtained filtrate contained in a suitable vessel. Stir or shake the mixture thoroughly, and, if it should become gelatinous, warm the vessel very gently, until the precipitate subsides. Then transfer the mixture to a new filter, and, when no more liquid drains from it, wash the filter and contents with enough Water to make the product weigh 1000 Gm. [or measure, old form, 8 pints]. Keep the Solution in well-stoppered bottles, protected from light, and in a cool place.

Double decomposition results in the formation of insoluble calcium carbonate or precipitated chalk, while sodium hypochlorite and sodium chloride remain in solution.

$$\underset{\text{Chlorinated Lime}}{Ca(OCl)_2 + CaCl_2} + \underset{\text{Sodium Carbonate}}{2Na_2CO_3} = \underset{\text{Chlorinated Soda}}{2NaOCl + 2NaCl} + \underset{\text{Calcium Carbonate}}{2CaCO_3}$$

Official Description.—A clear, pale greenish liquid.

Odor, Taste, and Reaction.—Faint odor of chlorine, and a disagreeable alkaline taste. The solution at first colors red litmus paper blue, and then bleaches it.

Specific Gravity.—About 1.050 at 25° C. (77° F.).

Test for Identity.—The addition of hydrochloric acid to the Solution causes an evolution of chlorine and carbon dioxide.

Quantitative Test.—If 7 Gm. of the Solution be mixed with 50 Cc. of water, and 2 Gm. of potassium iodide and 10 Cc. of hydrochloric acid be added, not less than 48 Cc. of tenth-normal sodium thiosulphate V.S. should be required to discharge the final yellow color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. corresponding to 0.05 percent. of available chlorine).

Uses.—Solution of chlorinated soda is principally employed as a disinfectant or bleaching solution; it is frequently termed *Labarraque's Solution*, and is sometimes substituted for *Eau de Javelle* (*Javelle's water*), a French preparation made with potassium carbonate instead of sodium carbonate.

BROMUM. U.S. Bromine

Br = 79.36

It should contain not less than 97 percent. of pure Bromine, and be kept in protected glass-stoppered bottles, in a cool place.

Preparation.—This non-metallic element, which is in the form of a dark red, volatile liquid, is produced largely in the United States, in Ohio, West Virginia, and Pennsylvania. It is prepared from the brine obtained from salt-wells by the following process. The brine is concentrated to separate chlorides, sulphates, etc., by crystallization. The mother liquor, containing the bromine principally in the form of magnesium bromide, is decomposed by treating it with chlorine gas produced from manganese dioxide and hydrochloric acid.

The manner of conducting this process is peculiar. The original salt liquor, or brine, is pumped out of the ground and evaporated to about 15° B. in large iron pans, then allowed to settle, and is further evaporated to the point of crystallization in wooden tanks heated by steam pipes. These tanks, five in number, are placed at different elevations, one above the other. Each day the liquor is run off from No. 1, the highest, to No. 2, next day to No. 3, and so on until it reaches No. 5, the crystallized salt being removed from each tank after draining off the liquor. The brine which reaches No. 5 is *bittern*, and consists chiefly of calcium, magnesium, sodium, and aluminum chlorides, with varying percentages of sodium and calcium bromides.

The bittern marking 30° to 38° B. is evaporated to about 45° B. The liquor is then run into stone stills, materials for generation of chlorine added, and heat applied by means of steam until the bromine has all been vaporized. It is condensed and collected in cooled receivers.

$$\underset{\substack{\text{Magnesium}\\\text{Bromide}}}{MgBr_2} + \underset{\text{Chlorine}}{2Cl} = \underset{\substack{\text{Magnesium}\\\text{Chloride}}}{MgCl_2} + \underset{\text{Bromine}}{2Br}$$

On account of its very caustic and irritating properties, *great care* must be used in handling bromine. Its vapor is very corrosive and suffocating.

Chemically, there is a close analogy between bromine and chlorine. Its combination with hydrogen is hydrobromic acid, which is official (see page 470).

The salts, termed bromides, are used very largely in medicine. They will be considered under the heads of their respective bases. *Bromates*, formed, like chlorates, by combination with the corresponding oxyacid, bromic acid, $HBrO_3$, are rarely used.

Tests for Bromine and Bromides

1. If a solution of a bromide be treated with a solution of silver nitrate, a yellowish-white precipitate of silver bromide is produced, which is insoluble in nitric acid and but slightly soluble in ammonia water.

2. If chlorine water be added to a strong solution of a bromide, bromine is liberated. This may be dissolved by agitation with carbon disulphide, chloroform, or ether.

3. If concentrated sulphuric acid be added to a bromide (not in solution), reddish vapors of bromine are evolved.

Official Description.—Bromine is a heavy, dark brownish-red, mobile liquid evolving, even at ordinary temperatures, reddish fumes, highly irritating to the eyes and lungs.

Odor.—Peculiar suffocating odor, resembling that of chlorine.

Specific Gravity.—About 3.016 at 25° C. (77°F.)

Solubility.—*Water.* In 28 parts at 25° C. (77° F.).

Other solvents. Readily in alcohol and ether (with gradual decomposition of these liquids); also in carbon disulphide, and in chloroform, with a deep reddish-yellow color.

Tests of Identity.—Boiling point, about 63° C. (145.4° F.).

On exposure to air or to heat, it is completely volatilized without leaving any residue.

It destroys the color of solutions of litmus and indigo, and imparts a yellow color to solution of starch.

Impurities and Tests for Impurities.—*Organic bromine compounds.* If Bromine be added to an excess of potassium hydroxide T.S., it should combine to form a permanently clear liquid, without the separation of oily drops.

Iodine. If an aqueous solution of Bromine be shaken with a slight excess of reduced iron until it becomes nearly colorless, the filtered liquid, on the addition of a small amount of ferric chloride and of starch T.S., should not assume a blue color.

Uses.—Bromine is rarely used in its undiluted condition. When diluted with water in the proportion of forty minims in a pint, it forms a powerful wash. It is the important ingredient in *Bibron's antidote* to rattlesnake poison, which is made by dissolving three hundred grains of bromine in half a pint of diluted alcohol, placing four grains of potassium iodide and two grains of corrosive mercuric chloride in a mortar; adding sufficient of the solution to dissolve the salts, and mixing it with the rest of the solution. The *utmost care* should be exercised in handling bromine: the vapor not only attacks the eyes and nostrils, but renders the air irrespirable. It acts on metallic surfaces, and may ruin balances if permitted to remain in contact with them.

IODUM. U.S. Iodine

$I = 125.90$

It should contain not less than 99 percent. of pure Iodine, and be kept in glass-stoppered bottles, in a cool place.

Preparation.—Iodine is a non-metallic element widely distributed in nature. It was formerly exclusively obtained from *kelp*, the ashes of certain sea-weeds. In addition to this source, it is now made from the mother liquors obtained from the crystallization of sodium nitrate in South America. These contain the iodine in the form of sodium iodide and sodium iodate. The iodides are decomposed by chlorine, iodine being set free, while the iodine from the iodates is precipitated by treatment with acid sodium sulphite. The liquid obtained by lixiviating kelp contains the iodine as sodium iodide and potassium iodide. A concentrated solution of the impure iodide is treated with sulphuric acid, then distilled with manganese dioxide; the separated iodine condenses in a series of glass receivers.

$$\underset{\substack{\text{Sodium}\\\text{Iodide}}}{2NaI} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} + \underset{\substack{\text{Manganese}\\\text{Dioxide}}}{MnO_2} = \underset{\text{Iodine}}{I_2} + \underset{\substack{\text{Manganese}\\\text{Sulphate}}}{MnSO_4} + \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4} + \underset{\text{Water}}{2H_2O}$$

Iodine of excellent quality is now readily obtained; the presence of a small quantity of water, however, is often noticed.

Tests for Iodine and Iodides

1. A dark blue color (fading upon the application of heat) is produced when iodine is brought in contact with starch mucilage.
2. An iodide is detected by first liberating the iodine by adding a little chlorine water and then using starch mucilage; or if carbon disulphide be added the iodine dissolves in it.
3. Silver nitrate produces with a solution of an iodide a yellowish-white precipitate of silver iodide, which is insoluble in nitric acid and but slightly soluble in ammonia water.
4. A yellow precipitate of lead iodide is produced by adding a solution of lead salt to a neutral solution of an iodide.
5. A red precipitate of mercuric iodide is produced by adding a solution of mercuric chloride to a neutral solution of an iodide.

Official Description.—Heavy, bluish-black, dry and friable, rhombic plates, having a metallic lustre.

Odor and Taste.—Distinctive odor; sharp, acrid taste.

Specific Gravity.—4.948 at 17° C. (62.6° F.).

Solubility.—*Water.* In about 5000 parts of water at 25° C. (77° F.).

Alcohol. In 10 parts of alcohol at 25° C. (77° F.).

Other solvents. Freely in ether, chloroform, or carbon disulphide; its solution in alcohol or in an aqueous solution of potassium iodide has a reddish color; its solution in chloroform or carbon disulphide has a violet color.

Tests for Identity.—Iodine imparts a deep brown, evanescent stain to the skin, and slowly destroys vegetable colors.

Soluble in about 5000 parts of water, and in 10 parts of alcohol at 25° C. (77° F.); freely soluble in ether, chloroform, or carbon disulphide; its solution in alcohol or in an aqueous solution of potassium iodide has a reddish color; its solution in chloroform or carbon disulphide has a violet color.

It volatilizes slowly at ordinary temperatures. When heated to about 114° C. (237.2° F.), it fuses, and is gradually dissipated in the form of a purple vapor, leaving no residue.

With starch T.S. a dark blue color is produced.

Impurities and Tests for Impurities.—*Moisture.* A solution of iodine in chloroform should be perfectly clear and limpid.

To determine the presence of cyanogen, chlorine, or bromine, proceed as follows:

Iodine cyanide. Triturate 0.5 Gm. of finely powdered Iodine with 20 Cc. of water, and filter the solution. To one-half of this solution, in a test-tube, carefully add tenth-normal sodium thiosulphate V.S., until the solution is just decolorized. Then add a few drops of ferrous sulphate T.S., and subsequently a little sodium hydroxide T.S., and heat the mixture gently. On now adding a slight excess of hydrochloric acid, the liquid should not assume a blue color.

Limit of chlorine or bromine. To the other half of the aqueous filtrate, in a test-tube, add a slight excess of silver nitrate T.S., shake the liquid actively, allow the precipitate to subside, and, having poured off the clear, supernatant liquid completely, shake the precipitate with a mixture of 1 Cc. of ammonia water and 9 Cc. of water, and filter. Upon the addition of a slight excess of nitric acid to the filtrate, not more than a slight opalescence should make its appearance.

Assay.—Place about 0.5 Gm. of Iodine in a tightly stoppered weighing bottle and weigh accurately; add 1 Gm. of potassium iodide and dissolve in 50 Cc. of water, then add tenth-normal sodium thiosulphate V.S. until the liquid is decolorized. The number of Cc. of tenth-normal sodium thiosulphate V.S. consumed, when multplied by 1.259, and divided by the weight of the Iodine taken, gives the percentage of pure Iodine present.

Iodine is closely related chemically to bromine and chlorine. Its combination with hydrogen (hydriodic acid) is official in the form of a diluted acid of 10 percent. strength and also as Syrupus Acidi Hydriodici, the syrup preserving it from decomposition. The iodides are largely used in medicine. The iodates, like the chlorates and bromates, are produced by combination with the oxyacids of iodine, iodic and periodic acids. They are of little interest pharmaceutically.

Uses.—Iodine is very largely used in medicine. It excites the action of the absorbent and glandular systems, and is employed both internally and externally.

TINCTURA IODI. U. S. Tincture of Iodine

An alcoholic solution containing 7 Gm. of Iodine and 5 Gm. of Potassium Iodide in 100 Cc. of Tincture. The addition of potassium iodide to the iodine solution was made in the 8th Revision of the U. S. Pharmacopœia, it being found by actual trial to prevent loss of iodine through gradual decomposition when the tincture was kept (see page 354).

If 5 Cc. of the Tincture be mixed with about 25 Cc. of Water and titrated with tenth-normal sodium thiosulphate V.S., about 27.25 Cc. of tenth-normal sodium thiosulphate V.S. should be required for complete decolorization (corresponding to about 6.86 Gm. of Iodine in 100 Cc.).

LIQUOR IODI COMPOSITUS. U. S. Compound Solution of Iodine

[Lugol's Solution]

An aqueous solution, which should contain not less than 5 percent. of iodine and 10 percent. of potassium iodide.

	Metric	Old form
***Iodine**	5 Gm.	½ oz. av.
Potassium Iodide	10 Gm.	1 oz. av.
Distilled Water, a sufficient quantity,		
To make	100 Gm.	8¾ fl. oz.

Dissolve the Iodine and Potassium Iodide in a sufficient quantity of Distilled Water to make the product weigh 100 Gm. [or measure, old form, 8¾ fl. oz.]. Keep the solution in glass-stoppered bottles.

In this Solution iodine is dissolved in water with the assistance of potassium iodide. Iodine dissolves sparingly in water, but freely in a solution of potassium iodide. In using this salt to render iodine more soluble in water, it is generally employed in a quantity twice the weight of the iodine. The Solution contains about 3.12 grains of iodine in the fluidrachm.

Quantitative Test.—For complete decolorization 6.3 Gm. of the Solution should require not less than 24.75 Cc. of tenth-normal sodium thiosulphate V.S. (each Cc. of the tenth-normal sodium thiosulphate V.S. corresponding to 0.2 percent. of Iodine).

Uses.—This Solution affords an efficient means of administering iodine internally. It is given in three minim (0.2 Cc.) doses, and, to prevent gastric irritation, it must be largely diluted.

UNGUENTUM IODI. U.S. Iodine Ointment

An ointment containing 4 percent. of Iodine, 4 percent. of Potassium Iodide, 12 percent. of Glycerin, and 80 percent. of Benzoinated Lard. (See Unguenta, Part V.)

ACIDUM HYDRIODICUM DILUTUM. U.S. Diluted Hydriodic Acid

This preparation was introduced into the U. S. Pharmacopœia (8th Revision), because the process adopted makes a stable preparation which is very convenient for diluting with syrup to make the official syrup of hydriodic acid (see page 290). It contains 10 percent. of absolute hydriodic acid.

SYRUPUS ACIDI HYDRIODICI. U.S. Syrup of Hydriodic Acid

This is a syrupy liquid containing 1 percent. of absolute hydriodic acid [HI; 126.9] and having the specific gravity 1.190 (see page 472). It is prepared officially by mixing 100 Gm. of Diluted Hydriodic Acid with 300 Gm. of Water and 600 Gm. of Syrup.

The object of this preparation is to furnish an agreeable mode of administering hydriodic acid, and also a liquid which will be reasonably stable. *Hydriodic acid*, HI, is easily decomposed in simple aqueous solution (unless protected by hypophosphorous acid as in the official process), free iodine being liberated, and if taken internally when in this condition, serious results might follow. Syrup of hydriodic acid was formerly made by passing hydrogen sulphide through an alcoholic solution of iodine (see U. S. P. 1880). The chemical reaction which takes place may be expressed as follows:

$$\underset{\text{Iodine}}{4I} + \underset{\substack{\text{Hydrogen}\\\text{Sulphide}}}{2H_2S} = \underset{\substack{\text{Hydriodic}\\\text{Acid}}}{4HI} + \underset{\text{Sulphur}}{2S}$$

Official Description.—A transparent, colorless, or not more than pale straw-colored liquid.

Odor and Taste.—Odorless, and having a sweet and acidulous taste.

Specific Gravity.—About 1.190 at 25° C. (77° F.).

Test for Identity.—The addition of silver nitrate T.S. to a small portion of the Syrup diluted with four volumes of water produces a pale yellow precipitate, nearly insoluble in ammonia water.

Impurity and Test.—*Limit of free iodine.* If a small portion of the Syrup be mixed with a little Starch T.S., and a few drops of chlorine water then added, the liquid will acquire a deep blue color. Not more than a faint bluish tint should be produced in the Syrup by starch T.S. alone.

Quantitative Test.—If 31.73 (31.725) Gm. of Syrup of Hydriodic Acid be diluted with distilled water to measure 50 Cc., and if to 10 Cc. of this solution about an equal volume of distilled water, 8 Cc. of tenth-normal silver nitrate V.S., and 5 Cc. of diluted nitric acid be added, followed by 3 Cc. of ferric ammonium sulphate T.S., then, after thoroughly shaking the mixture, not more than 3 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 0.2 percent. of absolute Hydriodic Acid).

Uses.—Syrup of hydriodic acid is used as an alterative. The dose is twenty to sixty minims (1.3 to 4 Cc.).

CHAPTER XXXV

SULPHUR AND PHOSPHORUS

S; 31.83. P; 30.77

THESE two elements furnish many important compounds to medicine. They present several analogies, both physically and chemically.

Sulphur S; 31.83

Sulphur is found uncombined in Sicily and in other parts of the world. In the form of sulphates and sulphides it is widely diffused. It is prepared for use by fusing it, allowing it to stand to permit the earthy impurities to settle, and then pouring it into cylindrical moulds. The sulphur in cylinders is termed *roll sulphur*.

Three forms of sulphur are official,—sublimed, washed, and precipitated sulphur.

Sulphur forms with hydrogen an offensive gas, which is known officially as hydrogen sulphide, H_2S. It is also termed *sulphuretted hydrogen* and *hydrosulphuric acid.* The formula for its preparation will be found under "Tests," in Part IV. It is used for proving the presence or absence of certain metallic salts, lead, bismuth, antimony, copper, mercury, zinc, etc., with which it produces characteristic precipitates. *Sulphides* are compounds of elements with sulphur. Some of the sulphides are analogous to acids, others to bases; and these different sulphides, by combining with one another, form compounds, which, from their analogy to salts, are called by Berzelius *sulpho-salts.* It forms with oxygen two oxides, *sulphurous* oxide, SO_2, and *sulphuric* oxide, SO_3. These oxides, by their union with water, form *sulphurous acid*, H_2SO_3, and *sulphuric acid*, H_2SO_4. These are considered in the chapter on inorganic acids. There is also known *hyposulphurous acid*, H_2SO_2, the corresponding oxide of which is not known, and *thiosulphuric acid* (frequently known as hyposulphurous acid), $H_2S_2O_3$, and a series of acids, $H_2S_2O_6$, $H_2S_3O_6$, $H_2S_4O_6$, and $H_2S_5O_6$, known as the *thionic series.* Sulphurous acid forms with bases salts which are termed *sulphites.* The salts similarly produced from sulphuric acid are termed *sulphates.* The sulphates are much more important salts. Pharmaceutically and medicinally, they have totally different properties. The official sulphites and sulphates will be considered under their respective bases.

Tests for Sulphites and Sulphurous Acid

1. Solution of barium chloride produces with sulphurous acid or a solution of a sulphite, a white precipitate of barium sulphite, which is soluble in hydrochloric acid.
2. If a solution of a sulphite or sulphurous acid be added to diluted sulphuric acid and zinc, hydrogen sulphide gas is liberated.
3. An acid solution of potassium permanganate is decolorized and deoxidized by sulphurous acid.

Tests for Sulphates and Sulphuric Acid

1. A solution of barium chloride produces a white insoluble precipitate of barium sulphate with sulphuric acid or a soluble sulphate.

2. A soluble salt of lead produces a white insoluble precipitate of lead sulphate with sulphuric acid or a soluble sulphate.

Sulphur and Phosphorus and their Official Preparations

Sulphur Sublimatum.—Made by subliming crude sulphur.
Sulphur Lotum.—Made by washing sublimed sulphur.
Sulphur Præcipitatum.—Made by precipitating a solution of calcium disulphide with HCl.
Sulphuris Iodidum.—Made by heating iodine with washed sulphur.
Unguentum Sulphuris.—Made by mixing 15 parts of washed sulphur with 85 parts of benzoinated lard.

Sulphur or Phosphorus loosely combined

Hydrogen Sulphide.—By acting on ferrous sulphide with diluted sulphuric acid. (See Tests.)
Carbonei Disulphidum.—By passing sulphur vapor over red-hot charcoal.
Phosphorus.—Made by deoxidizing phosphoric acid with carbon.
Pilulæ Phosphori.—Each pill contains $\frac{1}{100}$ of a grain of phosphorus.

Unofficial Compounds and Preparations of Sulphur and Phosphorus

Acidum Hyposulphurosum, H_2SO_2 Hyposulphurous Acid	Add metallic zinc to sulphurous acid contained in a closed vessel and separate the zinc sulphite
Acidum Metaphosphoricum, HPO_3 Metaphosphoric Acid	Evaporate a solution of phosphoric acid until the residue ceases to give off water
Acidum Phosphorosum, H_3PO_3 Phosphorous Acid	Expose phosphorus to moist air under a bell-jar, and collect the heavy white vapor which falls, in a vessel containing water
Acidum Pyrophosphorosum, $H_4P_2O_7$ Pyrophosphorous Acid	Precipitate sodium pyrophosphate with a solution of lead acetate, and decompose the well-washed lead pyrophosphate with hydrogen sulphide
Spiritus Phosphori Spirit of Phosphorus. U. S. P. 1890	Weigh 1.2 Gm. of phosphorus in a tared dish containing water, dry it quickly with the aid of blotting paper, and transfer it at once to a flask containing 1000 Cc. of absolute alcohol. Having connected the flask with an upright condenser, boil the liquid gently on a water-bath until the phosphorus is dissolved, cool, and add enough absolute alcohol to make 1000 Cc. Store in small dark-colored vials
Elixir Phosphori Elixir of Phosphorus. U. S. P. 1890	Add to 210 Cc. of spirit of phosphorus 2 Cc. oil of anise and 550 Cc. of glycerin. Repeatedly invert the bottle until they form a clear liquid, and then add enough aromatic elixir, in portions, gently agitating after each addition to make 1000 Cc. Keep in dark-colored, well-stoppered bottles in a cool place
Oleum Phosphoratum Phosphorated Oil. U. S. P. 1890	Heat 100 Gm. of expressed oil of almond, during 15 minutes, on a sand-bath, to 250° C. (482° F.), cool, filter, add 1 Gm. of phosphorus to 90 Gm. of filtered oil, contained in a stoppered bottle, and heat on a water-bath, with occasional agitation, until the phosphorus is dissolved. Lastly add enough ether to make the product weigh 100 Gm. and store in small glass-stoppered vials
Resina Phosphorata Phosphorated Rosin Phosphoretted Resin	Melt together, by the aid of a sand-bath, in a dry bottle having the nearly exact capacity of the ingredients, rosin free from moisture 96 parts and phosphorus 4 parts. Keep the whole at a temperature of 392° F. until the phosphorus is dissolved, cool, and keep in bottles protected from light

SULPHUR SUBLIMATUM. U.S. Sublimed Sulphur

S = 31.83

[FLOWERS OF SULPHUR]

It should contain not less than 99 percent. of pure Sulphur.

Preparation.—When vapors of sulphur are conducted into a chamber properly cooled, they are condensed in the form of a crystalline powder, which collects on the sides and bottom of the chamber. The yellowish powder is known as sublimed sulphur, or *flowers of sulphur*. *Ground roll sulphur* is sometimes sold as "*flour of sulphur*," it is not equal in quality to the official sublimed sulphur.

Official Description.—A fine yellow powder.
Odor, Taste, and Reaction.—Slight characteristic odor; faintly acid taste; acid reaction when agitated with water.
Solubility.—*Water.* Insoluble.
Alcohol and other solvents. Readily in carbon disulphide; slightly in absolute alcohol; more readily in petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides.
Tests for Identity.—At about 115° C. (239° F.) it fuses to a yellow, mobile fluid, which upon further heating, becomes dark and viscid, until a temperature above 300° C. (572° F.) is reached, when it becomes a thin liquid boiling at 448° C. (838.4° F.). In the air it burns to sulphur dioxide, characterized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas.
Quantitative Test.—The amount of residue left after volatilizing or burning a weighed portion of well-dried Sublimed Sulphur should not exceed 0.5 percent.

Uses.—Sublimed sulphur is given internally as a laxative and diaphoretic, in doses of from one to three drachms (4 to 12 Gm.). It is often combined with potassium bitartrate and administered to children mixed with honey or molasses. In diphtheritic croup it is sometimes used to remove the exudation by insufflation; externally, it is used as an ointment in scabies and other skin diseases.

SULPHUR LOTUM. U.S. Washed Sulphur

S = 31.83

Washed sulphur, when dried, should contain not less than 99.5 percent. of pure Sulphur.

	Metric	Old form
* **Sublimed Sulphur**	**100 Gm.**	16 oz. av.
Ammonia Water	**10 Cc.**	1½ fl. oz.
Water, a sufficient quantity		

Pass the Sublimed Sulphur through a No. 30 sieve, mix it thoroughly with 100 Cc. [old form 1 pint] of Water, add the Ammonia Water, and digest for three days, agitating occasionally. Then add 100 Cc. [old form 1 pint] of Water, transfer the mixture to a muslin strainer, and wash the Sulphur with Water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat, pass it through a No. 30 sieve, and keep it in well-stoppered bottles.

Sublimed Sulphur is frequently contaminated with small quantities of sulphuric acid and other impurities, and the object of the ammonia in the above process is to neutralize the acid, the ammonium sulphate being subsequently washed out.

Official Description.—A fine yellow powder.
Odor and Taste.—Without odor or taste.
Solubility.—*Water.* Insoluble.
Alcohol and other solvents. Readily in carbon disulphide; slightly in absolute alcohol; more readily in petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides.
Tests for Identity.—At about 115° C. (239° F.) it fuses to a yellow, mobile fluid, which upon further heating becomes dark and viscid, until a temperature above 300° C. (572° F.) is reached, when it becomes a thin liquid boiling at 448° C. (838.4° F.). If air be admitted, it burns to sulphur dioxide, which is identified by its characteristic odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas.
Impurities and Tests for Impurities.—*Earthy and metallic impurities.* If 0.5 Gm. of Washed Sulphur be boiled with 10 Cc. of sodium hydroxide T.S., it should be dissolved, leaving no appreciable residue.

Arsenic. If 0.5 Gm. of Washed Sulphur be digested for several hours with 10 Cc. of ammonia water, the liquid filtered, and the clear filtrate evaporated to dryness on a water-bath, then, after adding 1 Cc. of nitric acid and again evaporating, the solution obtained by dissolving the residue in 10 Cc. of hydrochloric acid (8 percent.) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Acid and ammonia. If 5 Cc. of water be agitated with 2 Gm. of Washed Sulphur, the liquid should not change the color of blue or red litmus paper.

Quantitative Test.—The amount of residue left after volatilizing or igniting a weighed portion of dried Washed Sulphur should not exceed 0.2 percent.

Uses.—Washed sulphur is preferred to sublimed sulphur for internal administration ; the small quantity of sulphuric acid present in the latter sometimes produces griping. The dose is from one to three drachms (4 to 12 Gm.). It is used in the preparation of Compound Licorice Powder, Sulphur Iodide, and Sulphur Ointment. (See Pulveres and Unguenta.)

SULPHUR PRÆCIPITATUM. U.S. Precipitated Sulphur

S = 31.83

Precipitated Sulphur, when dried, should contain not less than 99.5 percent. of pure Sulphur.

	Metric	Old form
* **Sublimed Sulphur**	**100 Gm.**	16 oz. av.
Lime	**50 Gm.**	8 oz. av.
Hydrochloric Acid,		
Water, each, a sufficient quantity		

Slake the lime, and mix it uniformly with 500 Cc. [old form 5 pints] of Water. Add the Sublimed Sulphur, previously sifted, and, after thorough mixing, add 1000 Cc. [old form 10 pints] of Water, and boil the mixture in a porcelain or glass vessel during one hour, stirring or agitating very frequently, and replacing the Water lost by evaporation. Then cover the vessel, and permit the contents to cool and become clear by subsidence. Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually, and with constant stirring, Hydrochloric Acid, previously diluted with an equal volume of Water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it, until the washings are tasteless and cease to give a precipitate upon the addition of ammonium oxalate test solution. Then dry the product rapidly, at a moderate heat, and keep it in well-stoppered bottles.

In the above process the lime and sulphur react so as to form calcium disulphide and calcium thiosulphate (hyposulphite) :

$$\underset{\substack{\text{Calcium}\\ \text{Oxide}}}{3CaO} + \underset{\text{Sulphur}}{6S} = \underset{\substack{\text{Calcium}\\ \text{Disulphide}}}{2CaS_2} + \underset{\substack{\text{Calcium}\\ \text{Thiosulphate}}}{CaS_2O_3}$$

On the addition of hydrochloric acid, the sulphur is precipitated :

$$\underset{\substack{\text{Calcium}\\ \text{Disulphide}}}{2CaS_2} + \underset{\substack{\text{Calcium}\\ \text{Thiosulphate}}}{CaS_2O_3} + \underset{\substack{\text{Hydrochloric}\\ \text{Acid}}}{6HCl} = \underset{\substack{\text{Calcium}\\ \text{Chloride}}}{3CaCl_2} + \underset{\text{Sulphur}}{6S} + \underset{\text{Water}}{3H_2O}$$

In some processes sulphuric acid is used instead of hydrochloric acid, and calcium sulphate is precipitated with the sulphur. This furnishes an inferior product, and is called *lac sulphuris,* or *milk of sulphur.*

Official Description.—A fine, amorphous powder, of a pale yellow color.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Insoluble.

Alcohol. Very slightly in absolute alcohol.

Other solvents. Readily in carbon disulphide, petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides.

Tests for Identity.—At 115° C. (239° F.) Precipitated Sulphur melts, and at a higher temperature it volatilizes, or if air be admitted, burns to sulphur dioxide.

If 1 Gm. of Precipitated Sulphur be ignited, it should not leave a weighable residue.

Impurities and Tests for Impurities.—*Arsenic.* If 1 Gm. of Precipitated Sulphur be digested for several hours with 10 Cc. of Ammonia water and the liquid filtered, one-half of the clear filtrate should not leave a residue on evaporation; if the remainder be evaporated to dryness on a water-bath, then, after adding 1 Cc. of nitric acid and again evaporating, the solution obtained by dissolving the residue in 10 Cc. of hydrochloric acid (8 percent.) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Acid and alkali. If 5 Cc. of water be agitated with 2 Gm. of Precipitated Sulphur, the liquid should not change the color of blue or red litmus paper.

Uses.—Precipitated sulphur is much to be preferred to the other forms in liquid mixtures, as the particles are lighter and more easily suspended; the ointments made with it are smoother than those made with sublimed sulphur. The dose is from one to three drachms (4 to 12 Gm.).

SULPHURIS IODIDUM. U.S. Sulphur Iodide

	Metric	Old form
***Washed Sulphur**	**20 Gm.**	60 grains
Iodine	**80 Gm.**	240 grains

Mix the Sulphur and Iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and by means of a water-bath, gradually and with occasional agitation apply a heat not exceeding 60° C. (140°F.), until the ingredients combine and become of a uniformly dark color throughout. Then increase the heat to the boiling point of water, so as to fuse the mass. Should any Iodine have sublimed and condensed on the glass, incline the flask so as to combine the Iodine with the fused mass, and then pour the latter upon a porcelain plate or other suitable cold surface. When it is cold, break the product into pieces of suitable size, and keep them in a glass-stoppered bottle, in a cool place.

This compound represents one of the instances of the direct chemical union of two elements, heat being the only agent used to effect the combination; it is sometimes called *subiodide of sulphur*, or *iodine disulphide*, S_2I_2. There are some doubts, however, as to its being a definite chemical compound.

Official Description.—Brittle masses of a crystalline fracture having a grayish-black, metallic lustre.

Odor and Taste.—Odor of iodine; somewhat acrid taste.

Solubility.—Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, and a solution of potassium iodide dissolve the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 percent. of sulphur as residue.

Tests for Identity.—On exposing Sulphur Iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature a sublimate is formed, containing both iodine and sulphur; at a still higher temperature, the whole is volatilized, leaving only a trace of residue.

Quantitative Test.—If 0.5 Gm. of finely pulverized Sulphur Iodide, together with 1 Gm. of potassium iodide, be dissolved in 20 Cc. of water (the sulphur separating), not less than 28 Cc. of tenth-normal sodium thiosulphate V.S. should be required for complete decolorization of the mixture, using starch T.S. as indicator.

Uses.—Sulphur iodide is principally used externally in skin diseases in the form of an ointment.

CARBONEI DISULPHIDUM. U.S. Carbon Disulphide

$CS_2 = 75.57$

[CARBON BISULPHIDE]

Carbon Disulphide should be kept in partially filled, well-stoppered bottles, or in tin cans, in a cool place, remote from lights or fire.

This sulphide is prepared by the direct combination of carbon and sulphur at a moderate red heat. To effect this, charcoal is heated to redness in a vertical cylinder, while sulphur is admitted through a lateral tubulure near the bottom. As the sulphur melts and vaporizes, it combines with the carbon, and the carbon disulphide formed distils over through a series of condensing tubes, which, while they serve to collect the crude carbon disulphide, allow of the escape of the hydrogen sulphide formed at the same time.

It is purified by agitation with mercury and distillation in contact with white wax. It can by repeated rectification be entirely freed from its usual disgusting odor.

Official Description.—A clear, colorless, highly refractive liquid, very diffusive.
Odor and Taste.—Strong, characteristic but not fetid odor; sharp, aromatic taste.
Specific Gravity.—1.256 to 1.257 at 25° C. (77° F.).
Solubility.—*Water.* In 526 parts of water at 25° C. (77° F.).
Alcohol. Very soluble.
Other solvents. Very soluble in ether, chloroform, fixed and volatile oils.
Tests for Identity.—Carbon Disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils at 46° to 47° C. (114.8° to 116.6° F.), and when ignited, burns with a bluish-white flame, producing carbon dioxide and sulphur dioxide.
Impurities and Tests for Impurities.—*Sulphur dioxide.* It should not affect the color of blue litmus paper moistened with water.
Dissolved sulphur. A portion evaporated spontaneously in a glass vessel should leave no residue.
Hydrogen sulphide. Lead acetate T.S. agitated with it should not be blackened.

Uses.—Carbon disulphide is used principally as a solvent. It is the best solvent for rubber and similar bodies. It is poisonous when taken internally, and the continuous inhalation of its vapor is very injurious.

PHOSPHORUS. U.S. Phosphorus

$P = 30.77$

It should contain not less than 99.5 percent. of pure Phosphorus, and be carefully kept under water, in strong, well-closed vessels, in a secure and moderately cool place, protected from light.

Preparation.—Phosphorus is a non-metallic element prepared by heating acid calcium phosphate with charcoal. The acid calcium phosphate is obtained by treating calcium phosphate with sulphuric acid, calcium sulphate also being formed; the latter is afterwards separated.

$$\underset{\substack{\text{Calcium}\\\text{Phosphate}}}{Ca_3(PO_4)_2} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} = \underset{\substack{\text{Acid Calcium}\\\text{Phosphate}}}{CaH_4(PO_4)_2} + \underset{\substack{\text{Calcium}\\\text{Sulphate}}}{2CaSO_4}$$

Of the allotropic forms of phosphorus, *red phosphorus*, or *amorphous phosphorus*, is the most important. It is obtained by allowing phosphorus to remain for several days in an atmosphere of carbon dioxide at a temperature varying from 215° C. (419° F.) to 250° C. (482° F.)

Red phosphorus is not luminous and not poisonous until it is heated to 280° C. (536° F.), when it is converted into ordinary phosphorus.

Phosphorus forms with oxygen two oxides,—*phosphorous*, P_2O_3, or *phosphorous trioxide*, and *phosphoric*, P_2O_5, or *phosphorous pentoxide*. Corresponding to the last of these are three acids, known as *orthophosphoric* (tribasic phosphoric), H_3PO_4, *pyrophosphoric*, $H_4P_2O_7$, and *metaphosphoric*, HPO_3. Orthophosphoric acid is formed by dissolving P_2O_5 in boiling water, or by the action of nitric acid upon phosphorus itself; pyrophosphoric acid, by the heating of the tribasic phosphoric acid to 213° C. (415.4° F.); and metaphosphoric acid, by the ignition of the tribasic variety, or by dissolving P_2O_5 in cold water. *Phosphorous acid*, H_3PO_3, cannot be formed directly from phosphorous trioxide. This is a dibasic acid, containing one hydrogen atom not replaceable by metal. *Hypophosphorous acid*, H_3PO_2, is not capable of being derived directly from hypophosphorous oxide. It is monobasic, containing two hydrogen atoms not replaceable by metal.

Tests for Phosphates and Phosphoric Acids

1. Solution of silver nitrate produces a yellow precipitate with a neutral solution of an orthophosphate, soluble both in nitric acid and in ammonia water. It produces a white precipitate with pyrophosphoric acid or metaphosphoric acid.
2. If albumin be added to metaphosphoric acid, or to a solution of a metaphosphate containing acetic acid, a white precipitate is produced. No precipitate occurs if it be added to pyrophosphoric acid or orthophosphoric acid.
3. Official test solution of magnesium (magnesia mixture, see Tests) produces with phosphoric acid or a solution of a phosphate a precipitate of ammonio-magnesium phosphate.
4. If solution of ammonium molybdate in diluted nitric acid be added in excess to phosphoric acid or to a solution of a phosphate in nitric acid, and heat applied, a yellow precipitate of ammonium phosphomolybdate will be produced.
5. If a solution of barium chloride be added to a neutral solution of a phosphate, a white precipitate of barium phosphate is produced, which is soluble in acids.

Tests for Hypophosphites

1. When heated, they evolve spontaneously inflammable hydrogen phosphide.
2. An acid solution of potassium permanganate is decolorized.
3. From solution of mercuric chloride, mercury is precipitated upon the addition of a solution of a hypophosphite.

Official Description.—Phosphorus is a translucent, nearly colorless solid, of a waxy lustre, having, at ordinary temperatures, about the consistence of beeswax. By long keeping the surface becomes white or red, and occasionally black. When exposed to the air, it emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic; on longer exposure to air, it often takes fire spontaneously.

Odor, Taste, and Reaction.—Distinctive and disagreeable odor and taste (*but should not be tasted, except in very diluted solution*).

Specific Gravity.—1.830 at 10° C. (50° F.), and 1.820 at 25° C. (77° F.).

Solubility.—*Water.* Insoluble, or nearly so, imparting, however, its characteristic, disagreeable odor and taste.

Alcohol. In 350 parts of absolute alcohol at 15° C. (59° F.); in 240 parts of boiling absolute alcohol.

Other solvents. In 80 parts of absolute ether, in about 50 parts of any fatty oil, and in about 25 parts of chloroform; very soluble in carbon disulphide, yielding a solution which must be handled with the greatest care to prevent evaporation, which would be followed by instant ignition.

Test for Identity.—Melting point, 44° C. (111.2° F.).

Impurities and Tests for Impurities.—To test for *arsenic* and *sulphur* proceed as follows:

Arsenic. Add 1 Gm. of Phosphorus to 10 Cc. of nitric acid diluted with 10 Cc. of distilled water, in a flask having a capacity of 50 Cc., and digest the mixture at a gentle heat on a water-bath while passing a current of carbonic acid gas into the flask over the surface of the liquid until the Phosphorus is dissolved. Transfer the solution to a dish, and evaporate it until no more nitrous vapors are given off, and then dilute the solution to 100 Cc. with distilled water. One Cc. of this solution should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of sulphur. On adding barium chloride T.S. to the remainder of the liquid, not more than a slight opalescence should be produced.

Uses.—Phosphorus is administered internally, in doses of one one-hundredth of a grain (0.0006 Gm.), as a nervous stimulant. Its value in this connection depends upon its being administered in a free state. The oxide of phosphorus, phosphoric acid, does not have the same action; hence all pharmaceutical preparations of phosphorus must be protected from oxidation. (See Pilulæ Phosphori). In large doses Phosphorus is poisonous.

CHAPTER XXXVI

CARBON, BORON, AND SILICON

C; 11.91. B; 10.9. Si; 28.2

THESE three elements present some analogies, and, although the number of pharmaceutical preparations made from them is not great, they are of considerable interest.

Official Preparations and Compounds of Carbon, Boron, and Silicon

Carbo Animalis.—Prepared by burning bones out of contact with air.
Carbo Animalis Purificatus.—Made by purifying animal charcoal with HCl.
Carbo Ligni.—Made by burning wood out of contact with air.
Carbonei Disulphidum.—See preparations of sulphur.
Acidum Boricum.—Made by purifying the natural product.
Sodii Boras.—See preparations of soda.
Kaolinum.—Native aluminum silicate.
Talcum.—Native hydrous magnesium silicate.
Talcum Purificatum.—Purified native hydrous magnesium silicate.

Carbon C; 11.91

Carbon is a very widely diffused element. It is a constituent of all organic substances, and is found in nature in the form of the diamond, graphite, plumbago, coal, etc.

Two compounds with oxygen are known,—carbon dioxide, CO_2, and carbon monoxide, CO.

Carbon dioxide, CO_2, is a colorless, odorless gas, with a slightly acid taste, heavier than ordinary air. It is not combustible, and not a supporter of combustion; indeed, it is used extensively as a means of putting out flames, and is generated for that purpose in fire extinguishers and other contrivances of the same character. Some pharmacists have in their cellars a series of pipes fastened to the ceiling with several outlets; a flexible pipe is connected with a soda water tank or cylinder, and thus one may always have a complete fire extinguisher in the cellar; nothing more is necessary to put out a small fire than to turn on the stopcock and close all doors and windows. Water is capable of absorbing its own volume of carbon dioxide, but many times its volume under pressure. This solution was formerly official, under the name of *Aqua Acidi Carbonici*, or carbonic acid water, the well-known "*soda water.*"

Carbonic acid, H_2CO_3, is produced when carbon dioxide is brought into contact with water.

$$\underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Carbonic}\\\text{Acid}}}{H_2CO_3}$$

The salts known as carbonates are widely diffused in nature, and many chemical processes are based upon the decomposition of carbonates by strong acids. Carbonic acid, although present everywhere, is one of the weakest acids known.

Carbon monoxide, CO, is of little interest in pharmacy.

The compounds of carbon and hydrogen are very numerous, and of great importance. They are mostly obtained from organic substances, and will be considered under Part IV. With nitrogen, carbon forms cyanogen, the compound radical of hydrocyanic or prussic acid.

Tests for Carbonates

1. If decomposed by the addition of a strong acid, and the gas passed through lime water, insoluble calcium carbonate is formed.
2. The solutions of many of the salts of the metals, like iron, copper, lead, etc., are precipitated by the soluble carbonates.

CARBO ANIMALIS. U.S. Animal Charcoal

Charcoal prepared from bone.

Preparation.—Animal charcoal is made by subjecting bones to a red heat in close vessels.

Bone consists of animal matter with calcium phosphate and carbonate. In consequence of the decomposition of the animal matter involved by the destructive distillation, the nitrogen and hydrogen, united as ammonia, distil over, while the greater part of the carbon is left in the cylinder, intermingled with the calcium salts.

The charcoal is termed *bone-black* or *ivory-black*, and in manufacturing it the bones are boiled in water, to separate the fat, before being subjected to destructive distillation in the iron cylinders. These are connected with vessels which receive the ammoniacal liquor, called *bone-spirit*, together with a dark tarry liquid (*bone-oil*).

Official Description.—Dull black, granular fragments, or a dull black powder.

Odor and Taste.—Odorless, nearly tasteless.

Solubility.—*Water.* Insoluble.
Alcohol. Insoluble.

Tests for Identity and Quality.—When ignited, it leaves a grayish or yellowish-white ash, amounting to about 85 percent. of the original weight of the portion taken, which should have been previously dried at 120° to 125° C. (248° to 257° F.) to a constant weight.

The ash should be soluble in hydrochloric acid with the aid of heat, leaving not more than a trifling residue.

If 1 Gm. of Animal Charcoal be boiled for several minutes with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of water, the filtrate should be colorless or nearly so (evidence of *complete carbonization*).

Uses.—Animal charcoal is used to deprive substances of color (see Decoloration, page 219).

CARBO ANIMALIS PURIFICATUS. U.S. Purified Animal Charcoal

	Metric	Old form
* **Animal Charcoal,** in No. 60 powder	100 Gm.	16 oz. av.
Hydrochloric Acid	300 Gm.	40 fl. oz.
Boiling Water, a sufficient quantity		

Introduce the Animal Charcoal into a capacious vessel, add 200 Gm. [old form 26 fl. oz.] of Hydrochloric Acid, and 400 Cc. [old form 4 pints] of Boiling Water. By means of a sand-bath keep the mixture gently boiling during eight hours, adding water occasionally to maintain the original volume. Then add 500 Cc. [old form 5 pints] of Boiling Water, transfer the mixture to a muslin strainer, and, when the liquid has run off, return the Charcoal to the vessel. Add to it

100 Gm. [old form 14 fl. oz.] of Hydrochloric Acid and 200 Cc. [old form 26 fl. oz.] of Boiling Water, boil for two hours, again add 500 Cc. [old form 5 pints] of Boiling Water, transfer the whole to a plain filter, and when the liquid has passed through, wash the residue with Boiling Water until the washings produce only a faint cloudiness with silver nitrate T.S. Dry the powder in a drying oven, and immediately transfer it to well-stoppered vials.

Official Description.—A dull black powder.
Odor and Taste.—Odorless; tasteless.
Solubility.—*Water.* Insoluble.
Alcohol. Insoluble.
Other solvents. Insoluble.

Tests for Quality and Impurities.—*Limit of silicates and other fixed inorganic matter.* If 2 Gm. of the powder be ignited at a red heat with free access of air in a broad, shallow porcelain or platinum dish, it should not leave a residue weighing more than 0.08 Gm., or 4 percent. of the original weight.

If 1 Gm. of the powder be boiled with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of water during three minutes, the filtrate should be colorless (evidence of *complete carbonization*).

Uses.—Its uses are the same as those for animal charcoal; the object of purifying animal charcoal by treatment with hydrochloric acid is to separate the calcium phosphate and carbonate which are invariably present in the crude bone-black. In some decolorizing operations these impurities are harmless, but in many delicate chemical processes they may be dissolved or decomposed, and thus seriously contaminate the products which the charcoal is intended to purify.

CARBO LIGNI. U.S. Charcoal

Charcoal prepared from soft wood, and very finely powdered.

Preparation.—It is made by burning wood out of contact with air, either in iron cylinders or in stacks. In the former case, the volatile substances resulting from the destructive distillation are collected by condensation, and contribute valuable products to pharmacy (see Acidum Aceticum). In the latter, the charcoal is made in the neighborhood of a cheap wood supply. Billets of wood are piled in a conical form, and covered with earth and sod to prevent the free access of air, several holes being left at the bottom and one at the top of the pile in order to produce a draught to commence the combustion. The wood is kindled from the bottom, and soon after ignition the hole at the top is closed, and when the wood is all ignited the holes at the bottom are stopped. The result is that the volatile portions of the wood, hydrogen, oxygen, water, etc., are dissipated, carbon being left.

Official Description.—A black powder, free from gritty matter.
Odor and Taste.—Odorless; tasteless.
Test for Identity.—If 1 Gm. of Charcoal be boiled with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of water for several minutes, the filtrate should be colorless or nearly so (evidence of *complete carbonization*).

Uses.—Charcoal is used in medicine as an absorbent and disinfectant. It is given in the form of powder, in doses of one to two drachms (4 to 8 Gm.). Owing to its absorbent powers, it should never be kept exposed to the air, as it will become unfit for use if subjected to the atmosphere of a laboratory or pharmacy. Tin cans with tightly fitting covers are appropriate containers.

Boron B; 10.9

Boron, like carbon, exists in three allotropic conditions,—amorphous, crystallized, and graphitoidal. Boron combines with hydrogen and oxygen, and boric (or boracic) acid is produced, H_3BO_3, the principal salt of which is sodium borate, or borax.

Tests for Borates and Boric Acid

1. A colorless flame is tinged green by an alcoholic solution of boric acid.

2. A solution of a borate, slightly acidified by hydrochloric acid, turns the yellow color of turmeric paper brown, if the paper is allowed to dry.

Official Compounds and Preparations of Boron

Acidum Boricum Boric Acid	Found native, and made by decomposing sodium borate with HCl
Unguentum Acidi Borici Ointment of Boric Acid	Ten percent. of Boric Acid with petrolatum and paraffin
Glyceritum Boroglycerini Glycerite of Boroglycerin	A solution of boric acid in glycerin used as a preservative
Sodii Boras Sodium Borate Borax	Made by purifying native borax or from boric acid by treating a solution with sodium carbonate and crystallizing
Liquor Antisepticus Antiseptic Solution	An aqueous solution of boric acid containing volatile oils, benzoic acid, thymol and alcohol

Unofficial Compounds of Boron

Acidum Metaboricum, HBO_2 Metaboric Acid	By heating boric acid to 38° C. (100° F.)
Acidum Pyroboricum, $H_2B_4O_7$ Pyroboric Acid	By heating boric acid for a long time to 60° C. (140° F.)
Boron Trisulphidum, B_2S_3 Boron Trisulphide	By heating boron in the vapor of sulphur and collecting the resulting white mass

ACIDUM BORICUM. U.S. Boric Acid

$H_3BO_3 = 61.54$

[BORACIC ACID]

It should contain not less than 99.8 percent. of pure Boric Acid $[B(OH)_3]$.

Preparation.—The lagoons of the volcanic districts of Tuscany formerly furnished the greater part of the boric acid and borax of commerce. Borax is now found native in California and some of the other Western States, and boric acid is produced by decomposing borax with hydrochloric acid.

$$\underset{\text{Sodium Borate}}{Na_2B_4O_7.10H_2O} + \underset{\text{Hydrochloric Acid}}{2HCl} = \underset{\text{Sodium Chloride}}{2NaCl} + \underset{\text{Boric Acid}}{4H_3BO_3} + \underset{\text{Water}}{5H_2O}$$

Boric Acid is required in very fine powder for most medical uses.

Official Description.—Transparent, colorless scales, of a somewhat pearly lustre, or six-sided, triclinic crystals, or a light, white, very fine powder, slightly unctuous to the touch; permanent in the air.

Odor, Taste, and Reaction.—Odorless; faintly bitter taste; acid reaction.

Solubility.—*Water.* In 18 parts at 25° C. (77° F.); in 3 parts of boiling water. The addition of hydrochloric acid decreases its solubility.

Alcohol. In 15.3 parts at 25° C. (77° F.); in 4.3 parts of boiling alcohol.

Other solvents. In 4.6 parts of glycerin at 25° C. (77° F.).

Tests for Identity.—When heated to 100° C. (212° F.), Boric Acid loses water, forming metaboric acid (HBO_2), which slowly volatilizes at that temperature.

Heated to 160° C. (320° F.), it fuses to a glassy mass of tetraboric (or pyroboric) acid ($H_2B_4O_7$); at a higher temperature the fused mass swells up, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent, hygroscopic, non-volatile mass.

Boric Acid readily volatilizes from a boiling aqueous solution.

Its solution in alcohol or glycerin, when ignited, burns with a flame enveloped with a green-colored mantle.

An aqueous solution of Boric Acid (1 in 50) colors blue litmus paper red, and yellow turmeric paper brownish-red after drying, even when the solution has been acidulated with hydrochloric acid; this brownish-red color is changed to bluish-black by ammonia water.

If 1 Gm. of Boric Acid be added to 10 Cc. of boiling alcohol in a test-tube, complete solution should result.

Impurities and Tests for Impurities.—*Limit of sulphates.* The aqueous solution of the Acid (1 in 20) should not at once become more than slightly cloudy after the addition of barium chloride T.S.; nor

Limit of chlorides. Immediately more than opalescent by the addition of silver nitrate T.S. with nitric acid;

Absence of calcium. It should not be precipitated by ammonium oxalate T.S.

Magnesium. Sodium phosphate T.S. and ammonia water, or

Heavy metals. Respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the saturated aqueous solution should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of iron. In a solution of 1 Gm. of Boric Acid in a mixture of 1 Cc. of hydrochloric acid and 49 Cc. of water, 0.5 Cc. of potassium ferrocyanide T.S. should not at once produce a blue color.

Quantitative Test.—One Gm. of Boric Acid, when dissolved in 50 Cc. of distilled water, after the addition of 50 Cc. of glycerin, should require not less than 16.2 Cc. of normal sodium hydroxide V.S., for neutralization (corresponding to at least 99.8 percent. of Boric Acid), phenolphthalein T.S. being used as indicator.

Uses.—Boric acid is used in antiseptic surgery, and externally in the form of an ointment. It is added in small quantities to various liquids, to prevent fermentation. It is well adapted for such uses, as it communicates but little taste. It has not been proved to be innocuous, however, and therefore should be sparingly used. (See Boroglycerinum, Part VI. ; also Glyceritum Boroglycerini, page 307, and Unguentum Acidi Borici, Part V.)

LIQUOR ANTISEPTICUS. U.S. Antiseptic Solution

	Metric	Old form
***Boric Acid**	20.00 Gm.	300 grains
Benzoic Acid	1.00 Gm.	15 grains
Thymol	1.00 Gm.	15 grains
Eucalyptol	0.25 Cc.	4 minims
Oil of Peppermint	0.50 Cc.	8 minims
Oil of Gaultheria	0.25 Cc.	4 minims
Oil of Thyme	0.10 Cc.	1½ minims
Alcohol	250.00 Cc.	8 fl. oz.
Purified Talc	20.00 Gm.	300 grains
Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Dissolve the Boric Acid in 700 Cc. [old form 22½ fl. oz.] of Water, and the Benzoic Acid in 150 Cc. [old form 5 fl. oz.] of Alcohol, and pour the aqueous solution into the alcoholic solution. Then dissolve, in a mortar, the Thymol in the Eucalyptol and Oils of Peppermint, Gaultheria, and Thyme; thoroughly incorporate the Purified Talc, and add, with constant trituration, the solution first prepared. Allow the mixture to stand, with occasional agitation, during forty-eight hours, filter, add 100 Cc. [old form 3 fl. oz.] of Alcohol to the clear filtrate, and a sufficient quantity of Water to make the finished product measure 1000 Cc. [old form 2 pints].

Uses.—This solution was introduced into the U. S. P. (8th Rev.) to furnish to physicians a formula for an antiseptic solution which experience has shown to be useful and which will obviate the difficulty of the present lack of uniformity in the solutions now in use. It is sometimes given internally in the dose of one fluidrachm (4 Cc.).

Silicon Si; 28.2

Very few of the compounds of the non-metallic element silicon are used medicinally. Silicon, like carbon and boron, is obtained in three allotropic states,—amorphous, crystalline, and graphitoidal. In some of its combinations, notably in glass, earthenware, china, mortar, and cements of various kinds, it is of vast importance commercially. Silicon is found in nature combined with aluminum, magnesium, or calcium, in *pumice stone*, *meerschaum*, *asbestos*, *talcum*, *soapstone*, etc.; or as an anhydride (silica), in *sand*, *flint*, *agate*, *quartz*, etc.

Silica, SiO_2, may be obtained in a pure condition by treating a solution of sodium silicate with hydrochloric acid.

$$\underset{\substack{\text{Sodium}\\\text{Silicate}}}{Na_2SiO_3} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{2HCl} = \underset{\text{Silica}}{SiO_2} + \underset{\substack{\text{Sodium}\\\text{Chloride}}}{2NaCl} + \underset{\text{Water}}{H_2O}$$

Test for Silicates

Silicates are insoluble in most reagents. If the soluble sodium and potassium silicates, in aqueous solution, be neutralized with hydrochloric acid, and ammonia water be added in excess, a gelatinous precipitate of silicic hydroxide will separate.

Official Compounds of Silicon

Kaolinum, Kaolin. Aluminum Silicate, $H_2Al_2Si_2O_8 + H_2O$	Used in making cataplasm of kaolin
Talcum, Talc. Magnesium Silicate, Mg_2SiO_3	Used when powdered as an absorbent
Talcum Purificatum. Purified Talc	Used in making medicated waters

Unofficial Compounds of Silicon

Silicon Dioxide, SiO_2, Silica	
Quartz (crystalline) in form of:	Amethyst, a gem Smoky quartz, a gem Rose quartz, a gem Granite, building stone Gneiss, building stone Syenite, building stone Sand, used in the manufacture of pottery, glass, and for many other purposes Pumice stone, volcanic rock Obsidian, volcanic glass Agate, mortars for chemists' use Kieselguhr (diatomaceous earth) used in the making of dynamite as an absorbent
Glass	Green Glass made from sand, soda ash, sodium nitrate, lime Blue Glass made from sand, soda ash, sodium nitrate, lime, antimony, manganese, and cobalt Flint Glass made from sand, soda ash, sodium nitrate, lime, antimony, and manganese Opal Glass made from sand, soda ash, sodium nitrate, zinc, fluorspar, cryolite, China clay, antimony, and manganese Amber Glass made from sand, soda ash, lime, salt, and carbon Lead Glass made from sand, soda ash, potash, sodium nitrate, lead, antimony, and manganese

Unofficial Compounds of Silicon—*Continued*

Meerschaum. Magnesium Silicate, Mg_2SiO_8	Used in making tobacco-pipes
Asbestos. Magnesium Silicate	Used for resisting action of fire, or heat
Sodium Silicate Liquor Sodii Silicatis Solution of Sodium Silicate. U. S. P. 1890	Made by fusing one part of fine sand and two parts of dried sodium carbonate, mixed in powder, in an earthenware crucible, pouring out the fused mass on a stone slab to cool, powdering, dissolving the soluble matter in boiling water, filtering and concentrating so as to contain about 30 percent. of sodium silicate

KAOLINUM. U. S. Kaolin

A native aluminum silicate, consisting chiefly of the pure silicate [$H_2Al_2Si_2O_8 + H_2O = 257.12$], powdered and freed from gritty particles by elutriation.

Kaolin is an official substance introduced for the first time in the U. S. P. (8th Rev.). The name is derived from the Chinese word "kaoling," meaning "high ridge," the name of a hill in China; it is sometimes called *China clay*, or *porcelain clay*, and is a valuable commercial product. Besides aluminum silicate, it often contains small quantities of aluminum hydroxide, ferric oxide, magnesium oxide, and calcium carbonate. For pharmaceutical purposes it should be purified by treatment with hydrochloric acid if calcium carbonate be present, and afterwards with diluted sulphuric acid to remove the other impurities; the kaolin should be thoroughly washed with water to remove the chlorides and sulphates.

Official Description.—A soft, white or yellowish-white powder, or in lumps.

Taste and Reaction.—Earthy or clay-like taste. When moistened with water, Kaolin assumes a darker color and develops a marked clay-like odor.

Solubility.—*Water.* Insoluble.

Other solvents. Insoluble in cold dilute solutions of the acids and alkali hydroxides.

Tests for Identity.—If 1 Gm. of Kaolin be mixed with 10 Cc. of water and 5 Cc. of sulphuric acid in a porcelain dish, no effervescence should occur, and if the mixture be evaporated until the excess of water has been removed, and further heated until dense white fumes of sulphuric acid anhydride appear, then after cooling and adding 20 Cc. of water, boiling for a few minutes and filtering, there should remain on the filter a gray insoluble residue of *impure silica*.

If to one-half of the filtrate ammonia water be added, a gelatinous precipitate of *aluminum hydroxide*, insoluble in excess, should be obtained.

If to the remaining half of the filtrate, sodium hydroxide T.S. be added, it should yield a gelatinous precipitate which is almost or completely soluble in an excess of the reagent.

Impurities and Tests for Impurities.—*More than traces of iron.* If 2 Gm. of Kaolin be rubbed in a mortar with 10 Cc. of water, the mixture should not acquire more than a slight reddish tint on the addition of 0.5 Gm. of sodium salicylate.

If Kaolin be ignited at a red heat, it should leave not less than 85 percent. of non-volatile residue.

Uses.—Kaolin forms the solid basis for the cataplasm of kaolin (Cataplasma Kaolini), and when purified it may be used as an absorbent in making medicated waters.

CATAPLASMA KAOLINI. U. S. Cataplasm of Kaolin

	Metric	Old form
* **Kaolin**, in very fine powder	577.0 Gm.	9 oz. av. 100 gr.
Boric Acid, in very fine powder	45.0 Gm.	315 grains
Thymol	0.5 Gm.	4 grains
Methyl Salicylate	2.0 Gm.	14 grains
Oil of Peppermint	0.5 Gm.	4 grains
Glycerin	375.0 Gm.	6 oz. av.
To make about	1000 Gm.	16 oz. av.

Heat the Kaolin in a suitable vessel at 100° C. (212° F.), with occasional stirring, for one hour; mix it intimately with the Boric Acid, and then incorporate the mixture thoroughly with the Glycerin; finally add the Thymol, which has been dissolved in the Methyl Salicylate and the Oil of Peppermint, and make a homogeneous mass. It should be kept in an air-tight container.

Uses.—The large demand for an external application containing glycerin led to the introduction of this cataplasm in the U. S. P. (8th Rev.); it is used to allay inflammation in the treatment of pneumonia, boils, carbuncles, etc., and in dermatological practice.

TALCUM. U. S. Talc

A native hydrous magnesium silicate.

Talc, also called *French Chalk*, or *Soapstone*, is found in America and other parts of the world; an excellent quality is now obtained from North Carolina.

Official Description.—A white or grayish-white powder or grayish-green irregular masses of waxy lustre; when rubbed upon the skin it imparts a feeling like greasiness; permanent in the air.

Odor and Taste.—Inodorous and tasteless.

Specific Gravity.—2.2 to 2.8.

Solubility.—*Water.* Insoluble.

Other solvents. Insoluble in dilute solutions of the acids and alkali hydroxides.

Tests for Identity.—Mix 0.5 Gm. of Talc with about 2 Gm. each of anhydrous sodium and potassium carbonates, heat the mixture in a platinum crucible until fusion is complete, and treat the resulting fused mass with hot water; then neutralize the liquid with diluted sulphuric acid, and, after adding an additional 10 Cc. of the latter, evaporate the mixture until the white fumes of sulphuric anhydride are evolved, then add 20 Cc. of water, and, after boiling the mixture and filtering, an insoluble residue of *silica* should be left. If to the filtrate ammonia water and ammonium chloride T.S. be added, a white, gelatinous precipitate of *aluminum hydroxide* may be formed, while the filtrate from this, upon the addition of sodium phosphate T.S., should yield a white, crystalline precipitate (*magnesium salts*).

Impurities and Tests for Impurities.—If 1 Gm. of Talc be boiled with 25 Cc. of diluted hydrochloric acid for one-half hour, adding water from time to time to maintain approximately the original volume, and the liquid filtered, then the filtrate should yield, upon evaporating to dryness, igniting, and quickly weighing, not more than 0.05 Gm. of residue.

Uses.—Powdered talc when purified (Talcum Purificatum) is used pharmaceutically as an absorbent in making medicated water. It is used extensively when perfumed or medicated as a toilet powder under the name of *Talcum Powder*.

TALCUM PURIFICATUM. U.S. Purified Talc

	Metric	Old form
* **Talc**, in fine powder	**500 Gm.**	16 oz. av.
Hydrochloric Acid	**75 Cc.**	2½ fl. oz.
Water, a sufficient quantity		

Mix the powdered Talc with 2500 Cc. [old form 5 pints] of boiling Water, gradually add 50 Cc. [old form 1½ fl. oz.] of the Hydrochloric Acid, and boil the mixture during fifteen minutes, then allow it to stand for fifteen minutes. Decant, and reject the supernatant liquid containing the finer particles of Talc in suspension, and again boil the residue with 2500 Cc. [old form 5 pints] of Water, mixed with the remainder of the Hydrochloric Acid, and allow it to stand for fifteen minutes. Again decant, and reject the finer suspended particles, and wash the coarser residue with Water by repeated decantation, until a portion of the wash-water, after filtering and acidifying with nitric acid, fails to become opalescent upon the addition of silver nitrate test solution. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it at 110° C. (230° F.).

Talc, as found in commerce, contains the impurities usually associated with native mineral substances. When treated with hydrochloric acid and water, as in this official process, aluminum, iron, and magnesium salts are removed.

Impurities and Tests for Impurities.—Purified Talc, when subjected to ignition at red heat, should lose not more than 5 percent. of its weight.

Limit of soluble substances. If 10 Gm. of Purified Talc be boiled with 50 Cc. of distilled water for one-half hour, adding water from time to time to maintain approximately the original volume, it should yield a filtrate which is neutral to litmus paper, and one-half of this filtrate, when evaporated and dried at 110° C. (230° F.), should yield not more than 0.005 Gm. of residue.

Iron. The remaining half of the filtrate, after slightly acidulating with hydrochloric acid, should not yield a blue color upon the addition of potassium ferrocyanide T.S.

Uses.—Purified Talc is used in making medicated waters (see Aquæ, page 272, and Talcum, page 508).

CHAPTER XXXVII

THE ALKALIES AND THEIR COMPOUNDS

Potassium, Sodium, Lithium, and Ammonium

K; 38.86. Na; 22.88. Li; 6.98. NH_4; 17.93

THE alkalies are bodies having strongly marked physical and chemical properties: 1. They combine with acids to form salts. 2. They restore the color of reddened litmus paper, and change the colors of vegetable blues to green, and of vegetable yellows to brown. 3. Their taste is never sour, but it is characteristic, and caustic if the alkali is in concentrated solution. The salts formed by their combinations with acids possess acid, alkaline, or neutral reactions according to the relative strength and proportion of the component parts.

The metals known as alkali metals, which form compounds of pharmaceutical interest, are potassium, sodium, and lithium. They are all univalent, and of a white color resembling that of silver, and are so prone to oxidation that they must be kept constantly immersed in some hydrocarbon or body free from oxygen, like naphtha or petroleum. They are so soft that they can be easily cut with a penknife. They float upon water, and inflame spontaneously and immediately when brought in contact with it.

The alkali metals are often called light metals, on account of their low specific gravity when compared with the others.

Their carbonates are all soluble in water, and each metal forms but one chloride.

Their oxides are strongly basic, restoring the color of reddened litmus quickly. The oxides are also very soluble in water, forming caustic and powerfully alkaline hydroxides, which cannot be decomposed by heat.

Their sulphates, phosphates, nitrates, sulphides, chlorides, bromides, iodides, and nearly all their salts, are soluble in water, are almost without exception colorless, or of an opaque white color, and many of them, if heated to redness, fuse without decomposition.

The processes for obtaining the metals are very similar, and formerly consisted in exposing their carbonates, intimately mixed with finely powdered charcoal, in suitable iron vessels, to an intense heat; carbon monoxide is liberated, and the vapors of the metals are condensed in flattened receivers. They are also largely made by electrolysis by subjecting the alkali hydroxide to a strong electric current.

Ammonium is a compound radical, NH_4, but has so many analogies with the alkali metals that it is classed with them.

CHAPTER XXXVIII

THE POTASSIUM SALTS

THE salts of potassium are among the most important of any that are used in medicine. They are generally very soluble, and, with a few exceptions, are colorless or of an opaque white color. The sole source of the potassium salts was formerly wood ashes, but at present cheaper sources have been discovered. The wood ashes were lixiviated, the liquid containing the soluble salts evaporated to dryness, and the residue allowed to cool. This constituted the crude *potash* of commerce.

Potash is now made from the ashes from beet sugar residues, from *suint*, the residue obtained by evaporating the water used to scour the fleeces of sheep, and from an impure potassium chloride obtained from the Stassfurt mines in Germany, which is now the principal source of the potassium compounds.

The salts are converted into potassium sulphate, and this into carbonate by heating with coal and limestone. For the purpose of converting the sulphate into the carbonate, it is heated in a reverberatory furnace with the proper quantity of coal and limestone, with the coal in order to form potassium sulphide, and with the limestone to convert the sulphide into carbonate, the sulphur uniting with the calcium to form calcium sulphide. The mass, after cooling, is lixiviated with water, and this solution of impure potassium carbonate is filtered to separate the insoluble calcium sulphide, and subsequently treated with milk of lime, by which insoluble calcium carbonate is precipitated, and potassium hydroxide in solution remains. The liquid is then evaporated to dryness.

Tests for Potassium Salts

Potassium may be recognized in its combinations by the following tests :

1. The addition of platinic chloride with a little alcohol and a few drops of hydrochloric acid produces a yellow crystalline precipitate, $PtCl_4 2KCl$ (double platinum and potassium chloride).
2. With an excess of concentrated solution of tartaric acid, a white crystalline precipitate is slowly formed when a strong solution of a potassium salt is added with stirring. This is the well known acid potassium tartrate (cream of tartar).
3. A colorless flame is tinted violet by pure potassium salts.
4. Potassium salts are soluble in water, and not volatile at a red heat.

Official Potassium Salts and Preparations

Official Name	Preparation
With Inorganic Radicals	
Potassii Bicarbonas	By passing carbon dioxide into a solution of carbonate, evaporating and crystallizing
Bromidum	By treating solution of potassium hydroxide with bromine and charcoal
Carbonas	By purifying pearlash by dissolving it in water, filtering, evaporating, and granulating
Chloras	By reacting on potassium chloride with calcium hypochlorite and by electrolysis
Cyanidum	By fusing potassium ferrocyanide with potassium carbonate, separating the insoluble precipitate of metallic iron, and pouring the fused mass on a slab
Dichromas	By treating potassium chromate with sulphuric acid, evaporating and crystallizing
Ferrocyanidum	By heating nitrogenized substances with iron and potassium hydroxide
Hydroxidum	From the ashes of plants, etc., by lixiviating, concentrating the solutions, evaporating to dryness, purifying by treating a diluted solution with lime, evaporating, fusing, and casting into moulds
Hypophosphis	By precipitating calcium hypophosphite with potassium carbonate
Iodidum	By treating solution of potassium hydroxide with iodine, evaporating to dryness, and heating with charcoal
Nitras	By decomposition of sodium nitrate with potassium chloride
Permanganas	By heating together manganese dioxide, potassium chlorate, and potassium hydroxide
Sulphas	By purifying the residue from nitric acid manufacture, and from other sources.
Liquor Potassii Arsenitis	By boiling potassium bicarbonate with arsenic trioxide and adding a small quantity of compound tincture of lavender.
Potassii Hydroxidi	About 5 percent. solution of potassium hydroxide made by dissolving the hydroxide in water
Trochisci Potassii Chloratis	Each troche contains two and a half grains of potassium chlorate, with sugar, tragacanth, and sufficient water to form a mass
With Organic Radicals	
Potassii Acetas	By decomposing potassium bicarbonate with acetic acid, and evaporating the filtered solution, carefully avoiding contact with iron
Bitartras	By purifying argol, the sediment deposited in wine casks during fermentation
Citras	By decomposing potassium bicarbonate with citric acid, evaporating and granulating
Citras Effervescens	By mixing finely powdered potassium citrate, sodium bicarbonate, tartaric acid, and citric acid, heating the mixture until it becomes uniformly moist, granulating, and drying
et Sodii Tartras	By treating solution of potassium bitartrate with sodium carbonate
Liquor Potassii Citratis	8 parts of potassium bicarbonate with 6 parts of citric acid in 100 parts of water

Unofficial Potassium Salts and Preparations

Potassa cum Calce. U. S. P. 1890	By mixing equal parts of well dried potassium hydroxide and lime
Potassa Sulphurata. U. S. P. 1890	By melting potassium hydroxide and sulphur together in a crucible, pouring the liquid on a slab and cooling
Potassii Antimonias, $KSbO_3$ Potassium Antimoniate	Deflagrating 1 part metallic antimony with 4 parts potassium nitrate, and lixiviating with water
Potassii Bisulphas, $KHSO_4$ Potassium Bisulphate	Residue remaining in retort on preparing nitric acid from potassium nitrate and sulphuric acid
Potassii Bisulphis, $KHSO_3$ Potassium Bisulphite	Passing an excess of sulphurous acid gas into a concentrated solution of potassium carbonate
Potassii Borotartras Potassium Borotartrate	Dissolve by heat 4 parts potassium bitartrate, and 1 part boric acid in 10 parts water, and evaporate to dryness
Potassii Chloridum, KCl Potassium Chloride	Obtained as a by-product in many salts

Unofficial Potassium Salts and Preparations—*Continued*

Potassii Chromas, K_2CrO_4 Potassium Chromate	Add potassium carbonate to a hot solution of potassium dichromate until effervescence ceases
Potassii et Ammonii Tartras, $KNH_4C_4H_4O_6$ Potassium and Ammonium Tartrate	Diffuse 1 part potassium bitartrate in 3 parts boiling water; then add ammonium carbonate until effervescence ceases; filter and crystallize
Potassii et Sodii Borotartras Potassium and Sodium Borotartrate	Dissolve 2 parts sodium borate in 20 parts distilled water, and digest with 5 parts potassium bitartrate
Potassii Ferricyanidum, $K_6Fe_2Cy_{12}$ Potassium Ferricyanide	Pass chlorine gas into a cold solution of potassium ferrocyanide until it ceases to produce a blue precipitate with ferric chloride
Potassii Iodas, KIO_3 Potassium Iodate	Pass chlorine gas into cold water containing iodine in suspension until wholly dissolved; then add potassium chlorate and warm. Dose, 6 to 8 grains (0.3 to 0.5 Gm.)
Potassii Iodohydrargyras, $(2KI.HgI_2)3H_2O$ Potassium Iodohydrargyrate (Potassio-Mercuric Iodide)	Dissolve 3 parts mercuric iodide in a concentrated solution of potassium iodide containing 2 parts of the salt; when cool, yellow prisms will deposit from the mother liquor. Dose, one-twelfth of a grain (0.005 Gm.)
Potassii Nitris, KNO_2 Potassium Nitrite	Made by heating the nitrate to redness and separating undecomposed nitrate; by dissolving the fused mass in water the nitrate will crystallize out; the mother liquor is treated with diluted acetic acid and twice its volume of alcohol, to separate more nitrate. The nitrite may be obtained by evaporating the solution over sulphuric acid. Dose, 3 grains (0.2 Gm.)
Potassii Perchloras, $KClO_4$ Potassium Perchlorate	Heat potassium chlorate until it melts; keep at this temperature until gas ceases to be evolved, and a portion tested with strong HCl acquires only a faint yellow color. Purify
Potassii Platinocyanidum, $2KCN.Pt(CN)_2.3H_2O$ Potassium Platinocyanide	Mix concentrated solutions of 1 part exsiccated platinic chloride and 2 parts potassium cyanide; heat until the precipitate is redissolved
Potassii Pyrosulphis, $K_2(SO)_2O$ Potassium Pyrosulphite	Pass sulphurous acid gas into a warm, saturated solution of potassium carbonate; on cooling, it deposits crystals
Potassii Salicylas, $(KC_7H_5O_3)_2.H_2O$ Potassium Salicylate	Dissolve 7 parts potassium bicarbonate in water; then add gradually 10 parts salicylic acid, and evaporate
Potassii Silicas, K_2SiO_3 Soluble glass	Fuse 10 parts potassium carbonate, 15 parts fine sand, and 1 part charcoal
Potassii Sulphidum, K_2S Potassium Sulphide	Pass hydrogen sulphide gas into a solution of potassium hydroxide as long as it is absorbed, and add an equal bulk of potassium hydroxide solution; evaporate
Potassii Sulphis, $K_2SO_3 + 2H_2O$ Potassium Sulphite	Pass sulphurous acid gas through a solution of potassium carbonate
Potassii Sulphocarbonas, K_2CS_3 Potassium Sulphocarbonate	Mix a solution of potassium sulphide with carbon disulphide; on evaporation, orange-yellow crystals are deposited
Potassii Sulphocyanas, KSCN Potassium Sulphocyanate	Melt together 17 parts potassium carbonate, 32 parts sulphur, and 46 parts anhydrous potassium ferrocyanide, and heat to low redness. When cool, treat with boiling alcohol
Potassii Tartras Potassium Tartrate	By treating solution of potassium bitartrate with potassium carbonate
Mistura Potassii Citratis. U. S. P. 1880 Neutral Mixture	By neutralizing 100 parts of lemon juice with 10 parts of potassium bicarbonate

POTASSII HYDROXIDUM. U.S. Potassium Hydroxide

$KOH = 55.74$

[Potassa, Pharm. 1890 Caustic Potash, Potassium Hydrate]

It should contain not less than 85 percent. of pure anhydrous Potassium Hydroxide, and not more than 2 percent. of other inorganic substances, with the exception of water. It should be kept in well-stoppered bottles made of hard glass.

Preparation.—Potassium Hydroxide, called commercially caustic potash, is made by evaporating a solution of potassium hydroxide rapidly in a silver or clean iron vessel until a fluid of oily consistence remains, a drop of which, when removed on a warm glass rod, solidifies on cooling. The hot caustic is poured into cylindrical moulds, and while the sticks are still warm they are bottled quickly, to prevent deliquescence.

Pure caustic potassium hydroxide is sometimes prepared in the form of powder by stirring the fused mass rapidly with a silver spatula until a granulated powder is formed. This must be placed in warm dry bottles and quickly sealed hermetically.

Potassa by Alcohol and *Potassa by Barytes* are terms used to designate pure caustic Potassium Hydroxide made by purifying with alcohol and barium hydroxide, alcohol dissolving only the potassium hydroxide, while the sulphate is separated by treatment with baryta water, forming the insoluble barium sulphate.

Official Description.—Dry, white or nearly white flakes, fused masses, or in pencils, hard and brittle, showing a crystalline fracture. Exposed to the air it readily absorbs carbon dioxide and moisture, and deliquesces.

Odor, Taste, and Reaction.—Odorless, or having a faint odor of lye, and a very acrid and caustic taste. *Great caution is necessary in tasting and handling it,* as it rapidly destroys organic tissues; intensely alkaline reaction.

Solubility.—Water. In about 0.4 parts at 25° C. (77° F.); very soluble in boiling water.

Alcohol. In 2 parts of alcohol; very soluble in boiling alcohol.

Other solvents. Slightly soluble in ether.

Tests for Identity.—When heated to about 530° C. (986° F.), Potassium Hydroxide melts to a clear, oily liquid, and at a bright red heat is volatilized unchanged. When introduced into a non-luminous flame, it imparts to it a violet color.

The aqueous solution (1 in 20) should be perfectly clear and colorless.

A concentrated solution of Potassium Hydroxide, after acidulation with hydrochloric acid yields a bright yellow precipitate with platinic chloride T. S.

A concentrated, aqueous solution (1 in 10), when added to an excess of tartaric acid T. S. produces a white, crystalline precipitate, which redissolves when the Potassium Hydroxide is added in excess.

Impurities and Tests for Impurities.—*Heavy Metals.* An aqueous solution of Potassium Hydroxide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of Carbonate. On adding an excess of diluted sulphuric acid to 10 Cc. of an aqueous solution of Potassium Hydroxide (1 in 10), no distinct effervescence should occur.

Quantitative Test.—Introduce about 1 Gm. of Potassium Hydroxide into a stoppered weighing bottle and weigh accurately. Dissolve this in about 50 Cc. of water and titrate the solution with normal sulphuric acid V. S., using methyl-orange T. S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V. S. consumed, by 5.574, and divide this product by the weight of the Potassium Hydroxide taken; the quotient, which must be not less than 85, represents the percentage of Potassium Hydroxide present.

Uses.—Potassium Hydroxide is used as a caustic, principally, however, in veterinary practice; the end of the stick may be inserted into a section of rubber tubing, or wrapped several times with tin foil, to avoid cauterizing the finger of the operator. When this form of potassium hydroxide is used for making official solution of potassium hydroxide, care should be taken to allow for the moisture contained in it; commercial caustic potash rarely contains less than 30 percent. of water.

LIQUOR POTASSII HYDROXIDI. U.S. Solution of Potassium Hydroxide

[Liquor Potassæ, Pharm. 1890 Solution of Potassa]

An aqueous solution, containing about 5 percent. of Potassium Hydroxide [KOH = 55.74].

	Metric	Old form
• **Potassium Hydroxide**	60 Gm.	1 oz. av. 20 gr.
Distilled Water	940 Gm.	15 fl. oz.
To make	1000 Gm.	1 pint

Dissolve the Potassium Hydroxide in the Distilled Water and add enough Distilled Water to weigh 1000 Gm. [or measure, old form, 1 pint].

The Potassium Hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (85 percent.). Potassium Hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken ; the proper amount for the above formula being ascertained by dividing 5100 by the percentage of absolute Potassium Hydroxide contained therein.

Solution of Potassium Hydroxide should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum.

Solution of Potassium Hydroxide was formally made by decomposing 85 Gm. of potassium bicarbonate through the action of 40 Gm. of Lime slaked with 20 Cc. of water with heat. The mixture was made up to 1000 Gm. and the clear solution decanted. The direction to heat the solution of potassium bicarbonate until effervescence ceases was for the purpose of driving off as much of the carbonic acid as possible by the simplest method ; the remainder was disposed of through double decomposition, as shown by the equation

$$\begin{array}{ccccccc} K_2CO_3 & + & Ca(HO)_2 & = & 2KHO & + & CaCO_3 \\ \text{Potassium} & & \text{Calcium} & & \text{Potassium} & & \text{Calcium} \\ \text{Carbonate} & & \text{Hydroxide} & & \text{Hydroxide} & & \text{Carbonate} \end{array}$$

Preference was given to the bicarbonate as the source of the potassium, because the cheaper carbonates nearly always contain silicates and other impurities in sufficient quantities to render the product inferior.

In making this solution in this way the proportion of water is not a matter of indifference. The quantity used should be at least five times as great as that of the bicarbonate, and the lime must greatly exceed the amount indicated by theory.

Official Description.—A clear, colorless liquid.

Odor, Taste, and Reaction.—Odorless ; a very acrid and caustic taste ; strongly alkaline reaction.

Specific Gravity.—About 1.046 at 25° C. (77° F.).

Tests for Identity.—It should conform to the reactions and tests for an aqueous solution of potassium hydroxide given under *Potassii Hydroxidum.*

Quantitative Test.—To neutralize 28 (27.87) Gm. of Solution of Potassium Hydroxide should require about 25 Cc. of normal sulphuric acid V.S., methyl-orange T.S. being used as indicator (each Cc. of normal sulphuric acid V.S. indicating 0.2 percent. of absolute Potassium Hydroxide).

Uses.—Solution of potassium hydroxide is a valuable antacid when given in doses of fifteen minims (1 Cc.), diluted with milk. If a large quantity should be swallowed accidentally, the proper antidotes would be mild acid liquids, like vinegar or lemon juice, accompanied with bland oils.

POTASSII ACETAS. U.S. Potassium Acetate

$KC_2H_3O_2 = 97.44$

It should contain, when thoroughly dried, not less than 98 percent. of pure Potassium Acetate [$CH_3.COOK$], and should be kept in well-stoppered bottles.

Preparation.—This salt may be made by adding crystals of potassium bicarbonate to pure acetic acid until effervescence ceases, and, after acidulating slightly with a few drops of the acid, cautiously evaporating to dryness in a porcelain evaporating dish by means of a sand-bath. Great care is necessary to avoid contamination with iron, and it is not safe to use an enamelled iron dish.

$$\underset{\substack{\text{Potassium}\\\text{Bicarbonate}}}{KHCO_3} + \underset{\text{Acetic Acid}}{HC_2H_3O_2} = \underset{\substack{\text{Potassium}\\\text{Acetate}}}{KC_2H_3O_2} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

The manufacturer nearly always uses the carbonate in making potassium acetate, instead of the bicarbonate, because it is much cheaper. The product from the carbonate is apt to be impure, however, because of the silica, sulphate, chlorides, etc., always present in the ordinary carbonate.

Official Description.—A white powder, or in crystalline masses of a satin-like lustre. Very deliquescent on exposure to the air.

Odor, Taste, and Reaction.—Odorless; warming, saline taste; the aqueous solution (1 in 20) is alkaline to litmus paper, but does not affect phenolphthalein T.S.

Solubility.—*Water.* In 0.4 part at 25° C. (77° F.); much more soluble with increasing temperature.

Alcohol. In 2 parts at 25° C. (77° F.); much more soluble with increasing temperature.

Tests for Identity.—When heated to 292° C. (557.6° F.), the salt fuses. At a higher temperature it decomposes, blackens, and evolves vapors having an empyreumatic odor (an alliaceous odor would indicate the presence of *arsenic*), and finally, if ignited on platinum, it leaves a white residue, which should be completely soluble in water.

The addition of sodium bitartrate T.S. to the concentrated aqueous solution of the salt causes a white, crystalline precipitate.

If a few particles of the salt be added to a mixture of 1 Cc. of sulphuric acid and 1 Cc. of alcohol, acetic ether will be formed, recognizable by its odor.

The addition of a little ferric chloride T.S. to a solution of the salt produces a deep red color, and, upon boiling, a pale brown, flocculent precipitate of basic ferric acetate separates.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of an aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Quantitative Test.—If 1 Gm. of dry Potassium Acetate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 20.1 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Potassium acetate is a reliable diuretic when given in doses of twenty grains to one drachm (1.2 to 4 Gm.). In larger doses it acts as a cathartic.

POTASSII BICARBONAS. U.S. Potassium Bicarbonate

$KHCO_3 = 99.41$

It should contain not less than 99 percent. of pure Potassium Bicarbonate [CO(OH)(OK)], and should be kept in well-stoppered bottles.

Preparation.—This salt is made by passing carbon dioxide through a solution of potassium carbonate until it is fully saturated, then filtering the liquid, and evaporating at a temperature below 71° C. (160° F.) to prevent decomposition. The crystals formed should be well washed and dried.

$$\underset{\substack{\text{Potassium}\\\text{Carbonate}}}{K_2CO_3} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Potassium}\\\text{Bicarbonate}}}{2KHCO_3}$$

The cheapest way to make this salt is to suspend a dish containing a concentrated solution of potassium carbonate within the fermenting tuns of a brewery; the carbon dioxide produced during fermentation is thus utilized. The crude salt obtained on evaporation is called *salæratus*. When purified by crystallization, it constitutes the official bicarbonate.

Official Description.—Colorless, transparent, monoclinic prisms, or a colorless, granular powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless; saline and slightly alkaline taste. The concentrated aqueous solution is slightly alkaline to litmus paper, but neutral to phenolphthalein T.S.

Solubility.—*Water.* In about 3 parts at 25° C. (77° F.), and in 1.9 parts at 50° C. (122° F.). At a higher temperature the solution rapidly loses carbon dioxide, and after being boiled, contains only potassium carbonate.

Alcohol. Almost insoluble.

Tests for Identity.—The dry salt begins to lose carbon dioxide at 100° C. (212° F.), and this loss increases at a higher temperature, until, at a red heat, the salt has lost 30.96 percent. of its original weight, leaving a residue of carbonate.

Tartaric acid T.S., added in excess to the concentrated aqueous solution, produces a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Limit of carbonate.* If 1 Gm. of the salt be dissolved without agitation in 20 Cc. of water at a temperature not above 15° C. (59° F.), and 0.2 Cc. of normal hydrochloric acid V.S. and 2 drops of phenolphthalein T.S. be added, a red tint should not appear immediately.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—To neutralize 1 Gm. of Potassium Bicarbonate not less than 19.9 Cc. of half-normal sulphuric acid V.S. should be required, methyl-orange T.S. being used as indicator.

Uses.—This salt is largely used as affording the purest available source of the potassium salts. The large quantity of carbonic acid which it yields on decomposition renders it useful in beverages and laxative draughts, such as solution of magnesium citrate. It is milder than the carbonate, and when administered internally it is more acceptable to the stomach. The dose is from fifteen to thirty grains (1 to 2 Gm.).

POTASSII BITARTRAS. U. S. Potassium Bitartrate

$KHC_4H_4O_6 = 186.78$

[CREAM OF TARTAR]

It should contain not less than 99 percent of pure Potassium Bitartrate [$C_2H_2(OH)_2(COOH)(COOK)$], and should be kept in well-stoppered bottles.

Preparation.—This well known salt is made by purifying *argol*, or *tartar*, a substance deposited in wine casks during the fermentation of the grape juice. (See Acid Saccharine Fruits, Part IV.)

Official Description.—Colorless or slightly opaque, rhombic crystals, or a white, somewhat gritty powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless; pleasant, acidulous taste; acid reaction.

Solubility.—*Water.* In about 200 parts at 25° C. (77° F.); in 16.7 parts of boiling water.

Alcohol. Very sparingly soluble.

Tests for Identity.—When a small portion of the salt is heated on platinum foil, it chars and emits inflammable vapors having the odor of burning sugar. At a higher temperature, with free access of air, the carbon of the black residue is oxidized, and a white, fused mass remains, which has an alkaline reaction and effervesces strongly with acids.

With sodium cobaltic nitrate T.S. the aqueous solution of the salt yields a copious yellow precipitate.

In the aqueous solution of the salt, rendered neutral by potassium hydroxide T.S., silver nitrate T.S. produces a white precipitate, which, on boiling, becomes black through the separation of metallic silver. If, before applying heat, just sufficient ammonia water be added to dissolve the white precipitate, and the solution boiled, a mirror will be deposited on the sides of the test-tube.

Impurities and Tests for Impurities.—*Starch, kaolin, calcium phosphate, and other insoluble matter.* A solution of 0.5 Gm. of the salt in 3 Cc. of ammonia water should leave no insoluble residue.

Heavy metals. The aqueous solution of the salt, slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Ammonia. The odor of *ammonia* should not be evolved on heating the salt with a slight excess of potassium hydroxide T.S.

Alum. If 1 Gm. of Potassium Bitartrate be well triturated with about 1 Gm. of potassium carbonate and 0.5 Gm. of potassium nitrate, and the mixture heated gradually to dull redness in a porcelain crucible, and if, upon cooling, the resulting mass be treated with a slight excess of diluted hydrochloric acid and filtered, the filtrate, upon being made slightly alkaline with potassium hydroxide T.S., should not yield a gelatinous precipitate soluble in excess of the reagent.

Phosphates. If a precipitate be produced which is insoluble, it should be collected and thoroughly washed with hot distilled water and dissolved in hot diluted nitric acid; the addition of an excess of ammonium molybdate T.S. to this solution should not produce a yellow precipitate.

Quantitative Test.—If 1 Gm. of Potassium Bitartrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 10.6 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Calcium tartrate is always present in grape juice, and a trace is permitted by the official test in potassium bitartrate, but the total impurities must not be in greater proportion than 1 percent.

Uses.—This salt is the source of tartaric acid and some of the tartrates. It is one of the ingredients in compound powder of jalap, and is frequently used as a refrigerant and purgative in doses of one to four drachms (4 to 16 Gm.)

POTASSII BROMIDUM. U.S. Potassium Bromide

$KBr = 118.22$

It should contain not less than 97 percent. of pure Potassium Bromide, and should be kept in well-stoppered bottles.

Preparation.—Two methods are used in making this salt. In the one which was formerly official, ferrous bromide, made by acting on iron with bromine, is treated with potassium carbonate; ferrous carbonate is precipitated, and potassium bromide remains in solution. The latter is filtered and evaporated, that crystals may form.

$$\underset{\substack{\text{Ferrous}\\\text{Bromide}}}{FeBr_2} + \underset{\substack{\text{Potassium}\\\text{Carbonate}}}{K_2CO_3} = \underset{\substack{\text{Ferrous}\\\text{Carbonate}}}{FeCO_3} + \underset{\substack{\text{Potassium}\\\text{Bromide}}}{2KBr}$$

In the other method, bromine is added to solution of potassium hydroxide, producing potassium bromide and bromate. The solution is evaporated to dryness, mixed with charcoal, and heated to redness. The bromate is deoxidized and converted into bromide, carbon monoxide escaping.

$$\underset{\substack{\text{Potassium}\\\text{Bromate}}}{2KBrO_3} + \underset{\text{Carbon}}{3C_2} = \underset{\substack{\text{Potassium}\\\text{Bromide}}}{2KBr} + \underset{\substack{\text{Carbon}\\\text{Monoxide}}}{6CO}$$

The presence of chlorides in potassium bromide often to the extent of 3 percent. is due to the difficulty of obtaining the bromine which is used in making it, free from chlorine.

Formerly this salt was imported. It is now made in the United States upon a large scale, and is exported.

Official Description.—Colorless, or white, cubical crystals, or granular powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless; strongly saline taste; neutral or scarcely perceptible alkaline reaction.

Solubility.—*Water.* In about 1.5 parts at 25° C. (77° F.); in less than 1 part of boiling water.

Alcohol. In about 180 parts at 25° C. (77° F.); in 16 parts of boiling alcohol.

Other solvents. Soluble in glycerin.

Tests for Identity.—On heating the salt upon platinum foil it decrepitates; and at a temperature near 700° C. (1292° F.) it fuses without decomposing, and at a bright red heat volatilizes, communicating a violet color to the flame.

The addition of tartaric acid T.S., or of sodium bitartrate T.S., to a concentrated aqueous solution of the salt produces a white crystalline precipitate.

Silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid and in a moderate excess of ammonia water.

Impurities and Tests for Impurities.—*Limit of alkali.* If 1 Gm. of Potassium Bromide be dissolved in 10 Cc. of water and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein T.S., even after heating.

Bromate. If diluted sulphuric acid be dropped upon crushed crystals of the salt, and the mixture be shaken with 1 Cc. of chloroform, the latter should not assume a yellowish-brown color.

Iodides. If to 10 Cc. of the aqueous solution of the salt (1 in 20), 1 Cc. of chloroform be added, and if chlorine water, which has been diluted with an equal volume of water, be introduced cautiously drop by drop with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Barium. Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Quantitative Test.—If 0.3 Gm. of the well-dried salt be dissolved in about 50 Cc. of water, and 2 or 3 drops of potassium chromate T.S. be added, it should require not less than 24.6 Cc. nor more than 25.85 Cc. of tenth-normal silver nitrate T.S to produce a permanent red color.

Uses.—Potassium bromide is largely used as a nervine, in doses of fifteen grains (1 Gm.), frequently repeated.

POTASSII CARBONAS. U.S. Potassium Carbonate

$K_2CO_3 = 137.27$

It should contain, when thoroughly dried, not less than 98 percent. of pure Potassium Carbonate [$CO(OK)_2$], and should be kept in well-stoppered bottles.

Preparation.—This salt, known commercially as *Sal Tartar*, is made by dissolving pearlash, or impure potassium carbonate, in an equal weight of cold water, allowing the mixture to stand a day or two, filtering the solution, pouring it into a bright iron dish, and evaporating over a gentle fire until it thickens, then removing it from the fire and stirring constantly with an iron spatula, so as to form a granular salt (see page 237).

A purer carbonate is produced by decomposing potassium bicarbonate by heating to redness, thus driving off water of crystallization and a portion of the carbon dioxide.

$$\underset{\text{Potassium Bicarbonate}}{2KHCO_3} = \underset{\text{Potassium Carbonate}}{K_2CO_3} + \underset{\text{Carbon Dioxide}}{CO_2} + \underset{\text{Water}}{H_2O}$$

Official Description.—A white, granular powder; very deliquescent.

Odor, Taste, and Reaction.—Odorless; strongly alkaline taste; strongly alkaline reaction.

Solubility.—*Water.* In 0.91 part at 25°C. (77°F.), and in about 0.65 part of boiling water.

Alcohol. Insoluble.

Tests for Identity.—When heated to 130° C. (266° F.), the salt loses all the water which it may have retained or absorbed; at a bright red heat it melts, and at a white heat it volatilizes, communicating to a non-luminous flame a pure violet color.

Its aqueous solution (1 in 20) effervesces with acids.

Its aqueous solution (1 in 10) yields with excess of tartaric acid T.S. a white crystalline precipitate.

Impurities and Tests for Impurities.—*Earthy Impurities.* No residue should be left on dissolving 1 Gm. of the salt in 20 Cc. of water.

Heavy Metals. An aqueous solution of Potassium Carbonate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Nitrate. If 5 Cc. of the aqueous solution (1 in 20) be carefully mixed with an equal volume of concentrated sulphuric acid, and, after cooling, 3 Cc. of ferrous sulphate T.S. be poured upon it so as to form a separate layer, no brown color should appear at the line of contact.

Quantitative Test.—One Gm. of Potassium Carbonate, weighed after having been thoroughly dried at 130° C. (266° F.), and dissolved in about 50 Cc. of water, should require not less than 14.3 (14.28) Cc. of normal sulphuric acid V.S. for neutralization, methyl-orange T.S. being used as indicator.

Uses.—Potassium carbonate is an antacid, but it is less agreeable than the bicarbonate. The dose is fifteen grains (1 Gm.), largely diluted. In large doses it is an irritant caustic, the proper antidotes to administer being diluted vinegar, lemon juice, or weak acids.

POTASSII CHLORAS. U.S. Potassium Chlorate

$KClO_3 = 121.68$

It should contain not less than 99 per cent. of pure Potassium Chlorate [$ClO_2.OK$], and should be kept in well-stoppered bottles. *Great caution should be observed in handling it,* as dangerous explosions are liable to occur when it is heated or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances.

Preparation.—Chlorate of Potash, as it is always termed commercially, was formerly made by passing chlorine gas into a solution of potassium hydroxide. This is a very wasteful process, as only one-fifth of the potassium hydroxide is obtained as chlorate, the rest passing into potassium chloride. It is now more economically prepared by boiling together solutions of potassium chloride and calcium hypochlorite, whereby potassium chlorate and calcium chloride are produced.

When a solution of calcium hypochlorite is boiled, it is decomposed, and calcium chlorate and calcium chloride are formed :

$$\underset{\text{Calcium Hypochlorite}}{3Ca(OCl)_2} = \underset{\text{Calcium Chloride}}{2CaCl_2} + \underset{\text{Calcium Chlorate}}{Ca(O_3Cl)_2}$$

When solution of calcium chlorate is heated in contact with potassium chloride, double decomposition takes place, as shown by the following equation :

$$\underset{\text{Calcium Chlorate}}{Ca(O_3Cl)_2} + \underset{\text{Potassium Chloride}}{2KCl} = \underset{\text{Potassium Chlorate}}{2KClO_3} + \underset{\text{Calcium Chloride}}{CaCl_2}$$

The potassium chlorate is easily separated from the calcium chloride, because it is much less soluble than the latter.

This salt is now made by electrolysis by placing opposite to each other in a solution of potassium chloride, anodes and cathodes, without being separated by a porous diaphragm. The electric current causes the formation of potassium hypochlorite in the solution, which by boiling is converted into potassium chlorate and potassium chloride.

Official Description.—Colorless, lustrous, monoclinic prisms or plates, or a white, granular powder. Permanent in the air.

Odor, Taste, and Reaction.—Odorless; cooling, characteristic taste; neutral reaction.

Solubility.—*Water.* In 16 parts at 25° C. (77° F.); in 1.7 parts of boiling water.

Alcohol. Slightly in diluted alcohol; insoluble in absolute alcohol.

Tests for Identity.—At 334° C. (633.2° F.) the salt fuses, and above 352° C. (665.6° F.) it is decomposed into oxygen and potassium perchlorate; above 400° C. (752° F.) all of its oxygen is liberated, and a white residue of potassium chloride remains, amounting to 60.8 percent. of the pure Chlorate employed. This residue is readily soluble in water, and the solution yields a white, curdy precipitate with silver nitrate T.S.

With excess of tartaric acid T.S., the solution (1 in 20) slowly yields a scant, white, crystalline precipitate; with platinic chloride T.S., a yellow crystalline precipitate is produced.

When heated with hydrochloric acid, the aqueous solution (1 in 20) assumes a greenish yellow color, and evolves chlorine.

Impurities and Tests for Impurities.—*Heavy Metals.* The aqueous solution of the salt (1 in 20) should not become discolored upon the addition of ammonium sulphide T.S.

Limit of nitrates and nitrites. If to 1 Gm. of Potassium Chlorate contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if in the upper portion of the test-tube a pledget of purified cotton be inserted, and over the mouth there be placed a piece of moistened red litmus paper, then if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper will be discernible.

Potassium chlorate should not be triturated with readily oxidizable or combustible substances, if explosions are to be avoided.

Uses.—Potassium chlorate is used chemically as a source for obtaining oxygen, and medicinally is largely employed in diphtheria, sore throat, scarlet fever, etc., in doses of from four to twenty grains (0.25 to 1.2 Gm.)

POTASSII CITRAS. U.S. Potassium Citrate

$K_3C_6H_5O_7 + H_2O = 322.08$

It should contain not less than 99 percent. of pure Potassium Citrate [$C_3H_4(OH)(COOK)_3 + H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This salt is made by adding potassium bicarbonate to a solution of citric acid until effervescence ceases, filtering the solution, evaporating to dryness, and granulating (see page 237).

$$\underset{\substack{\text{Potassium}\\\text{Bicarbonate}}}{3KHCO_3} + \underset{\text{Citric Acid}}{H_3C_6H_5O_7} = \underset{\substack{\text{Potassium}\\\text{Citrate}}}{K_3C_6H_5O_7} + \underset{\text{Water}}{3H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{3CO_2}$$

Manufacturers generally use the carbonate as the source of the potassium, as it is much cheaper than the bicarbonate. When carelessly made from the carbonate, silica may be present, which is to be suspected if the potassium citrate is not entirely soluble in water.

Official Description.—Transparent, prismatic crystals, or a white, granular powder. Deliquescent when exposed to the air.

Odor, Taste, and Reaction.—Odorless; cooling, saline taste; alkaline reaction with litmus paper, but does not affect phenolphthalein.

Solubility.—*Water.* In about 0.5 part at 25° C. (77° F.); very soluble in boiling water.

Alcohol. Sparingly soluble.

Tests for Identity.—When heated above 100° C. (212° F.), the salt begins to lose water; at 200° C. (392° F.) the water of crystallization (5.55 percent.) is completely lost. At 230° C. (446° F.) the salt begins to decompose, turns brown, and at a higher temperature carbonizes and emits inflammable gases which have a very pungent, acid odor. At a red heat a blackened mass of potassium carbonate and carbon is left, which has an alkaline reaction, and strongly effervesces with acids.

An aqueous solution of Potassium Citrate yields a white, crystalline precipitate with sodium bitartrate T.S.

On mixing 10 Cc. of the aqueous solution of the salt (1 in 20) with 10 Cc. of calcium chloride T.S., the liquid remains clear until it is boiled, when a white, granular precipitate is produced.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see U.S.P. Test No. 121, Chap. LXII).

Tartrate. A solution of 1 Gm. of Potassium Citrate in 1 Cc. of water, should not deposit any precipitate on the addition of 1 Cc. of acetic acid.

Quantitative Test.—If 1 Gm. of Potassium Citrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 18.4 Cc. of half-normal hydrochloric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Potassium citrate is principally employed in medicine as a diaphoretic, in doses of fifteen grains (1 Gm.). It is found in the official solution of potassium citrate.

POTASSII CITRAS EFFERVESCENS. U.S. Effervescent Potassium Citrate

	Metric	Old form
* **Potassium Citrate**	200 Gm.	4 oz. av.
Sodium Bicarbonate, dried and powdered	477 Gm.	9½ oz. av.
Tartaric Acid, dried and powdered	252 Gm.	5 oz. av.
Citric Acid, uneffloresced crystals	162 Gm.	3¼ oz. av.
To make about	1000 Gm.	20 oz. av.

Dry the Potassium Citrate on a water-bath, until it ceases to lose weight; after powdering the dried salt, mix it intimately with the powdered Citric Acid and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.).

When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.

Uses.—This forms an agreeable diaphoretic given in cold water in doses of thirty to sixty grains (2 to 4 Gm.).

LIQUOR POTASSII CITRATIS. U.S. Solution of Potassium Citrate

[NEUTRAL MIXTURE]

An aqueous liquid, containing in solution not less than 8 percent. of anhydrous Potassium Citrate [$C_3H_4(OH)(COOK)_3 = 304.2$], with small amounts of citric and carbonic acids.

	Metric	Old form
* **Potassium Bicarbonate**	8 Gm.	292 grains
Citric Acid	6 Gm.	219 grains
Distilled Water, a sufficient quantity,		
To make	100 Cc.	8 fl. oz.

Dissolve the Potassium Bicarbonate and Citric Acid, each, in 40 Cc. [old form 3 fl. oz.] of Distilled Water. Filter the solutions separately, and wash the filters with enough Distilled Water to obtain, in each case, 50 Cc. [old form 4 fl. oz.]. Finally, mix the two solutions, and, when effervescence has nearly ceased, transfer the liquid to a bottle. This preparation should be freshly made when wanted.

Official Description.—A clear, colorless liquid.

Odor, Taste, and Reaction.—Odorless; mildly saline taste; slightly acid reaction.

Tests for Identity.—It should conform to the reactions and tests for an aqueous solution of the salt given under *Potassii Citras.*

Quantitative Test.—If 10.14 Gm. of Solution of Potassium Citrate be evaporated to dryness and then thoroughly carbonized at a temperature not exceeding a low red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the filtrate should require, for complete neutralization, not less than 16 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator (each Cc. of the half-normal sulphuric acid V.S. consumed representing 0.5 percent. of anhydrous Potassium Citrate).

For this preparation it will be found convenient in dispensing practice to keep the separate solutions of Citric Acid and Potassium Bicarbonate on hand ready to be mixed when the solution of potassium citrate is needed. The solutions keep moderately well. The solution contains about 9 percent. of potassium citrate, with some free Citric Acid and carbonic acid gas. It responds to the reactions and tests of potassium citrate (see Potassii Citras).

Neutral Mixture in some localities is always understood to mean a more agreeable preparation than this solution. It is made by nearly saturating lemon juice with Potassium Bicarbonate. It was official in the U. S. P. 1880 under the name of *Mistura Potassii Citratis* (see page 513).

Uses.—Solution of potassium citrate is refrigerant and diaphoretic, in doses of four fluidrachms (16 Cc.).

POTASSII CYANIDUM. U.S. Potassium Cyanide

$KCN = 64.70$

It should contain not less than 95 percent. of pure Potassium Cyanide, and should be kept in well-stoppered bottles.

Preparation.—A process for making this salt was formerly official. It was prepared by mixing intimately 8 parts of potassium ferrocyanide, and 3 parts of potassium carbonate, and dropping it in small portions into a red-hot iron crucible. When effervescence ceased, and the iron had precipitated, the clear, hot liquid was poured into a shallow dish to solidify.

The reaction between the potassium ferrocyanide and the potassium carbonate results in the production of potassium cyanide, potassium cyanate, iron, and carbon dioxide. The iron is precipitated out in the form of a fine powder, carbon dioxide escapes, and potassium cyanide, with a small proportion of cyanate, is produced.

$$\underset{\substack{\text{Potassium}\\\text{Ferrocyanide}}}{K_4Fe(CN)_6} + \underset{\substack{\text{Potassium}\\\text{Carbonate}}}{K_2CO_3} = \underset{\substack{\text{Potassium}\\\text{Cyanide}}}{5KCN} + \underset{\substack{\text{Potassium}\\\text{Cyanate}}}{KOCN} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Iron}}{Fe}$$

Potassium cyanide is found in commerce of several qualities. The cheapest grade is used for mining and metallurgical processes and in the arts. A granulated salt is used medicinally. It is sometimes cast into sticks, and in this form, of German manufacture, is of good quality. Chemically pure crystallized potassium cyanide is also in the market.

Official Description.—White, opaque, amorphous pieces, or a white, granular powder; deliquescent in the air and exhaling the odor of hydrocyanic acid.

Odor, Taste, and Reaction.—Odorless when perfectly dry. *Great caution should be used in tasting and handling this salt.* Its aqueous solution (1 in 20) has a strongly alkaline reaction upon red litmus paper, and emits the odor of hydrocyanic acid.

Solubility.—*Water.* In about 2 parts at 25° C. (77° F.); boiling water dissolves its own weight of the salt, but rapidly decomposes it.

Alcohol. Sparingly soluble.

Tests for Identity.—At a low red heat the salt fuses.

With an equal volume of sodium bitartrate T.S. the solution yields a white, crystalline precipitate.

With sodium cobaltic nitrite T.S. a copious yellow precipitate is produced.

A few drops of a solution of the salt (1 in 20) yields with silver nitrate T.S. a white precipitate, which is soluble in an excess of the solution of Potassium Cyanide, also in ammonia water, and in concentrated nitric acid.

If 5 Cc. of a solution of the salt (1 in 20) be shaken with a few drops of ferrous sulphate T.S. and of ferric chloride T.S., and a slight excess of hydrochloric acid then added, a blue precipitate (Prussian blue) will be produced.

Impurities and Tests for Impurities.—*Limit of carbonate.* The addition of diluted hydrochloric acid to the aqueous solution of the salt (1 in 20) should produce not more than a slight effervescence.

Ferrocyanide. After the diluted hydrochloric acid has been added in slight excess, a drop of ferric chloride T.S. should not produce a blue color.

Sulphocyanate. Nor should a red color be produced.

Quantitative Test.—If 1 Gm. of Potassium Cyanide be dissolved in sufficient distilled water to measure 100 Cc., then 64.7 Cc. of this solution mixed with 5 Cc. of ammonia water and 3 drops of potassium iodide T.S. should require not less than 47.5 Cc. of tenth-normal silver nitrate V.S. before the appearance of a permanent precipitate (each Cc. of the tenth-normal silver nitrate V.S. indicating 2 percent. of pure Potassium Cyanide).

Uses.—The action of this salt upon animals as a *poison* is the same as that of hydrocyanic acid. The dose is *one-fifth of a grain* (0.010 Gm.). It is more stable than the acid, and is preferably used as a substitute for it.

POTASSII DICHROMAS. U. S. Potassium Dichromate

$K_2Cr_2O_7 = 292.28$

[POTASSII BICHROMAS, PHARM. 1890 POTASSIUM BICHROMATE]

It should contain not less than 99 percent. of pure Potassium Dichromate [$Cr_2O_5(OK)_2$], and should be kept in well-stoppered bottles.

Preparation.—The source of this salt is *chrome iron ore*, which is first roasted, then powdered, mixed with potassium carbonate and lime, and the mixture heated strongly with access of air.

The mixture of iron and calcium oxide, calcium chromate, and potassium chromate is thrown into water, and potassium carbonate added to the solution which converts the calcium chromate into potassium chromate.

The solution of the latter is treated with an acid, usually sulphuric, but nitric acid would be preferable on some accounts, potassium nitrate being more readily separated from potassium dichromate than potassium sulphate. Sulphuric acid, however, is cheaper.

$$\underset{\substack{\text{Potassium}\\\text{Chromate}}}{2K_2CrO_4} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Potassium}\\\text{Dichromate}}}{K_2Cr_2O_7} + \underset{\substack{\text{Potassium}\\\text{Sulphate}}}{K_2SO_4} + \underset{\text{Water}}{H_2O}$$

This salt is considered to be a compound of potassium chromate with chromic anhydride, K_2CrO_4,CrO_3.

Official Description.—Large, orange-red, transparent, triclinic prisms, or four-sided tabular crystals; permanent in the air.

Odor, Taste, and Reaction.—Odorless; acidulous, metallic taste; acid reaction.

Solubility.—*Water.* In about 9 parts at 25° C. (77° F.); in 1.5 parts of boiling water.

Alcohol. Insoluble.

Tests for Identity.—The salt fuses below a red heat, without loss of weight, forming a dark brown liquid. At a white heat it evolves oxygen and leaves a residue of neutral potassium chromate and green chromic oxide.

On mixing 4 Cc. of an aqueous solution (1 in 20) with 0.5 Cc. of alcohol, and then adding 1 Cc. of sulphuric acid, the liquid should assume a green color and emit the odor of aldehyde.

Sodium cobaltic nitrite T.S. produces in an aqueous solution a copious yellow precipitate.

Uses.—This salt is used in the preparation of chromium trioxide and valeric acid, and for forming an official volumetric solution, the value of which in testing depends upon its yielding its oxygen to acid liquids (see Test Solutions). When given internally, in large doses, it is an irritant poison; the proper dose is one-fifth of a grain (0.010 Gm.); soap, magnesia, or chalk would be suitable antidotes.

POTASSII ET SODII TARTRAS. U.S. Potassium and Sodium Tartrate

$KNaC_4H_4O_6 + 4H_2O = 280.18$

[Rochelle Salt]

It should contain not less than 99 percent. of pure Potassium and Sodium Tartrate [$C_2H_2(OH)_2(COOK)(COONa) + 4H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This salt is made by adding potassium bitartrate to a solution of sodium carbonate; the proportions are shown by a former official process, which is as follows:

Take of Carbonate of Sodium, 12 *troyounces;* Bitartrate of Potassium, in fine powder, 16 *troyounces;* Boiling Water, 5 *pints.* Dissolve the Carbonate of Sodium in the Water, and gradually add the Bitartrate of Potassium. Filter the solution, and evaporate until a pellicle begins to form; then set it aside to crystallize. Pour off the mother water, and dry the crystals on bibulous paper. Lastly, evaporate the mother water, that it may furnish more crystals.

It is advantageous to filter the solution after one-half of its volume has been evaporated and it has cooled and settled, in order to free it from the calcium tartrate which separates, otherwise the crystals will be contaminated.

The following equation shows the reaction:

$$\underset{\substack{\text{Potassium}\\\text{Bitartrate}}}{2KHC_4H_4O_6} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Potassium and}\\\text{Sodium Tartrate}}}{2KNaC_4H_4O_6} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

The chemical constitution of the tartrates will be fully explained under Acidum Tartaricum, but this opportunity will be embraced to note that tartaric acid is a dibasic acid; in its acid salts the remaining hydrogen can be replaced by a base, which in this case is sodium.

Official Description.—Colorless, transparent, rhombic prisms, or a white powder; slightly efflorescent in dry air.

Odor, Taste, and Reaction.—Odorless; cooling, saline taste. The aqueous solution is feebly alkaline to litmus paper, but does not affect phenolphthalein.

Solubility.—*Water.* In about 1.2 parts at 25° C. (77° F.), and in less than 1 part of boiling water.

Alcohol. Almost insoluble.

Tests for Identity.—When heated to 74° C. (165.2° F.), the salt fuses to a colorless liquid, which, at a higher temperature, froths, becomes brown, and gradually carbonizes, while inflammable vapors are emitted, having the odor of burning sugar. Finally, a black residue is left.

An aqueous solution of the salt (1 in 10) yields, with an equal volume of acetic acid, a white, crystalline precipitate.

With silver nitrate T.S. it produces a white precipitate, which becomes black on boiling.

Impurities and Tests for Impurities.—*Heavy Metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U.S. P. Test No. 121, Chap. LXII).

Ammonia. When heated with potassium hydroxide T.S., the solution should not evolve *ammonia.*

Quantitative Test.—If 1 Gm. of Potassium and Sodium Tartrate be thoroughly ignited at red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require, for complete neutralization, not less than 14.1 Cc. of half-normal hydrochloric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Rochelle salt, as it is habitually termed, is an efficient purgative in the dose of one-quarter ounce to an ounce (8 to 32 Gm.). It is an important ingredient in the well known Seidlitz powders.

POTASSII FERROCYANIDUM. U.S. Potassium Ferrocyanide

$K_4Fe(CN)_6 + 3H_2O = 419.62$

It should contain not less than 99 percent. of pure Potassium Ferrocyanide, and should be kept in well-stoppered bottles.

Preparation.—When refuse animal substances which contain nitrogen are heated in an iron pot with crude pearlash, impure potassium cyanide is formed. If the fused mass is lixiviated and treated with freshly precipitated ferrous carbonate, potassium ferrocyanide is produced, according to the following reaction :

$$\underset{\text{Potassium Cyanide}}{6KCN} + \underset{\text{Ferrous Carbonate}}{FeCO_3} = \underset{\text{Potassium Ferrocyanide}}{K_4Fe(CN)_6} + \underset{\text{Potassium Carbonate}}{K_2CO_3}$$

This salt is important, because it is the source of all the cyanogen compounds used in medicine.

Official Description.—Large, soft, transparent, yellow, four-sided, monoclinic tabular crystals or prisms ; slightly efflorescent on exposure to the air.

Odor, Taste, and Reaction.—Odorless ; mild, saline taste ; neutral reaction.

Solubility.—*Water.* In about 4 parts at 25°C. (77°F.) ; in 2 parts of boiling water.

Alcohol.—Insoluble.

Tests for Identity.—When heated to 60° C. (140° F.), the salt begins to turn white from loss of water of crystallization, and when heated at 100° C. (212° F.), it is rendered anhydrous.

With sodium bitartrate T.S. the concentrated aqueous solution yields a white, crystalline precipitate.

The color of the precipitate produced by the addition of ferric chloride T.S. to the diluted aqueous solution of the salt is dark blue ; that produced by copper sulphate T.S. is reddish-brown ; lead acetate T.S. or silver nitrate T.S. causes a white precipitate.

Impurities and Tests for Impurities.—*Carbonate.* No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt.

Ferricyanide. The precipitate produced by silver nitrate T.S. in the aqueous solution, acidulated with nitric acid, should be of a white color, without a tinge of red.

Uses.—This salt is rarely employed medicinally ; it is *not poisonous* if pure, but the absence of much acid in the stomach must be assured, as otherwise hydrocyanic acid in dangerous quantity might be liberated. Chemically, it is important as furnishing a reliable test for ferric salts.

POTASSII HYPOPHOSPHIS. U.S. Potassium Hypophosphite

$KPH_2O_2 = 103.39$

It should contain not less than 98 percent. of pure Potassium Hypophosphite [$PO.H_2OK$], and should be kept in well-stoppered bottles. Caution should be observed in dispensing Potassium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.

Preparation.—When solutions of calcium hypophosphite and potassium carbonate are mixed, potassium hypophosphite and calcium carbonate are produced by double decomposition, thus :

$$\underset{\text{Calcium Hypophosphite}}{Ca2H_2PO_2} + \underset{\text{Potassium Carbonate}}{K_2CO_3} = \underset{\text{Potassium Hypophosphite}}{2KH_2PO_2} + \underset{\text{Calcium Carbonate}}{CaCO_3}$$

The calcium carbonate is removed by filtration, and the clear solution is evaporated until a pellicle forms, after which it is constantly stirred, with continuance of the heat, until the salt granulates. The heat employed in the evaporation should be kept considerably below 100° C. (212° F.), for fear of explosion. If the salt is required to be pure, it should be dissolved in the granulated state, in official alcohol, and the solution evaporated and then set aside to crystallize.

Official Description.—White, opaque, hexagonal plates, or crystalline masses, or a granular powder; very deliquescent.

Odor, Taste, and Reaction.—Odorless; pungent, saline taste; neutral or slightly alkaline reaction.

Solubility.—*Water.* In about 0.5 part at 25°C. (77°F.); in 0.3 part of boiling water.

Alcohol. In 7 parts at 25°C. (77°F.); in 3.6 parts of boiling alcohol.

Other solvents. Insoluble in ether.

Tests for Identity.—When heated in a dry test-tube, the salt at first loses moisture, and then evolves spontaneously inflammable hydrogen phosphide gas, which burns with a bright yellow flame.

The aqueous solution (1 in 20) yields, with sodium bitartrate T.S., a white crystalline precipitate.

One Gm. of the dried salt, dissolved in about 10 Cc. of water should not require more than 1.5 Cc. of tenth-normal hydrochloric acid V.S. for neutralization (methyl-orange T.S. being used as indicator).

The diluted aqueous solution, slightly acidulated with diluted sulphuric acid, yields, with silver nitrate T.S., a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver.

On gently heating an aqueous solution of Potassium Hypophosphite with copper sulphate T.S., a reddish-brown precipitate is formed.

When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is at first formed. On further addition of an excess of the Potassium Hypophosphite solution, the precipitate becomes gray from reduction to metallic mercury.

Impurities and Tests for Impurities.—*Carbonate.* An aqueous solution of the salt (1 in 20) should not effervesce upon the addition of an acid.

Heavy metals. An aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. If 5 Cc. of an aqueous solution of Potassium Hypophosphite (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid diluted with about 10 Cc. of water, and the mixture be evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—The official use made of potassium hypophosphite is to form one of the ingredients of syrup and compound syrup of hypophosphites and the preparations into which they enter, and as an addition in the process for making diluted hydriodic acid. It may be given internally in the dose of eight grains (0.5 Gm.).

POTASSII IODIDUM. U.S. Potassium Iodide

$KI = 164.76$

It should contain not less than 99 percent. of pure Potassium Iodide, and should be kept in well-stoppered bottles.

Preparation.—An aqueous solution of potassium hydroxide is treated with iodine in slight excess. The result is the formation of two salts, potassium iodide and iodate.

$$\underset{\substack{\text{Potassium}\\\text{Hydroxide}}}{6KOH} + \underset{\text{Iodine}}{(I_2)_3} = \underset{\substack{\text{Potassium}\\\text{Iodide}}}{5KI} + \underset{\substack{\text{Potassium}\\\text{Iodate}}}{KIO_3} + \underset{\text{Water}}{3H_2O}$$

By evaporating the solution to dryness the mixed salts are obtained; and if the dry mass be exposed to a red heat, the iodate will be converted into potassium iodide, thus removing this impurity.

The mixed salts, toward the close of their evaporation to dryness, should be mixed with powdered charcoal, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the potassium iodide is dissolved out of the mass, and the solution is set aside to crystallize.

$$\underset{\substack{\text{Potassium}\\\text{Iodate}}}{KIO_3} + \underset{\text{Carbon}}{3C} = \underset{\substack{\text{Potassium}\\\text{Iodide}}}{KI} + \underset{\substack{\text{Carbon}\\\text{Monoxide}}}{3CO}$$

Potassium iodide is always crystallized from an alkaline solution if the manufacturer expects to avoid loss through the discoloration of the product from the separation of free iodine. The official test permits the presence of a small excess of alkali.

Official Description.—Colorless, transparent, translucent, or opaque white, cubical crystals, or a white, granular powder. Permanent in dry air, and but slightly deliquescent in moist air.

Odor, Taste, and Reaction.—Peculiar, faint, iodine-like odor; pungent, saline, afterwards bitter taste; neutral, or slightly alkaline reaction.

Solubility.—*Water.* In 0.7 part at 25° C. (77° F.); in 0.5 part of boiling water.

Alcohol. In about 12 parts at 25° C. (77° F.); in 6 parts of boiling alcohol.

Other solvents. In 2.5 parts of glycerin.

Tests for Identity.—When heated, the salt decrepitates. At a low red heat it fuses, and at a bright red heat it is volatilized without decomposition.

An aqueous solution of Potassium Iodide (1 in 20) yields a white, crystalline precipitate with sodium bitartrate T.S.

If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a light reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color.

Impurities and Tests for Impurities.—*Limit of alkali.* If 1 Gm. of the salt be dissolved in 10 Cc. of water, and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein T.S., even after heating.

Less soluble salts. No residue should be left when 1 Gm. of the salt is dissolved in 2 Cc. of diluted alcohol of specific gravity 0.928.

Limit of iodate. If to 0.5 Gm. of the salt, dissolved in 10 Cc. of distilled water, which has previously been boiled and cooled in a small flask, 2 drops of diluted sulphuric acid (free from sulphurous and nitrous acids) be added, no distinct yellow color should appear within half a minute.

Heavy metals. An aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of nitrates and nitrites. If to 1 Gm. of Potassium Iodide contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if, in the upper portion of the test-tube, a pledget of purified cotton be inserted, and over the mouth there be placed a piece of moistened red litmus paper, then, if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper should be discernible.

Barium. Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Cyanide. If 5 Cc. of the aqueous solution be gently heated with one drop of ferrous sulphate T.S. and 0.5 Cc. of potassium hydroxide T.S., no blue color should appear after acidulating the mixture with hydrochloric acid.

Limit of chlorides and bromides and absence of thiosulphate. If 0.2 Gm. of Potassium Iodide be dissolved in 2 Cc. of ammonia water (10 percent.), and 13 Cc. of tenth-normal silver nitrate V.S. be added, then, after thoroughly agitating and filtering, the filtrate, upon acidifying with nitric acid, should not become more than slightly turbid nor should any darkening appear within ten minutes.

Quantitative Test.—If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of distilled water, and about 3 drops of potassium chromate T.S. be added, it should require not more than 30.8 Cc. nor less than 30 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 99 percent. of pure Potassium Iodide).

Uses.—This is the most valuable medicinal compound of iodine, if the extent to which it is employed is a criterion. It is used as an alterative in eight-grain doses (0.5 Gm.); as an antisyphilitic, four drachms (16 Gm.), largely diluted, may be given.

POTASSII NITRAS. U.S. Potassium Nitrate

$KNO_3 = 100.43$

[NITRE]

It should contain not less than 99 percent. of pure Potassium Nitrate [$NO_2.OK$], and should be kept in well-stoppered bottles.

Preparation.—*Nitre*, or *Saltpetre*, is sometimes a natural product; usually, however, it is produced artificially in what are known as nitre beds, which are made up of earth and wood ashes, with animal and vegetable refuse; these are protected from rain by sheds. In time the ammonia, produced by the decomposition of the organic matter in the mixture, is oxidized, nitric acid is formed, which unites with the potassium hydroxide in the wood ashes, and potassium nitrate is gradually formed; this is separated by lixiviation, filtration, evaporation, and crystallization. It is generally imported from Europe or India in a crude state and refined in this country.

Official Description.—Colorless, transparent, six-sided, rhombic prisms, or a white crystalline powder; slightly hygroscopic in moist air.
Odor, Taste, and Reaction.—Odorless; cooling, saline, and pungent taste; neutral reaction.
Solubility.—*Water.* In 3.6 parts at 25° C. (77° F.); in 0.4 part of boiling water.
Alcohol. Very sparingly.
Tests for Identity.—When heated to 353° C. (667.4° F.) the salt melts. At a higher temperature it is decomposed, giving off oxygen at first, and then some of its nitrogen, leaving a residue of potassium nitrate, nitrite, and oxide. When thrown upon red-hot coals, the salt deflagrates.

With sodium bitartrate T.S. the aqueous solution (1 in 20) yields a white, crystalline precipitate.

If 5 Cc. of an aqueous solution (1 in 20) be agitated with an equal volume of sulphuric acid, and the liquid be cooled and a crystal of ferrous sulphate be placed in the liquid, a dark brown color should appear around the crystal.

If a drop of diphenylamine T.S. be mixed with 5 Cc. of an aqueous solution, and sulphuric acid be slowly added so as to form a separate layer, a deep blue color will appear at the line of contact.

Impurities and Tests for Impurities.—*Heavy metals.* An aqueous solution of Potassium Nitrate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test (see U. S. P. Test No. 121, Chap. LXII).

Iodide. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and if chlorine water be introduced, drop by drop, with agitation, the chloroform should not acquire a violet tint.

Chlorate and perchlorate. No yellow color should appear when 0.1 Gm. of the dry salt is sprinkled upon 1 Cc. of pure concentrated sulphuric acid.

Uses.—Potassium nitrate is diuretic and diaphoretic in doses of ten to twenty grains (0.6 to 1.2 Gm.). In concentrated solution it is antiseptic. It is most largely used in making gunpowder.

POTASSII PERMANGANAS. U.S. Potassium Permanganate

$KMnO_4 = 156.98$

It should contain not less than 99 percent. of pure Potassium Permanganate [$MnO_3.OK$], and should be kept in glass-stoppered bottles, protected from light.

Potassium Permanganate, when in concentrated solution or in the dry condition, should not be brought in contact with organic or other readily oxidizable substances.

Preparation.—This salt is made by boiling a solution of potassium manganate with water.

$$\underset{\text{Potassium Manganate}}{3K_2MnO_4} + \underset{\text{Water}}{3H_2O} = \underset{\text{Potassium Permanganate}}{K_2Mn_2O_8} + \underset{\text{Manganese Peroxide}}{MnO_3H_2} + \underset{\text{Potassium Hydroxide}}{4KHO}$$

Potassium manganate is made by heating manganese dioxide with potassium hydroxide with or without the aid of an oxidizing agent like potassium chlorate; the potassium hydroxide liberated by the reaction requires neutralization with an acid if all the permanganate is to be obtained, because the latter, in the presence of an excess of alkali remains in the condition of manganate.

It may also be made by the electrolysis of the manganate, the products being permanganate, potassium hydroxide and hydrogen.

Official Description.—Slender, monoclinic prisms, of a dark purple color, almost opaque by transmitted, and of a blue, metallic lustre by reflected, light; permanent in the air.

Odor, Taste, and Reaction.—Odorless; taste at first sweet, but afterwards disagreeable and astringent. Neutral reaction in aqueous solution.

Solubility.—*Water.* In about 15 parts at 25° C. (77° F.); in 3 parts of boiling water.
Alcohol. Decomposed.

Tests for Identity.—When heated, the salt decrepitates, and at 240° C. (464° F.) it decomposes, yielding oxygen, potassium manganate, and manganese dioxide.

The aqueous solution of the salt is of a deep violet-red color when concentrated, and of a rose color when much diluted, and the rose color is discharged by hydrogen sulphide, ferrous sulphate, oxalic acid, alcohol, hydrogen dioxide, and many other readily oxidizable substances, especially if the solution be first rendered acid by sulphuric acid.

Impurities and Tests for Impurities.—If 0.5 Gm. of Potassium Permanganate be boiled with 20 Cc. of water and 4 Cc. of alcohol until it is completely decomposed, and the liquid then filtered, the clear, colorless filtrate may be used for the following tests:

Limit of sulphate. If to 5 Cc. of the filtrate, acidulated with nitric acid, barium chloride T.S. be added, not more than a very slight turbidity should be produced.

Chloride. In another portion of 5 Cc., acidulated with nitric acid, silver nitrate T.S. should produce no precipitate or cloudiness.

Nitrate. If to another portion of 5 Cc. of the filtrate 1 drop of diphenylamine T.S. be added, and then 1 Cc. of sulphuric acid introduced, so as to form a layer beneath, no blue color should appear at the line of contact.

Quantitative Test.—If 0.1 Gm. of Potassium Permanganate be dissolved in 100 Cc. of distilled water, to which 1 Cc. of sulphuric acid and 35 Cc. of tenth-normal oxalic acid V.S. have been previously added, then the addition of not more than 3.5 Cc. of tenth-normal potassium permanganate V.S. should be required to impart a permanent pink tint.

Uses.—Potassium permanganate is one of the most powerful oxidizing agents known, and it is for this reason that the official cautionary note near the head of this article is properly appended. It is owing to the facility with which it parts with oxygen, when in contact with organic matter, that it is useful as a disinfectant; hence when used externally its application by means of lint, towels, etc., should be avoided, because its energy would be spent upon these instead of upon the part of the body intended to be affected by it. Chemically, it is used as a volumetric test and oxidizer, for which it is admirably adapted on account of the distinctness of its color reactions, although the difficulty of keeping the solution from partial decomposition through the action of light and air is a serious annoyance and interferes with the accuracy of the estimation. The dose is one grain (0.065 Gm.). It has been used successfully as an antidote to morphine poisoning and against snake bite. In the latter case a strong solution should be injected into the part which has been bitten.

POTASSII SULPHAS. U.S. Potassium Sulphate

$K_2SO_4 = 173.07$

It should contain not less than 99 percent. of pure Potassium Sulphate [$SO_2(OK)_2$].

Preparation.—Potassium sulphate is obtained as a by-product in many chemical processes, although since the introduction of sodium nitrate as the source of the nitrates it is not produced very largely. It is also obtained from *kainite*, the mineral found in the Stassfurt salt-beds, which is a double potassium and magnesium sulphate. It can be made by decomposing potassium nitrate with sulphuric acid.

$$\underset{\text{Potassium Nitrate}}{2KNO_3} + \underset{\text{Sulphuric Acid}}{H_2SO_4} = \underset{\text{Potassium Sulphate}}{K_2SO_4} + \underset{\text{Nitric Acid}}{2HNO_3}$$

Official Description.—Hard, colorless, transparent, six-sided, rhombic prisms terminated by pyramids, or a white powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless; somewhat bitter, saline taste; neutral reaction in aqueous solution.

Solubility.—*Water.* In about 9 parts at 25° C. (77° F.); in 4 parts of boiling water.

Alcohol. Insoluble.

Tests for Identity.—When heated, the crystals decrepitate. At a bright red heat they fuse, and at a white heat the salt suffers partial decomposition.

The aqueous solution is neutral to litmus paper.

The saturated aqueous solution of the salt yields a white, crystalline precipitate with excess of sodium bitartrate T.S.

An aqueous solution of the salt (1 in 20) yields with barium chloride T.S. a heavy white precipitate, insoluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of Potassium Sulphate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—The principal use for potassium sulphate in pharmacy has been to act as a diluent in powdering ipecac and opium in the so-called Dover's powder. It is well adapted for this purpose, for, on account of the hardness of the crystals, the ingredients are thoroughly blended during the time required to produce a fine powder.

CHAPTER XXXIX

THE SODIUM SALTS

THE sodium salts are generally more frequently used than those having potassium for their base, because they are relatively cheaper, and are often more soluble. The metal *Sodium* is a soft, malleable, ductile solid, which must be protected from the oxygen of the air by being constantly immersed in petroleum or naphtha. It is now largely and cheaply made by electrolysis.

Tests for Sodium Salts

Sodium may be recognized in its salts by the following reactions :

1. The intensely yellow color produced when even a trace of a sodium compound is introduced into a colorless flame.

2. A reliable and practical precipitant is yet to be discovered for the sodium salts, because the compounds are generally very soluble. Neutral solutions may be precipitated by potassium metantimoniate : this reaction, however, has but a limited application.

3. Sodium salts are generally colorless, and not volatile below a red heat.

Official Sodium Salts and Preparations

Official Name	Preparation
With Inorganic Radicals	
Sodii Arsenas	By heating together arsenic trioxide, sodium nitrate, and sodium carbonate
Arsenas Exsiccatus	By drying sodium arsenate until it ceases to lose weight
Bicarbonas	By exposing sodium carbonate to the action of carbon dioxide
Bisulphis	By saturating a solution of sodium carbonate with sulphurous acid
Boras	By purifying the native salt
Bromidum	By treating ferrous bromide with sodium carbonate
Carbonas Monohydratus	By crystallizing with agitation a concentrated solution of sodium carbonate at 35° C. (95° F.)
Chloras	By double decomposition between sodium bitartrate and potassium chlorate
Chloridum	By evaporating sea-water and purifying
Hydroxidum	By boiling solution of sodium carbonate with calcium hydroxide and evaporating
Hypophosphis	By double decomposition between calcium hypophosphite and sodium carbonate
Iodidum	By treating ferrous iodide with sodium carbonate
Nitras	By purifying the native salt
Nitris	By decomposing sodium nitrate by heating in contact with starch, lead, or other reducing substances
Phosphas	By treating acid calcium phosphate with sodium carbonate
Phosphas Effervescens	Prepared by mixing finely powdered exsiccated sodium phosphate, sodium bicarbonate, tartaric acid, and citric acid, heating until the whole becomes uniformly moist, granulating, and drying
Phosphas Exsiccatus	Made by drying the phosphate until it ceases to lose weight
Pyrophosphas	By heating sodium phosphate to redness, dissolving and crystallizing
Sulphas	By treating common salt with sulphuric acid
Sulphis	By decomposing sodium carbonate with sulphurous acid
Thiosulphas	By decomposing calcium thiosulphate with sodium sulphate

Official Sodium Salts and Preparations—*Continued*

Official Name	Preparation
Liquor Sodæ Chlorinatæ	Double decomposition between chlorinated lime and monohydrated sodium carbonate
Sodii Arsenatis	1 percent. solution of exsiccated sodium arsenate
Sodii Hydroxidi	By dissolving sodium hydroxide in water
Sodii Phosphatis Compositus, Compound Solution of Sodium Phosphate	Made by dissolving sodium phosphate, sodium nitrate, and citric acid in distilled water. 1 Cc. contains 1 Gm. of sodium phosphate
Trochisci Sodii Bicarbonatis	Each contains three grains of sodium bicarbonate
With Organic Radicals	
Sodii Acetas	By decomposing sodium carbonate with acetic acid
Benzoas	By decomposing sodium carbonate with benzoic acid
Citras	By saturating a solution of sodium carbonate with citric acid
Phenolsulphonas	By double decomposition between barium phenolsulphonate and sodium carbonate
Salicylas	By decomposing sodium carbonate with salicylic acid
Mistura Rhei et Sodæ	Contains sodium bicarbonate

Unofficial Sodium Salts and Preparations

Sodii Phenolas, NaC_6H_5O Sodium Phenolate	Add metallic sodium to phenol, and allow it to crystallize
Sodii-Citro-Tartras Effervescens Effervescent Sodium Citro-tartrate	17 parts sodium bicarbonate; 8 parts tartaric acid; 6 parts citric acid. Mix, and place in a dish heated to about 200° F. Stir constantly until a granular salt is obtained. Lastly, sift it
Sodii et Ammonii Phosphas $NH_4NaHPO_4+4H_2O$ Sodium and Ammonium Phosphate	Dissolve 5 parts crystallized sodium phosphate and 2 parts ammonium phosphate in 20 parts hot water; then add ammonia water until the liquid is alkaline, and crystallize
Sodii et Argenti Thiosulphas $2Na_2S_2O_3+Ag_2S_2O_3$ Sodium and Silver thiosulphate	Dissolve freshly precipitated silver oxide in a solution of sodium thiosulphate, evaporate and crystallize
Sodii Ethylas, C_2H_5NaO Sodium Ethylate	Caustic. Used in alcoholic solution; also applied externally mixed with olive oil
Sodii Ethylsulphas, $C_2H_5NaSO_4+H_2O$ Sodium Ethylsulphate, Sodium Sulphovinate	Cathartic
Sodii Nitro-Prussidum $Na_2Fe(CN)_5NO+2H_2O$ Sodium Nitro-Prusside	Digest 1 part potassium ferrocyanide with 2 parts nitric acid and 2 parts water until it ceases to produce a blue precipitate with iron salts. When cool, neutralize the mother liquor with sodium carbonate, then collect the red crystals
Sodii et Platini Chloridum $2NaCl.PtCl_4+6H_2O$ Sodium and Platinum Chloride	Dissolve 3 parts platinic chloride and 5 parts sodium chloride in water, and evaporate to dryness, stirring continually
Sodii Silicas, Na_2SiO_3 Sodium Silicate	Mix 1 part silica and 2 parts dried sodium carbonate; fuse in an earthenware crucible, and pour the mass on a slab. Dissolve in water, filter, concentrate, and crystallize
Sodii Silicofluoridum, Na_2SiF_6 Sodium Silico-Fluoride	Antiseptic. A mild caustic
Sodii Stannas, Na_2SnO_3 Sodium Stannate	Fuse tin ore with caustic soda and sodium nitrate
Sodii Sulphobenzoas, $C_6H_4(NaSO_3)COONa$ Sodium Sulphobenzoate	Non-poisonous antiseptic
Sodii Tartras, $Na_2C_4H_4O_6+2H_2O$ Sodium Tartrate	Dissolve 6 parts tartaric acid and 7½ parts sodium bicarbonate, each separately, in water. Mix solutions, filter, concentrate, and crystallize
Sodii Valeras, $NaC_5H_9O_2$ Sodium Valerate	Saturate valeric acid with sodium carbonate

SODII HYDROXIDUM. U.S. Sodium Hydroxide

$NaOH = 39.76$

[SODA, PHARM. 1890 CAUSTIC SODA, SODA, SODIUM HYDRATE]

It should contain not less than 90 percent. of pure anhydrous Sodium Hydroxide, and not more than two percent. of other inorganic substances, with the exception of water. It should be kept in well-stoppered bottles made of hard glass.

Preparation.—Owing to the improvements in the manufacture of metallic sodium and the cheapening of the product, sodium hydroxide can be found in commerce which has been made by oxidizing the metal by bringing it in contact with water and evaporating the pure solution of sodium hydroxide. When the pure hydroxide is not needed, the white caustic sodium hydroxide, in sticks, made by evaporating a solution of sodium hydroxide (see Liquor Sodii Hydroxidi) and casting the fused residue into moulds, is used. (See Potassii Hydroxidum, page 513.)

Official Description.—Dry, white or nearly white flakes, powder, fused masses, or translucent or opaque, white pencils. Exposed to the air it rapidly deliquesces, absorbs carbon dioxide, and becomes covered with a dry coating of carbonate.

Odor, Taste, and Reaction.—Odorless; caustic taste. *Great caution is necessary in tasting and handling it*, as it rapidly destroys organic tissues. Alkaline reaction.

Solubility.—*Water.* In about 1 part at 25° C. (77° F.); in 0.8 part of boiling water.
Alcohol. Very soluble.

Tests for Identity.—When heated to about 525° C. (977° F.), Sodium Hydroxide melts to a clear, oily liquid, and at a bright red heat it is slowly volatilized unchanged. When introduced into a non-luminous flame, it imparts to it an intense yellow color.

Impurities and Tests for Impurities.—*Organic matter and insoluble impurities.* The aqueous solution (1 in 20) should be perfectly clear and colorless, and

Limit of potassium. After being acidulated with acetic acid, it should yield no precipitate on the addition of an excess of tartaric acid T. S.

Heavy metals. The aqueous solution of Sodium Hydroxide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of carbonate. On adding a slight excess of diluted sulphuric acid to 10 Cc. of an aqueous solution of Sodium Hydroxide (1 in 10), no distinct effervescence should occur.

Limit of silicate, etc. If 0.7 Gm. of Sodium Hydroxide be dissolved in 1.5 Cc. of water, and the solution added to 10 Cc. of alcohol, not more than a slight, white precipitate should occur within ten minutes.

Quantitative Test.—Introduce about 1 Gm. of Sodium Hydroxide into a stoppered weighing bottle, and weigh accurately. Dissolve this in about 50 Cc. of water, and titrate the solution with normal sulphuric acid V. S., using methyl-orange T. S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V. S. consumed, by 3.976, and divide this product by the weight of the Sodium Hydroxide taken; the quotient represents the percentage of Sodium Hydroxide present.

Uses.—*Caustic Soda*, as sodium hydroxide is termed commercially, is sometimes preferred to the analogous potassium salt, in the belief that it is milder and less deliquescent. It is used pharmaceutically in making solution of sodium hydroxide.

LIQUOR SODII HYDROXIDI. U.S. Solution of Sodium Hydroxide

[Liquor Sodæ, Pharm. 1890 Solution of Soda]

An aqueous solution, containing about 5 percent. of Sodium Hydroxide [NaOH = 39.76].

	Metric	Old form
* **Sodium Hydroxide**	56 Gm.	1 oz. av.
Distilled Water	944 Gm.	15 fl. oz.
To make	1000 Gm.	1 pint

Dissolve the Sodium Hydroxide in the Distilled Water, and add Distilled Water to weigh 1000 Gm. [or to measure, old form, 1 pint].

The Sodium Hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (90 percent.). Sodium Hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 5040 by the percentage of absolute Sodium Hydroxide contained therein.

Solution of Sodium Hydroxide should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum.

This solution was directed to be made in the U. S. P. 1890 by a method similar to that for preparing the solution of potassium hydroxide (see page 514).

The sodium hydroxide is obtained in this process by decomposing the carbonate by heating it in contact with an aqueous mixture of calcium hydroxide; calcium carbonate is formed, and sodium hydroxide remains in solution.

$$\underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Calcium}\\\text{Hydroxide}}}{Ca(HO)_2} = \underset{\substack{\text{Sodium}\\\text{Hydroxide}}}{2NaHO} + \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3}$$

Official Description.—A clear, colorless liquid.

Odor, Taste, and Reaction.—Odorless; very acrid and caustic taste; strongly alkaline reaction.

Specific Gravity.—About 1.056 at 25° C. (77° F.).

Tests for Identity.—It should conform to the reactions and tests for an aqueous solution of sodium hydroxide given under *Sodii Hydroxidum.*

Quantitative Test.—To neutralize 20 (19.9) Gm. of Solution of Sodium Hydroxide there should be required about 25 Cc. of normal sulphuric acid V. S., methyl-orange T. S. being used as indicator (each Cc. of normal sulphuric acid V. S. indicating 0.2 percent. of absolute Sodium Hydroxide).

Uses.—Solution of sodium hydroxide is an antacid, and is used for the same purposes and in the same dose as solution of potassium hydroxide (see page 514).

SODII ACETAS. U.S. Sodium Acetate

$NaC_2H_3O_2 + 3H_2O = 135.10$

It should contain in an uneffloresced condition not less than 99.5 percent. of pure Sodium Acetate [$CH_3.COONa + 3H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This salt is obtained on the large scale in the process for making acetic acid. For medicinal purposes it may be made conveniently by saturating acetic acid with sodium carbonate, filtering the solution, concentrating it, and obtaining the salt in crystals.

$$\underset{\substack{\text{Acetic}\\\text{Acid}}}{2HC_2H_3O_2} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\\text{Acetate}}}{2NaC_2H_3O_2} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

It is sometimes granulated, and in this form it is more convenient for dispensing purposes than the usual large crystals.

Official Description.—Colorless, transparent, monoclinic prisms, or a granular, crystalline powder; efflorescent in warm, dry air.

Odor, Taste, and Reaction.—Odorless; cooling, saline taste. An aqueous solution (1 in 20) should be alkaline to red litmus paper, but should not affect phenolphthalein.

Solubility.—*Water.* In about 1 part at 25° C. (77° F.); in all proportions in boiling water. *Alcohol.* In 23 parts at 25° C. (77° F.); in all proportions in boiling alcohol.

Tests for Identity.—When heated to 60° C. (140° F.), the salt begins to liquefy. At 123° C. (253.4° F.) it becomes dry and anhydrous; at 315° C. (599° F.) it is decomposed, with evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intense yellow color, gives an alkaline reaction with litmus paper, and effervesces with acids.

If a few particles of the salt be added to a mixture of 1 Cc. of sulphuric acid and 1 Cc. of alcohol, and heated to boiling, acetic ether will be formed, recognizable by its odor.

On the addition of a few drops of ferric chloride T.S., the aqueous solution (1 in 20) assumes a deep red color, and, when boiled, yields a brown, flocculent precipitate of basic ferric acetate.

Impurities and Tests for Impurities.—*Limit of potassium.* A saturated aqueous solution should not be rendered turbid by the addition of sodium bitartrate T.S.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of Sodium Acetate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 14.7 (14.74) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Sodium acetate is often preferred to potassium acetate as a diuretic. It is not deliquescent like the latter, and is said to be as efficient, although milder in its action. The dose is from fifteen to sixty grains (1 to 4 Gm.).

SODII ARSENAS. U. S. Sodium Arsenate

$Na_2HAsO_4 + 7H_2O = 309.84$

It should contain in an uneffloresced condition not less than 98 percent. of pure Di-sodium-ortho-arsenate [$AsO(OH)(ONa)_2 + 7H_2O$], and should be kept in well-stoppered bottles.

Preparation.—A process for this salt was formerly official; it is as follows:

Take of Arsenious Acid (or Arsenic Trioxide), in fine powder, 960 *grains;* Nitrate of Sodium, in fine powder, 816 *grains;* Dried Carbonate of Sodium, in fine powder, 528 *grains;* Distilled Water, boiling hot, *half a pint.* Having mixed the powders thoroughly, put the mixture into a large clay crucible, and cover it with the lid. Expose it to a full red heat until effervescence has ceased and complete fusion has taken place. Pour the fused salt on a porcelain slab, and as soon as it has solidified, and while it is still warm, put it into the hot water, and stir until it is dissolved. Filter the solution, and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering paper, keep them in a well-stoppered bottle.

The rationale of this process is that when arsenic trioxide, sodium nitrate, and sodium carbonate are fused together, sodium pyroarsenate is formed, while nitrous anhydride and carbon dioxide escape as gases.

$$\underset{\substack{\text{Arsenic}\\\text{Trioxide}}}{As_2O_3} + \underset{\substack{\text{Sodium}\\\text{Nitrate}}}{2NaNO_3} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\\text{Pyroarsenate}}}{Na_4As_2O_7} + \underset{\substack{\text{Nitrous}\\\text{Anhydride}}}{N_2O_3} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

Sodium pyroarsenate is converted into the orthoarsenate (the official salt) by dissolving the former in water, filtering the solution, and crystallizing.

$$\underset{\substack{\text{Sodium}\\\text{Pyroarsenate}}}{Na_4As_2O_7} + \underset{\text{Water}}{15H_2O} = \underset{\substack{\text{Sodium}\\\text{Orthoarsenate}}}{2(Na_2HAsO_4, 7H_2O)}$$

Official Description.—Colorless, transparent, monoclinic prisms; efflorescent in dry air, and somewhat deliquescent in moist air.

Odor and Taste.—Odorless; mild, alkaline taste. *Caution should be used in tasting this salt, as it is very poisonous.*

Solubility.—*Water.* In 1.2 parts at 25° C. (77° F.), and very soluble in boiling water.
Alcohol. Very sparingly soluble in cold, but nearly insoluble in boiling alcohol.
Tests for Identity.—When gently heated, the salt loses 5 molecules of water (28.8 percent.), and is converted into a white powder. At 148° C. (298.4° F.) it loses all of its water of crystallization, at a higher temperature the salt fuses, and at a red heat it is converted into pyroarsenate.
Sodium Arsenate should respond to the tests of identity and purity prescribed under *Sodii Arsenas Exsiccatus.*

Uses.—The only advantage in using this salt in preference to arsenic trioxide is that the practitioner is more apt to get it of uniform quality; their properties are identical. The dose is from one-twelfth to one-third of a grain (0.005 to 0.02 Gm.).

SODII ARSENAS EXSICCATUS. U.S. Exsiccated Sodium Arsenate

$Na_2HAsO_4 = 184.68$

It should contain not less than 98 percent. of pure anhydrous Di-sodium-ortho-arsenate $[AsO(OH)(ONa)_2]$.

Sodium Arsenate Crystals, a sufficient quantity

Break the crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C. (104° and 122° F.) until they are completely disintegrated; then gradually increase the temperature to 150° C. (302° F.), and continue the drying until the product ceases to lose weight. Reduce it to a fine powder, and transfer it to dry, well-stoppered bottles.

Official Description.—An amorphous, white powder; permanent in dry air.
Odor and Taste.—Odorless; mildly alkaline taste. *It should be tasted with great caution, as the salt is very poisonous.*
Solubility.—*Water.* In 3 parts at 25° C. (77° F.), and very soluble in boiling water.
Alcohol. Very sparingly in cold, but nearly insoluble in boiling alcohol.
Tests for Identity.—When heated to 150° C. (302° F.), the salt should not lose weight; at red heat it is converted into pyroarsenate. It imparts an intense yellow color to a non-luminous flame.
The aqueous solution of the salt (1 in 20) yields a white precipitate with barium chloride T.S., or with calcium chloride T.S., and a dark red precipitate with silver nitrate T.S., all of which precipitates are soluble in nitric acid.
If 0.5 Cc. of an aqueous solution (1 in 20) be mixed with 2 Cc. of hydrochloric acid, and a drop of this mixture be placed upon a bright piece of copper-foil, then, upon applying a gentle heat, a dark steel-gray film will be deposited upon the copper.
Impurities and Tests for Impurities.—*Arsenite.* If to 2 Cc. of an aqueous solution (1 in 20), 5 Cc. of tenth-normal silver nitrate V.S. be added, and the precipitate redissolved by a slight excess of ammonia water, no black precipitate of reduced silver should appear on boiling.
Lead, copper, iron, etc. If to 5 Cc. of an aqueous solution (1 in 100), 1 Cc. of ammonium sulphide T.S. be added, no dark coloration should appear.

Uses.—Exsiccated Sodium Arsenate is used in making the official solution (see Liquor Sodii Arsenatis). The advantage in using it in preference to sodium arsenate is that greater definiteness is secured; the latter salt as found in commerce is more or less effloresced, and the solution if made from it would be variable in its arsenical strength. Sixty parts of exsiccated arsenate represent 100 parts of the official crystallized salt.

SODII BENZOAS. U.S. Sodium Benzoate

$NaC_7H_5O_2 = 143.01$

It should contain not less than 99 percent. of pure Sodium Benzoate $[C_6H_5.COONa]$, and should be kept in well-stoppered bottles.

Preparation.—Benzoic acid is added to a hot concentrated solution of pure sodium carbonate until effervescence ceases. The solution is evaporated, cooled, and allowed to crystallize, or, preferably, evaporated to dryness and granulated.

$$\underset{\text{Benzoic Acid}}{2HC_7H_5O_2} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\\text{Benzoate}}}{2NaC_7H_5O_2} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

The yield of granulated salt is about one and one-third times the quantity of benzoic acid used.

Official Description.—A white, amorphous, granular or crystalline powder; permanent in the air.

Odor, Taste, and Reaction. Odorless; sweetish, astringent taste; neutral or slightly alkaline in aqueous solution.

Solubility.—*Water.* In 1.6 parts at 25° C. (77° F.); in 1.3 parts of boiling water.
Alcohol. In 43 parts at 25° C. (77° F.); in 12 parts of boiling alcohol.

Tests for Identity.—When heated, the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intense yellow color.

If a few drops of ferric chloride T.S. be added to an aqueous solution of the salt, a salmon-colored precipitate will be deposited.

If 5 Cc. of diluted sulphuric acid be added to a solution of 1 Gm. of the salt in 10 Cc. of water, a white precipitate of benzoic acid will be produced, which, after being thoroughly washed, should conform to the tests of purity given under *Acidum Benzoicum.*

Impurities and Tests for Impurities.—*Heavy metals.* If an aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of dry Sodium Benzoate be thoroughly ignited at red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 13.85 Cc. of half-normal hydrochloric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Sodium benzoate has been prescribed as a remedy in phthisis, diphtheria, and similar complaints, in fifteen-grain doses (1 Gm.). It is employed also in rheumatism.

SODII BICARBONAS. U.S. Sodium Bicarbonate

$NaHCO_3 = 83.43$

It should contain not less than 99 percent. of pure Sodium Bicarbonate [CO(OH)(ONa), and should be kept in well-closed vessels, in a cool place.

All the processes for making this important salt of sodium, with one exception, consist in the addition of carbon dioxide to sodium carbonate. This operation cannot be carried on profitably upon the small scale; hence it is most advantageous for the pharmacist to buy commercial sodium bicarbonate and purify it for dispensing purposes (see page 539). Sodium carbonate contains ten molecules of water of crystallization; sodium bicarbonate contains none, hence provision must be made for the escape of this water, which is thrown out of combination during the process of carbonating. The crystallized sodium carbonate is placed upon false bottoms in chambers arranged so that the water can escape as it is liberated.

$$\underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Sodium}\\\text{Bicarbonate}}}{2HNaCO_3}$$

Sodium bicarbonate is more largely prepared by the ammonia-soda process, or *Solvay's*, as it is usually called. In this, carbon dioxide is passed into a solution of common salt in ammonia water, double decomposition ensues, sodium bicarbonate is precipitated, and ammonium chloride, being very soluble, remains in solution.

$$\underset{\text{Sodium Chloride}}{NaCl} + \underset{\text{Ammonia}}{NH_3} + \underset{\text{Carbon Dioxide}}{CO_2} + \underset{\text{Water}}{H_2O} = \underset{\text{Sodium Bicarbonate}}{HNaCO_3} + \underset{\text{Ammonium Chloride}}{NH_4Cl}$$

Sodium bicarbonate is still found in the market containing small quantities of impurities and having a disagreeable alkaline taste, and it should be purified.

This purification amounts to nothing more than washing the salt with distilled water. The common impurities, sodium carbonate, chloride, and sulphate, and ammonium salts, are much more soluble than the bicarbonate, and they are easily dissolved out, without any serious loss of the bicarbonate. Diluted alcohol is sometimes substituted for water for washing out the carbonate. (See official test for limit of carbonate.)

Official Description.—A white, opaque powder; permanent in dry air, but slowly decomposed in moist air.

Odor, Taste, and Reaction.—Odorless; cooling, mildly alkaline taste. The solution, when freshly prepared with cold distilled water, without shaking, gives a slightly alkaline reaction with litmus paper. The alkalinity increases by standing, agitation, or increase of temperature.

Solubility.—*Water.* In 12 parts at 15° C. (59° F.); above this temperature the solution gradually loses carbon dioxide, and at boiling heat the salt is entirely converted into normal carbonate.

Alcohol. Insoluble.

Tests for Identity.—When heated, the salt is decomposed into normal carbonate, water, and carbon dioxide, and finally, at 100° C. (212° F.), loses about 36.5 percent. of its weight. At a bright red heat it melts. To a non-luminous flame it imparts an intense yellow color.

With acids the solution effervesces strongly.

If Sodium Bicarbonate be heated in a test-tube, no odor of ammonia should be evolved.

If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should yield a perfectly clear and colorless solution, leaving no residue.

Impurities and Tests for Impurities.—*Limit of carbonate.* If 1 Gm. of the salt be dissolved without agitation in 20 Cc. of water, at a temperature not exceeding 15° C. (59° F.), and 0.2 Cc. of normal hydrochloric acid and 2 drops of phenolphthalein T.S. be added, a red tint should not appear immediately.

Sulphocyanate. If 5 Cc. of an aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride T.S.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—Two Gm. of Sodium Bicarbonate should require for complete neutralization not less than 23.7 (23.74) Cc. of normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—If *official* sodium bicarbonate were universally used, the preparations into which the commercial article now enters would be largely deprived of the disagreeable, bitter taste which is caused by the presence of carbonate. Sodium bicarbonate is largely used as a safe antacid, in doses of ten to fifteen grains (0.6 to 1 Gm.). It is preferably administered in carbonic acid water, and the draught is popularly known as "extra soda." The misnomer is caused by the erroneous use of the term "soda water."

SODII BISULPHIS. U.S. Sodium Bisulphite

$NaHSO_3 = 103.35$

It should contain not less than 90 percent. of pure Sodium Bisulphite, and should be kept in a cool place, in small, completely filled, well-stoppered bottles.

Preparation.—The acid sodium sulphite is used in solution in the arts, but, owing to its unstable character, it is inferior to the normal sulphite. It is prepared by passing sulphurous acid gas into a solution of sodium carbonate until saturation takes place and all the carbon dioxide is expelled; the liquid is then evaporated, and the crystals which form on cooling are washed and dried.

$$\underset{\substack{\text{Sodium}\\ \text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Sulphurous}\\ \text{Acid}}}{2H_2SO_3} = \underset{\substack{\text{Sodium}\\ \text{Bisulphite}}}{2NaHSO_3} + \underset{\substack{\text{Carbon}\\ \text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

It is converted by exposure to the air into sulphate and carbonate. It is largely manufactured for use in the arts as an *antichlor*, to neutralize the effects of the chlorine used in bleaching fabrics.

Official Description.—Opaque, prismatic crystals, or a granular powder; exposed to the air it loses sulphur dioxide, and is gradually oxidized to sulphate.

Odor, Taste, and Reaction.—Exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste; acid reaction in aqueous solution.

Solubility.—*Water.* In 3.5 parts at 25° C. (77° F.); in about 2 parts of boiling water.

Alcohol. In 70 parts at 25° C. (77° F.); in 49 parts of boiling alcohol.

Tests for Identity.—When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense yellow color.

On the addition of hydrochloric or sulphuric acid, an aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate T.S. and held over the escaping gas.

Impurities and Tests for Impurities.—*Thiosulphate.* If 1 Gm. of Sodium Bisulphite be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, the liquid should not become turbid.

Heavy metals. If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the sulphur dioxide, the remaining solution, after being restored to its original volume, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If to 50 Cc. of tenth-normal iodine V.S., measured from a burette into a glass-stoppered vial (of about 100 Cc. capacity), 0.25 Gm. of finely powdered crystals of Sodium Bisulphite be added, the solution allowed to stand for about an hour, and shaken at frequent intervals, then the addition of not more than 6.45 Cc. of tenth-normal sodium thiosulphate V.S. should be required to decolorize the solution.

Uses.—Sodium bisulphite is used as an antiseptic and antiferment, in doses of five to ten grains (0.3 to 0.6 Gm.). The sulphite, however, is usually preferred. Its solution is also used in volumetric analysis.

SODII BORAS. U.S. Sodium Borate

$Na_2B_4O_7 + 10H_2O = 379.32$

It should contain in the uneffloresced condition not less than 99 percent. of pure sodium tetraborate, and should be kept in well-stoppered bottles.

Preparation.—This salt is found in immense quantities in California as a crystalline deposit at Clear Lake and near Death Valley. It is probable that this will continue to be the principal source of borax for many years to come. The process of purification consists simply in picking the large and perfect crystals out, washing them, and lixiviating the earth, which is strongly impregnated with borax, evaporating the solution, and crystallizing. It is sometimes called *biborate of sodium.* It is also found as *calcium borate*, or "cotton balls," in the borax mines of California, and sodium borate is obtained by double decomposition by treating the solution of calcium borate with sodium carbonate. Borax is found native in Thibet, Persia, and other localities. It is sometimes called *tincal.* Crude boric acid, obtained from

Tuscany, is fused with dried sodium carbonate, and a hot solution of the residue is crystallized in order to produce borax.

Official Description.—Colorless, transparent, monoclinic prisms, or a white powder; slightly efflorescent in warm, dry air.

Odor, Taste, and Reaction.—Inodorous; sweetish, alkaline taste. An aqueous solution (1 in 20) colors red litmus paper blue, and yellow turmeric paper reddish-brown. After being acidulated with hydrochloric acid, the solution colors blue litmus paper red; yellow turmeric paper remains unchanged at first, but on drying, becomes brownish-red, and this color is temporarily changed to bluish-black by moistening with ammonia water.

Solubility.—*Water.* In 17 parts at 25° C. (77° F.); in 0.5 part of boiling water.

Alcohol. Insoluble.

Other solvents. In 1 part of glycerin at 80° C. (176° F.).

Tests for Identity.—When heated, the salt at first loses part of its water of crystallization, then melts, and, when further heated, swells up and forms a white, porous mass.

At a red heat it loses all of its water of crystallization (47 percent.), and fuses to a colorless glass. To a non-luminous flame it imparts an intense yellow color.

If a drop of the solution of Sodium Borate in glycerin be held in a non-luminous flame, a transient bright green color will appear.

If a slight excess of diluted sulphuric acid be added to a hot, saturated, aqueous solution of the salt, shining, scaly crystals of boric acid will separate on cooling, which, when dissolved in alcohol and the liquid ignited, impart a green color to the flame.

With 21 Cc. of water, 1 Gm. of Sodium Borate should yield a perfectly clear and colorless solution, leaving no residue.

Impurities and Tests for Impurities.—*Carbonate or bicarbonate.* The aqueous solution (1 in 20) should not effervesce with acids.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Phosphate. The aqueous solution (1 in 20) should not be rendered turbid by magnesia mixture.

Nitrate. If 1 Gm. of the salt be dissolved in 20 Cc. of diluted sulphuric acid by the aid of heat, and 3 drops of indigo T.S. be added, the blue color should not be discharged after heating for ten minutes on a water-bath.

Uses.—Borax, as it is almost universally called, is antacid and diuretic. It enters into many mouth washes, and is frequently applied in the form of powder to ulcers in the mouth, for which purpose it is admirably adapted, being mildly alkaline and not very soluble. It is used enormously in the household as an ingredient in soaps, cleansers, etc. Pharmaceutically, it is frequently used in small quantity to whiten ointments, particularly the ointment of rose water. It is used for this purpose by dissolving it in water, and incorporating the solution. The dose is eight grains (0.5 Gm.).

SODII BROMIDUM. U. S. Sodium Bromide

$NaBr = 102.24$

It should contain, when dried, not less than 97 percent. of pure Sodium Bromide, and should be kept in well-stoppered bottles.

Preparation.—The process most used in making this salt is by decomposing ferrous bromide by treating it with sodium carbonate. The ferrous bromide is made by acting on iron wire with bromine in the presence of water, and, after filtering the solution, adding solution of sodium carbonate. The reaction may be thus expressed:

$$\underset{\text{Ferrous Bromide}}{FeBr_2} + \underset{\text{Sodium Carbonate}}{Na_2CO_3} = \underset{\text{Sodium Bromide}}{2NaBr} + \underset{\text{Ferrous Carbonate}}{FeCO_3}$$

Sodium bromide may also be made by first producing ammonium bromide by treating a solution of ammonia with bromine (see Ammonii Bromidum), and then by double decomposition with sodium carbonate, forming sodium bromide and ammonium carbonate. The solution, by careful evaporation and granulation, may be made to yield sodium bromide, while ammonium carbonate, being composed of volatile compounds, is dissipated by the amount of heat used to granulate the sodium salt.

Official Description.—Colorless or white, cubical crystals, or a white, granular powder. It absorbs moisture from the air without deliquescing.

Odor, Taste, and Reaction.—Odorless; saline, slightly bitter taste. The aqueous solution (1 in 20) is neutral or has a faintly alkaline reaction.

Solubility.—*Water.* In about 1.7 parts at 25° C. (77° F.); in 0.8 part of boiling water. *Alcohol.* In 12.5 parts at 25° C. (77° F.); in 11 parts of boiling alcohol.

Tests for Identity.—When heated to a bright red heat, the salt melts, and, at a somewhat higher temperature, slowly volatilizes without decomposition. To a non-luminous flame it imparts an intense yellow color.

Silver Nitrate T.S. added to a concentrated aqueous solution produces a yellowish-white precipitate, insoluble in nitric acid and in a moderate excess of ammonia water.

Impurities and Tests for Impurities.—*Limit of alkali.* If 1 Gm. of the salt be dissolved in 10 Cc. of water and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein, T.S., even after boiling.

Iodide. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water which has been diluted with an equal volume of water be cautiously introduced, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Heavy metals. The aqueous solution of Sodium Bromide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Bromate. If diluted sulphuric acid be dropped upon some of the powdered salt, no yellow color should appear at once.

Barium. Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Quantitative Test.—If 0.3 Gm. of the well-dried salt be dissolved in about 50 Cc. of water, and 2 or 3 drops of potassium chromate T.S. be added, it should require not less than 28.5 nor more than 30 Cc. of tenth-normal silver nitrate V. S. to produce a permanent red color.

Uses.—Sodium bromide is used for the same purposes as potassium bromide. It is probably inferior to the latter as a nervous sedative, although frequently combined with it. The dose is fifteen to sixty grains (1 to 4 Gm.).

SODII CARBONAS MONOHYDRATUS. U.S. Monohydrated Sodium Carbonate

$Na_2CO_3 + H_2O = 123.19$

It should contain not less than 85 percent. of pure anhydrous Sodium Carbonate [$CO.(ONa)_2$], corresponding to not less than 99.5 percent. of the crystallized monohydrated salt.

Preparation.—Impure sodium carbonate, or soda-ash, is consumed in enormous quantities in the arts, and cheap methods of production have been long sought for. The process elaborated by Leblanc, a French apothecary, in 1784, has been most largely used, and it possesses an historic interest because of the public endorsements which it received from the French government in 1794. It is remarkable that this process has been successfully worked, without material modifications, *for a century*, and has supplied the world with cheap soap and cheap glass. It also furnishes a striking illustration of the unrequited labors of inventors and benefactors, from the fact that Leblanc died a pauper in a French asylum. Although the process has been superseded by other methods, it is worthy of study, and is as follows:

sodium carbonate is made from common salt by two steps, first, by converting the salt by sulphuric acid into sodium sulphate, and, secondly, by decomposing the sulphate by calcium carbonate and charcoal at a high temperature, so as to yield sodium carbonate. The chemical reactions are as follows:

$$\underset{\substack{\text{Sodium}\\\text{Chloride}}}{2NaCl} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{2HCl}$$

$$\underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4} + \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3} + \underset{\text{Carbon}}{C_4} = \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Calcium}\\\text{Sulphide}}}{CaS} + \underset{\substack{\text{Carbon}\\\text{Monoxide}}}{4CO}$$

The sulphate, first dried, is mixed with its own weight of ground limestone, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, where it fuses and forms a black mass. The coal, at the temperature employed, converts the sodium sulphate into sodium sulphide. This reacts with the limestone, so as to form calcium sulphide and sodium carbonate. The black mass is next digested in warm water, which takes up the alkali and other soluble matters, and leaves the insoluble impurities, called *soda waste,* largely utilized in the manufacture of sodium thiosulphate. The solution is evaporated to dryness, and the mass obtained is calcined with one-fourth of its weight of sawdust, to convert the alkali fully into carbonate, by means of the carbonic acid resulting from the combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. This soda-ash contains about 50 percent. of sodium carbonate.

Solvay's process for making sodium bicarbonate is given on page 538; the bicarbonate is easily converted into carbonate by heating, and the carbon dioxide is utilized in another part of the process.

The cryolite process is used largely in the United States. Cryolite, $Al_2F_6 + 6NaF$, consists mainly of a double fluoride of aluminum and sodium, containing, in 100 parts, 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with chalk, whereby calcium fluoride is formed, while the sodium and aluminum combine to form sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbon dioxide under pressure through the solution; and the alumina, separated from the soda, becomes insoluble, and is deposited.

$$\underset{\text{Cryolite}}{Al_2F_6 + 6NaF} + \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{6CaCO_3} = \underset{\substack{\text{Sodium}\\\text{Aluminate}}}{Al_2O_3.3Na_2O} + \underset{\substack{\text{Calcium}\\\text{Fluoride}}}{6CaF_2} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{6CO_2}$$

Monohydrated sodium carbonate was introduced into the U. S. P. (8th Rev.), because it is free from the excess of water of crystallization found in *sal soda* or ordinary sodium carbonate (63 percent.); it is practically impossible to prevent efflorescence in this salt, and in making preparations inconvenience arises from the necessity of calculating the varying quantities of water present. The monohydrated carbonate is made by crystallizing a concentrated solution of sodium carbonate at a temperature above 35° C. (95° F.), and stirring the liquid so as to produce small crystals, washing, and purifying. It contains about 15 percent. of water of crystallization and may replace the *exsiccated sodium carbonate* of former pharmacopœias.

Official Description.—A white, crystalline, granular powder. When exposed to the air, under ordinary conditions, it absorbs only a slight percentage of moisture; exposed to warm, dry air at or above 50° C. (122°F.) it effloresces, and at 100° C. (212° F.) it loses its water of crystallization (14.52 percent.).

Odor, Taste, and Reaction.—Odorless; strongly alkaline taste; alkaline reaction in aqueous solution.

Solubility.—*Water.* In 2.9 parts at 25° C. (77° F.); in 1.8 parts of boiling water.
Alcohol. Insoluble.
Other solvents. Insoluble in ether; soluble in 8 parts of glycerin.

Test for Identity.—The aqueous solution effervesces strongly with acids. To a non-luminous flame the solution imparts an intense yellow color.

Impurity and Test.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of Monohydrated Sodium Carbonate, or 0.855 Gm. of the anhydrous salt, be dissolved in 10 Cc. of distilled water, it should require not less than 32.3 Cc. of half-normal sulphuric acid V.S. for neutralization, 3 drops of methyl-orange T.S. being used as indicator.

Uses.—Monohydrated sodium carbonate is one of the most useful of the alkaline salts; it is the source of most of the sodium salts made by the pharmacist. It is rarely given internally. The dose is from two to ten grains (0.13 to 0.6 Gm.).

SODII CHLORAS. U. S. Sodium Chlorate

$NaClO_3 = 105.70$

It should contain not less than 99 percent. of pure Sodium Chlorate [$ClO_2.ONa$].

Preparation.—This salt is usually prepared by Wittstein's process, which consists in first preparing acid sodium tartrate by adding a strong solution containing nine and a half parts of tartaric acid to a hot aqueous solution of nine parts of sodium carbonate. The hot solution is mixed with one in which eight parts of potassium chlorate have been dissolved. Acid potassium tartrate separates, while sodium chlorate remains in solution. The filtered solution is evaporated and crystallized. If desired of absolute purity, it may be recrystallized from an alcoholic solution.

$$\underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Tartaric}\\\text{Acid}}}{2H_2C_4H_4O_6} = \underset{\substack{\text{Acid Sodium}\\\text{Tartrate}}}{2NaHC_4H_4O_6} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

$$\underset{\substack{\text{Acid Sodium}\\\text{Tartrate}}}{NaHC_4H_4O_6} + \underset{\substack{\text{Potassium}\\\text{Chlorate}}}{KClO_3} = \underset{\substack{\text{Sodium}\\\text{Chlorate}}}{NaClO_3} + \underset{\substack{\text{Acid Potassium}\\\text{Tartrate}}}{KHC_4H_4O_6}$$

Owing to the facility with which this salt parts with its oxygen, the following official cautionary direction should be borne in mind:

"This salt should be kept in well-stoppered bottles, and *great caution should be observed* in handling it, as dangerous explosions are liable to occur when it is heated, or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances."

Official Description.—Colorless, transparent crystals (principally cubes with tetrahedral facets), or a crystalline powder; permanent in dry air.

Odor, Taste, and Reaction.—Odorless; cooling, saline taste; neutral reaction.

Solubility.—*Water.* In about 1 part at 25° C. (77° F.); in 0.5 part of boiling water.
Alcohol. In about 100 parts at 25° C. (77° F.), and in about 40 parts of boiling alcohol.
Other solvents. Soluble in about 5 parts of glycerin.

Tests for Identity.—When heated, the salt melts, then gives off oxygen (about 45 percent. of its weight), and finally leaves a residue of sodium chloride, readily soluble in water, and yielding, with silver nitrate T.S., a white, curdy precipitate, insoluble in nitric acid. To a non-luminous flame it imparts an intense yellow color.

When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color, and emits the odor of chlorine.

Impurities and Tests for Impurities.—*Limit of potassium.* A saturated, aqueous solution should not be rendered turbid by sodium bitartrate T.S.

Lead, copper, etc. The aqueous solution of the salt (1 in 20), upon the addition of 1 Cc. of ammonium sulphide T.S., should not develop a dark coloration.

Uses.—This salt has an advantage over potassium chlorate in point of solubility, thus permitting the use of stronger solutions. The dose is from four to twenty grains (0.25 to 1.2 Gm.).

SODII CHLORIDUM. U.S. Sodium Chloride

$NaCl = 58.06$

It should contain when dried not less than 99 percent. of pure Sodium Chloride.

Preparation.—Common salt is universally distributed over the world, and may be mined, as rock salt, or obtained by evaporating sea-water, and afterwards purifying. If perfectly free from contaminating salts it will not become moist upon exposure to air.

Official Description.—Colorless, transparent, cubical crystals, or a white, crystalline powder; permanent in dry air.

Odor, Taste, and Reaction.—Odorless; purely saline taste; neutral reaction.

Solubility.—*Water.* In 2.8 parts at 25° C. (77° F.); in 2.5 parts of boiling water.
Alcohol. Almost insoluble.

Tests for Identity.—When heated, the salt decrepitates. At a red heat it fuses, and at a white heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense yellow color.

With silver nitrate T.S. the solution yields a white, curdy precipitate, insoluble in nitric acid, and readily soluble in ammonia water.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of Sodium Chloride (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Bromide and iodide. If 2 Gm. of the finely powdered salt be digested for some hours with 25 Cc. of warm alcohol, and, after cooling, the undissolved salt be removed by filtration, the filtrate evaporated to dryness, and the residue dissolved in 5 Cc. of water, and if 1 Cc. of chloroform be added, and chlorine water which has been diluted with twice its volume of water, cautiously introduced, drop by drop, with constant agitation, the chloroform should not acquire a violet, yellow, or orange color.

Quantitative Test.—If 1 Gm. of well-dried Sodium Chloride be dissolved in sufficient distilled water to measure 100 Cc., and 10 Cc. of the solution be mixed with a few drops of potassium chromate T.S., it should require not less than 17 (17.05) Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color.

Uses.—Sodium chloride is largely used as a condiment and an antiseptic. It undoubtedly serves a useful purpose in the animal economy, as many animals possess an instinctive craving for it. Salt baths are tonic, and valuable aids in many diseases. Common salt is used as a styptic in hemorrhage.

SODII CITRAS. U.S. Sodium Citrate

$2Na_3C_6H_5O_7 + 11H_2O = 709.20$

It should contain not less than 97 percent. of pure Sodium Citrate [$2C_3H_4(OH)(COONa)_3 + 11H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This salt is usually prepared by adding sodium carbonate to a solution of citric acid until effervescence ceases, evaporating and granulating the product.

Official Description.—A white, granular powder; slowly effloresces on exposure to dry air.
Odor, Taste, and Reaction.—Odorless; cooling, saline taste; slightly alkaline reaction.
Solubility.—*Water.* In 1.1 parts at 25° C. (77° F.); in 0.4 part of boiling water.
Alcohol. Slightly soluble.

Tests for Identity.—When heated to about 150° C. (302° F.) the salt loses all of its water of crystallization; on ignition at a red heat it decomposes and a mixture of sodium carbonate and carbon is left, which has an alkaline reaction and strongly effervesces with acids. To a non-luminous flame the salt imparts an intense yellow color.

The addition of 2 Cc. of calcium chloride T.S. to 10 Cc. of the aqueous solution of the salt (1 in 20) yields a clear solution, which, upon boiling, deposits a white granular precipitate.

Impurities and Tests for Impurities.—*Carbonate.* The aqueous solution (1 in 20) should not be colored red by a drop of phenolphthalein T.S., nor effervesce on the addition of an acid.

Heavy metals. The aqueous solution of the salt (1 in 20) slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of Sodium Citrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 16.4 (16.41) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—Sodium citrate is preferred to potassium citrate by some practitioners, and it is used in the process for making compound syrup of hypophosphites. The dose is four to fifteen grains (0.25 to 1 Gm.).

SODII HYPOPHOSPHIS. U.S. Sodium Hypophosphite

$$NaPH_2O_2 + H_2O = 105.29$$

It should contain not less than 98 percent. of pure Sodium Hypophosphite [$PO.H_2ONa + H_2O$], and should be kept in well-stoppered bottles; caution should be observed in dispensing Sodium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.

Preparation.—This salt is prepared by mixing a solution of six ounces of calcium hypophosphite in four pints of water with a solution of ten ounces of sodium carbonate in one and a half pints of water.

$$\underset{\substack{\text{Calcium}\\\text{Hypophosphite}}}{Ca2H_2PO_2} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\\text{Hypophosphite}}}{2Na_2HPO_2} + \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3}$$

Double decomposition takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution, and the former precipitated. After filtration to separate the calcium carbonate, the solution is evaporated to a pellicle, and then stirred constantly until the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sometimes the sodium hypophosphite explodes with violence during the evaporation of its solution; this was ascribed to the fact that the solution was overheated; but the same accident has occurred when the heat was applied by means of a water-bath. Evaporation, therefore, should be performed below 100° C. (212° F.).

$$\underset{\substack{\text{Sodium}\\\text{Hypophosphite}}}{5NaH_2PO_2} = \underset{\substack{\text{Sodium}\\\text{Pyrophosphate}}}{Na_4P_2O_7} + \underset{\substack{\text{Sodium}\\\text{Metaphosphate}}}{NaPO_3} + \underset{\substack{\text{Hydrogen}\\\text{Phosphide}}}{2PH_3} + \underset{\text{Hydrogen}}{2H_2}$$

The gases evolved by heat are hydrogen and hydrogen phosphide. The latter is well known to be spontaneously inflammable.

The acid present in this salt is *hypophosphorous acid.* It consists of one atom of phosphorus, two atoms of oxygen, and three atoms of hydrogen, only one of the latter being replaceable by a metal.

This acid is a powerful deoxidizer, and as it reduces mercury and silver from their combinations, it should not be prescribed with either.

Official Description.—Small, colorless, transparent, rectangular plates of a pearly lustre, or a white, granular powder. Very deliquescent on exposure to moist air.

Odor, Taste, and Reaction.—Odorless; bitterish-sweet, saline taste; neutral or slightly alkaline reaction.

Solubility.—*Water.* In about 1 part at 25° C. (77° F.); in 0.12 part of boiling water.

Alcohol. In about 25 parts at 25° C. (77° F.); in 1 part of boiling alcohol; slightly soluble in absolute alcohol.

Other solvents. Insoluble in ether.

Tests for Identity.—When heated in a test-tube, the salt at first loses its water of crystallization, and at about 200° C. (392° F.) it is decomposed, evolving hydrogen and hydrogen phosphide which burns spontaneously with a bright yellow flame. Finally, there is left a residue of sodium pyrophosphate and metaphosphate, sometimes mingled with a little red phosphorus. To a non-luminous flame the salt imparts an intense yellow color.

One Gm. of the dried salt, dissolved in about 10 Cc. of water, should not require more than 1.5 Cc. of tenth-normal hydrochloric acid V.S. for neutralization (methyl-orange T.S. being used as indicator).

The diluted aqueous solution, slightly acidulated with diluted sulphuric acid, yields, with silver nitrate T.S., a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver.

With copper sulphate T.S., on gentle heating, a reddish-brown precipitate is formed.

When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray from reduction to metallic mercury.

Impurities and Tests for Impurities.—*Caustic alkali and carbonate.* The aqueous solution (1 in 20) should not be colored red by the addition of a drop of phenolphthalein T.S., nor effervesce on the addition of an acid.

Heavy metals. The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. If 5 Cc. of the aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—Sodium hypophosphite is used in phthisis and other wasting diseases, and in cases of defective nerve nutrition; pharmaceutically it is an ingredient in the various official and unofficial preparations of the hypophosphites; the dose is fifteen grains (1 Gm.).

SODII IODIDUM. U.S. Sodium Iodide

$NaI = 148.78$

It should contain not less than 98 percent. of pure Sodium Iodide, and should be kept in well-stoppered bottles.

Preparation.—This iodide may be prepared by double decomposition between solutions of ferrous iodide and sodium carbonate, or by treating a solution of sodium hydroxide with iodine, exactly as in the preparation of potassium iodide. The former process is preferable if working on a small scale.

$$\underset{\substack{\text{Ferrous}\\ \text{Iodide}}}{FeI_2} + \underset{\substack{\text{Sodium}\\ \text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\ \text{Iodide}}}{2NaI} + \underset{\substack{\text{Ferrous}\\ \text{Carbonate}}}{FeCO_3}$$

By boiling the solution containing the ferrous carbonate the latter is rendered less bulky, and it can be easily separated by filtration.

Official Description.—Colorless, cubical crystals, or a white, crystalline powder. In moist air it deliquesces and frequently decomposes, the salt assuming a brown tint.

Odor, Taste, and Reaction.—Odorless; saline, and slightly bitter taste; slightly alkaline reaction.

Solubility.—*Water.* In about 0.5 part at 25° C. (77° F.); in 0.33 part of boiling water.

Alcohol. In about 3 parts at 25° C. (77° F.); in 1.4 parts of boiling alcohol.

Tests for Identity.—If to 5 Cc. of the aqueous solution (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated and impart to the solution a light reddish-brown color. On agitating this mixture with a few drops of chloroform, the latter will acquire a violet color.

When strongly heated, the salt melts, and at a bright red heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense yellow color.

Impurities and Tests for Impurities.—*Limit of alkali.* If 1 Gm. of the salt be dissolved in water, and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no red color should be produced by the addition of a drop of phenolphthalein T.S., even after heating.

Limit of potassium. A solution of 1 Gm. of the salt in 1 Cc. of water should yield no precipitate with 1 Cc. of sodium bitartrate T.S.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Free iodine. If 0.5 Gm. of the salt be dissolved in 10 Cc. of distilled water, which has been previously boiled and cooled in a small flask, the solution should not have a distinct yellow tint.

Limit of iodate. Nor should the solution acquire a yellow color within half a minute after the addition of 2 drops of diluted sulphuric acid (which should be free from sulphurous acid or nitrous acid).

Barium. Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Cyanide. If 5 Cc. of the aqueous solution be gently heated with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 Cc. of potassium hydroxide T.S., no blue color should appear after acidulating the mixture with hydrochloric acid.

Limit of nitrates and nitrites. If to 1 Gm. of Sodium Iodide, contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if in the upper portion of the test-tube a pledget of purified cotton be inserted, and over the mouth there be placed a piece of moistened red litmus paper, then if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper should be discernible.

Limit of chlorides and bromides, and absence of thiosulphate. If 0.2 Gm. of Sodium Iodide be dissolved in 2 Cc. of ammonia water, and 15 Cc. of tenth-normal silver nitrate V.S. be added, then after thoroughly agitating and filtering, the filtrate, upon supersaturating with nitric acid, should not become more than slightly turbid, nor should any darkening appear within ten minutes.

Quantitative Test.—If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of distilled water, and about 5 drops of potassium chromate T.S. be added, it should require not more than 34.6 Cc., nor less than 33 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 98 percent. of pure Sodium Iodide).

Uses.—Medicinally, this salt is preferred to potassium iodide by some practitioners, although apparently without good reason. The dose is from five to fifteen grains (0.3 to 1 Gm.).

SODII NITRAS. U.S. Sodium Nitrate

$NaNO_3 = 84.45$

It should contain not less than 99 percent. of pure Sodium Nitrate [$NO_2.ONa$], and should be kept in well-stoppered bottles.

Preparation.—Sodium nitrate, called also *cubic nitre*, and *Chili saltpetre*, is a native salt found in Chili and Peru, purified by crystallization from its aqueous solution. It is the cheapest source for obtaining nitrates, as explained elsewhere (see Acidum Nitricum).

Official Description.—Colorless, transparent, rhombohedral crystals; hygroscopic in moist air.

Odor, Taste, and Reaction.—Odorless; cooling, saline, and slightly bitter taste; neutral reaction.

Solubility.—*Water.* In about 1.1 parts at 25° C. (77° F.); in 0.6 part of boiling water.

Alcohol. In about 100 parts at 25° C. (77° F.); in 40 parts of boiling alcohol.

Tests for Identity.—When heated to 312° C. (593.6° F.), the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. When

Sodium Nitrate is heated with charcoal, the mixture deflagrates. To a non-luminous flame it imparts an intense yellow color.

If the aqueous solution be mixed in a test-tube with a drop of diphenylamine T.S., and sulphuric acid be carefully poured in, so as to form a separate layer, a deep blue color will appear at the line of contact.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Iodide. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water which has been diluted with an equal volume of water be introduced, drop by drop, with agitation, the chloroform should remain free from any violet tint.

Uses.—Sodium nitrate is used in a number of diseases, such as epilepsy, angina pectoris, dysentery, etc., but without marked effects. The dose is fifteen to twenty grains (1 to 1.2 Gm.).

SODII NITRIS. U.S. Sodium Nitrite

$NaNO_2 = 68.57$

It should contain not less than 90 percent. of pure Sodium Nitrite [NO.ONa], and should be kept in well-stoppered bottles.

Preparation.—Sodium nitrite has been made official solely on account of its use in preparing spirit of nitrous ether. It is made by heating sodium nitrate in contact with starch, or preferably by adding strips of sheet lead to sodium nitrate heated to the fusing point for several hours, lead oxide being formed at the same time. After cooling, the fused sodium nitrite is lixiviated with water, purified, and recrystallized.

Official Description.—White or nearly white, opaque, fused masses, or pencils, or colorless, transparent, hexagonal crystals.

Odor, Taste, and Reaction.—Odorless; mild, saline taste. An aqueous solution should be colorless, and give a slightly alkaline reaction with red litmus paper.

Solubility.—*Water.* In about 1.4 parts at 25° C. (77° F.), and very soluble in boiling water.

Alcohol. Slightly soluble.

Tests for Identity.—When exposed to the air, the salt deliquesces and is gradually oxidized to sodium nitrate, and becomes unfit for use.

When heated, the salt melts, and at a red heat it is decomposed, yielding oxygen, nitrogen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intense yellow color.

If the aqueous solution of the salt be mixed with some potassium iodide T.S, and a few drops of an acid added, iodine will be liberated, and nitrogen dioxide gas will escape with effervescence.

Impurities and Tests for Impurities.—*Heavy metals.* If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the gases, the resulting solution after restoring it to its original volume should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If to 30 Cc. of tenth-normal potassium permanganate V.S., diluted with about 150 Cc. of distilled water, 5 Cc. of sulphuric acid and 10 Cc. of a solution of 1 Gm. of Sodium Nitrite in sufficient distilled water to make 100 Cc. be successively added, the liquid brought to a temperature of 40° C. (104° F.) and allowed to stand for five minutes, not more than 3.75 Cc. of tenth-normal oxalic acid V.S. should be required to decolorize the solution (each Cc. of tenth-normal potassium permanganate consumed corresponding to 0.0034285 Gm. of pure Sodium Nitrite).

Uses.—This salt is used in making spirit of nitrous ether.

SODII PHENOLSULPHONAS. U.S. Sodium Phenolsulphonate

$NaC_6H_5O_4S + 2H_2O = 230.45$

[Sodii Sulphocarbolas, Pharm. 1890 Sodium Sulphocarbolate]

It should contain not less than 99 percent. of Pure Sodium Paraphenolsulphonate [$C_6H_4(OH)SO_3Na$ 1 : 4 + $2H_2O$], and should be kept in well-stoppered bottles.

Preparation.—Sodium phenolsulphonate may be made by mixing equal parts of pure phenol and strong sulphuric acid, whereby *phenolsulphonic acid*, $C_6H_5HSO_4$, is produced. The mixed liquids must be subjected to a temperature of 55° C. (131° F.) for several days, to convert this into *paraphenolsulphonic acid*, and then twenty parts of water should be added. Two parts of barium carbonate are mixed with the liquid, a little at a time, carefully graduating the quantity until effervescence ceases. The liquid is now allowed to stand, to permit the precipitation of the barium sulphate, and of any carbonate which may be present, and the liquid filtered. The solution of *barium paraphenolsulphonate* is decomposed by adding sodium carbonate until precipitation ceases, when the liquid is filtered from the barium carbonate, and the sodium paraphenolsulphonate may be obtained by evaporating the filtrate and crystallizing.

$$\underset{\text{Phenol}}{C_6H_5HO} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Phenolsulphonic}\\\text{Acid}}}{HC_6H_5SO_4} + \underset{\text{Water}}{H_2O}$$

Official Description.—Colorless, transparent, rhombic prisms; somewhat efflorescent in dry air.
Odor, Taste, and Reaction.—Odorless; cooling, saline, bitter taste; neutral reaction.
Solubility.—*Water.* In 4.8 parts at 25° C. (77° F.); in 0.7 part of boiling water.
Alcohol. In about 130 parts at 25° C. (77° F.); in 10 parts of boiling alcohol.
Tests for Identity.—When heated a little above 100° C. (212° F.), the salt loses all of its water of crystallization (15.5 percent.), and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue of sodium sulphate amounting to 30.6 percent. of the original weight. To a non-luminous flame it imparts an intense yellow color.

A diluted solution of the salt (1 in 100) is rendered pale violet by ferric chloride T.S., but remains clear; barium chloride T.S. leaves the solution clear, but if a portion of the salt be ignited, and the residue dissolved in water, the same reagent will produce in the solution a copious, white precipitate.

Impurity and Test.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—This salt is used as an antiferment, in doses of four to twenty grains (0.25 to 1.3 Gm.). It is also used in injections.

SODII PHOSPHAS. U.S. Sodium Phosphate

$Na_2HPO_4 + 12H_2O = 355.61$

It should contain, in an uneffloresced condition, not less than 99 percent. of pure Di-sodium-ortho-phosphate [$PO.(OH)(ONa)_2 + 12H_2O$], and should be kept in well-stoppered bottles, in a cool place.

Preparation.—The part of bones which is incombustible is obtained by burning them to whiteness, and consists of neutral calcium phosphate, called *bone-phosphate*, or *bone-ash*, associated with some calcium carbonate. When this is mixed with sulphuric acid, the calcium carbonate is entirely decomposed, giving rise to effervescence. The calcium phosphate undergoes partial decomposition; the greater part of the lime, being liberated, precipitates as calcium sulphate, while the phosphoric acid combines with the undecomposed portion of the phosphate, and remains in solution as an acid calcium phosphate, holding dissolved a small portion of calcium sulphate.

$$\underset{\substack{\text{Calcium}\\\text{Phosphate}}}{Ca_32PO_4} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} = \underset{\substack{\text{Acid Calcium}\\\text{Phosphate}}}{CaH_42PO_4} + \underset{\substack{\text{Calcium}\\\text{Sulphate}}}{2CaSO_4}$$

In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as acid phosphate is removed, which is known by the water which passes through having an acid reaction. The different liquids which have passed the strainer, consisting of the solution of acid calcium phosphate, are mixed and allowed to stand; by cooling a portion of calcium sulphate is deposited, which is removed by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The carbonic acid is liberated with effervescence, and the alkali, combining with the excess of acid of the acid phosphate, produces sodium phosphate, while the acid calcium phosphate, by the loss of its excess of acid, becomes the neutral phosphate and precipitates.

$$\underset{\substack{\text{Acid Calcium}\\\text{Phosphate}}}{CaH_42PO_4} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Calcium}\\\text{Phosphate}}}{CaHPO_4} + \underset{\substack{\text{Sodium}\\\text{Phosphate}}}{Na_2HPO_4} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

The calcium phosphate is separated by filtration; and the filtered liquid, which is a solution of sodium phosphate, is evaporated so as to crystallize.

Official Description.—Large, colorless, monoclinic prisms, or a granular, crystalline salt. The crystals effloresce in the air, and gradually lose 5 molecules of their water of crystallization (25.1 percent.).

Odor, Taste, and Reaction.—Odorless; cooling, saline taste. An aqueous solution is slightly alkaline to red litmus and phenolphthalein paper.

Solubility.—*Water.* In about 5.5 parts at 25° C. (77° F.).

Alcohol. Insoluble.

Tests for Identity.—When heated to about 40° C. (104° F.), the salt fuses, yielding a colorless liquid. At 100° C. (212° F.) it loses all its water of crystallization (60.3 percent.), and at a red heat it is converted into sodium pyrophosphate. It imparts to a non-luminous flame an intense yellow color.

An aqueous solution of the salt (1 in 20) yields a white, crystalline precipitate with magnesia mixture T.S.

With silver nitrate T.S. an aqueous solution yields a yellow precipitate, soluble in ammonia water and in nitric acid.

If 0.5 Cc. of the aqueous solution (1 in 20) be mixed with 1 Cc. of ammonium molybdate T.S., the mixture will at once assume a yellow color, and after being gently heated a few minutes will yield a yellow precipitate.

Impurities and Tests for Impurities.—*Limit of calcium, aluminum, etc.* Not more than a slight turbidity should appear on dissolving 1 Gm. of the salt in 20 Cc. of water.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Carbonate. No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (See U. S. P. Test No. 17, Chap. LXII).

Uses.—Sodium phosphate is principally used as a cathartic; it should be free from arsenic, and when purified it may be given in doses of half an ounce to one ounce (15.5 to 31.1 Gm.).

SODII PHOSPHAS EFFERVESCENS. U.S. Effervescent Sodium Phosphate

	Metric	Old form
* **Exsiccated Sodium Phosphate,** in fine powder	200 Gm.	4 oz. av.
Sodium Bicarbonate, dried and powdered	477 Gm.	9½ oz. av.
Tartaric Acid, dried and powdered	252 Gm.	5 oz. av.
Citric Acid, uneffloresced crystals	162 Gm.	3¼ oz. av.
To make	1000 Gm.	20 oz. av.

Powder the Citric Acid and mix it intimately with the Exsiccated Sodium Phosphate and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate.

Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence, by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.

Uses.—Effervescent Sodium Phosphate furnishes a pleasant means of administering sodium phosphate. Dose, two drachms (8 Gm.).

SODII PHOSPHAS EXSICCATUS. U.S. Exsiccated Sodium Phosphate

It should contain not less than 99 percent. of pure anhydrous Sodium Phosphate [$PO.(OH)(ONa)_2$], and should be kept in well-stoppered bottles.

Sodium Phosphate, a convenient quantity

Allow the crystals to effloresce for several days in warm air, at a temperature of from 25° to 30° C. (77° to 86° F.), then continue the drying in an oven; raise the temperature very gradually until 100° C. (212° F.) has been reached, and maintain this temperature until the salt ceases to lose weight. Powder and sift the residue, and preserve it in well-stoppered bottles.

A white powder which absorbs moisture readily, and which, after allowance is made for the loss of 60.3 percent. of water of crystallization, conforms to the reactions and tests given under *Sodii Phosphas.*

Uses.—This salt is used in making effervescent sodium phosphate. It may be given in fifteen grain (1 Gm.) doses.

LIQUOR SODII PHOSPHATIS COMPOSITUS. U.S. Compound Solution of Sodium Phosphate

	Metric	Old form
* **Sodium Phosphate,** uneffloresced crystals	1000 Gm.	33 oz. av. 167 gr.
Sodium Nitrate	40 Gm.	1 oz. av. 147 gr.
Citric Acid	130 Gm.	4 oz. av. 149 gr.
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

Triturate the Sodium Phosphate and Sodium Nitrate, in a mortar, with the Citric Acid, until completely liquefied, then add sufficient Distilled Water to make the product measure 1000 Cc. [old form 2 pints]. Filter the liquid. Keep the solution in well-stoppered bottles in a moderately warm place.

Tests for Identity.—If to 1 Cc. of the Solution, diluted with an equal volume of water, a slight excess of ammonia water, followed by 1 Cc. of magnesia mixture T. S., be added, a white crystalline precipitate will be obtained.

If 1 Cc. of the Solution, diluted with 5 Cc. of water, be mixed with an equal volume of sulphuric acid, and to the cooled mixture a crystal of ferrous sulphate be added, a dark brown zone will appear around the crystal.

If 5 Cc. of the Solution be neutralized with ammonia water, an excess of calcium chloride T.S. added, and the mixture filtered, the filtrate, upon boiling, should deposit a white precipitate.

Uses.—This solution, which represents the salt in the proportion of 1 Gm. in 1 Cc., was made official in the U. S. P. (8th Rev.) to furnish a convenient form for the exhibition of sodium phosphate, which, while soluble in water, is not rapidly dissolved; sodium nitrate and citric acid are added to prevent the solution from crystallizing; nevertheless, in cold weather the solution should be kept in a moderately warm place. The dose is two fluidrachms (8 Cc.).

SODII PYROPHOSPHAS. U.S. Sodium Pyrophosphate

$Na_4P_2O_7 + 10H_2O = 443.02$

It should contain, in an uneffloresced condition, not less than 99 percent. of pure Sodium Pyrophosphate [$(PO)_2O.(ONa)_4 + 10H_2O$], and should be kept in well-stoppered bottles.

Preparation.—Sodium pyrophosphate, as its name indicates, is prepared by heating sodium phosphate in a suitable vessel to redness. When sodium phosphate is subjected to a temperature of 44° C. (111.2° F.), it melts in its water of crystallization; if the heat be increased to 100° C. (212° F.), all the water is dispelled, and but 40 percent. of the original weight remains; at 390° C. (572° F.) it is converted into the tetrabasic phosphate or pyrophosphate. By dissolving this residue in water, filtering, and crystallizing, the salt may be obtained.

Official Description.—Colorless, transparent, monoclinic prisms, or a crystalline powder; slightly efflorescent in warm air.

Odor, Taste, and Reaction.—Odorless; cooling, saline, and feebly alkaline taste. Its aqueous solution is feebly alkaline to red litmus paper and to phenolphthalein paper.

Solubility.—*Water.* In about 11.5 parts at 25° C. (77° F.), and in 1.1 parts of boiling water. *Alcohol.* Insoluble.

Tests for Identity.—When heated to 100° C. (212° F.), the salt loses its water of crystallization (40.35 percent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass. To a non-luminous flame it imparts an intense yellow color.

An aqueous solution of the salt (1 in 20) yields with magnesia mixture a white precipitate; with silver nitrate T.S. it yields a white precipitate (distinction from *orthophosphate*).

With an excess of ammonium molybdate T.S. no precipitate is formed within fifteen or twenty minutes, even when a gentle heat is applied (distinction from *orthophosphate*).

Impurities and Tests for Impurities.—*Carbonate.* An aqueous solution of the salt (1 in 20) yields with silver nitrate T.S. a white precipitate which is soluble in ammonia water and also in nitric acid without effervescence.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—This salt is used principally in preparing ferric pyrophosphate. It may be given in doses of from ten to thirty grains (0.6 to 2 Gm).

SODII SALICYLAS. U.S. Sodium Salicylate

$NaC_7H_5O_3 = 158.89$

It should contain not less than 99.5 percent. of pure Sodium Salicylate [$C_6H_4(OH)COONa$], and should be kept in well-stoppered bottles, protected from heat and light.

Preparation.—Sodium salicylate is prepared by mixing one hundred parts of pure salicylic acid with sufficient distilled water to form a paste, and then with one hundred and four parts of pure crystallized sodium carbonate (uneffloresced) in a glass or porcelain vessel; carbon dioxide will be evolved, and sodium salicylate will remain in solution.

$$\underset{\text{Salicylic Acid}}{2HC_7H_5O_3} + \underset{\substack{\text{Sodium}\\ \text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Sodium}\\ \text{Salicylate}}}{2NaC_7H_5O_3} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\ \text{Dioxide}}}{CO_2}$$

The liquid may be strained through thoroughly washed muslin if necessary, and heated in a porcelain dish until the carbon dioxide is expelled.

It should not be filtered through ordinary paper, on account of the impurities generally present in paper; the slightest contact with iron will discolor the product, and for this reason the commercial sodium carbonate is unfitted for use in making this salt.

If alkaline to litmus paper, enough salicylic acid must be added to be slightly in excess, and the solution should be evaporated at a low heat to dryness. If the acid is not in excess, the salt will not be white, but gray or lead-colored; and if heated too much, the odor of phenol will be noticed.

Official Description.—White, microcrystalline powder or scales, or an amorphous, colorless powder, or having not more than a faint pink tinge.

Odor, Taste, and Reaction.—Odorless; sweetish, saline taste. An aqueous solution when freshly made should be colorless, and should slightly redden blue litmus paper.

Solubility.—*Water.* In 0.8 part at 25° C. (77° F.); very soluble in boiling water.

Alcohol. In 5.5 parts at 25° C. (77° F.); very soluble in boiling alcohol.

Other solvents. Soluble in glycerin.

Tests for Identity.—When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaves a residue of sodium carbonate. To a non-luminous flame it imparts an intense yellow color.

Ferric chloride T.S., added to an excess of a concentrated solution of the salt, produces a violet precipitate; but when added to a dilute solution (1 in 100), it produces a deep violet-blue color.

If copper sulphate T.S. be added to the aqueous solution (1 in 20), a green color is produced.

On adding to about 0.2 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and then, cautiously, drop by drop, about 1 Cc. of methyl alcohol, and heating the mixture to boiling, methyl salicylate will be evolved, recognizable by its odor.

Diluted hydrochloric or sulphuric acid produces in a concentrated aqueous solution of the salt a voluminous, white precipitate, which, after being separated by filtration, and washed, should conform to the reactions and tests given under *Acidum Salicylicum.*

Impurities and Tests for Impurities.—*Sulphites.* If to an aqueous solution of the salt (1 in 20), 3 drops of iodine T.S. and a slight excess of hydrochloric acid be added, the filtrate from this mixture should not yield a precipitate upon the addition of barium chloride T.S.

Heavy metals. If the aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of dry Sodium Salicylate be thoroughly ignited at a red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 12.5 (12.52) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.

Uses.—This salt is administered in rheumatic and neuralgic affections, in doses of fifteen to thirty grains (1 to 2 Gm.).

SODII SULPHAS. U.S. Sodium Sulphate

$Na_2SO_4 + 10H_2O = 319.91$

[GLAUBER'S SALT]

It should contain, in an uneffloresced condition, not less than 99 percent. of pure Sodium Sulphate [$SO_2(ONa)_2 + 10H_2O$], and should be kept in well-closed vessels, in a cool place.

Preparation.—This salt is largely obtained as a by-product in the manufacture of soda-ash, hydrochloric and nitric acids, ammonium chloride, etc.

Official Description.—Large, colorless, transparent, monoclinic prisms, or granular crystals. Effloresces rapidly in the air, and finally loses all of its water of crystallization.

Odor, Taste, and Reaction.—Odorless; bitter, saline taste; neutral reaction.

Solubility.—*Water.* In 2.8 parts at 15° C. (59° F.), in 0.25 part at 34° C. (93.2° F.), and in 0.47 part at 100° C. (212° F.).

Alcohol. Insoluble.

Other solvents. Soluble in glycerin.

Tests for Identity.—When heated to 33° C. (91.4° F.), the salt fuses, and, on continuing the heat to 100° C. (212° F.), it loses all of its water of crystallization (55.9 percent.). At a red heat the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intense yellow color.

An aqueous solution of Sodium Sulphate (1 in 20) yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Care must be employed, in using the formulas requiring this salt, to see that it is not effloresced, as such a salt may have lost half of its water of crystallization, and be therefore one-third stronger than it should be.

Uses.—This well known sulphate is largely used in veterinary practice. As a purgative it is not so well suited for administration to human beings, the magnesium sulphate being preferred. It may be given to adults in doses of half an ounce to one ounce (16 to 32 Gm.).

SODII SULPHIS. U. S. Sodium Sulphite

$$Na_2SO_3 + 7H_2O = 250.39$$

It should contain, in the uneffloresced and air-dried condition, not less than 94 percent. of pure Sodium Sulphite, and should be kept in well-stoppered bottles, in a cool place.

Preparation.—A very satisfactory mode of making this sulphite is by dissolving a convenient weight of sodium carbonate in a small quantity of water, then passing sulphurous acid gas through the solution until it is completely saturated and acid sodium sulphite is formed. The addition of an equal weight of sodium carbonate forms a solution of the neutral sulphite, which is to be evaporated and crystallized.

$$\underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} + \underset{\substack{\text{Sulphur}\\\text{Dioxide}}}{SO_2} = \underset{\substack{\text{Sodium}\\\text{Sulphite}}}{Na_2SO_3} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

The sodium sulphite which is most frequently used now is the *granulated sodium sulphite:* this is prepared by evaporating a solution of the sulphite to dryness in the usual manner. As thus prepared, it is much more stable than the crystallized salt; it should be remembered, however, that it is of nearly twice the strength of the latter, and the quantity used should be proportionately lessened. Theoretically, the quantity of water present in the crystals is exactly half their weight.

Official Description.—Colorless, transparent, monoclinic prisms. Exposed to the air, the salt effloresces, and is slowly oxidized to sulphate.

Odor, Taste, and Reaction.—Odorless; cooling, saline, sulphurous taste; neutral or feebly alkaline reaction.

Solubility.—*Water.* In 2 parts at 25° C. (77° F.), and in 1.4 parts of boiling water.

Alcohol. Sparingly soluble.

Tests for Identity.—When gently heated, the salt softens somewhat, but it does not fuse. Above 100° C. (212° F.) the crystals lose all their water (50 percent.), without fusing or changing their shape. At a red heat the salt fuses to a reddish-yellow mass of sodium sulphate and sodium sulphide. To a non-luminous flame the salt imparts an intense yellow color.

Upon the addition of hydrochloric acid to the salt, sulphur dioxide gas is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. and held in the escaping gas.

Impurities and Tests for Impurities.—*Thiosulphate.* If 1 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, the liquid should not become turbid.

Heavy metals.—If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid and heated sufficiently to expel the sulphur dioxide, the remaining solution, after being restored to its original volume, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If to 50 Cc. of tenth-normal iodine V.S., measured from a burette into a glass-stoppered vial (of about 100 Cc. capacity), 0.5 Gm. of the finely powdered crystals of Sodium Sulphite be added, and after solution has taken place, not more than 12.45 Cc. of tenth-normal sodium thiosulphate V.S. should be required to discharge the color of the solution.

Uses.—Sodium sulphite is one of the most useful antiferments. It is given in doses of ten to thirty grains (0.6 to 2 Gm.).

SODII THIOSULPHAS. U.S. Sodium Thiosulphate

$$Na_2S_2O_3 + 5H_2O = 246.46$$

[SODII HYPOSULPHIS, PHARM. 1890 SODIUM HYPOSULPHITE]

It should contain not less than 98 percent. of pure Sodium Thiosulphate, and should be kept in well-stoppered bottles.

Preparation.—Sodium thiosulphate, official in the U. S. P. 1890 as *sodium hyposulphite*, is made by decomposing soluble calcium thiosulphate, obtained by the oxidation of alkali waste, with either sodium sulphate or sodium carbonate.

$$\underset{\substack{\text{Calcium}\\ \text{Thiosulphate}}}{CaS_2O_3} + \underset{\substack{\text{Sodium}\\ \text{Sulphate}}}{Na_2SO_4} = \underset{\substack{\text{Sodium}\\ \text{Thiosulphate}}}{Na_2S_2O_3} + \underset{\substack{\text{Calcium}\\ \text{Sulphate}}}{CaSO_4}$$

Other methods of making "hyposulphite of soda" have been used, but the above process has superseded them because of its economy. It is now made on a very large scale.

Official Description.—Colorless, transparent, monoclinic prisms. Permanent in the air below 33° C. (91.4° F.), but efflorescent in dry air above that temperature; slightly deliquescent in moist air.

Odor, Taste, and Reaction.—Odorless; cooling, afterwards bitter taste; neutral or faintly alkaline reaction.

Solubility.—*Water.* In about 0.35 part at 25° C. (77° F.) at a boiling heat the solution is rapidly decomposed.

Alcohol. Insoluble.

Other solvents. Slightly soluble in oil of turpentine.

Tests for Identity.—When rapidly heated to 50° C. (122° F.), the salt melts. When slowly heated until it is effloresced, and afterwards to 100° C. (212° F.), it loses all of its water of crystallization (36.3 percent.), and at a red heat is decomposed, sulphur being liberated, while a residue of sodium sulphide and sodium sulphate remains. To a non-luminous flame it imparts an intense yellow color.

An aqueous solution of Sodium Thiosulphate readily dissolves many salts of silver (chloride, bromide, iodide, oxide, etc.), and discharges the color of a solution of iodine or of starch iodide.

If ferric chloride T.S. be dropped into the aqueous solution (1 in 20), a dark violet color will be produced, which disappears rapidly on agitation.

Addition of sulphuric or hydrochloric acid to the aqueous solution liberates from it sulphur dioxide (recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the escaping gas); a white precipitate of sulphur is also formed (distinction from *sulphite* or *bisulphite*).

Impurities and Tests for Impurities.—*Arsenic.* If to 5 Cc. of an aqueous solution of the salt (1 in 10), 3 Cc. of nitric acid be added, the solution cautiously evaporated to dryness on a water-bath, and the residue treated with distilled water, the liquid filtered, and the filtrate and washings evaporated to dryness, this residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Heavy metals. The residue from 20 Cc. of an aqueous solution (1 in 20), treated as directed above, when dissolved in 20 Cc. of water and slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Calcium. The aqueous solution (1 in 20) should not be rendered turbid by the addition of ammonium oxalate T.S.

Sulphide. An aqueous solution of the salt (1 in 20) should not be colored red by a drop of phenolphthalein T.S. (absence of *caustic alkali* or *carbonate*); nor should a drop of silver nitrate T.S. produce a brown or a black precipitate in 5 Cc. of this solution.

Quantitative Test.—If 1 Gm. of Sodium Thiosulphate be dissolved in 20 Cc. of water, it should require the addition of not less than 39.75 Cc. of tenth-normal iodine V.S. to produce a slight yellow tint.

Uses.—This compound is used in the official volumetric test solution of sodium thiosulphate, and occasionally in medicine, as an alterative and resolvent, in doses of ten to thirty grains (0.6 to 2 Gm.). Externally, it is used in baths, and also as an ointment. Its principal use is in the arts, as an *antichlor* in paper manufacture; while in photography, under the abbreviated name of "hypo," it is invaluable as a solvent for the unaltered silver chloride or bromide in the film.

CHAPTER XL

THE LITHIUM SALTS

THE lithium salts resemble those of potassium and sodium. The metal lithium is comparatively rare, for although widely distributed in nature, it occurs in such small quantities that the necessary labor to extract it makes it expensive; it is found in *lepidolite,* in *petalite*, in *spodumene*, and in many mineral waters.

Lithium is a metal resembling potassium and sodium, although much less prone to oxidation; it is soft, *and is the lightest of all known metals*, having the specific gravity of 0.5891. Heated in the air, lithium ignites at a temperature above its fusing point, burning with a bright white light; when thrown on water, it oxidizes, but does not fuse like sodium. Chemically, lithium is a monad, like sodium and potassium.

Tests for Lithium Salts

1. A colorless flame is colored a vivid red by volatile salts of lithium.

2. Concentrated solutions of lithium salts yield a white precipitate with ammonium carbonate; no precipitate is produced in dilute solution or if ammonium salts are present.

3. Sodium phosphate produces a white precipitate in alkaline or neutral solutions, which is soluble in acids and in solutions of ammonium salts.

Official Salts and Preparation of Lithium

Official Name	Preparation
Inorganic Radicals	
Lithii Bromidum	By decomposing ferrous bromide with lithium carbonate
Carbonas	By precipitating lithium sulphate with ammonium carbonate
Organic Radicals	
Lithii Benzoas	By treating lithium carbonate with benzoic acid
Citras	By treating lithium carbonate with citric acid
Citras Effervescens	Prepared by mixing finely powdered lithium citrate, sodium bicarbonate, tartaric acid, and citric acid, heating the mass until the whole is uniformly moist, granulating and drying
Salicylas	By treating lithium carbonate with salicylic acid

Unofficial Lithium Salts

Litbii Borocitras Lithium Borocitrate	Dissolve 20 Gm. citric acid, 4 Gm. lithium carbonate, and 6 Gm. boric acid in sufficient boiling water, evaporate carefully to dryness, and reduce to a powder
Lithii Chloridum, LiCl Lithium Chloride	Dissolve lithium carbonate in hydrochloric acid, concentrate, and crystallize
Lithii Diborocitras Lithium Diborocitrate	Dissolve 20 Gm. citric acid, 7 Gm. lithium carbonate, and 12 Gm. boric acid in sufficient boiling water, evaporate carefully to dryness, and reduce to a powder
Lithii Iodidum, LiI Lithium Iodide	Digest a solution of calcium iodide with lithium carbonate in slight excess, filter, and evaporate to dryness
Lithii Nitras, $LiNO_3$ Lithium Nitrate	Dissolve lithium carbonate in nitric acid, filter, concentrate, and crystallize
Lithii Phosphas, Li_3PO_4 Lithium Phosphate	Add a solution of lithium carbonate to a solution of sodium phosphate with sodium hydroxide; a crystalline powder will be precipitated
Lithii Sulphas, $Li_2SO_4+H_2O$ Lithium Sulphate	Dissolve lithium carbonate in sulphuric acid, filter, concentrate, and crystallize

LITHII BENZOAS. U.S. **Lithium Benzoate**

$LiC_7H_5O_2 = 127.11$

It should contain not less than 98.5 percent. of pure Lithium Benzoate [$C_6H_5.COOLi$], and should be kept in well-stoppered bottles.

Preparation.—This may be made by Shuttleworth's process, which is as follows:

One ounce (av.) of lithium carbonate is put in an evaporating dish with 9 fluidounces of water, the mixture is heated, and three and a quarter ounces (av.) of benzoic acid in small portions added, until the carbonate is all decomposed and effervescence ceases; the solution is filtered and evaporated to dryness, or crystallized if desired. The yield is three and a half ounces. The advantage of this process is a saving in time and labor in evaporating.

$$\underset{\text{Lithium Carbonate}}{Li_2CO_3} + \underset{\text{Benzoic Acid}}{2HC_7H_5O_2} = \underset{\text{Lithium Benzoate}}{2LiC_7H_5O_2} + \underset{\text{Water}}{H_2O} + \underset{\text{Carbon Dioxide}}{CO_2}$$

Official Description.—A light, white powder, or small, shining, crystalline scales; permanent in the air.

Odor, Taste, and Reaction.—Odorless, or of faint benzoin-like odor; cooling, sweetish taste. The aqueous solution (1 in 20) has an alkaline reaction upon litmus, but is neutral to phenolphthalein T.S.

Solubility.—*Water.* Soluble in 3 parts at 25° C. (77° F.), and in 2.5 parts of boiling water.

Alcohol. In 13 parts at 25° C. (77° F.), and in 10 parts of boiling alcohol.

Its solubility in water is increased by the presence of sodium benzoate, but lessened when alcohol is the solvent.

Tests for Identity.—When heated, the salt fuses; at a higher temperature it chars, emits inflammable vapors having a benzoin-like odor, and finally leaves a residue of lithium carbonate mixed with carbon. This residue imparts a crimson color to a non-luminous flame, and its aqueous solution has an alkaline reaction upon litmus paper.

The addition of a few drops of ferric chloride T.S. to the above solution will produce a voluminous flesh-colored precipitate of ferric benzoate.

If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.6 Gm. of Lithium Benzoate, a white precipitate of benzoic acid will be formed, which, after collecting upon a filter and thoroughly washing and drying, should respond to the tests of purity given under *Acidum Benzoicum.*

Impurities and Tests for Impurities.—*Limit of other alkalies.* If the filtrate and washings from this precipitate be evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and 10 Cc. of amyl alcohol (boiling point 132° C.) be added, and the mixture cautiously heated until the lower aqueous layer has evaporated, then, after the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.004 Gm. The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

If 1 Gm. of the salt be dissolved in 20 Cc. of water, and the benzoic acid precipitated by the addition of a sufficient quantity of hydrochloric acid, the filtrate should respond to the following tests of purity:

Limit of iron, aluminum, etc. The addition of ammonia water until the solution has an alkaline reaction should produce neither turbidity nor precipitation, either before or after boiling.

Heavy metals. Another portion of this solution should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Gravimetric Test.—If 0.5 Gm. of Lithium Benzoate be thoroughly mixed with about 1 Gm. of powdered anhydrous ammonium sulphate and cautiously ignited in a porcelain crucible, until of constant weight, the residue should weigh not less than 0.210 Gm., nor more than 0.216 Gm.

Uses.—Lithium benzoate is used as a remedy in gout and rheumatism, in doses of fifteen to twenty grains (1 to 1.3 Gm.).

LITHII BROMIDUM. U.S. **Lithium Bromide**

$LiBr = 86.34$

It should contain when well dried not less than 97 percent. of pure Lithium Bromide, and should be kept in well-stoppered bottles.

Preparation.—There are several methods of making this salt: 1. By dissolving lithium carbonate in hydrobromic acid. 2. By mixing solutions of lithium sulphate and potassium bromide. 3. By mixing lithium carbonate, bromine, and water together, and passing hydrogen sulphide gas through the mixture. 4. By placing 300 grains of iron and 2 fluidounces of water in a flask, and adding gradually 1 oz. av. of bromine, shaking with the application of moderate heat until the mixture has acquired a green color and lost the odor of bromine; the solution of ferrous bromide is then filtered, heated, and 200 grains of lithium carbonate are added. The solution is filtered, and evaporated until the salt granulates.

$$\underset{\substack{\text{Ferrous}\\\text{Bromide}}}{FeBr_2} + \underset{\substack{\text{Lithium}\\\text{Carbonate}}}{Li_2CO_3} = \underset{\substack{\text{Lithium}\\\text{Bromide}}}{2LiBr} + \underset{\substack{\text{Ferrous}\\\text{Carbonate}}}{FeCo_3}$$

Official Description.—A white, granular salt; very deliquescent.

Odor, Taste, and Reaction.—Odorless, and having a sharp, slightly bitter taste. The aqueous solution is slightly alkaline to litmus paper.

Solubility.—*Water.* Soluble in 0.6 part at 25° C. (77° F.), and in 0.3 part of boiling water.

Alcohol. Very soluble.

Other solvents. Soluble in ether.

Tests for Identity.—At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame.

Silver nitrate T.S. produces a yellowish-white precipitate insoluble in nitric acid, and in a moderate excess of ammonia water.

Impurities and Tests for Impurities.—*Iodine.* If there be added to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform, followed by chlorine water added cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Limit of potassium. If 0.5 Cc. of sodium cobaltic nitrite T.S. be added to 5 Cc. of an aqueous solution of the salt (1 in 20), no precipitate or turbidity should occur within 10 minutes.

Limit of other alkalies. If to 0.4 Gm. of Lithium Bromide contained in a flat-bottomed flask of 50 Cc. capacity, an excess of hydrochloric acid be added, and the mixture evaporated almost to dryness on a water-bath, and if 10 Cc. of amyl alcohol (boiling point 132° C.) be added and the mixture cautiously heated until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.007 Gm. The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

Limit of iron, aluminum, etc. The addition of a slight excess of ammonia water to the aqueous solution of the salt (1 in 20), which has been acidulated with hydrochloric acid, should produce neither turbidity nor precipitation, either before or after boiling.

Heavy metals. An aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 1 Gm. of dry Lithium Bromide be dissolved in sufficient distilled water to measure 100 Cc., then 20 Cc. of this solution, to which 2 drops of potassium chromate T.S. are added, should require not less than 22.5 Cc., nor more than 23.9 Cc., of tenth-normal silver nitrate V.S. to produce a permanent red color.

Uses.—Lithium bromide is probably the most efficient of all the bromides as an hypnotic. The dose is fifteen to thirty grains (1 to 2 Gm.).

LITHII CARBONAS. U.S. Lithium Carbonate

$Li_2CO_3 = 73.51$

It should contain not less than 98.5 percent. of pure Lithium Carbonate [$CO.(OLi)_2$], and should be kept in well-stoppered bottles.

Preparation.—Lithium carbonate may be prepared from lepidolite, one of the minerals in which it is found, in the following manner: 10 parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a wind furnace. The heavy silicate and barium sulphate sink to the bottom, and a layer of potassium and lithium sulphate is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate.

Official Description.—A light, white powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless, and having an alkaline taste. The aqueous solution has an alkaline reaction upon litmus paper.

Solubility.—*Water.* In 75 parts at 25° C. (77° F.), also in 140 parts of boiling water; much more soluble in water saturated with carbon dioxide.

Alcohol. Insoluble.

Other solvents. In diluted acids with active effervescence.

Tests for Identity.—At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. Its solution in hydrochloric acid imparts a crimson color to a non-luminous flame.

If 1 Gm. of Lithium Carbonate be dissolved in 40 Cc. of diluted acetic acid, no insoluble residue should remain.

If 1 part of Lithium Carbonate be mixed with 20 parts of water, and hydrochloric acid be added, drop by drop, with agitation until solution takes place, the resulting solution should, after boiling and cooling, respond to the following tests when applied to separate portions:

Impurities and Tests for Impurities.—*Limit of iron, aluminum, etc.* The addition of ammonia water, until the solution has an alkaline reaction, should produce neither turbidity nor precipitation, either before or after boiling.

Heavy metals. Another portion of this solution should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of other alkalies. If to 0.2 Gm. of Lithium Carbonate contained in a flat-bottomed flask of 50 Cc. capacity a slight excess of hydrochloric acid be added, and the mixture evaporated almost to dryness on a water-bath, and if 10 Cc. of amyl alcohol (boiling point 132° C.) be added and the mixture cautiously heated, until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.003 Gm. The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

Quantitative Test.—If 0.5 Gm. of Lithium Carbonate be dissolved in 20 Cc. of normal sulphuric acid V.S., the resulting solution should require not more than 6.6 Cc. of normal potassium hydroxide V.S. for complete neutralization, methyl-orange T.S. being used as indicator.

Uses.—This salt is the source of the lithium salts, and it is prescribed in gout, in doses of five to fifteen grains (0.3 to 1 Gm.).

LITHII CITRAS. U.S. Lithium Citrate

$$Li_3C_6H_5O_7 + 4H_2O = 280.08$$

It should, when carefully dried, contain not less than 98.5 percent. of pure Lithium Citrate [$C_3H_4(OH)(COOLi)_3$], and should be kept in well-stoppered bottles.

Preparation.—The process formerly official may be usefully employed in making this salt:

Take of Lithium Carbonate 100 grains; Citric Acid, in crystals, 200 grains; Distilled Water 2 fl. oz. Dissolve the Citric Acid in the water gently heated, and to the solution gradually add the Lithium Carbonate until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 240° F., then rapidly pulverize it, and preserve the powder in a well-stoppered bottle.

$$\underset{\substack{\text{Lithium}\\\text{Carbonate}}}{3Li_2CO_3} + \underset{\text{Citric Acid}}{2H_3C_6H_5O_7} = \underset{\text{Lithium Citrate}}{2Li_3C_6H_5O_7} + \underset{\text{Water}}{3H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{3CO_2}$$

Lithium citrate should be kept in well-stoppered bottles.

Official Description.—A white powder, or colorless crystals; deliquescent on exposure to moist air.

Odor, Taste, and Reaction.—Odorless, and having a cooling, faintly alkaline taste. The aqueous solution (1 in 20), is faintly alkaline to litmus paper, and should not redden phenolphthalein T.S.

Solubility.—*Water.* Soluble in about 2 parts at 25° C. (77° F.), and in 1.5 parts of boiling water.

Alcohol. Almost insoluble.

Other solvents. Almost insoluble in ether.

Tests for Identity.—At a red heat the salt chars, emits inflammable vapors having a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame.

If an aqueous solution of Lithium Citrate (1 in 20) be boiled with an equal volume of calcium chloride T.S., a white precipitate will form.

Impurities and Tests for Impurities.—*Limit of other alkalies.* If the residue obtained by igniting 0.2 Gm. of the salt at a red heat be treated with a slight excess of diluted hydrochloric acid, and the filtrate and washings evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and if 10 Cc. of amyl alcohol (boiling point 132° C.) be added, and the mixture cautiously heated until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.002 Gm. The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

Heavy metals. The solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of iron, aluminum, etc. The residue of lithium sulphate resulting from the ignition (see Gravimetric Test below), after being dissolved in 10 Cc. of boiling water and acidified with hydrochloric acid, should, upon the addition of ammonia water until the solution has an alkaline reaction, not become turbid or form a precipitate, either before or after boiling.

Gravimetric Test.—If 0.5 Gm. of Lithium Citrate dried at 150° C. (302° F.) be cautiously ignited in a porcelain crucible, and if, after cooling, the residue be moistened with a few drops each of nitric and sulphuric acids and again cautiously ignited, repeating the operation until the residue becomes white and of constant weight, then the residue of lithium sulphate should weigh not less than 0.387 Gm., nor more than 0.394 Gm.

Uses.—Lithium citrate is used for the same purpose as lithium carbonate; it is more soluble than the latter. The dose is from five to twenty grains (0.3 to 1.3 Gm.).

LITHII CITRAS EFFERVESCENS. U.S. Effervescent Lithium Citrate

	Metric	Old form
* **Lithium Citrate**	50 Gm.	1 oz. av.
Sodium Bicarbonate, dried and powdered	570 Gm.	11 oz. av. 175 gr.
Tartaric Acid, dried and powdered	300 Gm.	6 oz. av.
Citric Acid, uneffloresced crystals	195 Gm.	3 oz. av. 394 gr.
To make about	1000 Gm.	20 oz. av.

Powder the Citric Acid and mix it intimately with the Lithium Citrate and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.).

When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.

Uses.—This salt forms a pleasant mode of administering a lithium salt; the dose is one to two drachms (4 to 8 Gm.).

LITHII SALICYLAS. U.S. Lithium Salicylate

$LiC_7H_5O_3 = 142.99$

It should contain not less than 98.5 percent. of pure Lithium Salicylate [C_6H_4-(OH)COOLi], and should be kept in well-stoppered bottles.

Preparation.—This salt may be prepared by adding 60 grains of lithium carbonate to 1 fluidounce of distilled water and heating the mixture to boiling, then adding 220 grains of salicylic acid and continuing the heat until effervescence ceases, filtering, and evaporating.

$$\underset{\substack{\text{Lithium}\\\text{Carbonate}}}{Li_2CO_3} + \underset{\text{Salicylic Acid}}{2HC_7H_5O_3} = \underset{\substack{\text{Lithium}\\\text{Salicylate}}}{2LiC_7H_5O_3} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

This salt should be kept in well-stoppered bottles.

Official Description.—A white or grayish-white powder; deliquescent in a moist atmosphere.

Odor, Taste, and Reaction.—Odorless, and having a sweetish taste. The aqueous solution (1 in 20) should be neutral or slightly acid to litmus paper.

Solubility.—*Water.* Very soluble.

Alcohol. Very soluble.

Tests for Identity.—When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame.

If copper sulphate T.S. be added to an aqueous solution of the salt (1 in 20), the mixture should have a bright green color.

If a few drops of ferric chloride T.S. be added to an excess of a concentrated aqueous solution of Lithium Salicylate (1 in 4), a deep red color will be produced, which, after the liquid is largely diluted and mixed with more ferric chloride T.S., will change to a deep bluish-violet tint.

Upon adding to 0.5 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and cautiously, drop by drop, about 1 Cc. of methyl alcohol, then, on heating the mixture to boiling, the odor of oil of gaultheria will be evolved.

If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.7 Gm. of Lithium Salicylate, a voluminous precipitate of salicylic acid will be formed, which, after collecting upon a filter and thoroughly washing and drying, should conform to the reactions and tests given under *Acidum Salicylicum.*

Impurities and Tests for Impurities.—*Iron and organic coloring matters.* The aqueous solution should be colorless.

Carbonate. The aqueous solution should not effervesce upon the addition of diluted acids.

Limit of other alkalies. If the filtrate and washings from this precipitate be evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and 10 Cc. of amyl alcohol (boiling point 132° C.) added, and if, after cautiously heating until the lower aqueous layer has evaporated, 3 drops of hydrochloric acid be added and the solution boiled for three minutes, the resulting insoluble residue should weigh not more than 0.005 Gm. The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution.

If 1 Gm. of the salt be dissolved in 20 Cc. of water, and the salicylic acid precipitated by the addition of a sufficient quantity of hydrochloric acid, the filtrate should respond to the following tests of purity:

Limit of iron, aluminum, etc. The addition of ammonia water until the solution has an alkaline reaction should produce neither turbidity nor precipitation, either before or after boiling.

Heavy metals. Another portion of this solution should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Gravimetric Test.—If 0.5 Gm. of dry Lithium Salicylate be thoroughly mixed with about 1 Gm. of powdered anhydrous ammonium sulphate, and cautiously ignited in a porcelain crucible until of constant weight, the residue should weigh not less than 0.188 Gm., nor more than 0.192 Gm.

Uses.—This salicylate is used, like sodium salicylate, for rheumatism and gout; it is given in doses of fifteen to forty grains (1 to 2.6 Gm.).

CHAPTER XLI

AMMONIUM

THE ammonium salts resemble those of the alkali metals so closely in their physical and chemical properties that they are appropriately considered in this place.

The metal ammonium has not yet been isolated in the free state, so that its appearance cannot be described. An *ammonium amalgam* is known, however, made by dissolving potassium in mercury and adding a strong solution of ammonium chloride to it. It is a spongy, metallic substance, which easily decomposes into ammonia, mercury, and hydrogen.

Tests for Ammonium Salts

1. At high temperatures ammonium compounds are volatilized.

2. When heated with sodium, potassium, or calcium hydroxide, the odor of ammonia is evolved; the latter restores the color of reddened litmus paper, and darkens the blue color of paper moistened with solution of copper sulphate. Ammonia forms a white cloud with vapor of hydrochloric acid.

3. Solution of platinic chloride, with a few drops of hydrochloric acid, if added to a solution of an ammonium salt, produces a yellow precipitate.

4. Ammonium salts are mostly colorless, and generally very soluble in water.

Official Salts and Preparations of Ammonium

Official Name	Composition and Preparation
Aqua Ammoniæ	10 percent. by weight aqueous solution of NH_3
Ammoniæ Fortior	28 percent. by weight aqueous solution of NH_3
Spiritus Ammoniæ	10 percent. by weight alcoholic solution of NH_3
Ammoniæ Aromaticus	An aromatic hydro-alcoholic solution of ammonium carbonate
Linimentum Ammoniæ	35 Cc. ammonia water; 5 Cc. alcohol; 57 Cc. cotton seed oil; 3 Cc. oleic acid
Liquor Ammonii Acetatis	Made by mixing solution of acetic acid and ammonium carbonate
Ammonii Benzoas	By dissolving benzoic acid in ammonia water
Bromidum	By adding ammonia water gradually to bromine under water
Carbonas	By subliming a mixture of ammonium chloride and calcium carbonate
Chloridum	By subliming a mixture of ammonium sulphate and sodium chloride
Iodidum	By mixing solutions of potassium iodide and ammonium sulphate
Salicylas	By neutralizing ammonia water with salicylic acid
Valeras	By passing ammonia gas into monohydrated valeric acid
Trochisci Ammonii Chloridi	1.5 gr. ammonium chloride in each lozenge

Unofficial Salts and Preparations of Ammonium

Ammonii Arsenas, $(NH_4)_2HAsO_4$ Ammonium Arsenate	Saturate a concentrated solution of arsenic trioxide with ammonia water and allow it to evaporate spontaneously
Ammonii Bicarbonas, NH_4HCO_3 Ammonium Bicarbonate	Treat 1 Gm. powdered ammonium carbonate with 2 Gm. water, and decant the liquid, the residue being the bicarbonate

Unofficial Salts and Preparations of Ammonium—*Continued*

Ammonii Boras, $2(NH_4HBr_2O_4)+3H_2O$ Ammonium Borate	Dissolve 1 Gm. boric acid in 3 Gm. warm ammonia water, sp. gr. 0.960, and allow to cool slowly
Ammonii Carbonas Pyro-oleosus Pyro-oleous Ammonium Carbonate	Incorporate thoroughly 32 Gm. ammonium carbonate with 1 Gm. ethereal animal oil
Ammonii Citras, $(NH_4)_3C_6H_5O_7+3H_2O$ Ammonium Citrate	Dissolve 1 Gm. citric acid in water, add sufficient ammonia water to neutralize, filter, concentrate, and crystallize
Ammonii Dichromas, $(NH_4)_2Cr_2O_7$ Ammonium Dichromate	Add chromium trioxide to ammonia water, concentrate, and crystallize
Ammonii et Ferri Chloridum Ammonium and Iron Chloride	Mix 32 Gm. ammonium chloride with 9 Gm. solution of ferric chloride, and evaporate to dryness with constant stirring
Ammonii et Potassii Tartras Ammonium and Potassium Tartrate	Add ammonium carbonate to a hot solution of acid potassium tartrate until neutralized, evaporate, and crystallize
Ammonii Formas, NH_4CHO_2 Ammonium Formate	Neutralize formic acid with ammonia water, evaporate, and crystallize
Ammonii Fluoridum, NH_4F Ammonium Fluoride	Saturate hydrofluoric acid with ammonia water
Ammonii Nitras, NH_4NO_3 Ammonium Nitrate	Treat ammonium carbonate with nitric acid
Ammonii Nitris, NH_4NO_2 Ammonium Nitrite	Add a solution of ammonium chloride to one of silver nitrate, and evaporate the clear solution over sulphuric acid to dryness
Ammonii Phosphas, $(NH_4)_2HPO_4$ Ammonium Phosphate	By mixing solutions of phosphoric acid and ammonia
Ammonii Salicylas, $(NH_4)C_7H_5O_3$ Ammonium Salicylate	Neutralize salicylic acid with ammonia water, evaporate, and crystallize
Ammonii Sulphas, $(NH_4)_2SO_4$ Ammonium Sulphate	By saturating gas liquor with sulphuric acid and crystallizing
Ammonii Sulphis, NH_4HSO_3 Ammonium Sulphite	Pass sulphurous acid into an alcoholic solution of ammonia, and collect the precipitate
Ammonii Sulphocyanidum, NH_4CNS Ammonium Sulphocyanide	Dissolve carbon disulphide in alcohol, and heat in the presence of ammonia water. Lastly, concentrate and crystallize

AQUA AMMONIÆ. U.S. Ammonia Water

An aqueous solution of Ammonia [$NH_3=16.93$] containing 10 percent., by weight, of gaseous ammonia. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 percent., by weight, of the gas. Ammonia Water should be kept in glass-stoppered bottles, in a cool place.

Preparation.—This useful liquid is rarely prepared by the pharmacist, for the reason that it can be made more economically by the manufacturer. The official process of 1870 (see U. S. Dispensatory, 18th edition, page 203) directed that it should be made by mixing ammonium chloride, in small pieces, with milk of lime, and placing the mixture in a retort, connected with a cooled receiver by means of a glass tube, the end of which was dipped beneath the surface of distilled water contained in the receiver. The rationale of this process is that the lime is converted into calcium chloride, while the ammonia gas, liberated by the heat, is dissolved in the distilled water.

$$\underset{\text{Ammonium Chloride}}{2NH_4Cl} + \underset{\text{Calcium Hydroxide}}{Ca(OH)_2} = \underset{\text{Ammonia}}{2NH_3} + \underset{\text{Calcium Chloride}}{CaCl_2} + \underset{\text{Water}}{2H_2O}$$

The manufacturer rarely uses ammonium chloride; the sulphate is cheaper, and it is frequently employed instead. But upon the large scale the ammonia liquor obtained from gas works is used directly as the source, being mixed with milk of lime and heated; the gaseous ammonia is then passed through a series of tubes filled with charcoal, which retain the empyreumatic products. If the tubes are long enough, and sufficient charcoal is employed, a pure product is assured; but much of the commercial ammonia water is empyreumatic through defective purification.

Official Description.—A colorless, transparent liquid.

Odor, Taste, and Reaction.—Very pungent, characteristic odor; caustic alkaline taste; strongly alkaline reaction.

Specific Gravity.—0.958 at 25° C. (77° F.).

Tests for Identity.—It is completely volatilized at 100° C. (212° F.).

On bringing a glass rod dipped into hydrochloric acid near cold Ammonia Water, dense white fumes are produced.

Impurities and Tests for Impurities.—*Limit of readily oxidizable substances.* If 0.1 Cc. of tenth-normal potassium permanganate V.S. be added to 10 Cc. of ammonia water, which has been slightly supersaturated with diluted sulphuric acid, the pink color should not be completely destroyed within ten minutes.

Heavy metals. When neutralized and made slightly acid with hydrochloric acid, Ammonia Water should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Sulphates. If Ammonia Water be slightly supersaturated with nitric acid, it should not be affected by barium chloride T.S.

Chlorides. Nor by silver nitrate T.S.

Coal-tar bases and fixed impurities. If a third portion of the acidulated liquid be evaporated on a water-bath to dryness, it should afford a colorless residue which, on ignition, should be completely volatilized.

Quantitative Test.—Introduce into a stoppered weighing bottle 3 Cc. of Ammonia Water and weigh accurately. Dilute with 50 Cc. of distilled water and titrate with normal sulphuric acid V.S., using litmus or methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V.S. consumed, by 1.693, and divide this product by the weight of the Ammonia Water taken; the quotient represents the percentage of Ammonia gas.

Uses.—Pharmaceutically, ammonia water is frequently used to precipitate iron salts by combining with the acid radicals, ferric hydroxide being thrown down. Its advantage over the fixed alkalies consists in its volatility, any excess being readily detected by the odor. It is largely used for cleaning fabrics. The strength technically known as "Aqua Ammoniæ F. F. F.," or "20° Ammonia," is employed most frequently in the arts; the latter may be diluted with water, according to the formula given on page 98, if it is desirable to make official ammonia water from it. In round numbers, three parts of 20° ammonia water require two parts of water to reduce it to the strength of official ammonia water. Ammonia water is rarely used internally, the aromatic spirit being preferred. The dose is ten to twenty minims (0.6 to 1.2 Cc.), largely diluted. Externally, it is caustic and stimulating. Its old name is *Spirits of Hartshorn*, but it is desirable to supplant such names, and use those which are modern, the name *ammonia* is thoroughly established by common usage.

AQUA AMMONIÆ FORTIOR. U.S. Stronger Ammonia Water

An aqueous solution of Ammonia [$NH_3 = 16.93$] containing 28 percent., by weight, of gaseous ammonia. This solution deteriorates on keeping, and should be tested frequently. Stronger Ammonia Water should be kept in partially filled, strong, glass-stoppered bottles, in a cool place. *Great caution should be used in handling this liquid.*

Preparation.—Stronger ammonia water is prepared in the same way that ammonia water is, the only difference between the two solutions being that of relative strength.

Official Description.—A colorless, transparent liquid.

Odor, Taste, and Reaction.—Excessively pungent odor; very caustic and alkaline taste; strongly alkaline reaction.

Specific Gravity.—0.897 at 25° C. (77° F.).

Tests for Identity.—If Stronger Ammonia Water be diluted with twice its volume of distilled water, it should respond to the reactions and tests described under *Aqua Ammoniæ*.

Quantitative Test.—The percentage of ammonia gas in Stronger Ammonia Water should be determined by the same test as that given under *Aqua Ammoniæ*.

Uses.—This liquid is used externally as a caustic and vesicant, and for making ammonia water by dilution and also in spirit of ammonia. It is too strong for internal administration.

SPIRITUS AMMONIÆ. U.S. Spirit of Ammonia

An alcoholic solution of Ammonia [$NH_3 = 16.93$] containing 10 percent., by weight, of the gas. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 percent. of gaseous ammonia.

This is an alcoholic solution of ammonia gas, of exactly the same strength as ammonia water (see page 313 for the process). The object of selecting a stronger aqueous solution of the same gas, to furnish the active ingredient, was to obtain an accurate and uniform quantity of the latter conveniently and without contamination. Practically, considerable difficulty will be experienced in maintaining the temperature of 60° C. (140° F.) for ten minutes. The amount of ammonia present is determined by a volumetric assay (see below).

Official Description.—A colorless liquid.

Odor.—Strong odor of ammonia.

Specific Gravity.—About 0.808 at 25° C. (77° F.).

Tests for Identity.—When diluted with water, it should respond to the tests for identity and purity given under *Aqua Ammoniæ*.

Assay.—Introduce into a weighing bottle about 2 Cc. of the Spirit, weigh accurately, dilute with 50 Cc. of distilled water, and titrate with half-normal sulphuric acid V.S., using litmus T.S. as indicator. Multiply the number of Cc. of half-normal sulphuric acid V.S. consumed, by 0.008465, and this product by 100, and divide by the weight in grammes of the Spirit taken to obtain the percentage of ammonia gas.

Uses.—Spirit of ammonia is antacid and stimulant. It is not used internally to any extent, the aromatic spirit of ammonia being preferred. The dose is from ten to twenty minims (0.6 to 1.2 Cc.), largely diluted with water.

SPIRITUS AMMONIÆ AROMATICUS. U.S. Aromatic Spirit of Ammonia

	Metric	Old form
* **Ammonium Carbonate,** in translucent pieces	34 Gm.	1 oz. av. 1 dr.
Ammonia Water	90 Cc.	2 fl. oz. 7 fl. dr.
Oil of Lemon	10 Cc.	2½ fl. dr.
Oil of Lavender Flowers	1 Cc.	15 minims
Oil of Myristica	1 Cc.	15 minims
Alcohol	700 Cc.	22 fl. oz. 3 fl. dr.
Distilled Water, a sufficient quantity,		
To make	1000 Cc.	2 pints

To the Ammonia Water, contained in a flask, add 140 Cc. [old form 4½ fl. oz.] of Distilled Water, and afterwards the Ammonium Carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the Ammonium Carbonate is dissolved, and allow it to stand for twelve hours. Introduce the Alcohol into a graduated bottle of suitable capacity, add first the oils, then gradually the solution of Ammonium Carbonate, and afterwards enough Distilled Water to make the product measure 1000 Cc. [old form 2 pints]. Set the liquid aside during twenty-four hours in a cool place, occasionally agitating, then filter it, through paper, in a well-covered funnel.

As ordinarily prepared, from unselected ammonium carbonate, precipitation is very apt to take place ; this is due to the use of exposed and effloresced ammonium carbonate, which contains more than the proper quantity of bicarbonate (see Ammonii Carbonas). The addition of ammonia water in the formula is to convert the bicarbonate into the carbonate, the latter being soluble in the mixture of water and alcohol, while the bicarbonate is insoluble in alcohol. Sufficient time should be given to effect the solution. The ammonium carbonate should be carefully selected, and only the translucent pieces used.

Official Description.—A nearly colorless liquid when freshly prepared, but gradually acquiring a somewhat darker tint.
Odor and Taste.—Pungent odor and taste of ammonia.
Specific Gravity.—About 0.900 at 25° C. (77° F.).

Uses.—This is a very valuable and largely used antacid and stimulant. The dose is from twenty to sixty minims (1.3 to 4 Cc.), largely diluted with water.

LIQUOR AMMONII ACETATIS. U.S. Solution of Ammonium Acetate

[SPIRIT OF MINDERERUS]

An aqueous solution which should contain not less than 7 percent. of Ammonium Acetate [$CH_3.COONH_4 = 76.51$], with small amounts of acetic and carbonic acids.

	Metric	Old form
***Ammonium Carbonate**	**5 Gm.**	365 grains
Diluted Acetic Acid	**100 Cc.**	16 fl. oz.

Add the Ammonium Carbonate (which should be in translucent pieces, free from white, pulverulent bicarbonate) gradually to the cold Diluted Acetic Acid, and stir until it is dissolved.

This preparation should be freshly made when wanted.

Solution of Ammonium Acetate may also be prepared in the following manner :

	Metric	Old form
Ammonium Carbonate	**10 Gm.**	2 oz. av.
Acetic Acid	**28 Gm.**	4⅔ fl. oz.
Distilled Water	**142 Gm.**	about 27 fl. oz.

Dissolve the Ammonium Carbonate in 80 Gm. [old form 1 pint] of Distilled Water, and filter the solution. To the Acetic Acid add 62 Gm. [old form sufficient to make 1 pint] of Distilled Water. Keep the solutions in separate, well-stoppered bottles, and, when Solution of Ammonium Acetate is to be dispensed, weigh (or, if the alternative formula is used, measure) equal quantities of each solution and mix them.

The reaction involved in this process depends upon the decomposition of the ammonium carbonate with acetic acid ; the free carbonic acid is a desirable addition to the solution, which should be dispensed with a moderate amount in solution.

$$\underset{\text{Acid Ammonium Carbonate and Carbamate}}{(NH_4HCO_3)NH_4NH_2CO_2} + \underset{\text{Acetic Acid}}{3HC_2H_3O_2} = \underset{\text{Ammonium Acetate}}{3NH_4C_2H_3O_2} + \underset{\text{Carbon Dioxide}}{2CO_2} + \underset{\text{Water}}{H_2O}$$

It will be found in practice that the last formula is much more satisfactory than the first. The solutions keep well, and it is very convenient to mix them at the time of dispensing, and thus always be enabled to send out a fresh preparation, which retains sufficient carbonic acid to be grateful to the patient.

Official Description.—A clear, colorless liquid.
Odor, Taste, and Reaction.—Free from empyreuma; mildly saline, acidulous taste; acid reaction.
Tests for Identity.—It is wholly volatilized by heat.
When Solution of Ammonium Acetate is heated with potassium hydroxide T.S., ammonia is evolved.
If to 5 Cc. of the Solution 1 Cc. each of sulphuric acid and alcohol be added, and the mixture boiled, the odor of acetic ether will be developed.

Uses.—This solution is used as a diaphoretic or diuretic, in the dose of half a fluidounce (16 Cc.).

AMMONII BENZOAS. U.S. Ammonium Benzoate

$NH_4C_7H_5O_2 = 138.06$

It should contain not less than 98 percent. of pure Ammonium Benzoate [$C_6H_5.COONH_4$], and should be kept in well-stoppered bottles.

Preparation.—This salt may be advantageously prepared by a former official process, which is as follows:

Take of Benzoic Acid 480 grains; Ammonia Water, 3½ fl. oz., or a sufficient quantity; Distilled Water, 4. fl. oz. Dissolve the Acid in 3½ fl. oz. of the Ammonia Water, previously mixed with the Distilled Water; evaporate with a gentle heat, occasionally adding Ammonia Water, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat.

Ammonium Benzoate should be kept in well-stoppered bottles.

The process is one of direct combination, the reaction being as follows:

$$\underset{\substack{\text{Benzoic}\\\text{Acid}}}{HC_7H_5O_2} + \underset{\substack{\text{Ammonia}\\\text{Water}}}{NH_4HO} = \underset{\substack{\text{Ammonium}\\\text{Benzoate}}}{NH_4C_7H_5O_2} + \underset{\text{Water}}{H_2O}$$

The object of retaining an excess of alkali in the process is to prevent the formation of the acid benzoate, which is less soluble than the official salt.

Official Description.—Thin, white, laminar crystals or a crystalline powder; gradually losing ammonia on exposure to the air.
Odor, Taste, and Reaction.—Odorless, or having a slight odor of benzoic acid; saline, bitter, afterwards slightly acrid taste; neutral or very slightly acid reaction.
Solubility.—*Water.* In about 10.5 parts at 25° C. (77° F.); in 1.2 parts of boiling water.
Alcohol. In 28 parts at 25° C. (77° F.); in 7.6 parts of boiling alcohol.
Tests for Identity.—The salt fuses at 193° to 194° C. (379.4° to 381.2° F.), with decomposition, and when strongly heated emits vapors having the odor of ammonia and benzoic acid, and is finally completely volatilized.

A saturated aqueous solution of Ammonium Benzoate affords with ferric chloride T.S. a flesh-colored precipitate, and when such a solution is gently heated with potassium hydroxide T.S. ammonia is evolved.

Impurities and Tests for Impurities.—*Sulphate.* If diluted nitric acid be added in slight excess to the aqueous solution of the salt (1 in 10), the precipitated benzoic acid, after collecting and washing, should respond to the tests of purity and identity given under *Acidum Benzoicum*, and the filtrate from this precipitate should not be affected by barium chloride T.S.

Chloride. Or by silver nitrate T.S.

Heavy metals. If the aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No 121, Chap. LXII).

Uses.—Ammonium benzoate is used as a stimulant diuretic, in doses of five to twenty grains (0.3 to 1.3 Gm.).

AMMONII BROMIDUM. U.S. Ammonium Bromide

$NH_4Br = 97.29$

It should contain not less than 97 percent. of pure Ammonium Bromide, and should be kept in well-stoppered bottles.

Preparation.—Several methods have been employed in making this salt: 1. By double decomposition between solutions of ammonium sulphate and potassium bromide, alcohol being added to separate the ammonium bromide. 2. By adding ammonia water to a solution of ferrous bromide. 3. By Pile's process, one pound of bromine is poured carefully into four times its weight of distilled water in a stone jar, then about one quart of ammonia water is added *very gradually*, a fluidounce at a time, and the top of the jar covered with a glass plate when vapors arise; when all the ammonia has been added, and the solution is free from the smell of bromine, it is evaporated and the salt granulated; the yield is about twenty ounces.

$$\underset{\text{Bromine}}{6Br} + \underset{\text{Ammonia}}{8NH_3} = \underset{\substack{\text{Ammonium}\\\text{Bromide}}}{6NH_4Br} + \underset{\text{Nitrogen}}{N_2}$$

Official Description.—Colorless, transparent, prismatic crystals, or a white, crystalline powder; permanent in dry air.

Odor, Taste, and Reaction.—Odorless; pungent, saline taste; slightly acid reaction.

Solubility.—*Water.* In 1.2 parts at 25° C. (77° F.); in 0.7 part of boiling water.

Alcohol. In 12.5 parts at 25° C. (77° F.); in 9 parts of boiling alcohol.

Tests for Identity.—When heated, Ammonium Bromide volatilizes completely, without fusing.

When the aqueous solution is gently heated with potassium hydroxide T.S., ammonia is evolved.

Silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water.

Impurities and Tests for Impurities.—*Iodide.* If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and if chlorine water, which has been diluted with an equal volume of water, be cautiously introduced drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Bromate. If a few drops of diluted sulphuric acid be brought in contact with a little of the powdered salt on a porcelain plate, the salt should not at once assume a yellowish color.

Limit of iron. An aqueous solution of the salt (1 in 150) should not at once assume a blue color with potassium ferrocyanide T.S.

Barium. Ten Cc. of an aqueous solution of Ammonium Bromide (1 in 20), when acidulated with acetic acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 3 Gm. of the salt be dissolved in sufficient water to measure 100 Cc., then 10 Cc. of this solution, after the addition of a few drops of potassium chromate T.S., should require not more than 31.6 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red coloration.

Uses.—Ammonium bromide is sometimes preferred to potassium bromide as an hypnotic and sedative; it is asserted that it does not produce bromism. The dose is from ten to sixty grains (0.6 to 4 Gm.).

AMMONII CARBONAS. U.S. Ammonium Carbonate

$C_2H_{11}N_3O_5 = 156.01$

It should contain not less than 97 percent. of a mixture of Acid Ammonium Carbonate [$CO(OH)ONH_4$] and Ammonium Carbamate [$CO(NH_2)ONH_4$], and should yield not less than 31.58 percent. of ammonia gas. It should be kept in well-stoppered bottes; in a cool place. For dispensing purposes, only the translucent portions should be used.

Preparation.—The large consumption of this salt of ammonium has led to several methods of preparation. The one which is most used at present is the dry sublimation of ammonium sulphate with chalk or calcium carbonate; by double decomposition calcium sulphate and ammonium carbonate are produced.

$$\underset{\substack{\text{Ammonium}\\\text{Sulphate}}}{2(NH_4)_2SO_4} + \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{2CaCO_3} = \underset{\substack{\text{Ammonium Carbonate}\\\text{(Official)}}}{NH_4HCO_3.NH_4NH_2CO_2} + \underset{\text{Water}}{H_2O} + \underset{\text{Ammonia}}{NH_3} + \underset{\text{Calcium Sulphate}}{2CaSO_4}$$

The advantage claimed for the use of ammonium sulphate over ammonium chloride is simply that of greater economy.

Official ammonium carbonate is, chemically, a mixed salt. It consists of one molecule of acid ammonium carbonate or bicarbonate and one of ammonium *carbamate;* the latter may be regarded as ammonium carbonate minus a molecule of water. If ammonium carbamate is dissolved in water, it is soon changed to normal ammonium carbonate.

$$\underset{\substack{\text{Ammonium}\\\text{Carbamate}}}{NH_4NH_2CO_2} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Normal Ammonium}\\\text{Carbonate}}}{(NH_4)_2CO_3}$$

Hence an aqueous solution of commercial ammonium carbonate contains both the neutral and acid carbonates. If the official ammonium carbonate is exposed to the air, it is soon changed into the acid carbonate or bicarbonate, through loss of ammonia, and it is thus depreciated in quality. The bicarbonate may be converted back into the carbonate by treating it with ammonia water. This fact is officially recognized in the preparation of Aromatic Spirit of Ammonia, and *smelling salts* is frequently made by coarsely grinding ammonium carbonate, placing it in a bottle, and adding strong ammonia water until it is saturated.

The principal impurity in the commercial salt is empyreuma, due to the presence of substances which communicate a disagreeable, charred odor and taste. The official test provides for the detection of empyreumatic products by first neutralizing the alkali with nitric acid and evaporating on a water-bath. The residue should be odorless and colorless.

Official Description.—White, hard, translucent, striated masses On exposure to the air, the salt loses both ammonia and carbon dioxide, becoming opaque, and is finally converted into friable, porous lumps, or a white powder.

Odor, Taste, and Reaction.—Strong odor of ammonia without empyreuma; sharp, saline taste; alkaline reaction.

Solubility.—*Water.* Slowly but completely in about 4 parts at 25° C. (77° F.), it is decomposed by hot water, with the elimination of carbon dioxide and ammonia. By prolonged boiling with water, the salt is completely volatilized.

Alcohol. Alcohol dissolves the carbamate, and leaves the acid carbonate.

Tests for Identity.—When heated, Ammonium Carbonate is completely volatilized, without charring.

The aqueous solution effervesces with acids.

Impurities and Tests for Impurities.—*Sulphate.* The aqueous solution of the salt (1 in 20), when slightly supersaturated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No 121, Chap. LXII). Another portion of this solution should not be affected by barium chloride T.S.

Thiosulphate. The aqueous solution of the salt (1 in 20), on the addition of a slight excess of silver nitrate T.S., and subsequent supersaturation with nitric acid, should neither assume a brown color.

Limit of chloride. Nor become more than slightly opalescent within two minutes.

Empyreumatic or non-volatile matters. If an aqueous solution containing 1 Gm. of the salt be slightly supersaturated with nitric acid, and then evaporated to dryness on a water-bath, it should afford a colorless and odorless residue, which, upon gentle ignition, should be completely volatilized.

Quantitative Test.—If 2 gm. of unaltered, translucent Ammonium Carbonate be dissolved in a mixture of 50 Cc. each of distilled water and normal sulphuric acid V.S., boiled for a few minutes to expel the liberated carbon dioxide, and then cooled, not more than 12.7 Cc. of normal potassium hydroxide V.S. should be required for exact neutralization, litmus T.S. being used as indicator.

Uses.—Ammonium carbonate is a stimulant in doses of three to five grains (0.2 to 0.3 Gm.). It is generally administered in mucilaginous syrups. Pharmaceutically, it is employed in making the well known solution of ammonium acetate, in the aromatic spirit of ammonia, and in elixir of iron, quinine and strychnine phosphates.

AMMONII CHLORIDUM. U.S. Ammonium Chloride

$NH_4Cl = 53.11$

[Ammonium Muriate Muriate of Ammonia]

It should contain not less than 99.5 percent. of pure Ammonium Chloride.

Preparation.—*Sal ammoniac*, as it is termed commercially, is chiefly made from *gas liquor*, the ammonical liquid obtained from gas works during the destructive distillation of the coal. The ammonia is generally neutralized with hydrochloric acid, the solution evaporated, and the dry mass sublimed in iron pots. The tough, fibrous sublimate is fitted for pharmaceutical and medicinal purposes by purification. It nearly always contains traces of iron, due to the reaction of a portion of the salt upon the cast iron dome. This may be separated by treatment with ammonia water, as shown in the following process of purification, formerly official:

Take of Chloride of Ammonium, in small pieces, 20 oz. troy; Water of Ammonia, 5 fl. dr.; Water, 2 pints. Dissolve the Chloride of Ammonium in the Water, in a porcelain dish, with the aid of heat; add the Water of Ammonia, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring, at a moderate heat, until it granulates; the ferrous chloride is converted into insoluble ferric hydroxide, through the combination of the hydrochloric acid with ammonia water.

Official Description.—A white, crystalline powder; permanent in the air.

Odor, Taste, and Reaction.—Without odor; cooling, saline taste. The aqueous solution (1 in 20) in ice-cold water, should not redden blue litmus paper at once.

Solubility.—*Water.* In 3 parts at 25° C. (77° F.); in 1 part of boiling water.

Alcohol. In 80 parts at 25° C. (77° F.).

Other solvents. In 10 parts of glycerin at 25° C. (77° F.).

Tests for Identity.—On ignition, Ammonium Chloride is volatilized, without charring.

The aqueous solution of the salt (1 in 20) in ice-cold water, should not redden blue litmus paper at once; it affords, with silver nitrate T.S., a white, curdy precipitate, which is soluble in ammonia water.

The aqueous solution, when gently heated with potassium hydroxide T.S., evolves ammonia.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Sulphate. Nor should it be affected by barium chloride T.S.

Barium. Nor diluted sulphuric acid.

Calcium. Nor ammonium oxalate T.S.

Sulphocyanate. When acidulated with hydrochloric acid, the solution should not assume a red color on the addition of a few drops of ferric chloride T.S.

Limit of iron. Twenty Cc. of the aqueous solution of salt (1 in 150) should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S.

Limit of empyreumatic or non-volatile substances. If to 1 Gm. of the salt a little nitric acid be added, and the mixture evaporated to dryness in a porcelain dish on a water-bath, a white residue should be obtained, which, when ignited should yield not more than 0.0005 Gm. of non-volatile, residue.

Quantitative Test.—If 1 Gm. of Ammonium Chloride be dissolved in sufficient distilled water to measure 100 Cc., then 10 Cc. of this solution should, after the addition of 5 drops of potassium chromate T.S., require not less than 18.7 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color.

Uses.—Ammonium chloride is a stimulant, and largely used as an addition to expectorant remedies, in doses of five to ten grains (0.3 to 0.6 Gm.). It is sometimes used as an inhalation in catarrh, by drawing the vapors of hydrochloric acid and ammonia into a bottle, where they combine to form ammonium chloride in very fine powder. It should never be combined with potassium chlorate, particularly in compressed tablets; for, although the combination is often desirable from a therapeutic standpoint, in time the tablets explode and serious results have been experienced. The crude form of this salt, *sal ammoniac,* is used largely in solution as an exciting fluid for voltaic batteries.

AMMONII IODIDUM. U.S. Ammonium Iodide

$NH_4I = 143.83$

It should contain not less than 97 percent. of pure Ammonium Iodide, and should be kept in small amber-colored, well-stoppered vials, protected from light.

When deeply colored, the salt should not be dispensed, but it may be deprived of free iodine by adding to its concentrated aqueous solution sufficient ammonium sulphide T.S. to render it colorless, then filtering, and evaporating on a water-bath to dryness.

Preparation.—This salt may be made by a modification of a former official process, as follows:

Take of Iodide of Potassium, in coarse powder, 4 oz. troy; Sulphate of Ammonium, in coarse powder, 867 grains; Boiling Distilled Water 2 fl. oz.; Alcohol, Water, each, a sufficient quantity. Mix the salts, add them to the Boiling Water, stir well, and allow the mixture to cool; then add a fluidounce of Alcohol, mix well, and reduce the temperature, by a bath of iced water, to about 40° F.; throw the mixture into a cool glass funnel, stopped with moistened cotton, and, when the clear solution has passed, pour upon the salt a fluidounce of a mixture containing two parts of Water and one part of Alcohol. Lastly, evaporate the solution rapidly to dryness, stirring constantly; and preserve the residue in a well-stoppered bottle.

In this process double decomposition takes place, ammonium iodide and potassium sulphate being produced.

$$\begin{array}{ccccccc} 2KI & + & (NH_4)_2SO_4 & = & 2NH_4I & + & K_2SO_4 \\ \text{Potassium} & & \text{Ammonium} & & \text{Ammonium} & & \text{Potassium} \\ \text{Iodide} & & \text{Sulphate} & & \text{Iodide} & & \text{Sulphate} \end{array}$$

The object of cooling the mixture and adding alcohol is to cause as much of the potassium sulphate to separate as possible, potassium sulphate being almost insoluble in alcohol.

Official Description.—Minute, colorless, cubical crystals, or a white, granular powder. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to the air and light, owing to the loss of ammonia and the liberation of iodine.

Odor, Taste, and Reaction.—Without odor when colorless, but emitting a slight odor of iodine when colored; sharp, saline taste; neutral reaction.

Solubility.—*Water.* In 0.6 part at 25° C. (77° F.); in 0.43 part of boiling water.

Alcohol. In 9 parts at 25° C. (77° F.); in 3.7 parts of boiling alcohol.

Tests for Identity.—When heated on platinum foil, Ammonium Iodide evolves vapor of iodine, and volatilizes completely without fusing.

The aqueous solution of the salt, when gently heated with potassium hydroxide T.S., evolves ammonia.

If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated and impart to the solution a light reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color.

Impurities and Tests for Impurities.—*Barium.* Ten Cc. of the aqueous solution of Ammonium Iodide (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S.

Limit of iron. An aqueous solution of the salt (1 in 150) should not at once assume a blue color with potassium ferrocyanide T.S.

Limit of free iodine. Nor, after being agitated with 1 Cc. of chloroform, should the latter assume a violet color.

Heavy metals. The aqueous solution of Ammonium Iodide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

More than about 3 percent. of chlorides or bromides. If 0.25 Gm. of the salt, dried at 100° C. (212° F.), be dissolved in 5 Cc. of ammonia water (10 percent.), the solution shaken with 16.9 Cc. of tenth-normal silver nitrate V.S., and the filtrate supersaturated with 5 Cc. of nitric acid, no cloudiness should make its appearance within ten minutes.

Uses.—Ammonium iodide is used as a resolvent and alterative, for the same purposes as potassium iodide. The dose is from three to five grains (0.2 to 0.3 Gm.).

AMMONII SALICYLAS. U.S. Ammonium Salicylate

$NH_4C_7H_5O_3 = 153.94$

It should contain not less than 98 percent. of pure Ammonium Salicylate [$C_6H_4(OH)COONH_4$], and should be kept in well-stoppered bottles, protected from heat and light.

Preparation.—This salt may be made by adding salicylic acid to ammonia water until nearly saturated, evaporating the solution, crystallizing, and purifying the product by recrystallization.

Official Description.—Colorless, lustrous, monoclinic prisms, or plates, or a white, crystalline powder; permanent in dry air.

Odor, Taste, and Reaction.—Odorless, and having at first a slightly saline, bitter taste, with a sweetish after-taste; acid reaction.

Solubility.—*Water.* In 0.9 part at 25° C. (77° F.): freely in boiling water.

Alcohol. In 2.3 parts at 25° C. (77° F.); in 1 part of boiling alcohol.

Tests for Identity.—When heated, the salt fuses with decomposition, giving off inflammable vapors and an odor of phenol, and is finally completely volatilized.

The concentrated aqueous solution should be colorless, it should redden blue litmus paper, and when gently heated with potassium hydroxide T.S. evolves ammonia.

Ferric chloride T.S., added to an excess of a concentrated solution of Ammonium Salicylate, produces a dark red precipitate, but imparts to a very dilute solution (1 in 100) a deep violet-blue color.

If copper sulphate T.S. be added to the aqueous solution of the salt (1 in 20), a green color will be produced.

If to 0.2 Gm. of the salt, contained in a test-tube, about 1 Cc. of concentrated sulphuric acid be added, and then cautiously about 1 Cc. of methyl alcohol, drop by drop, on heating the mixture to boiling, methyl salicylate will be formed, which can be recognized by its odor.

If diluted nitric acid be added in slight excess to the aqueous solution of the salt (1 in 10), the precipitated salicylic acid, after collecting and washing, should respond to the tests of purity and identity given under *Acidum Salicylicum.*

Impurities and Tests for Impurities.—*Heavy metals.* If an aqueous solution of Ammonium Salicylate (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII)

Uses.—Ammonium salicylate is preferred to sodium salicylate by many physicians ; it is used in gout and rheumatism in doses of three to five grains (0.2 to 0.3 Gm.).

AMMONII VALERAS. U. S. Ammonium Valerate

[AMMONII VALERIANAS, PHARM. 1890 AMMONIUM VALERIANATE]

Ammonium Valerate should be kept in well-stoppered bottles.

Preparation.—This valerate, formerly called valerianate, may be prepared by passing dried gaseous ammonia into monohydrated valeric acid. The former official process may be used, which is as follows :

Take of Valerianic Acid 4 fl. oz. ; Chloride of Ammonium, Lime, each, a sufficient quantity. From a mixture of Chloride of Ammonium, in coarse powder, and an equal weight of Lime, previously slaked and in powder, contained in a suitable vessel, obtain gaseous ammonia, and cause it to pass, first through a bottle filled with pieces of Lime, and afterwards into the Valerianic Acid, in a tall, narrow, glass vessel, until the acid is neutralized. Then discontinue the process, and set the vessel aside that the Valerianate of Ammonium may crystallize. Lastly, break the salt into pieces, drain it in a glass funnel, dry it on bibulous paper, and keep it in a well-stoppered bottle.

The salt which is found in commerce is usually the acid salt ; hence, in making a solution of it, as in the process for elixir of ammonium valerate, the excess of acid should be neutralized by the addition of sufficient ammonia water.

Official Description.—Colorless, or white, quadrangular plates ; deliquescent in moist air.

Odor, Taste, and Reaction.—Emitting the odor of valeric acid ; sharp and sweetish taste; acid reaction.

Solubility.—*Water.* Very soluble.
Alcohol. Very soluble.
Other solvents. Soluble in ether.

Tests for Identity.—When heated, the salt fuses, gives off vapor of ammonia and of valeric acid, and is finally completely volatilized.

The aqueous solution, when gently heated with potassium hydroxide T.S., evolves ammonia.

If a concentrated, aqueous solution of Ammonium Valerate be slightly supersaturated with sulphuric acid, an oily layer of valeric acid will rise to the surface.

Impurities and Tests for Impurities.—*Acetate.* If a neutral solution of the salt be completely precipitated by ferric chloride T.S., the filtrate should not possess a deep red color.

Heavy metals. The aqueous solution of the salt (1 in 20), when slightly acidulated with hydrochloric acid and filtered through a small, wetted filter, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—Ammonium valerate is used in hysteria, neuralgia, and similar diseases as a nervine, in doses of five to twenty grains (0.3 to 1.3 Gm.). It is used pharmaceutically in the preparation of an elixir. See Elixir Ammonii Valerianas, N. F.

SATURATION TABLES. U. S. (8th Revision)

CHAPTER XLII

MAGNESIUM, CALCIUM, BARIUM, AND STRONTIUM

Mg; 24.18. Ca; 39.8. Ba; 136.4. Sr; 86.94

THE compounds of these metals form a natural group. They have numerous physical and chemical characteristics in common. Barium no longer enters into any official salts; although some of its compounds are used as tests. Strontium salts were admitted to the U. S. P. 1890, and they are used to a limited extent. Magnesium was formerly classed with the alkali earths, but it is now usually separated from them, because of its closer chemical analogies to zinc. It is so closely allied to the alkali earths in its pharmaceutical and medical aspects that it will be more useful to consider it in its former relation.

Magnesium, in the forms of chloride, sulphate, carbonate, magnesia-calcic carbonate, and silicate, is widely distributed. The metal is of a silver-white color, losing its lustre through the oxidation of its surface, and burning with a radiant light when heated to redness, magnesium oxide being formed. The oxide, MgO, is official, and is largely used medicinally.

Tests for Salts of Magnesium

1. The caustic alkalies produce gelatinous, white precipitates with solutions of magnesium salts, insoluble in excess, but soluble in solution of ammonium chloride.

2. Sodium carbonate or potassium carbonate produces white precipitates with solutions of magnesium salts.

3. Solution of sodium phosphate produces a white crystalline precipitate, on the addition of a small quantity of ammonia water, of ammonio-magnesium phosphate, NH_4MgPO_4.

Official Salts and Preparations of Magnesium

Official Name	Preparation
Magnesii Carbonas	Double decomposition between magnesium sulphate and sodium carbonate
Oxidum	Made by calcining light magnesium carbonate
Oxidum Ponderosum	Made by calcining heavy magnesium carbonate
Sulphas	By treating native magnesium hydroxide with sulphuric acid
Sulphas Effervescens	Prepared by powdering and thoroughly mixing, magnesium sulphate, sodium bicarbonate, tartaric acid, and citric acid, heating the whole until it is uniformly moist, granulating and drying
Liquor Magnesii Citratis	By dissolving magnesium carbonate in citric acid, flavoring, and adding potassium bicarbonate

Unofficial Salts of Magnesium

Magnesii Acetas, $Mg(C_2H_3O_2)_2$ Magnesium Acetate	By dissolving magnesium carbonate in sufficient acetic acid, filtering and concentrating, then crystallizing
Magnesii Iodidum, MgI_2 Magnesium Iodide	By dissolving magnesium oxide in hydriodic acid, filtering, and concentrating, then crystallizing

Unofficial Salts of Magnesium—*Continued*

Magnesii Lactas, $Mg_2C_3H_5O_3 + 3H_2O$ Magnesium Lactate	By dissolving separately in hot water 6 parts calcium lactate and 5 parts magnesium sulphate, mixing the solutions and filtering, evaporating the filtrate, then crystallizing.
Magnesii Salicylas Magnesium Salicylate	Given in typhoid fever, in daily doses of fifty to one hundred grains continuously
Magnesii Silicas, $H_2Mg_2Si_3O_9 + H_2O$ Magnesium Silicate	Occurs in nature as *asbestos*, as meerschaum, and in other forms
Magnesii Sulphas Exsiccatus, $MgSO_4$ Dried Magnesium Sulphate	By exposing the crystallized sulphate in a warm place until it has lost 35 percent. of its weight, then sifting it
Magnesii Sulphis Magnesium Sulphite	By treating in suspension with sulphurous acid
Magnesii Phenolsulphonas, $Mg2C_6H_5SO_4 + 7H_2O$ Magnesium Phenolsulphonate	By mixing concentrated solutions of barium phenolsulphonate and magnesium carbonate and collecting the precipitate
Crab Orchard Salt	A mild saline purgative, consisting mainly of magnesium sulphate, obtained by evaporating the waters of Crab Orchard Springs, Kentucky. Dose, from one to two teaspoonfuls

MAGNESII CARBONAS. U.S. Magnesium Carbonate

Approximately $(MgCO_3)_4.Mg(OH)_2 + 5H_2O = 482.26$

Magnesium Carbonate $[(CO.O_2Mg)_4.Mg(OH)_2 + 5H_2O]$ should yield, upon ignition, not less than 40 percent. of residue, of which not less than 96 percent. should consist of pure magnesium oxide.

Preparation.—The process of the British Pharmacopœia is as follows: Take of Magnesium Sulphate 10 ounces [avoirdupois]; Sodium Carbonate 12 ounces [avoird.]; Boiling Distilled Water, a sufficient quantity. Dissolve the Magnesium Sulphate and Sodium Carbonate each in a pint [Imp. Meas.] of the Distilled Water, mix the two solutions, and evaporate to dryness; digest the residue for half an hour with two pints [Imp. Meas.] of the Distilled Water, and, having collected the insoluble matter on a calico filter, wash it repeatedly with Distilled Water, until the washings are free from sulphates; dry the product at a temperature not exceeding 212° F. (100° C.).

Magnesium carbonate varies in composition somewhat according to the process used. The reaction in making the U. S. carbonate would in its preparation be as follows:

$$\underset{\text{Magnesium Sulphate}}{5MgSO_4} + \underset{\text{Sodium Carbonate}}{5Na_2CO_3} + \underset{\text{Water}}{H_2O} = \underset{\text{Magnesium Carbonate}}{4MgCO_3.Mg(HO)_2} + \underset{\text{Sodium Sulphate}}{5Na_2SO_4} + \underset{\text{Carbon Dioxide}}{CO_2}$$

The process for making light magnesium carbonate differs from the above in the substitution of a larger proportion of cold water for the boiling water. This furnishes a good illustration of the rule in precipitation, that dilute solutions produce light precipitates, and dense solutions heavy precipitates.

Official Description.—Light, white, friable masses, or a bulky, white powder; permanent in the air.

Odor and Taste.—Without odor; slightly earthy taste.

Solubility.—*Water.* Practically insoluble, imparting, however, a slightly alkaline reaction.
Alcohol. Insoluble.
Other solvents. Soluble in dilute acids with effervescence.

Tests for Identity.—When strongly heated, the salt loses water and carbon dioxide, and is converted into magnesium oxide.

A filtered solution of the salt in diluted sulphuric acid, when mixed with ammonium chloride T. S. and an excess of ammonia water, yields with sodium phosphate T. S. a white crystalline precipitate.

If 1 Gm. of Magnesium Carbonate be ignited in a porcelain crucible, the residue should weigh not less than 0.40 Gm.

Impurities and Tests for Impurities.—*Limit of foreign soluble salts.* If a mixture of 1 Gm. of Magnesium Carbonate with 50 Cc. of water be heated to boiling, and, after cooling, filtered, the filtrate, if evaporated to dryness upon a water-bath, should leave not more than 0.01 Gm. of residue.

Limit of calcium. Ten Cc. of a solution of the salt (1 in 50), prepared by the addition of sufficient acetic acid for solution, should not be rendered more than slightly opalescent within five minutes by ammonium oxalate T.S.

Limit of iron. If 1 Gm. of Magnesium Carbonate be dissolved in 20 Cc. of diluted hydrochloric acid and 130 Cc. of water the solution should be colorless and not give an immediate blue coloration upon the addition of potassium ferrocyanide T.S.

Heavy metals. Nor should another solution of the same strength respond to the Time-Limit Test for other *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Quantitative Test.—If 0.400 Gm. of recently ignited and cooled Magnesium Carbonate be dissolved in 25 Cc. of normal sulphuric acid V.S., not more than 5.8 Cc. of normal potassium hydroxide V.S. should be required for neutralization, methyl-orange T. S. being used as an indicator (each Cc. of normal sulphuric acid V.S. consumed, being equivalent to 5 percent. of pure magnesium oxide).

Uses.—Magnesium carbonate is antacid, and in large doses cathartic. The dose is from thirty to sixty grains (2 to 4 Gm.). It has been largely employed in making medicated waters to assist in diffusing the oils used in preparing them.

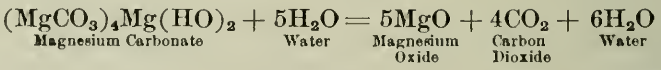
MAGNESII OXIDUM. U.S. Magnesium Oxide Magnesia

$MgO = 40.06$

[MAGNESIA, PHARM. 1890 CALCINED MAGNESIA LIGHT MAGNESIA]

It should contain, after ignition, not less than 96 percent. of pure Magnesium Oxide. It should be kept in well-closed vessels.

Preparation.—Magnesium carbonate is exposed in crucibles to a red heat, carbon dioxide and water are expelled, and magnesium oxide is left.



$$\underset{\text{Magnesium Carbonate}}{(MgCO_3)_4Mg(HO)_2} + \underset{\text{Water}}{5H_2O} = \underset{\text{Magnesium Oxide}}{5MgO} + \underset{\text{Carbon Dioxide}}{4CO_2} + \underset{\text{Water}}{6H_2O}$$

Magnesium Oxide is rendered less soluble if heated too strongly. It should always be kept in well closed vessels ; exposure to air and moisture causes the formation of carbonate and hydroxide.

Official Description.—A white, very bulky, and very fine powder. On exposure to the air, it slowly absorbs moisture and carbon dioxide.

Odor, Taste, and Reaction.—Without odor, and having an earthy, but not a saline, taste. When moistened with water, it has a faintly alkaline reaction upon red litmus paper.

Solubility.—*Water.* Almost insoluble.

Alcohol. Insoluble.

Other solvents. Soluble in dilute acids.

Tests for Identity.—On stirring 1 part of Magnesium Oxide with 15 parts of water, in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient consistence to prevent it from dropping out when the beaker is inverted.

A solution of Magnesium Oxide in diluted sulphuric acid, mixed with ammonium chloride T.S. and an excess of ammonia water, yields, with sodium phosphate T.S., a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Limit of foreign soluble salts.* If a mixture of 1 Gm. of Magnesium Oxide with 50 Cc. of water be heated to boiling, and, after cooling, filtered, the filtrate should not show more than a faintly alkaline reaction with red litmus paper, and when evaporated to dryness should not leave more than 0.04 Gm. of residue.

Limit of carbonate. If a mixture of 0.1 Gm. of Magnesium Oxide with 5 Cc. of water be heated to boiling, and, after cooling, be poured into 5 Cc. of acetic acid, solution should take place without the evolution of more than a few isolated gas bubbles.

Limit of calcium. Ten Cc. of a solution of Magnesium Oxide (1 in 50), prepared by the addition of sufficient acetic acid for solution, should not be rendered more than slightly opalescent within five minutes by ammonium oxalate T.S.

Limit of iron. If 1 Gm. of Magnesium Oxide be dissolved in 50 Cc. of diluted hydrochloric acid, the solution should be colorless and not give an immediate blue coloration upon the addition of potassium ferrocyanide T.S.

Heavy metals. A solution of Magnesium Oxide (1 in 20) in diluted hydrochloric acid and 100 Cc. of water should not respond to the Time-Limit Test for other *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of water of hydration. If Magnesium Oxide be exposed to a low red heat in a porcelain crucible, it should not lose more than 15 percent. of its weight.

Quantitative Test.—If 0.400 Gm. of recently ignited and cooled Magnesium Oxide be dissolved in 25 Cc. of normal sulphuric acid V.S., not more than 5.8 Cc. of normal potassium hydroxide V.S. should be required for neutralization, methyl-orange T.S. being used as indicator (each Cc. of the normal sulphuric acid V.S. consumed being an equivalent to 5 percent. of pure Magnesium Oxide).

Uses.—Magnesium Oxide or *magnesia* is popularly used as a laxative and antacid, in doses of thirty grains (2 Gm.). In administering, the magnesia should be added to the diluent (water or milk), and not *vice versa.*

MAGNESII OXIDUM PONDEROSUM. U.S. Heavy Magnesium Oxide Heavy Magnesia

$MgO = 40.06$

[MAGNESIA PONDEROSA, PHARM. 1890]

Heavy magnesium oxide is preferable to the ordinary magnesium oxide, on account of its density. This often permits the decrease in bulk of the dose in the ratio of nearly four to one. Magnesium oxide is rendered less bulky by trituration, and if the heavy carbonate is used for the calcination, a heavier powder is produced.

Official Description.—A white, dense, and very fine powder, which should conform to the reactions and tests given under *Magnesii Oxidum.*

It differs, however from the latter in not readily uniting with water to form a gelatinous hydroxide.

Uses.—The uses of heavy magnesia are the same as those of the light magnesia.

MAGNESII SULPHAS. U.S. Magnesium Sulphate

$MgSO_4 + 7H_2O = 244.69$

[EPSOM SALT]

It should contain not less than 99.7 percent. of pure Magnesium Sulphate [$SO_2.O_2Mg + 7H_2O$], and should be kept in well-closed vessels.

Preparation.—This well known salt is prepared from a number of mineral substances, but in the United States, from a silicious magnesium hydroxide, which is practically free from lime. The mineral is reduced to a fine powder and treated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert into red oxide any ferrous sulphate which may be present. It is then dissolved in water, and calcium sulphide added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it.

Magnesium sulphate is largely made as a by-product in the manufacture of carbonated waters; the mineral magnesite is decomposed by sulphuric acid and the carbon dioxide passed into the water.

$$\underset{\text{Magnesite}}{MgCO_3} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{H_2SO_4} = \underset{\substack{\text{Magnesium}\\\text{Sulphate}}}{MgSO_4} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

In England, Epsom salt is sometimes prepared from *dolomite*, the double carbonate of magnesium and calcium, by driving off the carbon dioxide by heat, converting the residue into hydroxides, and then treating these with hydrochloric acid. Calcium chloride is formed; this is dissolved out by washing with water, and the purified magnesium oxide is converted into sulphate by treating it with sulphuric acid.

Official Description.—Small, colorless, prismatic needles or rhombic prisms; slowly efflorescent in the air.

Odor, Taste, and Reaction.—Without odor; cooling, saline, and bitter taste; neutral reaction.

Solubility.—*Water.* Soluble in 1.1 parts at 25° C. (77° F.), and in 0.13 part of boiling water. *Alcohol.* Insoluble.

Tests for Identity.—When heated to 52° C. (125.6° F.), or exposed to warm air, the salt loses one molecule of water, and is converted into a white powder. At about 130° C. (266° F.) it still retains 1 molecule of water, and at a temperature between 200° and 238° C. (392° and 460.4° F.) it is rendered anhydrous.

When mixed with ammonium chloride T.S. and ammonia water, the aqueous solution of the salt yields with sodium phosphate T.S., a white crystalline precipitate. With barium choride T.S. it yields a white precipitate insoluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Heavy metals.* Ten Cc. of the aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—Magnesium sulphate is a valuable refrigerant cathartic, in doses of from one-half to one ounce (16 to 32 Gm.); if dissolved in iced water, its nauseous taste is not so perceptible as when water of ordinary temperature is used.

MAGNESII SULPHAS EFFERVESCENS. U.S. Effervescent Magnesium Sulphate

	Metric	Old form
* **Magnesium Sulphate,** uneffloresced crystals	500 Gm.	10 oz. av.
Sodium Bicarbonate, dried and powdered	403 Gm.	8 oz. av.
Tartaric Acid, dried and powdered	211 Gm.	4¼ oz. av.
Citric Acid, uneffloresced crystals	136 Gm.	2¾ oz. av.
To make about	1000 Gm.	20 oz. av.

Dry the Magnesium Sulphate on a water-bath, until it ceases to lose weight, then, after powdering the dry salt, mix it intimately with the Citric Acid, which has previously been powdered, and the Tartaric Acid, and thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.).

When the mixture has acquired a moist consistence by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.

Uses.—This effervescent salt was introduced into the U. S. P. (8th Rev.) in preference to retaining the effervescent magnesium citrate (U. S. P. 1890). The dose is four drachms (16 Gm.).

LIQUOR MAGNESII CITRATIS. U.S. Solution of Magnesium Citrate

	Metric	Old form
* **Magnesium Carbonate**	15.0 Gm.	230 grains
Citric Acid	33.0 Gm.	1 oz. av. 65 gr.
Syrup of Citric Acid	60.0 Cc.	2 fl. oz.
Potassium Bicarbonate	2.5 Gm.	39 grains
Water, a sufficient quantity		

Dissolve the Citric Acid in 120 Cc. [old form 4 fl. oz.] of Water, and, having added the Magnesium Carbonate, stir until it is dissolved. Filter the solution into a strong bottle of the capacity of about 360 Cc. [old form 12 fl. oz.], containing the Syrup of Citric Acid. Then add enough Water to nearly fill the bottle, drop in the Potassium Bicarbonate, and immediately stopper the bottle securely. Lastly, shake the mixture occasionally, until the Potassium Bicarbonate is dissolved. This solution should be freshly prepared when wanted.

A few modifications in the manipulation of the official process are advisable. The bulky magnesium carbonate may be replaced by one-half of the quantity of light calcined magnesia. The syrup of citric acid should be introduced into the bottle, and the filtered solution of magnesium citrate very carefully poured in without stirring up the syrup. (For this purpose a hard rubber funnel, having the neck closed but with perforations on the side so that the liquid is delivered gently on the sides of the bottle, may be advantageously used.) The potassium bicarbonate, in large crystals (or in compressed blocks of the proper weight), is dropped into the bottle,—they gradually dissolve in the syrup of citric acid,—and the cork is at once inserted, to prevent loss of carbonic acid gas, but special bottles with patent stoppers are preferred (see Fig. 444). The bottle is not disturbed until it is called for, when a careful shake mixes the solution of the bicarbonate in the bottom of the bottle with the acid liquid above, liberating the carbonic acid gas, and the solution can then always be dispensed in a sparkling condition. Fig. 444 shows the top of an improved form of "Citrate bottle" made by the Whitall Tatum Company. It has many advantages and obviates the troublesome process of using corks for stoppers. It is a modification of the well known "beer bottle" stopper.

FIG. 444

Top of citrate bottle

The quantity of citric acid was slightly increased in the eighth revision of the U. S. Pharmacopœia in order to make a solution which would be more stable.

Uses.—"Solution of citrate of magnesia," as it will probably be always called, is one of the most agreeable cathartics known. It is usually given to adults in the quantity of the official formula, twelve fluidounces (360 Cc.). The practice of dividing the dose, taking one-half three or four hours after the other, is often preferable.

Calcium. Ca; 39.8

Calcium is a very abundant element, occurring in nature as carbonate, sulphate, phosphate, silicate, chloride, fluoride, etc. It belongs to the class of metals. When heated it burns with a bright light. It is of a light yellow color, and is ductile, like gold; it may be hammered into very thin sheets. It forms but one chloride. The oxide, carbonate, sulphate, phosphate, and hypophosphite are of pharmaceutical interest.

Tests for Salts of Calcium

1. Alkaline carbonates produce white precipitates with soluble salts of calcium, insoluble in excess.

2. The soluble oxalates (ammonium or potassium oxalate) produce, even in dilute solutions of calcium salts, a white precipitate of calcium oxalate, not soluble in an excess of acetic acid, but soluble in an excess of hydrochloric acid.

Official Salts and Preparations of Calcium

Official Name	Preparation
Calx	Made by calcining chalk or limestone
Chlorinata	By treating calcium hydroxide with chlorine
Sulphurata	By heating dried calcium sulphate, charcoal, and starch to a low red heat
Calcii Bromidum	By dissolving lime in hydrobromic acid
Carbonas Precipitatus	By double decomposition between calcium chloride and sodium carbonate
Chloridum	By acting on calcium carbonate with hydrochloric acid
Hypophosphis	By heating phosphorus with milk of lime
Phosphas Precipitatus	By treating bone ash with HCl, and precipitating with ammonia
Sulphas Exsiccatus	By heating calcium sulphate
Creta Præparata	By elutriating chalk and forming into cones
Pulvis Cretæ Compositus	Prepared chalk, sugar, and acacia, for making chalk mixture
Mistura Cretæ	Compound chalk powder suspended in cinnamon water and water
Liquor Calcis	By dissolving lime in water
Linimentum Calcis	Equal parts of lime water and linseed oil
Syrupus Calcis	A saccharine solution of lime
Calcii Lactophosphatis	A saccharine solution of calcium lactophosphate

Unofficial Salts of Calcium

Calcii Benzoas, $Ca(C_7H_5O_2)_2 + 3H_2O$ Calcium Benzoate	Made by adding calcium carbonate to a hot aqueous solution of benzoic acid, filtering, evaporating, and crystallizing
Calcii Hydroxidum, $Ca(OH)_2$ Calcium Hydroxide	By adding 1 part water to 2 parts lime contained in a metal pot, covering and setting aside to cool, sifting and preserving the fine powder
Calcii Iodas, $Ca2IO_3 + 6H_2O$ Calcium Iodate	By mixing gradually an alcoholic solution of iodine with excess of filtered aqueous solution of chlorinated lime. After decolorization, slightly acidulating with hydrochloric acid, heating to boiling, filtering, then crystallizing
Calcii Iodidum, CaI_2 Calcium Iodide	By dissolving slaked lime in hydriodic acid and concentrating, then crystallizing. Dose, one to four grains (0.06 to 0.2 Gm.)
Calcii Salicylas, $Ca(C_7H_5O_3)_2 + H_2O$ Calcium Salicylate	Dose, seven to twenty grains (0.45 to 1.2 Gm.) for diarrhœa and gastro-enteritis
Calcii Sulphidum, CaS Calcium Sulphide	By mixing 12 parts powdered gypsum with 4 parts powdered charcoal, and heating the mixture in a covered crucible until gas ceases to be evolved
Calcii Sulphas, $CaSO_4 + 2H_2O$ Calcium Sulphate	Occurs in nature
Calcii Sulphis, $CaSO_3$ Calcium Sulphite	By mixing concentrated solutions of sodium sulphite and calcium chloride and collecting the precipitate
Calcii Phenolsulphonas, $Ca2C_6H_5SO_4 + 6H_2O$ Calcium Phenolsulphonate	By mixing concentrated solutions of barium phenolsulphonate and calcium carbonate and collecting the precipitate
Calcii Sulphydras, CaH_2S_2 Calcium Sulphydrate	By passing hydrogen sulphide into a mixture of 2 parts slaked lime and 3 parts water as long as absorbed
Calcii Thiosulphas, $CaS_2O_3 + 6H_2O$ Calcium Thiosulphate	Medical properties are those of the sulphites. Dose, from ten to twenty grains (0.6 to 1.2 Gm.)

CALX. U.S. Lime Calcium Oxide

$CaO = 55.68$

Prepared by calcining white marble, or the purest varieties of native calcium carbonate, and containing, when in the anhydrous state, not less than 90 percent. of pure Calcium Oxide. It should be kept in well-closed vessels, in a dry place.

Preparation.—Lime, or calcium oxide, is a very important alkaline earth, and is made by calcining limestone, or native calcium carbonate, in kilns with strong heat; carbon dioxide and water are expelled.

Official Description.—Hard, white, or grayish-white masses, which, in contact with the air, gradually attract moisture and carbon dioxide, and fall to a white powder.
Odor, Taste, and Reaction.—Odorless; caustic taste; alkaline reaction.
Solubility.—*Water.* In about 760 parts at 25° C. (77° F.); in about 1600 parts of boiling water.
Alcohol. Insoluble.
Other solvents. It forms readily soluble salts with diluted acetic, hydrochloric, or nitric acids.
Tests for Identity.—When sprinkled with about half its weight of water, Calcium Oxide becomes heated, and is gradually converted into a white powder (calcium hydroxide or slaked lime). When this is mixed with about 3 or 4 parts of water, it forms a smooth magna (milk of lime).
Impurities and Tests for Impurities.—*Limit of carbonate.* If 1 Gm. of Calcium Oxide be slaked and then thoroughly mixed with 50 Cc. of water, and the greater portion of the milky liquid decanted, the addition of hydrochloric acid to this residue should not cause more than a slight effervescence.

For applying tests of identity and of purity, 5 Gm. of Calcium Oxide, after slaking, are mixed with 100 Cc. of distilled water, followed by hydrochloric acid, added drop by drop, with agitation until solution takes place. The resulting solution should, after boiling and cooling, be of acid reaction and not deposit more than 0.025 Gm. of insoluble matter.

With a portion of this solution, after neutralizing with ammonia water, ammonium oxalate T.S. produces a white precipitate of calcium oxalate, insoluble in acetic acid, but soluble in hydrochloric acid.

Uses.—Externally, lime acts as an escharotic; it enters into the composition of many depilatory powders; internally, in solution, it is a valuable antacid.

LIQUOR CALCIS. U.S. Lime Water Solution of Calcium Hydroxide

A saturated aqueous solution, which should contain not less than 0.14 percent. of pure Calcium Hydroxide [$Ca(OH)_2 = 73.56$].

The percentage of Calcium Hydroxide varies with the temperature at which the saturated solution is prepared, being about 0.17 percent. at 15° C. (59° F.), the percentage diminishing as the temperature rises.

	Metric	Old form
* **Lime**	12 Gm.	195 grains
Distilled Water, a sufficient quantity		

Slake the Lime by the very gradual addition of 400 Cc. [old form 1 pint] of Distilled Water, and agitate occasionally during half an hour. Allow the suspended particles to subside, decant the supernatant liquid and reject it. Then add to the residue 3600 Cc. [old form 8 pints] of Distilled Water, agitate thoroughly, let the mixture stand for twenty-four hours, agitate again, then let the coarser particles of solid matter subside, and pour the liquid, holding the undissolved calcium hydroxide in suspension, into a glass-stoppered bottle. From time to time shake the bottle, so as to keep the solution saturated.

Pour off the clear liquid when required for use.

Lime water is very extensively used in pharmacy; the object of keeping it upon undissolved lime is to insure a saturated solution. Lime is but sparingly soluble in water, and less soluble in hot water than in cold; when the solution is heated, a deposition of lime takes place, which is redissolved on cooling. A solution of lime containing particles of undissolved lime in suspension is termed *milk of lime.*

Official Description.—A clear, colorless liquid.
Odor, Taste, and Reaction.—Without odor; alkaline taste; strongly alkaline reaction.
Tests for Identity.—A clear, colorless liquid without odor, and having an alkaline taste.
It absorbs carbon dioxide from the air, a pellicle of calcium carbonate forming on the surface of the liquid.
On being heated it becomes turbid, due to the separation of calcium hydroxide, which redissolves when the liquid is cooled.
In other respects it should conform to the reactions and tests for an aqueous solution of lime given under *Calx*.
Impurities and Test.—*Alkalies and their carbonates.* The alkaline reaction of the Solution should entirely disappear, after it has been saturated with carbon dioxide, and subsequently boiled.
Quantitative Test.—Fifty Cc. should require, for complete neutralization, not less than 19 Cc. of tenth-normal sulphuric acid V.S. (corresponding to about 0.14 percent. of calcium hydroxide), phenolphthalein T.S. being used as indicator.

Uses.—Probably the most extensive use of lime water in medicine is in checking nausea. It is usually administered with milk when used for this purpose. It is employed externally to allay inflammation, and in washes of various kinds. The dose of lime water is from one to two fluidounces (30 to 60 Cc.).

SYRUPUS CALCIS. U.S. Syrup of Lime

A syrupy liquid made by boiling 65 Gm. of lime and 350 Gm. of sugar in 500 Cc. of water, during five minutes, adding sufficient water to measure 950 Cc., filtering and then adding water to filtrate, to make 1000 Cc. Lime is more soluble in syrup than in water, and hence this syrup is more strongly alkaline than lime water; this is accounted for by the fact that lime forms soluble saccharates with sugar (see page 291).

Official Description.—A transparent, pale yellow liquid.
Taste and Reaction.—Alkaline taste and reaction.
Specific Gravity.—About 1.145 at 25° C. (77° F.).
Tests for Identity.—The addition of a solution of an alkali carbonate produces a white precipitate, soluble in acids with effervescence.
The addition of ammonium oxalate T.S. produces a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.

LINIMENTUM CALCIS. U.S. Lime Liniment

This liniment is made by mixing equal measures of lime water and linseed oil. It is used largely as an external application for burns, and is sometimes called Carron oil (see page 322).

CALX CHLORINATA. U.S. Chlorinated Lime

The activity of this compound depends upon the amount of chlorine present, and it is therefore most appropriately considered under that head (see page 486).

CALX SULPHURATA. U.S. Sulphurated Lime

[Crude Calcium Sulphide]

A mixture containing at least 55 percent. of calcium sulphide [$CaS = 71.63$], together with unchanged calcium sulphate [$CaSO_4 = 135.15$], and carbon, in varying proportions.

	Metric	Old form
* **Exsiccated Calcium Sulphate,** in fine powder	70 Gm.	7 oz. av.
Charcoal, in fine powder	10 Gm.	1 oz. av.
Starch	2 Gm.	87 grains

Mix the powder thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small, glass-stoppered vials.

This is not a definite chemical compound, but contains varying amounts of the active constituent calcium sulphide.

Official Description.—A pale gray powder, gradually decomposing by exposure to moist air.

Odor and Taste.—Exhaling a faint odor of hydrogen sulphide; nauseous and alkaline taste.

Solubility.—*Water.* Very slightly in cold water, more readily in boiling water, which partially decomposes it.

Alcohol.—Insoluble.

Tests for Identity.—When Sulphurated Lime is decomposed by diluted acetic acid, calcium acetate is formed, hydrogen sulphide gas is evolved, and a residue of calcium sulphate and carbon remains.

The filtrate from this yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid.

Quantitative Test.—If 1 Gm. of Sulphurated Lime be added to a cold solution of 1.9 Gm. of cupric sulphate in 50 Cc. of water, followed by 10 Cc. of diluted hydrochloric acid, added in small portions, with constant stirring, and the mixture digested on a water-bath for 15 minutes and filtered, the addition of an excess of ammonia water should impart no color to the filtrate (presence of at least 55 percent. of pure Calcium Sulphide).

Uses.—Sulphurated lime is used as a depilatory for removing superfluous hair from the body, by mixing a small quantity with water and applying the paste to the part. It is used internally in acne and other skin diseases. The dose is one-half grain to one grain (0.3 to 0.065 Gm.).

CALCII BROMIDUM. U.S. Calcium Bromide

$CaBr_2 = 198.52$

It should contain not less than 97 percent. of pure Calcium Bromide, and should be kept in well-stoppered bottles.

Preparation.—Calcium bromide may be made by the simple process of adding precipitated calcium carbonate, in excess, to hydrobromic acid, filtering, evaporating the solution to dryness, and granulating the product.

It may also be made by adding milk of lime to a boiling solution of ammonium bromide until ammoniacal vapors cease to be evolved. The solution is then filtered, and the salt granulated. Care should be used to protect the product from moisture.

$$\underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3} + \underset{\substack{\text{Hydrobromic}\\\text{Acid}}}{2HBr} = \underset{\substack{\text{Calcium}\\\text{Bromide}}}{CaBr_2} + \underset{\text{Water}}{H_2O} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2}$$

Official Description.—A white, granular salt; very deliquescent.

Odor, Taste, and Reaction.—Odorless; sharp, saline taste; neutral reaction.

Solubility.—Very soluble in water and alcohol.

Tests for Identity.—The aqueous solution of the salt (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid.

Silver nitrate T.S. produces a light yellow precipitate, insoluble in nitric acid and in a moderate excess of ammonia water.

Impurities and Tests for Impurities.—*Iodides.* If to 10 Cc. of the aqueous solution of the salt (1 in 20), 1 Cc. of chloroform be added, then chlorine water, which has been diluted with an equal volume of water, added cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color free from any violet tint.

Insoluble impurities. If 1 Gm. of Calcium Bromide be added to 20 Cc. of water, it should form a clear, colorless solution, leaving no residue.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Barium. If 1 Gm. of Calcium Bromide and 1 Gm. of sodium acetate be dissolved in 5 Cc. of distilled water, and the solution made slightly acid through the addition of from 3 to 5 drops (or a sufficient quantity) of diluted acetic acid, after boiling and thoroughly cooling, the solution should not become cloudy within five minutes upon the addition, with agitation, of 5 drops of potassium dichromate T.S.

Bromate. If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color.

Limit of nitrate and ammonia. To 5 Cc. of an aqueous solution of the salt (1 in 100), contained in a test-tube of about 40 Cc. capacity, add 5 Cc. of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire. In the upper portion of the test-tube, insert a plug of purified cotton or gauze, and over the mouth, a piece of moistened red litmus paper; place the tube in a bath of boiling water, and after fifteen minutes no blue coloration of the paper should be discernible.

Uses.—Calcium bromide is used as an hypnotic, in doses of fifteen to sixty grains (1 to 4 Gm.).

CALCII CARBONAS PRÆCIPITATUS. U.S. Precipitated Calcium Carbonate

$CaCO_3 = 99.35$

It should contain not less than 99 percent. of pure Calcium Carbonate.

Preparation.—This salt is readily prepared by double decomposition. The following process was official in the British Pharmacopœia:

Take of Chloride of Calcium 5 oz. av.; Carbonate of Soda 13 oz. av.; Boiling Distilled Water a sufficiency. Dissolve the Chloride of Calcium and the Carbonate of Soda each in 2 pints [Imperial measure] of the Water; mix the two Solutions; and allow the precipitate to subside. Collect this on a calico filter, wash it with boiling Distilled Water until the washings cease to give a precipitate with nitrate of silver, and dry the product at the temperature of 212° (F.).

Calcium carbonate precipitates, and sodium chloride remains in solution.

$$\underset{\substack{\text{Calcium}\\\text{Chloride}}}{CaCl_2} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3} + \underset{\substack{\text{Sodium}\\\text{Chloride}}}{2NaCl}$$

The fineness of the powder is greatly promoted by using hot, dense solutions.

This salt of calcium is also obtained as a by-product in the process for making solution of chlorinated soda, double decomposition taking place between solution of chlorinated lime and solution of monohydrated sodium carbonate. The precipitated calcium carbonate must be boiled in water, and afterwards thoroughly washed, to free it from the chlorinous odor; the product is unfit for internal use.

Official Description.—A fine, white powder; permanent in the air.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Nearly insoluble; the solubility is increased by the presence of ammonium salts, and especially by carbon dioxide; alkali hydroxides diminish its solubility.

Alcohol. Insoluble.

Other solvents. In diluted acetic, hydrochloric, or nitric acid, it is completely soluble with effervescence.

Tests for Identity. When heated to full redness, with access of air, the salt gradually loses carbon dioxide, and a residue of calcium oxide remains.

For applying tests of identity and of purity, 5 Gm. of Calcium Carbonate are mixed with 100 Cc. of distilled water, followed by hydrochloric acid, added drop by drop, with agitation, until solution takes place. The resulting solution should, after boiling and cooling, be of acid reaction, and there should not remain more than traces of insoluble matter.

In a portion of this acid solution, after neutralizing with ammonia water, ammonium oxalate T.S. produces a white precipitate of calcium oxalate, insoluble in acetic acid but soluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Limit of iron, aluminum, phosphates, etc.* If to 20 Cc. of the acid solution, ammonia water be added until of alkaline reaction, no turbidity or precipitation should take place either before or after boiling.

Heavy metals. The acid solution should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of soluble impurities. If 1 Gm. of the salt be agitated with 50 Cc. of water, the filtrate should not show an alkaline reaction with litmus paper, and, on evaporation, should not leave a weighable residue.

Uses.—This form of calcium carbonate, known popularly as *precipitated chalk*, is largely used in tooth powders and similar preparations; it is inferior to the prepared chalk as an ingredient in chalk mixtures, because it does not possess the adhesive powers of the latter. Dose, fifteen grains (1 Gm.).

CRETA PRÆPARATA. U.S. Prepared Chalk

$CaCO_3 = 99.35$

[DROP CHALK]

Native Calcium Carbonate, freed from most of its impurities by elutriation.

Preparation.—The process formerly official is as follows:

Take of Chalk a *convenient quantity*. Add a little water to the Chalk, and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquor, while yet turbid, into another vessel. Treat the coarser particles of the Chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly, set the liquor by, that the powder may subside, and, having poured off the water, dry the powder.

The object of this process is to effect the separation of the gritty particles in ordinary chalk by elutriation (see page 187). It is usual to form the moist powder into cones by trochiscation (see page 187). While elutriation effects the purification of the chalk to a certain extent, it does not separate the insoluble fine particles, and hence prepared chalk is chemically not so pure as precipitated calcium carbonate.

Prepared chalk differs greatly in appearance from precipitated chalk, even after it has been reduced to a fine powder. It is usually not so white as the latter, and it adheres to the fingers when handled. This adhesiveness fits it for many purposes. *Whiting*, a cheap form of prepared chalk, is used for polishing.

Official Description.—A white to grayish-white, very fine amorphous powder, often moulded into conical drops; permanent in the air.

Odor and Taste.—Odorless and tasteless.

Solubility.—*Water.* Almost insoluble.

Alcohol. Insoluble.

Other solvents. In diluted acetic, hydrochloric, or nitric acids, with copious effervescence, leaving not more than a trifling residue.

Test for Identity.—When heated to full redness, Prepared Chalk gradually loses carbon dioxide, and is converted into calcium oxide.

Uses.—This is the form of chalk which is used in medicine almost exclusively; it is an antacid, and is admirably adapted for the treatment of diarrhœa. It is used in the compound chalk powder. Dose, fifteen grains (1 Gm.).

CALCII CHLORIDUM. U.S. Calcium Chloride

$CaCl_2 = 110.16$

Calcium Chloride, rendered anhydrous by fusion at the lowest possible temperature. It should contain not less than 99 percent. of pure Calcium Chloride, and should be kept in well-stoppered bottles.

Preparation.—Calcium chloride may be readily formed by saturating hydrochloric acid with chalk or marble, evaporating to dryness, and heating to redness.

$$\underset{\substack{\text{Calcium}\\\text{Carbonate}}}{CaCO_3} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{2HCl} = \underset{\substack{\text{Calcium}\\\text{Chloride}}}{CaCl_2} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{CO_2} + \underset{\text{Water}}{H_2O}$$

It is frequently obtained as a by-product in chemical operations.

Official Description.—White, slightly translucent, hard fragments; very deliquescent.
Odor, Taste, and Reaction.—Odorless; sharp, saline taste; strictly neutral reaction.
Solubility.—*Water.* In 1.3 parts at 25° C. (77° F.); very freely in boiling water, usually leaving a slight residue.
Alcohol. In 8 parts at 25° C. (77° F.); in 1.5 parts of boiling alcohol.
Tests for Identity.—Below a red heat the salt fuses, and, on cooling, solidifies without change in composition.
When perfectly pure, Calcium Chloride dissolves in water without residue.
When the salt has been overheated in fusing, the solution has an alkaline reaction, and a small residue of calcium oxide is left, which is soluble in hydrochloric acid.
The aqueous solution (1 in 20) yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid.
With silver nitrate T.S. it yields a white precipitate insoluble in nitric acid.
Impurities and Tests for Impurities.—*Limit of iron, aluminum, phosphates, etc.* If to the aqueous solution of the salt (1 in 20) ammonia water be added, until of alkaline reaction, no turbidity or precipitation should take place either before or after boiling.
Limit of magnesium and alkalies. If from 10 Cc. of the solution the calcium be completely precipitated by ammonium oxalate T.S., the filtrate should, on evaporation and ignition, leave not more than 0.1 percent. of fixed residue.
Arsenic. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic* or *lead* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—Calcium chloride, when in fused masses, is used in chemical processes for dehydrating gases; this it does through its powerful affinity for water.

CALCII HYPOPHOSPHIS. U.S. Calcium Hypophosphite

$Ca(PH_2O_2)_2 = 168.86$

It should contain not less than 98 percent. of pure Calcium Hypophosphite [$(PO.OH_2)_2Ca$], and should be kept in well-stoppered bottles; caution should be observed in dispensing Calcium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.

Preparation.—This salt is made by boiling milk of lime and phosphorus together until the spontaneously inflammable gas, hydrogen phosphide, ceases to be evolved; it is necessary to provide for the safe escape of this gas by conducting it by a hood into a powerful draught.

$$\underset{\text{Phosphorus}}{8P} + \underset{\substack{\text{Calcium}\\\text{Hydroxide}}}{3Ca(OH)_2} + \underset{\text{Water}}{6H_2O} = \underset{\substack{\text{Calcium}\\\text{Hypophosphite}}}{3CaH_4(PO_2)_2} + \underset{\substack{\text{Hydrogen}\\\text{Phosphide}}}{2PH_3}$$

The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and refiltered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated till a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat, and stirring.

The heat employed in evaporating the solution should not be above 85° C. (185° F.), for fear of explosions, several accidents having occurred through carelessness in this respect, even when the evaporation was conducted with a water bath.

Official Description.—Colorless, transparent, monoclinic prisms, or small, lustrous scales, or a white crystalline powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless; nauseous and bitter taste. One Gm. of the salt dissolved in 20 Cc. of water, should not require the addition of more than 1 Cc. of tenth-normal potassium hydroxide V.S. to produce a pink color (phenolphthalein being used as indicator).

Solubility.—*Water.* In 6.5 parts of water at 25° C. (77° F.), and in 6 parts of boiling water. *Alcohol.* Insoluble.

Tests for Identity.—When heated in a test-tube the salt decrepitates, and above 300° C. (572° F.) it begins to decompose, giving off water, and emitting inflammable gases (hydrogen and hydrogen phosphide), and leaving a residue of calcium pyrophosphate and metaphosphate, with some red phosphorus.

The aqueous solution (1 in 20) yields, with ammonium oxalate T.S., a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid.

The diluted aqueous solution, slightly acidulated with diluted nitric acid, yields with silver nitrate T.S. a precipitate, which is white at first but rapidly turns brown and black, due to the separation of metallic silver.

With copper sulphate T.S., on gentle heating, a reddish-brown precipitate is formed.

When the aqueous solution of Calcium Hypophosphite (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray in color, due to its reduction to metallic mercury.

Impurities and Tests for Impurities.—*Phosphate and Sulphate.* If 1 Gm. of the salt be added to 20 Cc. of water and well shaken, not more than a trace of residue should remain.

Arsenic. If 5 Cc. of an aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Heavy metals. The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—Calcium hypophosphite is used pharmaceutically to prepare the other hypophosphites, hypophosphorous acid, and as an ingredient in the syrup and compound syrup of hypophosphites and other preparations. Medicinally, it is used in phthisis and other wasting diseases, and in cases of defective nerve nutrition. The dose is from five to thirty grains (0.3 to 2 Gm.).

SYRUPUS HYPOPHOSPHITUM. U.S. Syrup of Hypophosphites

This syrup is made by dissolving 45 Gm. of calcium hypophosphite and 15 Gm. each of sodium and potassium hypophosphites in water, aiding the solution by the use of 2 Gm. of diluted hypophosphorous acid. After the addition of 2 Cc. of tincture of fresh lemon peel, the liquid is filtered and 650 Gm. of sugar and sufficient water to make 1000 Cc. of finished syrup are added (see page 293). There is usually a trifling residue left after dissolving the hypophosphites; this consists generally of insoluble calcium salts.

SYRUPUS HYPOPHOSPHITUM COMPOSITUS. U.S. Compound Syrup of Hypophosphites

This compound syrup is made by dissolving 2.25 Gm. each of ferric hypophosphite and manganese hypophosphite, with the aid of 3.75 Gm. of sodium citrate, in 30 Cc. of water, then dissolving 35 Gm. of calcium hypophosphite, and 17.5 Gm. each of sodium and potassium hypophosphite in 450 Cc. of water, to which 5 Cc. of diluted hypophosphorous acid has been added, then dissolving 1.10 Gm. of quinine, and 0.11 Gm. of Strychnine in 30 Cc. of water, with the aid of 10 Cc. of diluted hypophosphorous acid, and finally dissolving 775 Gm. of sugar in these mixed solutions, and adding enough water to make 1000 Cc. (see page 293).

CALCII PHOSPHAS PRÆCIPITATUS. U.S. Precipitated Calcium Phosphate

$Ca_3(PO_4)_2 = 307.98$

It should contain not less than 99 percent. of pure Calcium Phosphate $[(PO.O_3)_2Ca_3]$.

Preparation.—Take of Bone, calcined to whiteness, and in fine powder, 4 oz. troy; Hydrochloric acid, 8 oz. troy; Ammonia Water, 12 fl. oz., or a sufficient quantity; Distilled Water, a sufficient quantity. Macerate the Bone in the Acid, diluted with a pint of Distilled Water, until it is dissolved, and filter the solution. Add another pint of Distilled Water, and then, gradually, Ammonia Water, until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling Distilled Water, and pour the whole upon a strainer. Wash the precipitate with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly, dry the precipitate with a gentle heat.

Calcium phosphate exists in calcined bone; it is soluble in hydrochloric acid, but is precipitated from its solution by ammonia water, ammonium chloride remaining in solution.

Official Description.—A white, amorphous powder; permanent in the air.

Odor and Taste.—Odorless; tasteless.

Solubility.—*Water.* Almost insoluble in cold water; partly decomposed by boiling water, which dissolves out the acid salt.

Alcohol. Insoluble.

Other solvents. Almost insoluble in acetic acid, except when freshly precipitated; easily soluble in hydrochloric or nitric acid.

Tests for Identity.—At an intense white heat, the salt fuses without decomposition.

When moistened with silver nitrate T.S., either before or after ignition, the salt acquires a yellow color (distinction from *acid calcium phosphate*, which, after ignition, when moistened with silver nitrate T.S., remains white).

Impurities and Tests for Impurities.—*Carbonate.* For applying tests of identity and of purity, shake 2 Gm. of Precipitated Calcium Phosphate with 20 Cc. of water, add nitric acid, drop by drop, until solution is effected, and then add sufficient water to make the liquid measure 40 Cc. While making this solution, no effervescence should occur on adding the acid.

From a portion of this solution the salt is precipitated unchanged by a slight excess of ammonia water.

From another portion ammonium molybdate T.S. precipitates yellow ammonium phosphomolybdate: the reaction is accelerated by gentle heat, not exceeding 65° C. (149° F.).

Limit of chloride. If to 5 Cc. of the solution, acidulated with nitric acid, 0.5 Cc. of silver nitrate T.S. be added, not more than a slight turbidity should result.

Barium. If to 5 Cc. of the solution, strongly acidulated with nitric acid, 1 Cc. of potassium sulphate T.S. be added, no turbidity should result upon standing.

Heavy metals. An aqueous solution of Calcium Phosphate (1 in 20), obtained by shaking the salt with water, adding hydrochloric acid, drop by drop, and heating until solution is effected, should not respond to the Time-Limit Test for *heavy metals* omitting the addition of ammonia water (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of a solution (1 in 10) of Calcium Phosphate, in diluted hydrochloric acid should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—Precipitated calcium phosphate, on account of its insolubility in water, was used in making medicated waters in preference to magnesium carbonate and other similar substances in the U. S. P. 1890, but has been replaced by purified talc in the 8th Decennial Revision. It is admininistered largely now in proprietary medicines, in combination with lactic acid and phosphoric acid, for use in cases of defective nutrition. The dose is from ten to thirty grains (0.6 to 2 Gm.).

SYRUPUS CALCII LACTOPHOSPHATIS. U.S. Syrup of Calcium Lactophosphate

This syrup is made by dissolving precipitated calcium carbonate in lactic and phosphoric acids. Water, orange flower water, and sugar are added to the solution to complete the syrup (see page 291 for the working formula). It is sometimes made extemporaneously by dissolving 200 grains of calcium lactophosphate in one pint of syrup of orange flowers, which contains one fluidrachm of hydrochloric acid. It is given in doses of one to four fluidrachms (4 to 16 Cc.).

CALCII SULPHAS EXSICCATUS. U.S. Exsiccated Calcium Sulphate

[Dried Calcium Sulphate]

A powder containing about 95 percent., by weight, of Calcium Sulphate [$CaSO_4 = 135.15$], and about 5 percent. of water; prepared from the purer varieties of native gypsum [$CaSO_4 + 2H_2O = 170.91$], by carefully heating until about three-fourths of the water has been expelled.

Exsiccated Calcium Sulphate should be kept in well-closed vessels, carefully protected from moisture.

Official Description.—A fine, white powder.

Odor, Taste, and Reaction.—Without odor or taste; neutral reaction in saturated aqueous solution.

Solubility.—*Water.* In about 378 parts of water at 25° C. (77° F.), and in 451 parts at 100° C. (212° F.).

Alcohol. Insoluble.

Other solvents. Readily in diluted nitric or hydrochloric acid; also in saturated solutions of potassium nitrate, sodium thiosulphate, and of various ammonium salts.

Tests for Identity.—From moist air it attracts water, becomes granular, and then loses the property of hardening with water.

When mixed with half its weight of water, Exsiccated Calcium Sulphate forms a smooth, cohesive paste, which rapidly hardens.

When heated above 204° C. (399.2° F.), Exsiccated Calcium Sulphate becomes anhydrous and loses the property of forming a paste with water which hardens rapidly.

Its saturated solution in water forms white precipitates with barium chloride T.S., with ammonium oxalate T.S., and with alcohol.

Impurity and Test.—*Carbonate.* No effervescence should occur on the addition of diluted acids to Exsiccated Calcium Sulphate.

Uses.—This substance, known commonly as *Plaster of Paris*, is largely used by surgeons in the treatment of fractures, by filling the interstices of a soft cotton cloth bandage with the powder and then moistening with water, and applying the bandage to the fractured part in such a way that, when the dried gypsum has hardened, a support is afforded.

PULVIS CRETÆ COMPOSITUS. U.S. Compound Chalk Powder

The preparation is made by mixing 30 Gm. of prepared chalk with 20 Gm. of powdered acacia and 50 Gm. of powdered sugar. It is used for making chalk mixture (see page 305).

MISTURA CRETÆ. U.S. Chalk Mixture

This mixture is made by rubbing 20 Gm. of compound chalk powder with 40 Cc. of cinnamon water, and adding sufficient water to make 100 Cc. (see page 305).

Barium. Ba; 136.4

This element furnishes salts for use officially in making tests or test solutions. Barium Dioxide was used in the process for making solution of hydrogen dioxide, official in the U. S. P. 1890, but as that process is no longer official the salt has been omitted from the Pharmacopœia. *Barium* occurs abundantly as carbonate and sulphate. It is a malleable metal, having a silver-white lustre, decomposing water, and gradually oxidizing in the air.

Tests for Salts of Barium

1. A soluble barium salt produces with sulphuric acid or soluble sulphate a white precipitate of barium sulphate, which is entirely insoluble in all acids.

2. Barium causes a colorless flame to be colored green.

3. Alkaline carbonates produce white precipitates with soluble barium salts, insoluble in excess.

Official Test Solutions of Barium

Test solution of Barium Chloride	Used in testing for sulphates
Test solution of Barium Hydroxide	Known as baryta water and used in testing for sulphates
Test solution of Barium Nitrate	Used in testing for sulphates

Unofficial Salts of Barium

Barii Acetas, $Ba(C_2H_3O_2)_2$ Barium Acetate	By decomposing barium carbonate with acetic acid, evaporating, then crystallizing
Barii Benzoas, . $Ba(C_7H_5O_2)_2 + 2H_2O$ Barium Benzoate	By adding to a solution of barium carbonate benzoic acid until neutralized, then evaporating and crystallizing
Barii Boras Barium Borate	By adding to a solution of barium carbonate a solution of sodium borate, collecting and drying the precipitate
Barii Bromidum, $BaBr_2 + 2H_2O$ Barium Bromide	By saturating baryta water with hydrobromic acid, evaporating, then crystallizing
Barii Carbonas, $BaCO_3$ Barium Carbonate	Witherite, a native mineral used as a source of many barium salts, or it may be made by adding ammonium carbonate and ammonia water to a solution of barium chloride, washing precipitate, and drying
Barii Chloridum, $BaCl_2 + 2H_2O$ Barium Chloride (See U. S. P. Test Solution)	By dissolving barium carbonate in hydrochloric acid, evaporating, then crystallizing
Barii Chromas, $BaCrO_4$ Barium Chromate	By adding baryta water to a solution of potassium chromate, collecting and drying the precipitate
Barii Citras, $Ba_3 2C_6H_5O_7$ Barium Citrate	By adding citric acid to baryta water in excess, and collecting the precipitate
Barii Dioxidum, BaO_2 Barium Dioxide	By heating barium oxide to about 450° C. (874° F.)
Barii Hydroxidum, $Ba(OH)_2 + 8H_2O$ Barium Hydroxide (See U. S. P. Test Solution)	By treating barium monoxide with water
Barii Iodidum, $BaI_2 + 2H_2O$ Barium Iodide	Alterative. Dose, one-eighth of a grain three times a day, gradually increased to three grains
Barii Nitras, $Ba2NO_3$ Barium Nitrate (See U. S. P. Test Solution)	By adding to a solution of barium chloride a solution of sodium nitrate, and collecting and drying the precipitate
Barii Oxalas, $BaC_2O_4 + 2H_2O$ Barium Oxalate	By adding a solution of oxalic acid to an excess of baryta water, and collecting the precipitate
Barii Sulphas, $BaSO_4$ Barium Sulphate	By adding to a solution of barium chloride, sulphuric acid, and collecting the precipitate

Strontium. Sr; 86.94

Strontium enters into three official salts. It occurs in nature chiefly as sulphate and carbonate. It is a yellow metal, sp. gr. 2.5; malleable, but somewhat harder than lead. Its use in medicine is due to Laborde's demonstration in 1890 that its salts are not poisonous in ordinary doses, but, in certain cases, beneficial.

Tests for Salts of Strontium

1. A soluble strontium salt produces with alkaline carbonates or with soluble phosphates a white precipitate.
2. Strontium causes a colorless flame to be colored red.
3. Solution of calcium sulphate produces a white precipitate with soluble strontium salts. Slow precipitation is hastened by the addition of alcohol.

Official Salts of Strontium

Strontii Bromidum Strontium Bromide	Made by dissolving strontium carbonate in hydrobromic acid
Strontii Iodidum Strontium Iodide	Made by evaporating a solution of strontium hydroxide in hydriodic acid
Strontii Salicylas Strontium Salicylate	Made by neutralizing salicylic acid with strontium carbonate

Unofficial Salts of Strontium

Strontii Carbonas, $SrCO_3$ Strontium Carbonate	Occurs native as strontianite
Strontii Chloridum, $SrCl_2$ Strontium Chloride	Made by treating strontianite (native carbonate) with hot hydrochloric acid
Strontii Chromas, $SrCrO_4$ Strontium Chromate	Made by precipitating a strong solution of chloride or nitrate with neutral potassium chromate
Strontii Hydroxidum, $Sr(OH)_2$ Strontium Hydroxide	Obtained by treating the oxide with water
Strontii Lactas, $Sr(C_3H_5O_3)_2 + 3H_2O$ Strontium Lactate	Made by dissolving freshly precipitated strontium carbonate in lactic acid
Strontii Nitras, $Sr(NO_3)_2$ Strontium Nitrate	By treating the carbonate with diluted nitric acid, evaporating and crystallizing
Strontii Oxidum, SrO Strontium Oxide	Obtained by heating the nitrate to redness or igniting the carbonate
Strontii Sulphas, $SrSO_4$ Strontium Sulphate	Occurs native as celestine

STRONTII BROMIDUM. U.S. Strontium Bromide

$SrBr_2 + 6H_2O = 352.94$

It should contain not less than 97 percent. of pure Strontium Bromide, and should be kept in glass-stoppered bottles.

This salt may be made in several ways, but the simplest method is to dissolve strontium carbonate in hydrobromic acid and then evaporate and crystallize the salt from the solution.

Official Description.—Colorless, transparent, hexagonal crystals; very deliquescent, and also occasionally efflorescent.

Odor, Taste, and Reaction.—Odorless, and having a bitter, saline taste; neutral reaction.

Solubility.—*Water.* Soluble in about 1 part of water at 25° C. (77° F.), and in 0.4 part of boiling water.

Alcohol. Readily soluble in alcohol, and is precipitated from this solution upon the addition of an equal volume of ether, in which it is insoluble.

Tests for Identity.—When heated, the crystals at first melt, and then lose all their water (30.4 percent.). The anhydrous salt fuses at 630° C. (1166° F.).

To a non-luminous flame the salt communicates an intense red color.

With calcium sulphate T.S. the aqueous solution (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the same reaction occurs more quickly with diluted sulphuric acid and the readily soluble sulphates.

With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid.

With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid.

Impurities and Tests for Impurities.—*Iodide.* If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water, which has been diluted with an equal volume of water, introduced cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Heavy metals. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of barium. If 1 Gm. each of Strontium Bromide and sodium acetate be dissolved in 5 Cc. of distilled water, and the solution made slightly acid by the addition of from 3 to 5 drops, or a sufficient quantity, of diluted acetic acid, the solution should not, upon the addition of 5 drops of potassium dichromate T.S. and agitating, become cloudy within three minutes.

Quantitative Test.—If 0.5 Gm. of Strontium Bromide be dissolved in about 50 Cc. of distilled water, and a few drops of potassium chromate T.S. be added, it should require the addition of not less than 27.4 (27.48) Cc. nor more than 29.4 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 97 percent. of pure Strontium Bromide).

Uses.—Strontium bromide is used in place of potassium and sodium bromides in epilepsy. Dose, fifteen to thirty grains (1 to 2 Gm.).

STRONTII IODIDUM. U.S. Strontium Iodide

$$SrI_2 + 6H_2O = 446.02$$

It should contain not less than 98 percent. of pure Strontium Iodide, and should be kept in small, glass-stoppered vials, carefully protected from light.

This salt may be made by evaporating a solution of strontium hydroxide in hydriodic acid.

Official Description.—Colorless, transparent, hexagonal plates, or white granular powder, or crystalline crusts; deliquescent, and colored yellow by exposure to air and light.

Odor, Taste, and Reaction.—Odorless; bitter, saline taste; neutral or very slightly alkaline reaction.

Solubility.—*Water.* Soluble in about 0.5 part of water at 25° C. (77° F.), and in 0.27 part of boiling water.

Alcohol. Soluble in alcohol.

Other solvents. Slightly soluble in ether.

Tests for Identity.—When cautiously heated, the crystals melt and gradually lose their water (24.05 percent.), becoming anhydrous. At a red heat, the salt is decomposed, losing iodine, and leaving a residue of strontium oxide.

To a non-luminous flame it imparts an intense red color.

With calcium sulphate T.S. it slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid and the readily soluble sulphates.

With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid.

With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid.

If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a light reddish-brown color; on agitating the mixture with a few drops of chloroform, the latter will acquire a violet color.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of barium. If 1 Gm. each of Strontium Iodide and sodium acetate be dissolved in 5 Cc. of distilled water, and the solution be made slightly acid by the addition of from 3 to 5 drops, or a sufficient quantity, of diluted acetic acid, the solution should not, upon the addition of 5 drops of potassium dichromate T.S., and agitating, become cloudy within three minutes.

Quantitative Test.—If 0.5 Gm. of Strontium Iodide be dissolved in about 100 Cc. of distilled water contained in a flask, and 25 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of nitric acid, and 5 Cc. of ferric ammonium sulphate T.S. be successively added, the flask stoppered and thoroughly shaken, then the addition of not less than 1.7 Cc. nor more than 3.1 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent red tint (corresponding to 98 percent. of pure Strontium Iodide).

Uses.—This salt was introduced into the U. S. P. 1890 as a substitute for potassium iodide, as it is believed to be less irritating to the intestinal tract, or less depressing to the general nutrition. Dose, five to twenty grains (0.3 to 1.3 Gm.).

STRONTII SALICYLAS. U.S. Strontium Salicylate

$Sr(C_7H_5O_3)_2 + 2H_2O = 394.72$

It should contain not less than 98.5 percent. of pure Strontium Salicylate $[(C_6H_4.OH.COO)_2Sr + 2H_2O]$, and should be kept in well-stoppered bottles, protected from heat and light.

It may be made by decomposing strontium carbonate with a strong hot solution of salicylic acid, filtering and crystallizing.

Official Description.—A white, crystalline powder.

Odor, and Taste.—Odorless; sweetish, saline taste.

Solubility.—*Water.* In 18 parts at 25° C. (77° F.); in 3.5 parts of boiling water.
Alcohol. In 66 parts at 25° C. (77° F.); in 10.5 parts of boiling alcohol.

Tests for Identity.—When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a gray residue of strontium carbonate.

To a non-luminous flame its solution imparts an intense red color.

Its aqueous solution should be colorless, and slightly alkaline to litmus paper.

Ferric chloride T.S., when added to an excess of a concentrated aqueous solution of the salt, produces a violet precipitate; but when added to a very dilute solution (1 in 100), it produces a deep violet-blue color.

If copper sulphate T.S. be added to the aqueous solution (1 in 20), a green color will be produced.

On adding about 1 Cc. of concentrated sulphuric acid to about 0.2 Gm. of the salt, in a test-tube, then about 1 Cc. of methyl alcohol, in drops, and heating the mixture to boiling, the odor of methyl salicylate will be evolved.

With calcium sulphate T.S., the aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the same reaction occurs more quickly with diluted sulphuric acid or a readily soluble sulphate.

With potassium chromate T.S., Strontium Salicylate forms a yellow precipitate of strontium chromate, soluble in acetic acid.

With ammonium carbonate T.S., or sodium carbonate T.S., the salt forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid.

Impurities and Tests for Impurities.—*Heavy metals.* If to the aqueous solution of Strontium Salicylate (1 in 20) 5 drops of hydrochloric acid be added, and the mixture agitated and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of barium. If 2 Gm. of Strontium Salicylate be agitated with 10 Cc. of diluted acetic acid, heated, cooled, and filtered, the filtrate, upon the addition of 5 drops of potassium dichromate T.S., should not become cloudy within three minutes.

Quantitative Test.—If to 0.5 Gm. of Strontium Salicylate, contained in a porcelain crucible, 1 Cc. of sulphuric acid be added, the mixture cautiously heated until no more vapors are given off, the residue again moistened with a few drops of the acid, again heated, and finally ignited until white and of constant weight, the residue of strontium sulphate should weigh not less than 0.227 Gm.

Uses.—Strontium salicylate is used in place of sodium salicylate in doses of ten to fifteen grains (0.6 to 1 Gm.).

CHAPTER XLIII

ZINC, ALUMINUM, CERIUM, AND CADMIUM

Zn ; 64.9. Al ; 26.9. Ce ; 139.2. Cd ; 111.6

THESE metals are grouped together on account of the similarity in some of their physical properties, rather than because of the chemical analogies existing between them.

ZINCUM. U.S. Zinc

Zn = 64.9

It should contain not less than 99 percent. of pure metallic Zinc.

Preparation.—Zinc is made by roasting *calamine*, or the impure zinc carbonate, with charcoal, in powder, and collecting the zinc by distillation, the vapors being conducted into water, where the zinc is condensed. It is bivalent, and combines with oxygen, chlorine, and phosphorus, forming zinc oxide, chloride, and phosphide, and with numerous acids to form salts.

Tests for Zinc Salts

1. Ammonium sulphide, if added to a solution of a zinc salt containing an excess of alkaline hydroxide, produces a characteristic white precipitate of zinc sulphide.
2. The alkali hydroxides of either sodium, potassium, or ammonium produce white precipitates of zinc hydroxide, freely soluble in an excess of alkali.
3. Sodium and potassium carbonates yield white precipitates, insoluble in an excess.
4. The zinc salts are all colorless.

Official Description.—A bluish-white metal, showing a crystalline fracture; in the form or thin sheets, or in irregular, granulated pieces, or moulded into thin pencils, or in fine powder.

Specific Gravity.—Ranging from 6.9 when it is cast to 7.2, after it is rolled.

Solubility.—Soluble in diluted sulphuric or hydrochloric acid with evolution of hydrogen.

Tests for Identity.—When heated above 100° C. (212° F.) and not above 150° C. (302° F.), the metal becomes malleable and ductile; above 200° C. (392° F.) it becomes sufficiently brittle to be powdered in an iron mortar; at 412° to 415° C. (773.6° to 779° F.) it melts, and at 940° C. (1724° F.) it boils, and may be readily distilled.

Impurities and Tests for Impurities.—*Absence of sulphur.* If 1 Gm. of Zinc be added to 20 Cc. of diluted hydrochloric acid, the liberated hydrogen should not have a disagreeable odor, nor should it color a strip of paper moistened with lead acetate T.S.

Absence of arsenic, antimony, and phosphorus. Or with silver nitrate T.S. The resulting solution should be clear and colorless, and should yield a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S.

Arsenic, cadmium, lead, and copper. If 1 Gm. of Zinc be dissolved in a mixture of 10 Cc. each of nitrohydrochloric acid and water, the solution evaporated to dryness, the residue moistoned with 2 Cc. of hydrochloric acid and again evaporated, and the final residue dissolved in 10 Cc. of water, this solution should not respond to the Time-Limit Test for *arsenic, cadmium, lead, and copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Uses.—Zinc is used in making hydrogen and in preparing the zinc salts.

Zinc and Official Salts and Preparations

Official Name	Preparation
Zincum	Made by roasting the impure carbonate with charcoal and distilling
Zinci Acetas	By treating zinc carbonate with acetic acid
Bromidum	By double decomposition of zinc sulphate and potassium bromide
Carbonas Præcipitatus	By double decomposition of zinc sulphate and sodium carbonate
Chloridum	By evaporating the solution of zinc chloride
Iodidum	By digesting zinc with iodine diffused in water
Oxidum	By calcining zinc carbonate
Phenolsulphonas	By mixing solutions of barium phenolsulphonate and zinc sulphate, evaporating the supernatant liquid, and collecting the crystals
Stearas	By mixing solutions of castile soap and zinc sulphate, collecting precipitate, and drying
Sulphas	By acting on zinc with diluted sulphuric acid
Valeras	By double decomposition of zinc sulphate and sodium valerate
Liquor Zinci Chloridi	By treating zinc with hydrochloric acid
Unguentum Zinci Oxidi	By incorporating zinc oxide with benzoinated lard
Zinci Stearatis	By incorporating zinc stearate with white petrolatum

Unofficial Salts of Zinc

Zinci Cyanidum, $Zn(CN)_2$ Zinc Cyanide	By adding hydrocyanic acid to a solution of zinc acetate and collecting the precipitate
Zinci et Potassii Cyanidum, K_2ZnCN_4 Zinc and Potassium Cyanide	By dissolving zinc cyanide in a solution of pure potassium cyanide, filtering, concentrating, then crystallizing
Zinci Ferrocyanidum, $Zn_2FeCN_6 + 2H_2O$ Zinc Ferrocyanide	By making a solution of zinc sulphate and one of potassium ferrocyanide, mixing them, and collecting the precipitate
Zinci Lactas, $Zn(C_3H_5O_3)_2 + 3H_2O$ Zinc Lactate	Dissolving, by the aid of heat, zinc carbonate in diluted lactic acid, filtering and concentrating, then crystallizing
Zinci Phosphidum Zinc Phosphide	By passing vapors of phosphorus over fused zinc in a current of dry hydrogen
Zinci Salicylas, $Zn(C_7H_5O_3)_2 + 3H_2O$ Zinc Salicylate	By heating salicylic acid with distilled water, gradually adding zinc oxide suspended in water, until no longer dissolved, filtering, and then crystallizing
Zinci Tartras Zinc Tartrate	By mixing hot concentrated solutions of zinc sulphate and neutral potassium tartrate, collecting the precipitate, and drying it
Oleatum Zinci Oleate of Zinc. U.S.P. 1890	By sifting zinc oxide upon oleic acid and heating gently until dissolved

ZINCI ACETAS. U.S. Zinc Acetate

$$Zn(C_2H_3O_2)_2 + 2H_2O = 217.82$$

It should contain in the uneffloresced condition not less than 99.5 percent. o pure Zinc Acetate [$(CH_3.COO)_2Zn + 2H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This salt may be made by a former official process: Take of Commercial Oxide of Zinc, 2 oz. troy; Acetic Acid, 8½ fl. oz.; Distilled Water, 5 fl. oz. Mix the Acid and Water, and digest the Oxide of Zinc in the mixture for half an hour, then heat to the boiling point, filter while hot, and set aside to crystallize. Drain the crystals in a funnel, and dry them upon bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother liquor to one-half, slightly acidulating with acetic acid, and crystallizing.

The reaction is expressed as follows:

$$\underset{\text{Zinc Oxide}}{ZnO} + \underset{\text{Acetic Acid}}{2HC_2H_3O_2} = \underset{\text{Zinc Acetate}}{Zn(C_2H_3O_2)_2} + \underset{\text{Water}}{H_2O}$$

Official Description.—Soft, white, six-sided, monoclinic plates, of a pearly lustre. Exposed to the air, the salt gradually effloresces and loses some of its acid.

Odor, Taste, and Reaction.—Faintly acetous odor; in dilute solutions an astringent, metallic taste; acid reaction.

Solubility.—*Water.* In about 2.5 parts at 25° C. (77° F.); in 1.5 parts of boiling water. On protracted boiling with water acetic acid is lost, and an insoluble basic salt formed.

Alcohol. In 36 parts at 25° C. (77° F.); in 0.6 part of boiling alcohol.

Tests for Identity.—When heated, the salt is partially fused, losing water and acid. At a higher temperature it is decomposed, evolving acetone and other combustible vapors, and leaving a residue of zinc oxide.

The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and with ammonium sulphide T.S. a pure white precipitate.

The addition of a few drops of ferric chloride T.S. to an aqueous solution of the salt (1 in 20) produces a red color.

Ammonium carbonate T.S., or potassium hydroxide T.S., when added in small portions to the aqueous solution of the salt (1 in 20), produces at first a precipitate of a pure white color, which dissolves completely upon the addition of an excess of the reagent.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* Ten Cc. of the aqueous solution of the salt (1 in 20), to which 1 Cc. of hydrochloric acid has been added, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Sulphate. The aqueous solution of the salt (1 in 20), after the addition of a few drops of diluted nitric acid, should remain clear upon the addition of either barium chloride T.S.

Chloride. Or silver nitrate T.S.

Uses.—Zinc acetate is used principally as a local remedy, in eye washes, injections, etc.

ZINCI BROMIDUM. U.S. Zinc Bromide

$ZnBr_2 = 223.62$

It should contain, when anhydrous, at least 97 percent. of pure Zinc Bromide, and should be kept in small, glass-stoppered bottles.

Preparation.—Zinc bromide may be made by the process suggested by Lyons, of dissolving potassium bromide and crystallized zinc sulphate, each, in the smallest quantity of hot water, and mixing while hot. When the mixture has cooled, twice its bulk of alcohol is added, and the whole filtered through asbestos to separate the potassium sulphate. The filtrate is evaporated to dryness, and the residue granulated.

This salt may also be made by adding bromine to water and dropping in *mossy zinc*, a form of metallic zinc made by pouring the pure melted metal in water (the pieces bear some resemblance to moss); zinc bromide remains in solution, and may be obtained by filtration, evaporation, and granulation.

$$\underset{\substack{\text{Zinc}\\\text{Sulphate}}}{ZnSO_4} + \underset{\substack{\text{Potassium}\\\text{Bromide}}}{2KBr} = \underset{\substack{\text{Zinc}\\\text{Bromide}}}{ZnBr_2} + \underset{\substack{\text{Potassium}\\\text{Sulphate}}}{K_2SO_4}$$

Official Description.—A white, or nearly white, granular powder; very deliquescent.

Odor, Taste, and Reaction.—Odorless, having, even in dilute solutions, a sharp, saline and metallic taste; slightly acid reaction.

Solubility.—*Water.* Readily.

Alcohol. Readily.

Tests for Identity.—When heated to 394° C. (741.2° F.), the salt fuses, and, with a careful increase of heat, may be sublimed in the form of needle-shaped prisms.

The aqueous solution of the salt (1 in 20) yields a pure white precipitate with hydrogen sulphide T.S. and ammonium sulphide T.S., and also with potassium ferrocyanide T.S.

Silver nitrate T.S. produces a yellowish-white precipitate insoluble in nitric acid and in a moderate excess of ammonia water.

On adding ammonium carbonate T.S. to the aqueous solution of Zinc Bromide, a white precipitate is produced, which should completely redissolve in an excess of the reagent.

Impurities and Tests for Impurities.—*Iodide.* If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, then chlorine water (which has been diluted with an equal volume of water), cautiously introduced, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint.

Arsenic, cadmium, lead, and copper. The aqueous solution of the salt (1 in 20), to which sufficient hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Sulphate. Another portion of this aqueous solution should not be rendered turbid by the addition of barium chloride T.S.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of chloride. If 1 Gm. of Zinc Bromide be dissolved in 50 Cc. of acetic acid, 2 Gm. of lead dioxide (free from chloride) be added, and the mixture evaporated in a small beaker to at least 10 Cc., then the residue, diluted with 10 Cc. of distilled water and filtered, should give not more than a slight turbidity on the addition of 2 Cc. of nitric acid and a few drops of silver nitrate T.S.

Quantitative Test.—If 0.3 Gm. of the anhydrous salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require not less than 26 Cc. nor more than 26.8 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color, corresponding to not less than 97 percent. of the pure salt.

Uses.—Zinc bromide is used medicinally as an hypnotic, in doses of from two to five grains (0.12 to 0.3 Gm.).

ZINCI CARBONAS PRÆCIPITATUS, U.S. Precipitated Zinc Carbonate

Hydrated Zinc Carbonate, which, upon ignition, should yield not less than 72 percent. of zinc oxide [$ZnO = 80.78$].

Preparation.—This salt may be made by a former official British process, as follows:

Take of Sulphate of Zinc, 10 oz. av.; Carbonate of Soda, 10½ oz. av.; Boiling Distilled Water, a sufficiency. Dissolve the Carbonate of Soda with a pint [Imperial measure] of the Water in a capacious porcelain vessel, and pour into it the Sulphate of Zinc also dissolved in a pint [Imp. meas.] of the Water, stirring diligently. Boil for fifteen minutes after effervescence has ceased, and let the precipitate subside. Decant the supernatant liquor, pour on the precipitate 3 pints of boiling Distilled Water, agitating briskly; let the precipitate again subside; and repeat the process of affusion of hot Distilled Water and subsidence, till the washings are no longer precipitated by chloride of barium. Collect the precipitate on calico, let it drain, and dry it with a gentle heat.

$$\underset{\substack{\text{Sodium}\\\text{Carbonate}}}{5Na_2CO_3} + \underset{\substack{\text{Zinc}\\\text{Sulphate}}}{5ZnSO_4} + \underset{\text{Water}}{3H_2O} = \underset{\text{Zinc Carbonate}}{(ZnCO_3)_2 3Zn(HO)_2} + \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{5Na_2SO_4} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{3CO_2}$$

If cold solutions of zinc sulphate and sodium carbonate are mixed together, neutral zinc carbonate is precipitated. This carbonate quickly decomposes, carbon dioxide being evolved, which, upon escaping, makes a portion of the precipitate soluble. This loss is prevented by conducting the precipitation at the boiling temperature, whereby the carbon dioxide is driven off as quickly as it is formed, and solution is thereby prevented.

Official Description.—An impalpable, white powder, of somewhat variable chemical composition. Permanent in the air.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Completely in diluted acids with copious effervescence; also soluble in ammonia water, and in ammonium carbonate T.S.

Tests for Identity.—When strongly heated, the salt loses water and carbon dioxide, and leaves a residue, which is yellow while hot, but becomes white on cooling.

When a small portion of the salt is moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid green color.

For making tests of identity and purity, make a solution by adding 10 Cc. of diluted sulphuric acid and 10 Cc. of water to 1.25 Gm. of the salt, and, after effervescence has ceased, remove the undissolved excess by filtration.

In a portion of this solution a white gelatinous precipitate is produced by potassium ferrocyanide T.S., and a pure white precipitate by ammonium sulphide T.S.

Another portion of the solution, acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Another portion of the solution should yield, with ammonium carbonate T.S., a white precipitate, which should redissolve completely in an excess of the reagent.

Impurity and Test.—*Limit of alkali.* If 1 Gm. of the salt be placed in a flask with 10 Cc. of boiling water, and 2 drops of phenolphthalein T.S. added, not more than 1 Cc. of tenth-normal hydrochloric acid V.S. should be required to discharge the red color.

Quantitative Test.—One Gm. of Zinc Carbonate, after strong ignition in a porcelain crucible, should leave a residue of zinc oxide weighing not less than 0.720 Gm.

Uses.—Precipitated zinc carbonate is used principally in ointments, and takes the place of the former impure carbonate termed *calamine.* It is sometimes dusted upon inflamed surfaces as an astringent and absorbent.

ZINCI CHLORIDUM. U.S. Zinc Chloride

$ZnCl_2 = 135.26$

It should contain, when anhydrous, not less than 99.5 percent. of pure Zinc Chloride, and should be kept in small, glass-stoppered bottles.

Preparation.—Zinc chloride is easily prepared by digesting metallic zinc in hydrochloric acid and evaporating the solution to dryness; or, preferably, by evaporating the official solution of zinc chloride.

$$\underset{\text{Zinc}}{2Zn} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{4HCl} = \underset{\substack{\text{Zinc}\\\text{Chloride}}}{2ZnCl_2} + \underset{\text{Hydrogen}}{4H}$$

Official Description.—A white, or nearly white, granular powder, or porcelain-like masses, irregular, or moulded in pencils. Very deliquescent.

Odor, Taste, and Reaction.—Odorless, *of such intensely caustic properties as to make tasting dangerous,* unless the salt be dissolved in much water; the dilute solution has an astringent, metallic taste; acid reaction.

Solubility.—*Water.* In about 0.4 part of water at 25° C. (77° F.), forming a clear solution, which, on protracted boiling, deposits a basic salt.

Alcohol. Very soluble.

Tests for Identity.—When heated to 115° C. (239° F.), Zinc Chloride fuses to a clear liquid. At a higher temperature it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide.

The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and with ammonium sulphide T.S. a pure white precipitate.

Silver nitrate T.S. produces a white precipitate insoluble in nitric acid.

If ammonium carbonate T.S. be added, in small portions, to the aqueous solution (1 in 20), the precipitate produced should be of a pure white color, and should redissolve completely in an excess of the reagent.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* The aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Limit of oxychloride. The aqueous solution (1 in 20) should be clear, or at most only very slightly opalescent; and if it be mixed with an equal volume of alcohol, a single drop of hydrochloric acid should suffice to render 10 Cc. of the mixture perfectly clear.

Sulphate. The aqueous solution of the salt (1 in 20), after the addition of 1 Cc. of diluted hydrochloric acid, should not be rendered turbid by the addition of barium chloride T.S.

Quantitative Test.—Dissolve 0.5 Gm. of Zinc Chloride in 200 Cc. of boiling distilled water, add about 5 drops of phenolphthalein T.S., and then sufficient sodium carbonate T.S., with constant stirring, to cause the solution to assume a permanent red color; transfer the resulting precipitate to a plain filter, wash it with boiling distilled water until all soluble matter has been removed, then dissolve it in a sufficient quantity of nitric acid, evaporate the solution to dryness, and ignite the salt until it ceases to lose weight; the residue should weigh not less than 0.297 Gm.

Uses.—Zinc chloride in solution is used as an antiseptic and disinfectant (see Liquor Zinci Chloridi, below). Externally, mixed with flour and water, it is used as an escharotic.

LIQUOR ZINCI CHLORIDI. U.S. Solution of Zinc Chloride

An aqueous solution, containing about 50 percent., by weight, of Zinc Chloride [$ZnCl_2 = 135.26$].

	Metric	Old form
* **Zinc,** granulated	240 Gm.	6¼ oz. av.
Hydrochloric Acid	840 Gm.	21 oz. av. 5 dr.
Nitric Acid	12 Gm.	100 minims
Precipitated Zinc Carbonate	12 Gm.	136 grains
Distilled Water, a sufficient quantity,		
To make about	1000 Gm.	1 pint

To the Zinc, contained in a glass or porcelain vessel, add 150 Cc. [old form 4½ fl. oz.] of Distilled Water; then gradually add the Hydrochloric Acid, and digest until reaction ceases and the Acid is saturated. Pour off the solution, add the Nitric Acid, and heat the solution at a temperature not exceeding 115° C. (239° F.), until a portion, if removed and cooled, solidifies. Allow it to cool, and dissolve the solidified mass in a sufficient quantity of Distilled Water to make the product weigh 1000 Gm. [or measure, old form, 1 pint]. Then add the Precipitated Zinc Carbonate, agitate the mixture occasionally during twenty-four hours, and set it aside until it has become clear by subsidence. Finally, separate the clear Solution by decantation, or by means of a siphon.

When zinc is treated with hydrochloric acid, hydrogen is evolved and zinc chloride is produced.

$$\underset{\text{Zinc}}{2Zn} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{4HCl} = \underset{\substack{\text{Zinc}\\\text{Chloride}}}{2ZnCl_2} + \underset{\text{Hydrogen}}{4H}$$

Zinc is almost invariably contaminated with iron, and more or less ferrous chloride is present in the first solution. Nitric acid is added, and the solution is evaporated to dryness. The iron salt is thus oxidized, and it is then precipitated by the addition of zinc carbonate, the insoluble ferric hydroxide and carbonate, with any excess of zinc carbonate, being filtered out.

Official Description.—A clear, colorless liquid.
Odor, Taste, and Reaction.—Odorless, having a very astringent, metallic taste, and an acid reaction.
Specific Gravity.—About 1.548 at 25° C. (77° F.).
Tests for Identity.—It should conform to the reactions and tests for an aqueous solution of the salt given under *Zinci Chloridum* (see page 606).

Uses.—This solution, sometimes called *Burnett's disinfecting fluid*, is used principally as an antiseptic and disinfectant. Among its advantages, absence of odor is one of the most prominent.

ZINCI IODIDUM. U.S. Zinc Iodide

$ZnI_2 = 316.70$

It should contain, when anhydrous, not less than 98 percent. of pure Zinc Iodide, and should be kept in small, glass-stoppered bottles protected from light.

Preparation.—Zinc iodide may be formed by digesting an excess of zinc with iodine diffused in water, in a manner similar to that used in making the corresponding iron salt.

$$\underset{\text{Zinc}}{Zn} + \underset{\text{Hydriodic Acid}}{2HI} = \underset{\text{Zinc Iodide}}{ZnI_2} + \underset{\text{Hydrogen}}{2H}$$

Official Description.—A white, or nearly white, granular powder. Very deliquescent, and, upon exposure to air and light, becoming brown from liberated iodine.

Odor, Taste, and Reaction.—Odorless; sharp, saline and metallic taste; acid reaction.

Solubility.—*Water.* Readily.

Alcohol. Readily.

Other solvents. Readily soluble in ether.

Tests for Identity.—When heated to about 446° C. (834.8° F.), the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decomposed and leaves a residue of zinc oxide.

An aqueous solution of the salt (1 in 20) yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a pure white precipitate with ammonium sulphide T.S.

With silver nitrate T.S. it yields a pale yellow precipitate, insoluble in ammonia water; with mercuric chloride T.S., a red precipitate, soluble in potassium iodide T.S.

If ammonium carbonate T.S. be added to the aqueous solution of the salt (1 in 20), a pure white precipitate will form, which should redissolve completely in an excess of the reagent.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* The aqueous solution of the salt (1 in 20), to which sufficient diluted hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Sulphate. Another portion of the aqueous solution should not be rendered turbid upon the addition of barium chloride T.S.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of Chloride. If 1 Gm. of Zinc Iodide be mixed with 5 Cc. of distilled water, and sufficient ammonia water be added to redissolve the precipitate formed, followed by a solution of 1.5 Gm. of silver nitrate in 10 Cc. of water, then, after shaking and filtering, the filtrate should not be rendered more than slightly turbid by the addition of an excess of nitric acid.

Quantitative Test.—If 0.5 Gm. of dry Zinc Iodide be dissolved in 20 Cc. of water, and if 35 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of nitric acid, and 3 Cc. of ferric ammonium sulphate T.S. be added, and the mixture well shaken, then the addition of not less than 3.4 Cc. nor more than 4 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to give a permanent reddish-brown tint to the solution.

Uses.—Zinc iodide is used as an alterative, in doses of one-half grain to two grains (0.03 to 0.12 Gm.).

ZINCI OXIDUM. U.S. Zinc Oxide

$ZnO = 80.78$

It should contain not less than 99 percent. of pure Zinc Oxide.

Preparation.—Zinc oxide may be prepared by a former official process, as follows:

Take of Precipitated Carbonate of Zinc 12 oz. troy. Expose it, in a shallow vessel, to a low red heat until the water and carbonic acid are wholly expelled.

$$\underset{\text{Zinc Carbonate}}{2ZnCO_3.3Zn(OH)_2} = \underset{\text{Zinc Oxide}}{5ZnO} + \underset{\text{Carbon Dioxide}}{2CO_2} + \underset{\text{Water}}{3H_2O}$$

Commercial zinc oxide is made on the large scale by heating calamine and coal ground together, roasting in a furnace of peculiar construction, and separating the impurities by blowing the mixed vapors up a large tower, allowing the heavier particles to subside in the tower, and then by a powerful draught blowing the zinc oxide into a room containing muslin bags, when the oxide is deposited.

This kind of zinc oxide will not usually conform to the official tests; it is generally very white and filled with hard lumps, which are difficult to reduce to powder. The official powder has a marked cream tint, and can be mixed with ointment so that a smooth preparation is easily made without trituration. (See Unguentum Zinci Oxidi.)

Official Description.—A very fine, amorphous, white or yellowish-white powder, free from gritty particles; it gradually absorbs carbon dioxide from the air.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Completely without effervescence, in diluted acids; also in ammonia water, and in ammonium carbonate T.S.

Tests for Identity.—When heated, it assumes a yellow color, which disappears on cooling.

If a small portion of Zinc Oxide be moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid green color.

For making tests of identity and purity, digest 1 Gm. of Zinc Oxide, with occasional agitation, in a mixture of 10 Cc. of diluted hydrochloric acid and 10 Cc. of water until saturated; then remove the undissolved Zinc Oxide by filtration.

In a portion of the filtrate a white gelatinous precipitate is produced by potassium ferrocyanide T.S., and a pure white precipitate by ammonium sulphide T.S.

Another portion of the filtrate, acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Another portion of the filtrate should yield, upon the gradual addition of ammonium carbonate T.S., a pure white precipitate, which should almost completely redissolve in an excess of the reagent.

Impurities and Tests for Impurities.—*Limit of alkali.* If 1 Gm. of Zinc Oxide be placed in a flask with 10 Cc. of boiling water, and 2 drops of phenolphthalein T.S. be added, not more than 1 Cc. of tenth-normal hydrochloric acid V.S. should be required to discharge the red color.

Chloride. If 1 Gm. of Zinc Oxide be dissolved in a sufficient quantity of diluted nitric acid, the solution should remain clear upon the addition of silver nitrate T.S.

Limit of sulphate. The above solution should not become more than slightly turbid upon the addition of barium chloride T.S.

Quantitative Test.—If 1 Gm. of freshly ignited Zinc Oxide be digested with 30 Cc. of normal hydrochloric acid V.S. until solution is complete, and 2 drops of methyl-orange T.S. be added, not more than 5.5 Cc. of normal potassium hydroxide V.S. should be required for neutralization (each Cc. of normal hydrochloric acid consumed corresponding to 4.04 percent. of zinc oxide). The normal potassium hydroxide V.S. should be added slowly with constant stirring, waiting until the precipitated zinc hydroxide has redissolved before adding further portions of the reagent.

Uses.—Zinc oxide is rarely used internally; externally, it is used as an exsiccant to inflamed surfaces, and it may be dusted on the part or used in the form of an ointment.

UNGUENTUM ZINCI OXIDI. U. S. Ointment of Zinc Oxide

Made by incorporating 200 Gm. of zinc oxide with 800 Gm. of benzoinated lard. (See Unguenta, Part V.)

ZINCI PHENOLSULPHONAS. U. S. Zinc Phenolsulphonate

$Zn(C_6H_5O_4S)_2 + 8H_2O = 551.56$

[Zinc Sulphocarbolate]

It should contain, in uneffloresced crystals, not less than 99.5 percent. of pure Zinc Paraphenolsulphonate [$(C_6H_4(OH)SO_3)_2Zn$ 1 : 4 + $8H_2O$], and should be kept in small, well-stoppered bottles.

This salt is made by mixing solutions of barium phenolsulphonate and zinc sulphate; barium sulphate is precipitated, the solution is evaporated, and the crystals which separate are washed and dried.

Official Description.—Colorless, transparent, rhombic prisms or tabular crystals. Exposed to the air the salt effloresces, and upon exposure to light and air may become slightly pink.

Odor, Taste, and Reaction.—Odorless; astringent, metallic taste; acid reaction.

Solubility.—*Water.* In 1.7 parts at 25° C. (77° F.); in 0.3 part of boiling water.

Alcohol. In 1.7 parts at 25° C. (77° F.); in 0.56 part of boiling alcohol.

Tests for Identity.—When heated to 100° C. (212° F.), the salt loses 6 molecules of water of crystallization, and it loses the remainder at 125° C. (257° F.). At a higher temperature it chars, emitting inflammable vapors having the odor of phenol, and finally leaves a residue amounting to about 14.6 percent. of the original weight.

A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S.

The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and, with ammonium sulphide T.S., a pure white precipitate.

Ammonium carbonate T.S., or potassium hydroxide T.S., when added in small portions to the aqueous solution of the salt (1 in 20), produces a precipitate of a pure white color, which dissolves completely upon the addition of an excess of the reagent.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* The aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Sulphate. The aqueous solution of the salt (1 in 20) should not become turbid upon the addition of barium chloride T.S.

Chloride. Or silver nitrate T.S.

Arsenic. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—Zinc phenolsulphonate is used as an antiseptic astringent and stimulant. When used internally it may be given in doses of two grains (0.12 Gm.).

ZINCI STEARAS. U.S. Zinc Stearate

This salt is made by adding a solution of 75 Gm. of Zinc Acetate in 5000 Cc. of water to a solution of 200 Gm. of dried Castile Soap in 3000 Cc. of hot water. The latter solution must be cold before mixing. The precipitate is washed and dried without heat.

Official Description.—A very fine, white powder. Zinc Stearate contains a small but varying proportion of zinc palmitate.

Odor, Taste, and Reaction.—Very faint odor, resembling that of fat; tasteless; neutral reaction.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Insoluble in ether.

Tests for Identity.—When heated, the salt fuses. At a higher temperature it is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaves about 13.5 percent. of residue, which consists chiefly of zinc oxide.

If 0.5 Gm. of Zinc Stearate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid, stearic acid will be liberated and float as an oily layer on the surface of the liquid.

Impurities and Tests for Impurities.—*Alkalies, alkali earths, etc.* If, after filtering this liquid through a small wetted filter, all of the zinc be precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation.

More than traces of chlorides If 0.5 Gm. of Zinc Stearate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of nitric acid, and filtered, the filtrate should not become more than slightly turbid upon the addition of silver nitrate T.S.

Quantitative Test.—If 1 Gm. of Zinc Stearate be boiled with 50 Cc. of distilled water containing 2 Cc. of nitric acid, and filtered through a wetted filter, after thoroughly washing the precipitate with boiling water, the filtrate and washings, when evaporated to dryness and ignited, should leave a residue weighing not less than 0.14 Gm. and not more than 0.16 Gm.

Uses.—Zinc stearate is used in the official ointment of zinc stearate, and as a dusting powder in dermatological practice.

UNGUENTUM ZINCI STEARATIS. U.S. Ointment of Zinc Stearate

Made by incorporating 50 Gm. of zinc stearate with 50 Gm. of white petrolatum (see page 1267).

ZINCI SULPHAS. U.S. Zinc Sulphate

$ZnSO_4 + 7H_2O = 285.41$

It should contain, in uneffloresced crystals, not less than 99.5 percent. of pure Zinc Sulphate [$SO_2.O_2Zn + 7H_2O$], and should be kept in well-stoppered bottles.

Preparation.—Zinc sulphate is made by acting on metallic zinc with diluted sulphuric acid, hydrogen being evolved; the resulting solution is freed from the contamination of iron by first passing chlorine into it, when ferric chloride is produced, and, upon the addition of zinc carbonate, decomposition takes place, ferric hydroxide separating as an insoluble precipitate, which is removed by filtration, and a small quantity of zinc chloride is formed, which, being very soluble, remains in the mother liquor after the crystallization of the sulphate.

$$\underset{\text{Zinc}}{2Zn} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} + \underset{\text{Water}}{H_2O} = \underset{\substack{\text{Zinc}\\\text{Sulphate}}}{2ZnSO_4} + \underset{\text{Hydrogen}}{4H} + \underset{\text{Water}}{H_2O}$$

Official Description.—Colorless, transparent, rhombic crystals, or a granular crystalline powder. Efflorescent in dry air.

Odor, Taste, and Reaction.—Without odor; astringent, metallic taste; acid reaction.

Solubility.—*Water.* Completely in 0.53 part of water at 25° C. (77° F.), and in 0.2 part of boiling water.

Alcohol. Insoluble.

Other solvents. In about 3 parts of glycerin.

Tests for Identity.—When rapidly heated, the salt melts. At a higher temperature it is partly decomposed, losing both water and sulphuric acid. When very gradually heated to 50° C. (122° F.), it loses 5 molecules of its water of crystallization (31.2 percent.) without melting. At 100 C. (212° F.), a sixth molecule is lost, while the last is removed, with decomposition of the salt, at a temperature of about 240° C. (464° F.).

The aqueous solution of the salt (1 in 20) yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S., and with barium chloride T.S.

If a small portion of the salt be moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid green color.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* The aqueous solution of Zinc Sulphate (1 in 20), after being acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic, cadmium, lead,* and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

The aqueous solution should yield, with ammonium carbonate T.S., a white precipitate, which should redissolve completely in an excess of the reagent.

Limit of chloride. The aqueous solution (1 in 20) should not be rendered more than slightly turbid by silver nitrate T.S.

Free acid. If 1 Gm. of Zinc Sulphate, in small fragments, be agitated for some time with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus paper.

Uses.—This salt is the most important of those made from zinc. It is used medicinally as a prompt and certain emetic in doses of ten to thirty grains (0.6 to 2 Gm.); as a tonic and astringent, one to two grains (0.065 to 0.12 Gm.).

ZINCI VALERAS. U.S. Zinc Valerate

$Zn(C_5H_9O_2)_2 + 2H_2O = 301.28$

[ZINCI VALERIANAS, PHARM. 1890 ZINC VALERIANATE]

It should contain not less than 99 percent. of pure Zinc Valerate [$(C_4H_9.COO)_2Zn + 2H_2O$], and should be kept in small, well-stoppered bottles.

Preparation.—The process for making this salt affords an illustration of the rather rare instance of "upward precipitation," the crystals of zinc valerate being lighter than the mixed solutions.

"Take of Sodium Valerate, 2½ oz. troy; Zinc Sulphate, 2 oz. troy, 420 grains; Distilled Water, a sufficient quantity. Dissolve the salts separately, each in 20 fluidounces of Distilled Water, and, having heated the solutions to 100° C. (212° F.), mix them, and set the mixture aside to crystallize. Decant the mother water from the crystals, and put them upon a filter in a funnel to drain. Mix the mother water and the drainings, evaporate at a heat not exceeding 93.3° C. (200° F.) to 4 fluidounces, and again set aside to crystallize. Add the crystals, thus obtained, to those in the funnel, wash the whole with a little Distilled Water, and, having removed them with the filter, spread them on bibulous paper, and dry them with a heat not exceeding 93.3° C. (200° F.)."

$$\underset{\text{Sodium Valerate}}{2NaC_5H_9O_2} + \underset{\text{Zinc Sulphate}}{ZnSO_4} = \underset{\text{Zinc Valerate}}{Zn(C_5H_9O_2)_2} + \underset{\text{Sodium Sulphate}}{Na_2SO_4}$$

Official Description.—White, pearly scales. On exposure to the air, it slowly loses valeric acid.

Odor, Taste, and Reaction.—Odor of valeric acid; sweetish, astringent, and metallic taste; acid reaction.

Solubility.—*Water.* In about 50 parts at 25° C. (77° F.). Boiling renders the aqueous solution turbid from loss of acid and formation of a basic salt.

Alcohol. In about 35 parts at 25° C. (77° F.); somewhat more soluble in absolute alcohol.

Tests for Identity.—When heated, the salt melts. At a higher temperature it is decomposed, giving off inflammable vapors, and finally leaving a residue of zinc oxide.

Zinc Valerate should dissolve without residue in ammonium carbonate T.S.

If 0.5 Gm. of Zinc Valerate be dissolved in a mixture of 0.5 Cc. of hydrochloric acid and 9 Cc. of water, the valeric (isovaleric) acid will be liberated and float as an oily layer on the surface of the liquid.

Impurities and Tests for Impurities.—*Arsenic, cadmium, lead, and copper.* After filtering through a small wetted filter, the clear solution should not respond to the Time-Limit Test for *arsenic, cadmium, lead*, and *copper* (see U. S. P. Test No. 121, Chap. LXII); in applying this test the addition of ammonia water should be omitted.

Sulphate. If 0.5 Gm. of Zinc Valerate be dissolved in a mixture of 0.5 Cc. of nitric acid and 4.5 Cc. of distilled water, and the mixture filtered through a small wetted filter, the filtrate should show but a faint cloudiness upon the addition of either barium chloride T.S.

Chloride. Or silver nitrate T.S.

Acetate. If 0.5 Gm. of Zinc Valerate be triturated with 3 Cc. of water, and 0.2 Cc. of ferric chloride T.S. added, the filtrate should not show a red color.

Butyrate. If a concentrated solution of copper acetate in water be added to a concentrated aqueous solution of Zinc Valerate, the mixture should remain perfectly clear.

Arsenic. If 0.5 Gm. of Zinc Valerate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid and filtered, the filtrate should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—Zinc valerate is used as a nervine and antispasmodic, in doses of one to three grains (0.065 to 0.19 Gm.).

Aluminum. Al; 26.9

This metal is found largely in combination with silicic acid, in the rocks and clays forming a great portion of the earth's surface. Some of the precious stones and valuable minerals are compounds of aluminum; the ruby and sapphire, corundum and emery, are crystallized forms of aluminum oxide. Aluminum is of a silver-white color. The metal, owing to improvements in its extraction, is much cheaper than it was formerly, and it is used in making ornamental and useful articles. Owing to its very low specific gravity (2.67), it is used for grain weights, because they are much larger, and thus more easily handled, than they would be if made from brass (see page 69). Aluminum forms but one class of compounds used in medicine; it is trivalent. The oxides and sulphates unite with those of the alkali metals and form double salts, called alums.

Tests for Salts of Aluminum

1. Potassium or sodium hydroxide produces white, gelatinous precipitates of aluminum hydroxide in solutions of alum, which are freely soluble in excess of the alkali.
2. Ammonia water produces a similar precipitate, insoluble in excess.
3. The alkaline carbonates precipitate the hydroxide, carbon dioxide being evolved.
4. Ammonium sulphide also precipitates the hydroxide, hydrogen sulphide being evolved.

Official Salts of Aluminum

Official Name	Preparation
Alumen	By treating alum clay with sulphuric acid and potassium sulphate
Exsiccatum	By heating alum to a temperature of 205° C. (401° F.)
Alumini Hydroxidum	By double decomposition of alum and sodium carbonate
Sulphas	By treating aluminum hydroxide with sulphuric acid and crystallizing

Unofficial Salts of Aluminum

Alumini Acetas, $Al(C_2H_3O_2)_3$ Aluminum Acetate	By dissolving aluminum hydroxide in cold acetic acid, filtering and concentrating, then crystallizing
Alumini Bromidum, $AlBr_3$ Aluminum Bromide	By passing the vapor of bromine over a heated mixture of aluminum oxide and carbon
Alumini Chloridum, $AlCl_3$ Aluminum Chloride	By dissolving aluminum hydroxide in hydrochloric acid and evaporating carefully, then crystallizing
Alumini Iodidum, AlI_3 Aluminum Iodide	By heating aluminum and iodine together in closed tubes and collecting the crystals
Alumini Nitras, $Al(NO_3)_3 + 9H_2O$ Aluminum Nitrate	By dissolving aluminum hydroxide in nitric acid, filtering and concentrating, then crystallizing
Alumini Oxidum, Al_2O_3 Aluminum Oxide	Occurs in nature
Alumini Phosphas, $AlPO_4$ Aluminum Phosphate	By adding a neutral solution of aluminum hydroxide to a solution of sodium phosphate, and collecting the gelatinous precipitate

ALUMEN. U.S. Alum

$$AlK(SO_4)_2 + 12H_2O = 471.02$$

[ALUMINUM AND POTASSIUM SULPHATE POTASSIUM ALUM]

It should contain not less than 99.5 percent. of pure Aluminum and Potassium Sulphate.

Preparation.—This valuable salt is made principally from alum clay, which is chiefly aluminum silicate, by treating it with sulphuric acid, thereby forming aluminum sulphate. Potassium sulphate is then added, when the double salt $AlK(SO_4)_2$ is produced. It crystallizes with twelve molecules of water. Ammonia alum, $AlNH_4(SO_4)_2$, is generally found in the market, because of its greater cheapness.

Official Description.—Large, colorless, octahedral crystals, sometimes modified by cubes, or in crystalline fragments.

Odor, Taste, and Reaction.—Without odor; sweetish and strongly astringent taste; acid reaction.

Solubility.— *Water.* In 9 parts at 25° C. (77° F.); in 0.3 part of boiling water.
Alcohol. Insoluble.
Other solvents. Freely soluble in warm glycerin.

Tests for Identity.—When gradually heated, it loses water; at 92° C. (197.6° F.) it fuses, and if the heat be gradually increased to 200° C. (392° F.), it loses all of its water of crystallization (45.55 percent. of its weight), leaving a voluminous white residue (see *Alumen Exsiccatum*).

An aqueous solution of the salt affords, with ammonia water, a white, gelatinous, precipitate, which is almost insoluble in an excess of ammonia; with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid.

When a saturated solution of Alum is shaken with sodium bitartrate T.S., it produces, within half an hour, a white, crystalline precipitate.

The aqueous solution of Alum affords, with potassium hydroxide T.S., a white, gelatinous precipitate, which is completely soluble in an excess of the alkali.

Impurities and Tests for Impurities.—*Heavy metals.* The aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII). (The subsequent addition of ammonia water, as directed in this test, should be omitted.)

Limit of iron. The addition of 5 drops of potassium ferrocyanide T.S., to 20 Cc. of an aqueous solution of alum (1 in 150) should not at once produce a blue coloration.

Uses.—Alum is a powerful astringent. When powdered, it is used as an emetic in croup, in doses of a teaspoonful. It is sometimes used as a local styptic, and is frequently employed in making astringent lotions and injections. The dose as an astringent is from five to twenty grains (0.3 to 1.3 Gm.).

ALUMEN EXSICCATUM. U.S. Exsiccated Alum

$AlK(SO_4)_2 = 256.46$

[ALUMEN USTUM DRIED ALUM BURNT (BURNED) ALUM]

Exsiccated Alum should contain not less than 99 percent. of pure anhydrous Aluminum and Potassium Sulphate.

	Metric	Old form
* **Alum,** in small pieces	**100 Gm.**	20 oz. av.
To make	**55 Gm.**	11 oz. av.

Place the Alum in a tared shallow porcelain dish so as to form a thin layer, and heat it on a sand-bath until it liquefies. Then continue the application of a moderate heat, with constant stirring, until aqueous vapor ceases to be disengaged and a dry, white, porous mass weighing 55 Gm. [old form 11 oz. av.] is obtained. When cold, reduce the product to a fine powder, and preserve it in well-stoppered bottles.

This preparation represents alum nearly deprived of its water of crystallization; the latter exists in alum in the enormous proportion of nearly 45 percent., thus constituting almost half of its weight.

Official Description.—A white, granular powder; attracting moisture on exposure to the air.

Odor and Taste.—Without odor; sweetish, astringent taste.

Solubility.—*Water.* Slowly but completely in about 17 parts at 25° C. (77° F.); quickly in 1.4 parts of boiling water.

Tests for Identity.—Its aqueous solution should respond to the reactions and tests given under *Alumen.*

Uses.—It is used as an escharotic. It is more powerful than alum, although not so soluble.

ALUMINI HYDROXIDUM. U.S. Aluminum Hydroxide

[ALUMINI HYDRAS, PHARM. 1890]

	Metric	Old form
* **Alum**	100 Gm.	16 oz. av.
Monohydrated Sodium Carbonate	43 Gm.	6 oz. av. 385 gr.
Water, a sufficient quantity		

Dissolve each salt separately in 1000 Cc. [old form 10 pints] of Water, filter the solutions and heat them to boiling. Then having poured the hot solution of Monohydrated Sodium Carbonate into a capacious vessel, gradually pour in the hot solution of alum with constant stirring, and add 2000 Cc. [old form 20 pints] of boiling Water. Allow the precipitate to subside, decant the clear liquid, and pour upon the precipitate 2000 Cc. [old form 20 pints] of hot Water. Again decant, transfer the precipitate to a strainer, and wash it with hot Water, until the washings produce not more than a faint cloudiness with barium chloride T.S. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder.

$$\underset{\substack{\text{Potassium}\\\text{Alum}}}{2AlK(SO_4)_2} + \underset{\substack{\text{Sodium}\\\text{Carbonate}}}{3Na_2CO_3} + \underset{\text{Water}}{3H_2O} = \underset{\substack{\text{Aluminum}\\\text{Hydroxide}}}{2Al(OH)_3} + \underset{\substack{\text{Potassium}\\\text{Sulphate}}}{K_2SO_4} + \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{3Na_2SO_4} + \underset{\substack{\text{Carbon}\\\text{Dioxide}}}{3CO_2}$$

The direction to add the alum solution to that of the sodium carbonate is important. If the mixing of the solution is reversed, the precipitated hydroxide will be contaminated with the alkali sulphates, so that it will be much more difficult to separate them.

Official Description.—A white, light, amorphous powder; permanent in dry air.

Odor and Taste.—Odorless and tasteless.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Completely in hydrochloric or sulphuric acid and in potassium hydroxide T.S.

Test for Identity.—When heated to redness it loses about 34 percent. of its weight.

Impurities and Tests for Impurities.—*Limit of iron.* A solution of 1 Gm. of Aluminum Hydroxide in 20 Cc. of diluted hydrochloric acid and 130 Cc. of water should not at once assume a blue color on the addition of 1 drop of potassium ferrocyanide T.S.

Limit of sulphate. The above solution should not give more than a faint cloudiness with barium chloride T.S.

Limit of alkali salts. If 1 Gm. of the powder be boiled with 20 Cc. of distilled water, and the liquid filtered, the filtrate should not have an alkaline reaction, and on evaporation should leave a residue weighing not more than 0.005 Gm.

Heavy metals. A solution of the powder (1 in 20) in diluted hydrochloric acid should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII). (The subsequent addition of ammonia water, as directed in this test, should be omitted.)

Uses.—Aluminum hydroxide is a desiccant powder; it is absorbent and antacid. The dose is from two to five grains (0.13 to 0.3 Gm.). Externally, it is used like zinc oxide, by dusting on the inflamed surface.

ALUMINI SULPHAS. U.S. Aluminum Sulphate

$Al_2(SO_4)_3 + 16H_2O = 625.93$

It should contain not less than 99.5 percent. of pure Aluminum Sulphate.

Preparation.—This sulphate may be made by the process formerly official.

Take of Alum, Carbonate of Sodium, each, 4 oz. troy; Sulphuric Acid, 1 oz. troy, 150 gr.; Water, a sufficient quantity. Dissolve the salts separately, each in 6 fluidounces of boiling water, and pour the solution of the Alum gradually into that of the Carbonate of Sodium; then digest with a gentle heat until the evolution of carbonic acid ceases. Collect upon a filter the precipitate formed, and wash it with water, until the washings are no longer affected by chloride of barium. Next, with the aid of heat, dissolve the precipitate in the Sulphuric Acid, previously diluted with half a pint of Water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water-bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stoppered bottle.

Another method may be used: the hydroxide obtained by the process given on page 615 may be dissolved in diluted sulphuric acid, the solution evaporated, and the salt granulated.

Official Description.—A white, crystalline powder, or shining plates, or crystalline fragments; permanent in the air.

Odor, Taste, and Reaction.—Without odor; sweetish, and afterwards an astringent taste; acid reaction.

Solubility.—*Water.* In 1 part of water at 25° C. (77° F.), more soluble in boiling water.

Alcohol. Insoluble.

Tests for Identity.—When gradually heated to about 200° C. (392° F.), it loses its water of crystallization (45.7 percent. of its weight).

The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid; and with potassium hydroxide T.S., a white, gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride T.S.

Impurities and Tests for Impurities.—*Ammonia.* If 1 Gm. of Aluminum Sulphate be gently heated with 5 Cc. of potassium hydroxide T.S., the liquid should not evolve the odor of *ammonia.*

Limit of free acid. A filtered, aqueous solution of the salt (1 in 10) should not become more than faintly opalescent within five minutes after the addition of an equal volume of tenth-normal sodium thiosulphate V.S.

Heavy metals. The aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII). (The subsequent addition of ammonia water, as directed in this test, should be omitted.)

Limit of iron. The addition of 5 drops of potassium ferrocyanide T.S. to 20 Cc. of the aqueous solution of the salt (1 in 150) should not produce at once a blue coloration.

Uses.—Aluminum sulphate is antiseptic; it is rarely used internally.

Cerium. Ce; 139.2

Cerium is a metal occurring in *cerite*, *gadolinite*, etc.; it is of a chocolate-brown color, in masses; it takes fire more easily than magnesium; at ordinary temperatures it oxidizes in a moist atmosphere. Two oxides of cerium are known, Ce_2O_3, *cerous oxide*, and CeO_2, *ceric oxide*.

Test for Cerium Compounds

If sodium hypochlorite be added to a solution of a colorless cerous salt, a red precipitate separates; this dissolves in warm hydrochloric acid, and evolves chlorine.

Official Salt of Cerium

Official Name	Preparation
Cerii Oxalas	By precipitating cerium chloride with oxalic acid

Unofficial Salts of Cerium

Ceroso-cerii Oxidum, Ce_3O_4 Ceroso-ceric Oxide	By igniting cerium oxalate in an open vessel and then collecting the mass
Cerii Chloridum, $CeCl_2$ Cerium Chloride	By burning cerium in chlorine gas and then collecting the mass
Cerii Nitras, $CeNO_3 + 2H_2O$ Cerium Nitrate	By dissolving ceroso-ceric oxide in nitric acid in presence of alcohol or some other reducing substance
Cerii Oxidum, CeO Cerium Oxide	By heating cerium oxalate in a current of dry hydrogen perfectly free from air
Cerii Sulphas, $Ce_2(SO_4)_3$ Cerium Sulphate	By dissolving ceric oxide in sulphuric acid, and evaporating, then crystallizing

CERII OXALAS. U.S. Cerium Oxalate

Cerium Oxalate consists chiefly of a mixture of the oxalates of cerium, didymium, and lanthanum, and of other rare earths of this group.

Preparation.—This salt is made by decomposing the silicates in the powdered mineral containing the metal, with strong sulphuric acid, then heating the mass, and subsequently treating it with nitric acid and hydrogen sulphide to separate contaminating metals. Hydrochloric acid is now added in small quantity, and the cerium compounds are precipitated by oxalic acid. This oxalate is impure, containing lanthanum and didymium compounds; it is therefore mixed with magnesium carbonate, and the mixture heated to redness to decompose the oxalates; the residue is dissolved in a small quantity of nitric acid, and the solution added to water containing a little sulphuric acid; ceric sulphate is produced, which is dissolved in sulphuric acid, and sodium thiosulphate added to reduce it to cerous sulphate; this is collected and treated with oxalic acid, when cerium oxalate precipitates. The complication in the method of preparation of this salt is due to the presence of the two rare metals didymium and lanthanum, which can be separated only with difficulty.

Cerium oxalate as found in commerce is never pure, and the official definition and tests are therefore not very explicit.

Official Description.—A fine, white powder; permanent in the air.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Insoluble in ether, or in solutions of potassium or sodium hydroxide; insoluble in cold, but soluble in hot, diluted sulphuric or hydrochloric acid.

Tests for Identity.—When heated to redness it is decomposed, leaving a residue of reddish-brown ceric and other rare-earth oxides, constituting not less than 47 percent. of the salt.

On boiling the salt with potassium hydroxide T.S., an insoluble residue of white hydroxides is produced; if the filtrate from this residue be supersaturated with acetic acid, the addition of calcium chloride T.S. will produce a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid.

If the residue left after heating Cerium Oxalate be dissolved in concentrated sulphuric acid, and a small crystal of strychnine added, a deep blue color will appear, which will rapidly change to purple and then to red.

From the solution in diluted hydrochloric or sulphuric acid, potassium hydroxide T.S. precipitates white hydroxides, which do not redissolve in an excess of the reagent, and gradually turn yellow in contact with air. Ammonium carbonate T.S. precipitates from the same solution white cerous and other rare-earth carbonates, which are somewhat soluble in an excess of the reagent.

If 0.1 Gm. of Cerium Oxalate be dissolved in 1 Cc. of sulphuric acid, and 2 Cc. of potassium sulphate T.S. be added, small, colorless crystals of cerium and other rare-earth potassium sulphates will, after some time, be deposited.

Impurities and Tests for Impurities.—*Carbonates.* No effervescence should occur when the salt is dissolved in diluted hydrochloric acid.

Heavy metals. The solution of the salt (1 in 20) in diluted hydrochloric acid should not respond to the Time-Limit Test for *heavy metals*, omitting the addition of the ammonia water (see U. S. P. Test No. 121, Chap. LXII).

Arsenic. Five Cc. of the solution of the salt (1 in 10) in diluted hydrochloric acid should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No 17, Chap. LXII).
Aluminum. On boiling the salt with potassium hydroxide T.S. and filtering, no precipitate should be produced in the filtrate by the addition of either ammonium chloride T.S.
Zinc. Or ammonium sulphate T.S.

Uses—Cerium oxalate is a valuable remedy in controlling nausea. It is given in doses of one to ten grains (0.065 to 0.6 Gm.).

Cadmium. Cd; 111.6

This metal is associated with zinc in its ores. Although it enters into *no official preparations*, it is used to some extent in medicine, and hence merits a notice here. It is a white metal, resembling tin, but somewhat heavier and more tenacious. Like that metal, it crackles when bent. Its specific gravity is 8.7. It is little affected by the air, but when heated combines with an atom of oxygen, forming a reddish-brown or orange-colored oxide, CdO. It combines with chlorine, iodine, bromine, and sulphur.

Tests for Cadmium Salts

1. Hydrogen sulphide and ammonium sulphide produce precipitates of a yellow color (sulphide) when added to solutions of cadmium salts.

2. Sodium or potassium hydroxide produces, with cadmium salts, white precipitates (hydroxides), insoluble in excess. Ammonia water produces similar precipitates, soluble in excess.

3. Sodium or potassium carbonate produces white precipitates of cadmium carbonate, insoluble in excess.

Unofficial Compounds of Cadmium

Cadmii Bromidum, $CdBr_2$ Cadmium Bromide	By double decomposition between potassium bromide and cadmium sulphate
Cadmii Chloridum, $CdCl_2$ Cadmium Chloride	By treating cadmium or cadmium carbonate with hydrochloric acid
Cadmii Iodidum, CdI_2 Cadmium Iodide	By double decomposition between potassium iodide and cadmium sulphate
Cadmii Oxidum, CdO Cadmium Oxide	By igniting cadmium nitrate or carbonate
Cadmii Sulphidum, CdS Cadmium Sulphide	By passing hydrogen sulphide through a solution of cadmium chloride, nitrate, or sulphate
Cadmii Sulphas, $CdSO_4 + 4H_2O$ Cadmium Sulphate	By treating cadmium carbonate or oxide with diluted sulphuric acid

CHAPTER XLIV

MANGANESE, IRON, AND CHROMIUM

Mn ; 54.6. Fe ; 55.5. Cr. ; 51.7

THESE three metals form a group exhibiting some chemical and physical analogies. They unite with oxygen, producing basic oxides.

Manganese. Mn ; 54.6

Manganese is found, as a mineral, quite extensively in the state of black oxide, as *pyrolusite, braunite,* and *hausmannite.* The carbonate also is sometimes found. The metal is very hard and brittle ; when powdered, it decomposes water readily. With oxygen it forms five—possibly seven—compounds. The *monoxide,* MnO, is of a light green color, and is the oxide present in or corresponding to manganous salts. The *sesquioxide,* Mn_2O_3, is black or dark brown, when in the hydrated state ; the magnetic oxide, Mn_3O_4, is red ; the dioxide, MnO_2, is black ; and the permanganic oxide, Mn_2O_7, is, when in the free state, a very unstable dark reddish-brown liquid. The monoxide is a stable base, the sesquioxide feebly basic, and the dioxide when acted upon by acids yields manganous salts, while oxygen is evolved. The highest oxide is acid-forming, yielding permanganic acid, $HMnO_4$, the salts of which are known as permanganates. There exists also an acid, H_2MnO_4 (manganic), of which the salts formed are called manganates. The corresponding oxide, however, is not known.

Tests for Salts of Manganese

1. Ammonium sulphide, added to a solution of a manganese salt, produces a flesh-colored precipitate of manganese sulphide.

2. Potassium or sodium carbonate in solution produces white precipitates, which are insoluble in excess of solution of ammonium carbonate.

3. With the blowpipe, manganese gives with borax a bead having an amethystine color in the oxidizing flame, and a colorless bead in the deoxidizing flame.

4. If manganese be heated with sodium carbonate, *green* sodium manganate is produced. If this be added to water, it communicates a purplish-red color.

Official Salts of Manganese

Official Name	Preparation
Mangani Dioxidum Præcipitatum	Manganese dioxide, containing at least 88 percent. of pure oxide made by adding ammonia water and solution of hydrogen dioxide to a solution of manganese sulphate, collecting the precipitate, washing and drying
Hypophosphis	By reaction between manganous carbonate and calcium hypophosphite
Sulphas	Made by treating manganese dioxide with sulphuric acid
Potassii Permanganas	By heating manganese dioxide, potassium hydroxide, and potassium chlorate together

Unofficial Salts of Manganese

Mangani Arsenas, $MnHAsO_4$ Manganese Arsenate	By saturating a solution of arsenic acid with freshly precipitated manganese carbonate
Mangani Benzoas Manganese Benzoate	By adding to a solution of benzoic acid manganese carbonate as long as combination is effected
Mangani Carbonas, $MnCO_3$ Manganese Carbonate	By adding to a solution of manganese sulphate a solution of potassium carbonate, and collecting and drying the precipitate
Mangani Chloridum, $MnCl_2$ Manganese Chloride	By treating manganese dioxide with hydrochloric acid, purifying from iron salts, evaporating, and crystallizing
Mangani Citras Manganese Citrate	By digesting manganese carbonate with citric acid, and collecting the precipitate
Mangani Oxalas, $2\ MnC_2O_4 + 5H_2O$ Manganese Oxalate	By adding to a solution of manganese sulphate a solution of oxalic acid, and collecting the precipitate
Mangani Tartras Manganese Tartrate	By adding a solution of neutral potassium tartrate to a solution of manganous chloride, and, after the acid potassium tartrate has deposited, collecting the colorless crystals.

MANGANI DIOXIDUM PRÆCIPITATUM. U.S. Precipitated Manganese Dioxide

[To replace MANGANI DIOXIDUM, PHARM. 1890]

Chiefly Manganese Dioxide [$MnO_2 = 86.36$] with small amounts of other oxides of manganese, corresponding to not less than 80 percent. of Manganese Dioxide.

	Metric	Old form
* **Manganese Sulphate**	50 Gm.	2 oz. av.
Ammonia Water	250 Cc.	9 fl. oz. 153 min.
Solution of Hydrogen Dioxide	250 Cc.	9 fl. oz. 153 min.
Distilled Water, a sufficient quantity		

Dissolve the Manganese Sulphate in 1000 Cc. [old form 37 fl. oz.] of Distilled Water. Dilute the Ammonia Water with an equal volume of Distilled Water, and mix it with the Solution of Hydrogen Dioxide, which has also been diluted with an equal volume of Distilled Water. Pour the mixed solutions slowly, with constant stirring, into the solution of Manganese Sulphate. Allow the mixture to stand for one hour, stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by affusion and decantation with hot Distilled Water, using 1000 Cc. [old form 37 fl. oz.] each time. Collect the precipitate on a plain filter, and continue the washing with hot Distilled Water until the washings no longer have an alkaline reaction upon red litmus paper, and produce no turbidity when mixed with barium chloride test solution. Allow the precipitate to drain, then dry it at 150° C. (302° F.).

Black oxide of manganese is frequently found in commerce of poor and variable quality; some pyrolusite from Nova Scotia was examined by the author a few years ago, however, which assayed 96 percent. of pure oxide. It is the safest rule to buy it only upon assay, and, when a good sample can be found, to secure a large quantity of it.

In order to secure a uniformly reliable product, the above process for its preparation has been introduced into the 8th Decennial Revision of the U. S. P.

Official Description.—A heavy, very fine, black powder; permanent in the air

Odor and Taste.—Odorless and tasteless.

Solubility.—*Water.* Insoluble.
Alcohol. Insoluble.

Tests for Identity.—It is not affected by concentrated sulphuric acid, but when heated with this acid it is converted into manganese sulphate, with the evolution of oxygen.

When heated with hydrochloric acid, it is converted into manganous chloride, with the evolution of chlorine. At a red heat Precipitated Manganese Dioxide gives off oxygen, and is converted into reddish-brown manganoso-manganic oxide (Mn_3O_4).

On intimately mixing 1 part of the Dioxide with 1 part of potassium hydroxide and 1 part of potassium chlorate, introducing the mass into a crucible, moistening with water, drying, and igniting, a dark fused mass is obtained which yields, with water, a green solution, changing to purplish-red on being boiled, or on the addition of diluted sulphuric acid.

Impurities and Tests for Impurities.—*Antimony sulphide and insoluble substances.* If to 1 Gm. of the Dioxide and 2 Gm. of oxalic acid, 20 Cc. of water be added, followed by 3 Cc. of sulphuric acid, and the mixture digested for several hours on a water-bath, complete solution should be effected.

Quantitative Test.—If 0.2 Gm. of Precipitated Manganese Dioxide be dissolved in a mixture of 50 Cc. of tenth-normal oxalic acid V.S. and 3 Cc. of sulphuric acid contained in a flask and heated on a water-bath, the resulting solution, after dilution with 100 Cc. of warm water, should require the addition of not more than 13 (12.95) Cc. of tenth-normal potassium permanganate V.S. to produce a slight pink tint (corresponding to not less than 80 percent. of pure Manganese Dioxide).

Uses.—Precipitated manganese dioxide is occasionally used internally, in doses of three to twenty grains (0.19 to 1.3 Gm.). The commercial manganese dioxide is principally used to form the salts of manganese.

MANGANI HYPOPHOSPHIS. U.S. Manganese Hypophosphite

$Mn(PH_2O_2)_2 + H_2O = 201.54$

It should contain not less than 97 percent. of pure Manganous Hypophosphite [$(PH_2O.O)_2Mn + H_2O$], and be kept in well-stoppered vials.

Official Description.—A pink crystalline powder; permanent in the air.

Odor, Taste, and Reaction.—Odorless, and nearly tasteless. The aqueous solution (1 in 20) is acid to litmus paper, and yields, with ammonium sulphide T.S., a salmon-colored precipitate of maganese sulphide, soluble in acetic acid.

Solubility.—*Water.* Soluble in 66 parts at 25° C. (77° F.), and in 6 parts of boiling water.

Alcohol. Almost insoluble.

Tests for Identity.—When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and on complete ignition leaves a residue of manganous pyrophosphate.

Manganese Hypophosphite is readily oxidized by nitric acid and other oxidizing agents.

If a small quantity of an aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid, and mercuric chloride T.S. added in excess, a white precipitate of mercurous chloride will be produced, which, upon further addition of the acidulated solution, is reduced to metallic mercury.

Impurities and Tests for Impurities.—*Carbonate.* If to 0.5 Gm. of the salt 5 Cc. of acetic acid be added, no effervescence should occur.

Phosphate. If 0.25 Gm. of the salt be boiled with 10 Cc. of potassium hydroxide T.S., a light salmon-colored precipitate will be produced which gradually acquires a brown color on exposure to the air, and if the filtered liquid, after being slightly acidulated with hydrochloric acid and then rendered alkaline with ammonia water, be divided into two portions, one should yield no precipitate upon the addition of magnesia mixture T.S.

Calcium. The remaining portion should not be affected by ammonium oxalate T.S.

Arsenic. If 5 Cc. of the aqueous solution of the salt (1 in 10) be poured into an evaporating dish containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Uses.—This salt has been introduced in the U. S. P. (8th Rev.) solely for use in compound syrup of hypophosphites. It may be given in the dose of three grains (0.2 Gm.).

MANGANI SULPHAS. U.S. Manganese Sulphate

$MnSO_4 + 4H_2O = 221.47$

It should contain not less than 99.5 percent. of pure Manganous Sulphate [$SO_2.O_2Mn + 4H_2O$], and should be kept in well-stoppered bottles.

Preparation.—This rose-colored salt is best made by Prof. Diehl's process, by heating manganese dioxide and charcoal together to redness in a covered crucible, until all of the charcoal is consumed, treating the residue, after cooling, with sulphuric acid, and evaporating to dryness, then returning the mixture to the covered crucible and again heating to redness; when cool, the residue is rubbed to powder, if necessary, and treated twice with eight parts of boiling water, the mixed liquors are filtered, evaporated until a pellicle forms, and set aside to crystallize. (See U. S. Dispensatory, p. 849.)

In this process it is important that the dish containing the liquid which is set aside to crystallize be removed from the fire as soon as a pellicle begins to form, to prevent the formation of an insoluble sulphate.

Official Description.—Colorless, or pale rose-colored, translucent, tetragonal prisms (crystallized at a temperature between 20° and 30° C. (68° and 86° F.), and containing 4 molecules, or 32.29 percent. of water of crystallization); slightly efflorescent in the air.

Odor, Taste, and Reaction.—Odorless, and having a slightly bitter and astringent taste. The aqueous solution (1 in 20) is neutral, or very slightly acid to litmus paper, and yields with ammonium sulphide T.S., a salmon-colored precipitate soluble in dilute acids; with potassium ferrocyanide T.S., a reddish-white precipitate; and with potassium ferricyanide T.S., a brown precipitate.

Solubility.—*Water.* In about 0.7 parts at 25° C. (77° F.), and in 0.53 part of boiling water.

Alcohol. Insoluble.

Tests for Identity.—With barium chloride T.S., it yields a white precipitate insoluble in hydrochloric acid.

If a fragment of Manganese Sulphate be mixed with a little sodium hydroxide and the mixture fused, it will yield a dark green mass, dissolving in water with a green color.

If 1 Gm. of the salt be gently ignited, in a porcelain crucible, it should lose not more than 0.323 Gm. of its weight (distinction from *Manganese Sulphate containing a larger amount of water of crystallization*).

Impurities and Tests for Impurities.—*Limit of iron.* The aqueous solution of the salt (1 in 100), to which a few drops of hydrochloric acid and a few drops of chlorine water have been added, should, after having been boiled, not be colored red by potassium sulphocyanate T.S.

Heavy metals. Another solution (1 in 20) should not respond to the Time-Limit Test for *heavy metals*, omitting the addition of ammonia water (see U. S. P. Test No. 121, Chap. LXII).

Salts of the alkalies, and of magnesium. If the manganese be completely precipitated from an aqueous solution of 3 Gm. of the salt by the addition of ammonium carbonate T.S., the filtrate, on evaporation and gentle ignition, should leave no weighable residue.

Zinc. A solution of 1 Gm., each, of the salt, and of sodium acetate, in 10 Cc. of water, to which a few drops of acetic acid have been added, should not be affected by hydrogen sulphide T.S.

Uses.—Manganese sulphate is used as a cholagogue and tonic, in doses of four to twenty grains (0.25 to 1.3 Gm.). It is also used as a purgative when given in doses of from one to two drachms (4 to 8 Gm.) and may be given dissolved in a flavored syrup.

POTASSII PERMANGANAS. U.S. Potassium Permanganate

$KMnO_4 = 156.98$

It should contain not less than 99 percent. of pure Potassium Permanganate [$MnO_3.OK$], and should be kept in glass-stoppered bottles, protected from light.

Potassium Permanganate, when in concentrated solution or in the dry condition, should not be brought in contact with organic or other readily oxidizable substances.

This is the most important official compound of manganese. It is considered under the potassium compounds (page 529).

Iron. Fe; 55.5

Iron, the most useful and abundant of the metals, is widely diffused in nature; it is found not only in the mineral kingdom, but in animal and vegetable products as well.

Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a slightly styptic taste, having a sensible odor when rubbed. Its specific gravity is 7.8. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen. At a red heat its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a reddish matter, called *rust*, which is hydrated ferric oxide. It combines with all the non-metallic elements except hydrogen and nitrogen, and with most of the metals. It forms three compounds with oxygen,—ferrous and ferric oxide, which, by their union, form the native magnetic oxide, and a teroxide possessing acid properties, called ferric acid.

Tests for Iron Salts

1. Potassium *ferrocyanide* produces a nearly white precipitate with a ferrous salt, which rapidly turns blue on exposure to the air; with a ferric salt it strikes a deep blue color (Prussian blue) at once.

2. Potassium *ferricyanide* produces a deep blue color (Turnbull's blue) at once with a ferrous salt, and a greenish or olive color with a ferric salt.

3. Tannin does not change the color of a solution of ferrous salt, provided it has not been oxidized; with a ferric salt a dark greenish-black precipitate (ink) is produced.

4. Ammonium sulphide produces a black precipitate (sulphide) with either a ferrous or a ferric salt.

5. Ammonia water precipitates from ferrous salts, ferrous hydroxide, a white precipitate turning green, then black, and finally a brown color; the same reagent precipitates brown ferric hydroxide from ferric salts.

Official Salts and Preparations of Iron

Official Name	Preparation
Ferrum	Metallic iron in the form of fine, bright, and non-elastic wire
Reductum	Made by passing hydrogen over iron carbonate
Ferri Carbonas Saccharatus	Double decomposition between ferrous sulphate and sodium bicarbonate; the precipitate is preserved with sugar
Massa Ferri Carbonatis	Double decomposition between ferrous sulphate and monohydrated sodium carbonate; the precipitate is preserved with sugar and honey
Mistura Ferri Composita	6 Gm. ferrous sulphate; 18 Gm. myrrh; 18 Gm. sugar; 8 Gm. potassium carbonate; 60 Cc. spirit of lavender; rose water sufficient to make 1000 Cc.
Pilulæ Ferri Carbonatis	16 Gm. granulated ferrous sulphate; 8 Gm. potassium carbonate; 4 Gm. sugar; 1 Gm. powdered tragacanth; 1 Gm. powdered althea; glycerin, water, to make 100 pills
Ferri Chloridum	By evaporating 100 Gm. of solution of ferric chloride to 40 Gm. and setting it aside to crystallize
Liquor Ferri Chloridi	By oxidizing solution of ferrous chloride with nitric acid
Tinctura Ferri Chloridi	350 Cc. of solution of ferric chloride with sufficient alcohol to make 1000 Cc.
Liquor Ferri et Ammonii Acetatis	40 Cc. tincture ferric chloride; 60 Cc. diluted acetic acid; 500 Cc. solution ammonium acetate; 120 Cc. aromatic elixir; 120 Cc. glycerin; sufficient water to make 1000 Cc.

Official Salts and Preparations of Iron—*Continued*

Official Name	Preparation
Ferri Citras	By evaporating and scaling a solution of ferric citrate
et Ammonii Citras	By adding ammonia water to solution of ferric citrate, evaporating, and scaling
Vinum Ferri	40 Gm. iron and ammonium citrate; 60 Cc. tincture of sweet orange peel; 100 Cc. syrup; sufficient white wine to make 1000 Cc.
Ferri et Quininæ Citras	By dissolving quinine (alkaloid) in a solution of ferric citrate, evaporating, and scaling
et Quininæ Citras Solubilis	By adding ammonia water to a solution of iron and quinine citrate, evaporating, and scaling
Vinum Ferri Amarum	50 Gm. soluble iron and quinine citrate; 60 Cc. tincture of sweet orange peel; 300 Cc. syrup; sufficient white wine to make 1000 Cc.
Ferri et Strychninæ Citras	By adding to a solution of iron and ammonium citrate, citric acid and strychnine, and scaling
et Ammonii Sulphas	By dissolving ammonium sulphate in solution of ferric sulphate, evaporating, and crystallizing
et Ammonii Tartras	By dissolving ferric hydroxide in a solution of acid ammonium tartrate, and scaling
et Potassii Tartras	By adding to ferric hydroxide, acid potassium tartrate and a trace of ammonia water, and scaling
Hydroxidum	By adding ammonia water to solution of ferric sulphate, and collecting and washing the precipitate
Hydroxidum cum Magnesii Oxido	By mixing solution of ferric sulphate with magnesia and water
Hypophosphis	Double decomposition between calcium hypophosphite and ferrous sulphate
Syrupus Ferri Iodidi	By adding solution of ferrous iodide to sugar (5 percent. Fe I)
Pilulæ Ferri Iodidi	4 Gm. reduced iron; 5 Gm. iodine; 4 Gm. glycyrrhiza; 4 Gm. sugar; 1 Gm. ext. glycyrrhiza; 1 Gm. acacia; water q. s. to make 100 pills
Ferri Phosphas Solubilis	By mixing solutions of ferric citrate and sodium phosphate, evaporating, and scaling
Pyrophosphas Solubilis	By mixing solutions of ferric citrate and sodium pyrophosphate, evaporating, and scaling
Glyceritum Ferri, Quininæ et Strychninæ Phosphatum	By dissolving in an acid solution of soluble ferric phosphate, quinine and strychnine, and adding glycerin
Syrupus Ferri, Quininæ et Strychninæ Phosphatum	By mixing 250 Cc. of glycerite of the phosphates of iron, quinine, and strychnine with 750 Cc. of syrup
Elixir Ferri, Quininæ et Strychninæ Phosphatum	By preparing a solution of soluble ferric phosphate, quinine, and strychnine and adding it to aromatic elixir
Ferri Sulphas	By treating iron with diluted sulphuric acid, evaporating, and crystallizing
Sulphas Exsiccatus	By exsiccating ferrous sulphate at a temperature not above 100° C. (212° F.)
Sulphas Granulatus	By cooling rapidly a hot, concentrated, aqueous solution of ferrous sulphate, stirring as crystallization occurs, collecting and drying the granulated salt
Pilulæ Aloes et Ferri	7 Gm. purified aloes; 7 Gm. exsiccated ferrous sulphate; 7 Gm. aromatic powder; confection of rose q. s. to make 100 pills
Liquor Ferri Subsulphatis	By heating ferrous sulphate in a mixture of sulphuric and nitric acids
Ferri Tersulphatis	By heating ferrous sulphate in a mixture of nitric and sulphuric acids, sulphuric acid being largely in excess

Unofficial Salts and Preparations of Iron

Ferri Acetas, $Fe(C_2H_3O_2)_3$ Ferric Acetate	By dissolving ferric hydroxide in acetic acid, evaporating, then crystallizing
Liquor Ferri Acetatis Solution of Ferric Acetate. U. S. P. 1890	By dissolving ferric hydroxide in glacial acetic acid
Ferri Arsenas, $3Fe(FeO)AsO_4 + 16H_2O$ Ferric Arsenate	By dissolving 1 oz. sodium arsenate and ¾ oz. sodium acetate in 8 oz. water, then dissolving 2 oz. ferrous sulphate in 10 fl. oz. water, mixing both solutions, collecting in precipitate, washing, and drying
Ferri Benzoas, $Fe(C_7H_5O_2)_3 + 3H_2O$ Ferric Benzoate	By adding to a solution of normal ferric sulphate a concentrated solution of sodium benzoate, collecting the precipitate, washing, and drying
Ferri Bromidum, $FeBr_2$ Ferrous Bromide	By adding 2 parts bromine to 1 part iron filings and 10 parts water, digesting until the liquid assumes a greenish color, then filtering and evaporating to dryness

Unofficial Salts and Preparations of Iron—*Continued*

Liquor Ferri Citratis Solution of Ferric Citrate	By dissolving ferric hydroxide in a solution of citric acid
Ferri et Sodii Pyrophosphas Iron and Sodium Pyrophosphate	By adding to a solution of 50 parts sodium pyrophosphate in 100 parts water sufficient ferric chloride in aqueous solution so that a permanent precipitate is not produced, then adding 250 parts alcohol and collecting the precipitate
Ferri Ferrocyanidum, $Fe_4(FeCN_6)_3$ Iron Ferrocyanide	By dissolving 4½ oz. potassium ferrocyanide in 1 pint water, adding the solution to 8 fl. oz. solution of normal ferric sulphate diluted previously with 8 fl. oz. water, stirring continually, collecting the precipitate, washing, and drying
Ferri Nitras, $Fe(NO_3)_3$ Ferric Nitrate	By concentrating a solution of ferric nitrate, filtering, and allowing to crystallize
Liquor Ferri Nitratis Solution of Ferric Nitrate. U. S. P. 1890	By dissolving ferric hydroxide in diluted nitric acid
Ferri Lactas, $Fe(C_3H_5O_3)_2 + 3H_2O$ Ferrous Lactate	By acting on iron with lactic acid and crystallizing the solution
Ferri Oxalas Ferrous Oxalate	By mixing solutions of ferrous sulphate and oxalic acid and collecting the precipitate
Ferri Oxidum Magneticum, Fe_3O_4 Magnetic Iron Oxide	By dissolving 2 oz. ferrous sulphate in 2 pints water and adding 5½ fl. oz. solution of normal ferric sulphate, then mixing this with 4 pints solution of sodium hydroxide, stirring well, boiling, letting it stand for 2 hours, occasionally stirring, collecting the precipitate, washing, and drying carefully
Ferri Oxidum Rubrum Red Oxide of Iron	By igniting ferrous sulphate in contact with air
Ferri Phosphas Albus, $Fe_22PO_4 + 4H_2O$ White Ferric Phosphate	By mixing 4 fl. oz. solution of normal ferric sulphate with a solution of 1 oz. sodium acetate, then adding solution of sodium phosphate, collecting the precipitate, washing, and drying
Ferri Salicylas Ferric Salicylate	By mixing a solution containing 24 grains of ferrous sulphate and 20 grains of sodium acetate in half a fluidounce of water with a solution made by dissolving 30 grains of sodium salicylate in half a fluidounce of water. Dose, a teaspoonful
Ferri Subcarbonas Ferric Oxyhydrate	By mixing solutions of 8 oz. ferrous sulphate and 9 oz. sodium carbonate, collecting the precipitate, washing, and drying without heat
Ferri Sulphidum, FeS Ferrous Sulphide	By mixing 3 parts iron filings with 2 parts sublimed sulphur, then placing in small portions the above mixture into a crucible heated to redness, and keeping covered after each addition
Ferri Valeras Ferric Valerate	By double decomposition between ferric sulphate and sodium valerate

FERRUM. U. S. Iron

$Fe = 55.5$

Metallic iron, in the form of fine, bright, and non-elastic wire.

Iron, when employed in pharmaceutical operations, should be of the purest kind ; hence the pharmacopœias generally direct it, when wanted in small masses, to be in the form of *iron wire*, which is necessarily made from the purest, because the softest and most ductile iron, and is readily cut into pieces. Such wire is very flexible and without elasticity.

The wire clippings and the ends of card teeth obtained from the manufacturers of cotton cards are frequently used in Philadelphia for making iron preparations. They are very convenient ; and it may be incidentally mentioned that they are sometimes used as a substitute for sand, in sand baths. Iron scraps and waste from steel pen factories are also used to make preparations of iron.

FERRUM REDUCTUM. U. S. Reduced Iron

Reduced Iron should contain not less than 90 percent. of pure metallic iron.

Preparation.—Reduced iron may be made by a process originally proposed by Prof. Procter, and afterwards made official in 1870:

Take of Subcarbonate of Iron 30 oz. troy. Wash the Subcarbonate thoroughly with water until no traces of sulphate of sodium are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet-iron in the form of an incomplete cylinder, and introduce this into a wrought iron reduction tube, about four inches in diameter. Place the reduction tube in a charcoal furnace, and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through solution of subacetate of lead, diluted with three times its volume of water, and through milk of lime, severally contained in four-pint bottles about one-third filled. Connect with the further extremity of the reduction tube a lead tube bent so as to dip into water. Make all the junctions airtight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction tube, occupied by the Subcarbonate, to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapor. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the Reduced Iron, keep it in a well-stoppered bottle. When thirty troyounces of Subcarbonate of Iron are operated on, the process occupies from five to eight hours.

The subcarbonate directed in the above formula is, more correctly, a ferric oxyhydrate, and the hydrogen combines with the oxygen to form water, metallic iron, in fine powder, being left.

$$\underset{\substack{\text{Ferric}\\\text{Oxide}}}{Fe_2O_3} + \underset{\text{Hydrogen}}{6H} = \underset{\text{Iron}}{2Fe} + \underset{\text{Water}}{3H_2O}$$

Official Description.—A very fine, grayish black, lustreless powder; permanent in dry air.

Odor, Taste, and Reaction.—Without odor or taste. If 1 Gm. of Reduced Iron be shaken with 5 Cc. of water, the liquid should not change the color of red litmus paper.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Test for Identity.—When ignited in contact with air, it glows and is converted into black ferrosoferric oxide.

Impurities and Tests for Impurities.—*Limit of sulphide.* One Gm. of Reduced Iron, when treated with 20 Cc. of diluted sulphuric acid, in a test-flask (see page 1028), causes the evolution of nearly odorless hydrogen gas, which should not affect, within five minutes, paper moistened with lead acetate T. S., and on applying a gentle heat, the Iron should dissolve in the acid without leaving more than 1 percent. of residue.

Arsenic. To 0.5 Gm. of Reduced Iron, contained in a small covered beaker, add 20 Cc. of diluted sulphuric acid; after the reaction has somewhat subsided, warm the liquid on a water-bath until the reaction ceases, then collect any minute undissolved residue of impure iron arsenide upon a very small filter, rinse the beaker with water, add the rinsings to the filter, and wash the residue with water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, and, after adding about 0.25 Gm. of potassium chlorate and 5 Cc. of hydrochloric acid, evaporate the solution slowly to dryness on a water-bath. Dissolve the residue in sufficient water to measure 50 Cc., then add 5 Cc. of this solution to 5 Cc. of a saturated solution of sulphurous acid and heat the liquid on a water-bath for fifteen minutes, until all traces of sulphurous acid have been removed. The resulting solution should not respond to the Modified Gutzeit's test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Assay for Metallic Iron.—Introduce about 2.6 Gm. of iodine into a 100 Cc. flask and weigh accurately, then add 6 Cc. of water, 2 Gm. of potassium iodide, and 0.555 Gm. of Reduced Iron. Securely stopper the flask, and, after thoroughly mixing the contents by rotating the flask, set it aside for one hour. Then dilute the contents with sufficient distilled water to make the liquid measure exactly 100 Cc., mix well and to 25 Cc. of this solution add a few drops of starch T.S., followed by tenth-normal sodium thiosulphate V.S., added slowly with constant stirring, until the blue or greenish color has been discharged. Divide the weight of iodine taken, by 0.02518, and subtract from the quotient twice the number of Cc. of tenth-normal sodium thiosulphate V.S. used; the remainder represents the percentage of metallic iron present in the Reduced Iron, and this should not be less than 90 percent.

NOTE.—The percentage purity of the iodine employed should be accurately determined by a previous experiment, and in place of the 2.6 Gm. above directed, its equivalent in pure (100 percent.) iodine may be taken (see U. S. P. Test No. 137, Chap. LXII).

Uses.—Powder of iron, or reduced iron, is one of the best of the chalybeate tonics. It is generally given in pill form, in doses of one to six grains (0.065 to 0.38 Gm.). An elegant form of administering it is combined with chocolate in the form of lozenges.

FERRI CARBONAS SACCHARATUS. U. S. Saccharated Ferrous Carbonate

Saccharated Ferrous Carbonate should contain not less than 15 percent. of Ferrous Carbonate [$FeCO_3 = 115.05$], and should be kept in small, well-stoppered bottles.

	Metric	Old form
* **Ferrous Sulphate**	50 Gm.	5 oz. av.
Sodium Bicarbonate	35 Gm.	3½ oz. av.
Sugar, in fine powder,		
Distilled Water, each, a sufficient quantity,		
To make	100 Gm.	10 oz. av.

Dissolve the Ferrous Sulphate in 200 Cc. [old form 20 fl. oz.] of hot Distilled Water, and the Sodium Bicarbonate in 500 Cc. [old form 3 pints] of Distilled Water at a temperature not exceeding 50° C. (122° F.), and filter the solutions separately. To the solution of Sodium Bicarbonate contained in a flask having a capacity of about 1000 Cc. [old form 6 pints] add, gradually, the solution of Ferrous Sulphate, and mix thoroughly by rotating the flask. Fill the flask with boiling Distilled Water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear supernatant liquid by means of a siphon, and then fill the flask again with hot Distilled Water, and shake it. Again draw off the clear liquid, and repeat the washing with hot Distilled Water in the same manner until the decanted liquid gives merely a slight cloudiness with barium chloride T.S. Finally, drain the precipitate thoroughly on a muslin strainer, transfer it to a porcelain dish containing 80 Gm. [old form 8 oz. av.] of Sugar, and mix it intimately. Evaporate the mixture to dryness, by means of a water-bath, reduce it to powder, and mix intimately with it, if necessary, enough well-dried Sugar to make the final product weigh 100 Gm. [old form 10 oz. av.].

In this preparation ferrous carbonate is formed, sodium sulphate remaining in solution. Sodium bicarbonate is preferred because the evolution of carbonic acid during the decomposition measurably prevents oxidation; it would have been an improvement to use syrup in the solutions to protect them still further.

The object of boiling the water that is used in washing, is to expel the air, so that the ferrous carbonate may escape its oxidizing action; the evaporation of the mixture should be conducted as rapidly as possible, for the same reason.

$$\underset{\text{Ferrous Sulphate}}{FeSO_4} + \underset{\text{Sodium Bicarbonate}}{2NaHCO_3} = \underset{\text{Sodium Sulphate}}{Na_2SO_4} + \underset{\text{Ferrous Carbonate}}{FeCO_3} + \underset{\text{Water}}{H_2O} + \underset{\text{Carbon Dioxide}}{CO_2}$$

Official Description.—A greenish-brown powder, gradually becoming oxidized by contact with air.

Odor and Taste.—Without odor, and having at first a sweetish, afterwards a slightly ferruginous taste.

Solubility.—*Water.* Only partially soluble, but completely soluble upon the addition of hydrochloric acid, with copious evolution of carbon dioxide, forming a clear, greenish-yellow liquid.

Impurity and Test.—*Sulphate.* If 1 Gm. of Saccharated Ferrous Carbonate be dissolved in 5 Cc. of hydrochloric acid, and the solution diluted with water until it measures 50 Cc., portions of this solution will yield a blue precipitate with both potassium ferrocyanide T.S. and potassium ferricyanide T.S., but should not give more than a slight cloudiness with barium chloride T.S.

Quantitative Test.—If 1.15 Gm. of Saccharated Ferrous Carbonate be dissolved in 10 Cc. of diluted sulphuric acid (1 to 5) and the solution diluted with water to about 100 Cc., it should require not less than 15 Cc. of tenth-normal potassium dichromate V.S. for complete oxidation, potassium ferricyanide T.S. being used as indicator (corresponding to not less than 15 percent. of ferrous carbonate).

Uses.—Saccharated ferrous carbonate is used as a tonic, in doses of four to thirty grains (0.25 to 2 Gm.).

MASSA FERRI CARBONATIS. U.S. Mass of Ferrous Carbonate

[VALLET'S MASS]

	Metric	Old form
* **Ferrous Sulphate,** in clear crystals	100 Gm.	8 oz. av.
Monohydrated Sodium Carbonate	46 Gm.	3 oz. av. 5 dr.
Clarified Honey	38 Gm.	3 oz. av.
Sugar, in coarse powder	25 Gm.	2 oz. av.
Syrup,		
Distilled Water, each, a sufficient quantity,		
To make	100 Gm.	8 oz. av.

Dissolve the Ferrous Sulphate and the Monohydrated Sodium Carbonate, each separately, in 200 Cc. [old form 1 pint] of boiling Distilled Water, and, having added 20 Cc. [old form 1½ fl. oz.] of Syrup to the solution of the Iron salt, filter both solutions, and allow them to become cold. Introduce the solution of Monohydrated Sodium Carbonate into a bottle having a capacity of about 500 Cc. [old form 3 pints], and gradually add the solution of the Iron salt, rotating the flask constantly or frequently, until carbonic acid gas no longer escapes. Add a sufficient quantity of Distilled Water to fill the bottle; then cork it and set it aside, so that the Ferrous Carbonate may subside. Pour off the supernatant liquid, and, having mixed Syrup and Distilled Water in the proportion of one volume of Syrup to nineteen volumes of Distilled Water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the Water as possible. Lastly, mix the precipitate at once with the Honey and Sugar, and, by means of a water-bath, evaporate the mixture in a tared dish, with constant stirring, until it is reduced to 100 Gm. [old form 8 oz. av.].

This preparation consists of ferrous carbonate preserved from oxidation by contact with syrup and honey. The reaction is as follows:

$$\underset{\substack{\text{Ferrous}\\ \text{Sulphate}}}{FeSO_4} + \underset{\substack{\text{Sodium}\\ \text{Carbonate}}}{Na_2CO_3} = \underset{\substack{\text{Ferrous}\\ \text{Carbonate}}}{FeCO_3} + \underset{\substack{\text{Sodium}\\ \text{Sulphate}}}{Na_2SO_4}$$

Uses.—Mass of ferrous carbonate is widely known as *Vallet's mass;* it is a valuable chalybeate tonic, and is administered in pill form, in doses of four to fifteen grains (0.25 to 1 Gm.).

MISTURA FERRI COMPOSITA. U.S. Compound Iron Mixture

This mixture depends for its usefulness upon the ferrous carbonate produced by double decomposition between ferrous sulphate and potassium carbonate. The myrrh, sugar, spirit of lavender, and rose water are used as adjuvants and diluents (see page 305).

PILULÆ FERRI CARBONATIS. U.S. Pills of Ferrous Carbonate

Each pill contains $2\frac{1}{2}$ gr. of ferrous sulphate, $1\frac{1}{4}$ gr. of potassium carbonate, about $\frac{3}{4}$ gr. of sugar, with sufficient tragacanth, althæa, glycerin, and water to form a mass. Ferrous carbonate is produced through the reaction between the ferrous sulphate and the potassium carbonate.

FERRI CHLORIDUM. U.S. Ferric Chloride

[IRON PERCHLORIDE]

Ferric Chloride should contain not less than 22 percent. of metallic iron in the form of chloride.

	Metric	Old form
***Solution of Ferric Chloride**	**100 Gm.**	10 oz. av.
To make	**40 Gm.**	4 oz. av.

Evaporate the Solution of Ferric Chloride on a water-bath until it weighs 40 Gm. [old form 4 oz. av.]; then set it aside in a glass-covered vessel, until it forms a crystalline mass. Lastly, break the salt into pieces, and keep it in glass-stoppered bottles, protected from light.

Official Description.—Orange-yellow, crystalline pieces; very deliquescent in moist air.

Odor, Taste, and Reaction.—Odorless, or having a faint odor of hydrochloric acid; strongly styptic taste; acid reaction.

Solubility.—*Water.* Freely and completely soluble.

Alcohol. Freely and completely soluble.

Other solvents. Freely and completely soluble in a mixture of 1 part of ether and 3 parts of alcohol.

Tests for Identity.—At 35.5° C. (96° F.) the salt fuses to a reddish-brown liquid. When strongly heated, it decomposes, losing water and hydrochloric acid, while the anhydrous salt sublimes, leaving a residue of ferric oxide.

The dilute, aqueous solution of the salt shows an acid reaction with blue litmus paper, yields a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in nitric acid, with silver nitrate T.S.

Impurities and Tests for Impurities.—*Heavy metals.* If 1 Gm. of the salt, dissolved in 25 Cc. of boiling water, be treated with an excess of ammonia water, the filtrate should be colorless, and, after acidulation with hydrochloric acid, 20 Cc. of the solution should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Limit of nitric acid. On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and an aqueous solution of the salt (1 in 10), the crystal should not become brown in color, nor should a brownish-black color be developed around it within five minutes.

Ferrous salt. If to a solution of the salt (1 in 50) a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, which should not turn at once to a green or greenish-blue.

Quantitative Test.—If 1 Gm. of dry Ferric Chloride be dissolved in sufficient water to measure 100 Cc., then 55.5 Cc. of this solution, when measured into a glass-stoppered flask of the capacity of about 250 Cc., followed by 3 Cc. of hydrochloric acid, and 2 Gm. of potassium iodide, should, after securely stoppering the flask and heating for half an hour at 40° C. (104° F.), and cooling, require not less than 22 Cc. of tenth-normal sodium thiosulphate V.S. for complete decolorization (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—Ferric chloride is used externally as a styptic, and internally as a chalybeate tonic, in doses of one to five grains (0.065 to 0.3 Gm.).

LIQUOR FERRI CHLORIDI. U.S. Solution of Ferric Chloride

An aqueous solution of Ferric Chloride, which should contain not less than 29 percent. of the anhydrous salt [$FeCl_3 = 161.04$], corresponding to 10 percent. of metallic iron.

	Metric	Old form
* **Iron,** in the form of fine, bright wire, and cut into small pieces	**125 Gm.**	2 oz. av. 325 gr.
Hydrochloric Acid	**680 Gm.**	12 fl. oz. 3 fl. dr.
Nitric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	**1000 Gm.**	1 pint

Introduce the Iron Wire into a flask having a capacity of about 2000 Cc. [old form 3 pints], pour upon it a mixture of 420 Gm. [old form 7 fl. oz. 5 fl. dr.] of Hydrochloric Acid and 250 Cc. [old form 5½ fl. oz.] of Distilled Water, and heat upon a water-bath for not less than one hour and fifteen minutes, or until effervescence ceases; then boil the liquid, filter it through paper, and, having rinsed the flask and Iron Wire with a little hot Distilled Water, pass the rinsings through the filter. To the filtered liquid add 220 Gm. [old form 4 fl. oz.] of Hydrochloric Acid, add the mixture slowly and gradually, in a stream, to 65 Gm. [old form 468 minims] of Nitric Acid contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, stirring occasionally, until the liquid is free from Nitric Acid. If the solution has acquired a black color, continue the addition of Nitric Acid, drop by drop, until red fumes are no longer evolved and the solution assumes a clear reddish-brown color. Finally, add the remaining 40 Gm. [old form 6 fl. dr.] of Hydrochloric Acid and enough Distilled Water to make the Solution weigh 1000 Gm., or measure [old form 1 pint].

In the first step of the process, ferrous chloride is produced; thus:

$$\underset{\text{Iron}}{Fe_2} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{4HCl} = \underset{\substack{\text{Ferrous}\\\text{Chloride}}}{(FeCl_2)_2} + \underset{\text{Hydrogen}}{4H}$$

Ferrous chloride is converted into ferric chloride by the addition of nitric and hydrochloric acids; thus:

$$\underset{\substack{\text{Ferrous}\\\text{Chloride}}}{6FeCl_2} + \underset{\substack{\text{Hydrochloric}\\\text{Acid}}}{6HCl} + \underset{\substack{\text{Nitric}\\\text{Acid}}}{2HNO_3} = \underset{\substack{\text{Ferric}\\\text{Chloride}}}{6FeCl_3} + \underset{\substack{\text{Nitrogen}\\\text{Dioxide}}}{N_2O_2} + \underset{\text{Water}}{4H_2O}$$

If this solution, when finished, has a blackish color, it is due to incomplete oxidation, and the remedy is to heat it to boiling in a capacious dish, adding a few drops of nitric acid until the color changes to a clear ruby-red and effervescence ceases. If a brown precipitate is deposited upon dilution or standing, deficiency of hydrochloric acid is indicated, and the solution must be heated, and a few drops of the acid added until the precipitate is dissolved.

The strength of this solution was lowered in the U. S. P. (8th Rev.) so as to make the percentage of metallic iron to which it corresponds 10 percent., instead of 13 percent. This does not affect the strength of tincture of ferric chloride, as the proportion of the solution in the tincture was increased.

Official Description.—A reddish-brown liquid.

Odor, Taste, and Reaction.—Faint odor of hydrochloric acid; an acid, strongly styptic taste, and an acid reaction.

Specific Gravity.—From 1.280 to 1.290 at 25° C. (77° F.).

Tests for Identity.—The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S.

Impurities and Tests for Impurities.—*Zinc or copper.* If the iron be completely precipitated from a portion of the Solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a precipitate with hydrogen sulphide T.S.

Salts of the fixed alkalies. Nor should it leave a fixed residue on evaporation and gentle ignition.

Nitric acid. On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the solution (1 in 10), the crystal should not become colored brown, nor should a brownish-black color develop around it.

Ferrous salts. If to a diluted portion of the Solution (about 1 in 20) a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, which should not at once turn green or greenish-blue.

Oxychloride. If to three drops of Solution of Ferric Chloride, 10 Cc. of tenth-normal sodium thiosulphate V.S. be added, and then slowly heated to boiling, no brownish-red precipitate of ferric hydroxide should separate.

Quantitative Test.—If 10 Gm. of the Solution be diluted to measure 100 Cc., and 11.1 Cc. of this be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require not less than 20 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron).

Uses.—This solution is occasionally used as a hæmostatic; its principal use, however, is to form, by dilution with alcohol, the well-known tincture of ferric chloride. The dose is from one to two minims (0.06 to 0.12 Cc.).

TINCTURA FERRI CHLORIDI. U.S. Tincture of Ferric Chloride

This tincture is made by diluting 350 Cc. of solution of ferric chloride with 650 Cc. of alcohol, the mixture to stand in a closely covered vessel at least three months; it is then to be transferred to glass-stoppered bottles (see page 351). The object of allowing the mixture to stand three months before it is to be used is to permit the formation of ethyl chloride and other similar ethereal compounds, the result of the action of the free acid on the alcohol. These ethers are supposed to give to the tincture diuretic properties. If a brownish-red precipitate of ferric oxychloride takes place upon diluting the solution of ferric chloride, it shows that the solution has not been properly made, and is deficient in free hydrochloric acid (see above).

Official Description.—A bright, brownish liquid.

Odor, Taste, and Reaction.—Slightly ethereal odor; very astringent, styptic taste; acid reaction.

Specific Gravity.—About 1.005 at 25° C. (77° F.).

Tests for Identity.—The Tincture yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S.

After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide T.S., showing the presence of some ferrous salt, due to reduction.

Impurities and Test for Impurities.—*Nitric acid.* On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Tincture (1 in 10), the crystal should not become colored brown, nor should there be a brownish-black zone developed around it.

Quantitative Test.—Evaporate 2.22 Gm. of the Tincture to dryness on a water bath, add 2 Cc. of hydrochloric acid and 5 Cc. of solution of hydrogen dioxide, and again evaporate the mixture to dryness; dissolve the residue in 10 Cc. of water, pour the solution into a glass-stoppered bottle having a capacity of about 100 Cc., rinsing the vessel with 10 Cc. more of water, add 1 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and keep the mixture for half an hour at a temperature of 40° C. (104° F.), then cool and add a little starch T.S.; it should require not less than 18.3 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue color of the liquid (each Cc. of the volumetric solution used indicating 0.25 percent. of metallic iron).

Uses.—Tincture of ferric chloride is undoubtedly the most important liquid iron preparation that is used; it is an efficient chalybeate, tonic, and styptic. The dose is from eight to thirty minims (0.5 to 2 Cc.), diluted with water; it should be sucked through a glass tube, to prevent injury to the teeth.

FERRI CITRAS. U.S. Ferric Citrate

It should contain Ferric Citrate corresponding in amount to not less than 16 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light.

Official Description.—Thin, transparent, garnet-red scales.

Odor, Taste, and Reaction.—Without odor, and having a slightly ferruginous taste.

Solubility.—*Water.* Slowly but completely at 25° C. (77° F.), and readily in hot water, but diminishing in solubility with age.

Alcohol. Insoluble.

Tests for Identity.—An aqueous solution of the salt is not precipitated, but rendered darker in color, by ammonia water.

With potassium ferrocyanide T.S. the aqueous solution yields a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid (difference from *iron and ammonium citrate*)

If Ferric Citrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, without evolving ammonia.

If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually afford a white crystalline precipitate.

Impurities and Tests for Impurities.—*Tartrate.* Another portion of the acidulated and cooled liquid (see above), when allowed to stand for twenty-four hours, should not deposit a white crystalline precipitate.

Citrates or tartrates of the alkali metals. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper.

Quantitative Test.—If 0.555 Gm. of Ferric Citrate be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., with the aid of a gentle heat, and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 16 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This salt is *very slowly* soluble in water, and hence is not largely used in making solutions. It is very useful in making pills, its slow solubility being an advantage in preventing the flattening which usually takes place when a more soluble form is used. The dose is four to twenty grains (0.25 to 1.3 Gm.).

FERRI ET AMMONII CITRAS. U.S. Iron and Ammonium Citrate

[AMMONIO-FERRIC CITRATE SOLUBLE FERRIC CITRATE]

It should contain Iron and Ammonium Citrate corresponding in amount to not less than 16 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light.

Preparation.—Iron and Ammonium Citrate may be made by the official process of 1890, in which a mixture of 100 Cc. of solution of ferric citrate and 40 Cc. of ammonia water were evaporated at a temperature not exceeding 60° C. (140° F.) to the consistence of syrup, and spread on glass plates to dry.

Prof. J. U. Lloyd modifies this process with advantage by using, instead of ammonia water, a definite quantity of ammonium citrate in solution (see U. S. Dispensatory, 18th edition, page 610).

Official Description.—Thin, transparent, garnet-red scales; deliquescent in moist air.

Odor, Taste, and Reaction.—Without odor, and having a saline, mildly ferruginous taste; neutral reaction.

Solubility.—*Water.* Readily and completely.

Alcohol. Insoluble.

Tests for Identity.—The aqueous solution is not precipitated, but rendered darker in color, by ammonia water.

With potassium ferrocyanide T.S. the solution does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid (difference from *ferric citrate*).

If Iron and Ammonium Citrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, and ammonia is evolved.

If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Tartrate.* Another portion of the acidulated and cooled liquid (see above), when allowed to stand for twenty-four hours, should not yield a white, crystalline precipitate.

Citrate or tartrates of the alkali metals. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction with red litmus paper.

Quantitative Test.—If 0.555 Gm. of the salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 16 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—Iron and ammonium citrate is a useful modification of ferric citrate, the object of adding the ammonia water being to make the salt more quickly soluble. The dose is four to twenty grains (0.25 to 1.3 Gm.).

LIQUOR FERRI CITRATIS. U.S. 1890 Solution of Ferric Citrate

An aqueous solution of Ferric Citrate, corresponding to about 7.5 percent. of metallic iron.

	Metric	Old form
Solution of Ferric Sulphate	1050 Gm.	10½ oz. av.
Citric Acid	300 Gm.	3 oz. av.
Ammonia Water	880 Cc.	8¾ fl. oz.
Water, a sufficient quantity,		
To make	1000 Gm.	10 oz. av.

Mix the Ammonia Water with 3000 Cc. [old form 30 fl. oz.] of cold Water, and the Solution of Ferric Sulphate with 10000 Cc. [old form 6 pints] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, with constant stirring. Pour the mixture on a wet muslin strainer, and allow the liquid to run off and the precipitate to drain. Then remove the moist mass from the strainer, mix it well with 6000 Cc. [old form $3\frac{1}{2}$ pints] of cold Water, again pour it on the strainer, and let it drain. Repeat this washing with several successive portions of cold Water in the same manner, until the washings cease to produce more than a slight cloudiness with barium chloride test solution. Then allow the precipitate to drain completely, transfer it to a porcelain capsule, add the Citric Acid, and heat the mixture on a water-bath, to 60° C. (140° F.), stirring constantly, until the precipitate is dissolved. Lastly, filter the liquid, and evaporate it, at the above-mentioned temperature, until it weighs 1000 Gm. [old form 10 oz. av.].

In this preparation ferric hydroxide is precipitated, ammonium sulphate being washed out, and the former is then dissolved in citric acid and the solution brought to a definite strength.

$$\underset{\text{Ferric Sulphate}}{Fe_2 3SO_4} + \underset{\substack{\text{Ammonium}\\ \text{Hydroxide}}}{6NH_4HO} = \underset{\text{Ferric Hydroxide}}{2Fe(OH)_3} + \underset{\substack{\text{Ammonium}\\ \text{Sulphate}}}{3(NH_4)_2SO_4}$$

This solution was dropped at the last revision of the U. S. Pharmacopœia (8th Revision), but it is retained here as it furnishes a process for making ferric citrate. It is a dark brown liquid (sp. gr. about 1.250).

Uses.—This solution deserves to be known better and used oftener than it has been in the past. It keeps well, and much labor will be saved by the pharmacist if he will use it in all cases where an aqueous solution of ferric citrate is needed. It is of just *half* the strength of the scaled salt, and therefore the use of a double quantity of this solution will be found very convenient.

VINUM FERRI. U.S. Wine of Iron

This preparation is made by dissolving 40 Gm. of iron and ammonium citrate in a mixture of 100 Cc. of syrup, 60 Cc. of tincture of sweet orange peel, and sufficient white wine to make 1000 Cc. It is used as an agreeable chalybeate tonic, in doses of one to two fluidrachms (4 to 8 Cc.) (see page 369).

FERRI ET QUININÆ CITRAS. U.S. Iron and Quinine Citrate

It should contain not less than 11.5 percent. of dried quinine, and ferric citrate corresponding in amount to not less than 13.5 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light.

The process of the U. S. P. 1890 is appended, no process being given in the U. S. P. (8th Rev.).

	Metric	Old form
Ferric Citrate	85 Gm.	13 oz. av. 262 gr.
Quinine, dried at 100° C. (212° F.) to a constant weight	12 Gm.	1 oz. av. 400 gr.
Citric Acid	3 Gm.	210 grains
Distilled Water, a sufficient quantity,		
To make	100 Gm.	16 oz. av.

Dissolve the Ferric Citrate in 160 Cc. [old form 26 fl. oz.] of Distilled Water by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid, previously triturated with 20 Cc. [old form $3\frac{1}{4}$ fl. oz.] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light.

This well known salt is simply a ferric citrate containing quinine in the proper quantity to make a good medicinal preparation. No symbolic formula is officially given to it, for the sufficient reason that it is not regarded as a definite chemical compound. It is often found deficient in quinine, and sometimes with a cheaper alkaloid substituted for it.

It frequently occurs in the market in light green scales. This color is due to the use of ammonia or ammonium citrate with the view of making the salt more soluble.

Iron and quinine citrate is not intended to be very soluble, the bitter taste being much less perceptible than when ammonia is combined with the citric acid. (See Ferri et Quininæ Citras Solubilis. page 636).

Official Description.—Thin, transparent scales, of a reddish-brown color; slowly deliquescent.

Odor, Taste, and Reaction.—Without odor, and having a bitter, mildly ferruginous taste. The aqueous solution of the salt shows an acid reaction with blue litmus paper.

Solubility.—*Water.* Slowly, but completely soluble in cold water, more readily soluble in hot water, partially soluble in alcohol. Its solubility is diminished by age.

Tests for Identity.—On the addition of a slight excess of ammonia water the color of the solution is deepened, and a white, curdy precipitate is produced.

The filtrate from this precipitate does not afford a blue color with potassium ferrocyanide T.S., unless it be acidulated with hydrochloric acid.

Another portion of the filtrate, heated with an excess of potassium hydroxide T.S., deposits a brownish-red precipitate.

If an aqueous solution of the salt (1 in 10) be deprived of its iron and quinine by boiling with an excess of potassium hydroxide T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, gradually deposits a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Tartrate.* Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate.

Citrates or tartrates of the alkali metals. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper.

Assay.—*For the quinine.* Introduce 1.11 Gm. of Iron and Quinine Citrate into a dish, and, with the aid of a gentle heat, dissolve it in 20 Cc. of water. Transfer the solution, together with the rinsings of the dish, to a separator, allow the liquid to become cold, then add 5 Cc. of ammonia water and 10 Cc. of chloroform, and shake the separator for one minute. Allow the liquids to separate, draw off the chloroformic layer, and shake the residuary liquid a second and a third time with portions of 10 Cc. each of chloroform. Allow the combined chloroformic solutions to evaporate spontaneously in a tared dish, and dry the residue at 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.1276 Gm. (corresponding to at least 11.5 percent. of dried quinine), and should conform to the reactions and tests under *Quinina.*

For the iron. Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water-bath, until the odor of chloroform and of ammonia have disappeared, allow it to cool, and dilute it with water to the volume of 50 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered flask having the capacity of about 100 Cc., add 3 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and, after securely closing the flask, allow the mixture to stand for half an hour at 40° C. (104° F.). After it has been allowed to cool, it should require not less than 13.5 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This is a valuable tonic combination, and is particularly useful in making pills, because of its slow solubility (see Ferri Citras). To supply the demand for a more popular salt, the soluble iron and quinine citrate was made official. The dose of the salt is from four to ten grains (0.25 to 0.6 Gm.).

FERRI ET QUININÆ CITRAS SOLUBILIS. U.S. Soluble Iron and Quinine Citrate

It should contain not less than 11.5 percent. of dried quinine, and ferric citrate corresponding in amount to not less than 13.5 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light.

The process of the U.S.P. 1890 is appended, no process being given for this scaled salt in the U.S.P. (8th Rev.).

	Metric	Old form
Ferric Citrate	**85 Gm.**	13 oz. av. 262 gr.
Quinine, dried at 100° C. (212° F.) to a constant weight	**12 Gm.**	1 oz. av. 400 gr.
Citric Acid	**3 Gm.**	210 grains
Ammonia Water,		
Distilled Water, each, a sufficient quantity,		
To make	**100 Gm.**	16 oz. av.

Dissolve the Ferric Citrate in 160 Cc. [old form 26 fl. oz.] of Distilled Water, by heating on a water bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid previously triturated with 20 Cc. [old form $3\frac{1}{2}$ fl. oz.] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Then add gradually, and with constant stirring, 50 Cc. [old form 8 fl. oz.], or a sufficient quantity, of Ammonia Water, so that, after the addition of each portion of the latter, the precipitated Quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

Keep the product in well-stoppered bottles, protected from light.

Official Description.—Thin, transparent scales, of a greenish, golden-yellow color; deliquescent.

Odor, Taste, and Reaction.—Without odor, and having a bitter, mildly ferruginous taste; slightly acid reaction.

Solubility.—*Water.* Rapidly and completely soluble in cold water.

Alcohol. Partially soluble.

Tests for Identity.—On the addition of a slight excess of ammonia water the color of the liquid is deepened, and a white, curdy precipitate is produced.

With potassium ferrocyanide T.S. a portion of the filtrate from this precipitate does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid.

When heated with potassium hydroxide T.S., the salt affords a brownish-red precipitate, and ammonia is evolved.

If an aqueous solution of the salt (1 in 10) be deprived of its iron and quinine by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Tartrate.* Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not give a white, crystalline precipitate.

Citrates or tartrates of the alkali metals. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper.

Assay.—Soluble Iron and Quinine Citrate, when assayed for Quinine and Iron by the method described under *Ferri et Quininæ Citras*, should respond to the same requirements as the latter.

Uses.—This is the soluble form of iron and quinine citrate, and is preferred by pharmacists when solutions are needed quickly. It differs from the salt considered on page 634 only in containing ammonia. The dose is the same.

VINUM FERRI AMARUM. U.S. Bitter Wine of Iron

This wine is made by dissolving 50 Gm. of soluble iron and quinine citrate in 500 Cc. of white wine, and adding 60 Cc. of tincture of sweet orange-peel, 300 Cc. of syrup, and sufficient white wine to make 1000 Cc. (see page 369). It is used as a mild ferruginous tonic, in doses of two to four teaspoonfuls (8 to 16 Cc.).

FERRI ET STRYCHNINÆ CITRAS. U.S. Iron and Strychnine Citrate

It should contain not less than 0.9 nor more than 1 percent. of strychnine, and ferric citrate corresponding in amount to not less than 16 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light.

No process was given in the U. S. P. (8th Rev.) for this salt ; the process of the U. S. P. 1890 is appended.

	Metric	Old form
Iron and Ammonium Citrate	98 Gm.	490 grains
Strychnine	1 Gm.	5 grains
Citric Acid	1 Gm.	5 grains
Distilled Water	120 Cc.	11 fl. dr.
To make	100 Gm.	500 grains

Dissolve the Iron and Ammonium Citrate in 100 Cc. [old form 9 fl. dr.] of Distilled Water, and the Strychnine, together with the Citric Acid, in 20 Cc. [old form 2 fl. dr.] of Distilled Water. Mix the two solutions, evaporate the mixture by means of a water-bath at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light. This salt contains 1 percent. of strychnine.

Official Description.—Thin, transparent scales, varying in color from garnet-red to yellowish-brown ; deliquescent in moist air.

Odor, Taste, and Reaction.—Without odor ; bitter, slightly ferruginous taste ; slightly acid reaction.

Solubility.—*Water.* Readily and completely soluble.

Alcohol. Partially soluble.

Tests for Identity.—The aqueous solution of Iron and Strychnine Citrate is not immediately precipitated, but rendered darker in color, by ammonia water.

With potassium ferrocyanide T.S. the aqueous solution does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid.

On heating with potassium hydroxide T.S., the salt affords a brownish-red precipitate, evolving ammonia.

If an aqueous solution of the salt (1 in 10) be deprived of its iron and strychnine by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Tartrate.* Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not deposit a white, crystalline precipitate.

Citrates or tartrates of the alkali metals. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction with red litmus paper.

Assay.—*For the strychnine.* Dissolve 4.11 Gm. of Iron and Strychnine Citrate, in a separator, in 15 Cc. of water, add 5 Cc. of ammonia water and 10 Cc. of Chloroform, and shake the separator for one minute. Allow the liquids to separate, draw off the chloroformic layer, and shake the residuary liquid a second and a third time with portions of 10 Cc. each of chloroform. Allow the combined chloroformic liquids to evaporate spontaneously in a tared dish, and dry the residue at 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.04 (0.0399) Gm., nor more than 0.0444 Gm. (corresponding to not less than 0.9 nor more than 1 percent. of strychnine), and should respond to the reactions and tests given under *Strychnina.*

For the iron. Heat the aqueous liquid, from which the strychnine has been removed in the manner just described, on a water-bath, until the odors of chloroform and of ammonia have disappeared, allow it to cool, and dilute it with water to the volume of 100 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered flask having the capacity of about 100 Cc., add 4 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and, after securely closing the flask, allow the mixture to stand for half an hour at 40° C. (104° F.). After it has been allowed to cool, it should require not less than 32 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of tenth-normal sodium thiosulphate V.S. indicating one-half percent. of metallic iron).

Uses.—This salt is used as a bitter ferruginous tonic, in doses of two to five grains (0.12 to 0.3 Gm.).

GLYCERITUM FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Glycerite of the Phosphates of Iron, Quinine and Strychnine

This glycerite is made by dissolving 80 Gm. of soluble ferric phosphate, 104 Gm. of quinine, and 0.8 Gm. of strychnine in 200 Cc. of phosphoric acid, 500 Cc. of glycerin, and sufficient water to make 1000 Cc. (see page 308).

It was introduced into the present Pharmacopœia and is used as a stock solution, from which the Syrup of Iron, Quinine, and Strychnine Phosphates may be readily made extemporaneously by adding to it three parts of syrup. The glycerite is more permanent, not darkening or precipitating as readily as the syrup.

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Elixir of the Phosphates of Iron, Quinine and Strychnine

This elixir is prepared by dissolving 8.75 Gm. of quinine and 0.275 Gm. of strychnine in 60 Cc. of alcohol, and adding 2 Cc. of phosphoric acid, 350 Cc. of aromatic elixir, a solution of ammonium acetate, then enough aromatic elixir to measure 880 Cc., and finally 120 Cc. of a solution containing 17.5 Gm. of soluble ferric phosphate (see page 318).

SYRUPUS FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U.S. Syrup of the Phosphates of Iron, Quinine and Strychnine

[EASTON'S SYRUP]

This is made by adding 250 Cc. of the glycerite (see above) to sufficient syrup to make 1000 Cc. On keeping, it gradually deposits a precipitate which contains a portion of the alkaloids, it should therefore only be made as wanted. The dose is one or two teaspoonfuls (4 to 8 Cc.).

FERRI ET AMMONII SULPHAS. U.S Ferric Ammonium Sulphate

$FeNH_4(SO_4)_2 + 12H_2O = 478.69$

[AMMONIO-FERRIC ALUM AMMONIO-FERRIC SULPHATE IRON AMMONIUM ALUM]

It should contain, in the uneffloresced condition, 99.5 percent. of pure Ferric Ammonium Sulphate, and not less than 11.5 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light.

Preparation.—Ammonio-ferric alum may be made by the process formerly official:

Take of Solution of Tersulphate of Iron 2 pints, Sulphate of Ammonium 4½ oz. troy. Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air.

$$\underset{\substack{\text{Ferric}\\\text{Sulphate}}}{Fe_23SO_4} + \underset{\substack{\text{Ammonium}\\\text{Sulphate}}}{(NH_4)_2SO_4} = \underset{\substack{\text{Ammonio-ferric}\\\text{Sulphate}}}{2FeNH_4(SO_4)_2}$$

It is well to choose the cold winter weather to prepare this salt, if it is possible to make a choice, as handsome crystals may then be obtained with little labor. This compound is not very stable, melting oftentimes in hot summer weather in its water of crystallization.

Official Description.—Pale violet, octahedral crystals; efflorescent on exposure to the air.

Odor, Taste, and Reaction.—Without odor, and having an acid, styptic taste; an acid reaction.

Solubility.—*Water.* In 2.7 parts at 25° C. (77° F.), and in 0.8 part of boiling water. *Alcohol.* Insoluble.

Tests for Identity.—When strongly heated, the crystals fuse, lose their water of crystallization, expand, and finally leave a pale brown residue.

The aqueous solution of the salt yields with potassium ferrocyanide T.S. a blue precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid.

With potassium hydroxide T.S. Ferric Ammonium Sulphate yields a brownish-red precipitate, and if the mixture be heated, ammonia gas is evolved.

Impurities and Tests for Impurities.—*Aluminum.* If the iron be wholly precipitated from a solution of the salt by treating it with an excess of potassium hydroxide T.S., the resulting filtrate, when neutralized with hydrochloric acid, and then mixed with ammonia water, should not yield a white, gelatinous precipitate.

Chlorides. The addition of 3 Cc. of nitric acid to 30 Cc. of a solution of the salt (1 in 20), followed by a few drops of silver nitrate T.S., should not produce any turbidity.

Quantitative Test.—If 0.555 Gm. of the uneffloresced crystals of the salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 11.5 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—Iron alum is used as a styptic in saturated solution. It partakes more of the characteristics of an alum than of an iron salt. The dose is eight grains (0.5 Gm.).

FERRI ET AMMONII TARTRAS. U.S. Iron and Ammonium Tartrate

[AMMONIO-FERRIC TARTRATE]

It should contain Iron and Ammonium Tartrate corresponding in amount to not less than 13 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light.

A process for making this salt will be found in the third edition of this work on page 673. No process is given in the U. S. P. (8th Rev.). Theoretically, this salt is supposed to have the following composition: $2(FeO)NH_4.C_4H_4O_6 + 3H_2O$. The formula indicates a double tartrate, in which the two basylous hydrogen atoms have been substituted by the iron and ammonium radical. The scaled salts are, however, not definite compounds.

The object in this process is to form a compound in which ferric hydroxide is made soluble by acid ammonium tartrate, and the double salt, iron and ammonium tartrate, is produced.

Official Description.—Thin, transparent scales, varying in color from garnet-red to reddish-brown; slightly deliquescent in the air.

Odor, Taste, and Reaction.—Without odor; sweetish, slightly ferruginous taste; acid reaction.

Solubility.—*Water.* Very soluble.
Alcohol. Insoluble.

Tests for Identity.—An aqueous solution of Iron and Ammonium Tartrate is not precipitated, but rendered darker in color, by ammonia water.

With potassium ferrocyanide T.S. the solution does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid.

If Iron and Ammonium Tartrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, and ammonia is evolved.

If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate.

Impurities and Tests for Impurities.—*Citrates or tartrates of the alkali metals.* When strongly heated, the salt chars, emits fumes having the odor of burning sugar, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper.

Quantitative Test.—If 0.555 Gm. of the dry salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 13 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This preparation is a mild chalybeate, the dose being four to thirty grains (0.25 to 2 Gm.).

FERRI ET POTASSII TARTRAS. U. S. Iron and Potassium Tartrate

[Potassio-Ferric Tartrate]

It should contain Iron and Potassium Tartrate corresponding in amount to not less than 15 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light.

No process is given in the U. S. P (8th Rev.) for this scaled salt; the process of the U. S. P. 1890, will be found in the third edition of this work, page 674. The hydrogen in the acid potassium tartrate in this compound is replaced by iron, so that a double salt like potassium and sodium tartrate is produced.

Official Description.—Thin, transparent scales, varying in color from garnet-red to reddish-brown; slightly deliquescent in the air.

Odor, Taste, and Reaction.—Without odor, and having a sweetish, ferruginous taste; neutral reaction.

Solubility.—*Water.* Very soluble.
Alcohol. Insoluble.

Tests for Identity.—When strongly heated, the salt chars, emits fumes having an odor resembling that of burning sugar, and finally leaves a dark brown residue, having a strongly alkaline reaction, and effervescing with acids (distinction from *iron and ammonium tartrate*).

An aqueous solution of Iron and Potassium Tartrate is not precipitated, but rendered darker in color, by ammonia water.

With potassium ferrocyanide T.S. the solution does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid.

When heated with potassium hydroxide T.S., the salt yields a brownish-red precipitate.

If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate.

Quantitative Test.—If 0.555 Gm. of the dry salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 15 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This is a mild ferruginous tonic, and is given in doses of four to thirty grains (0.25 to 2 Gm.).

The French use this salt by making it into an olive shaped ball, to which a loop of string is attached; a lead pencil or any convenient stick is run through the loop, and the ball suspended over a glass containing wine or water, at such a height as to dip into the liquid, so as to dissolve the necessary quantity ; the liquid is soon impregnated with the iron salt, and a second dose is prepared like the first by refilling the glass. This form is called "*Boule de Mars,*" and furnishes a ready method of obtaining a mild chalybeate draught.

FERRI HYDROXIDUM. U.S. Ferric Hydroxide

$Fe(OH)_3 = 106.14$

[FERRI OXIDUM HYDRATUM, PHARM. 1890 FERRIC HYDRATE HYDRATED OXIDE OF IRON]

	Metric	Old form
* **Solution of Ferric Sulphate**	**100 Cc.**	10 fl. oz.
Ammonia Water	**138 Cc.**	13¾ fl. oz.
Water, a sufficient quantity		

To the Ammonia Water, previously diluted with 500 Cc. [old form 3 pints] of cold Water, add, with constant stirring, the Solution of Ferric Sulphate, previously diluted with 1000 Cc. [old form 6 pints] of cold Water. As soon as the precipitate has subsided, draw off the clear liquid by means of a siphon, then mix the precipitate intimately with about 1000 Cc. [old form 6 pints] of cold Water, again draw off the clear liquid after subsidence of the precipitate, and repeat this operation, until a portion of the decanted liquid gives not more than a slight cloudiness with barium chloride test solution. Finally, transfer the precipitate to a wet muslin strainer, and, after it has drained, mix it with sufficient cold Water to make the mixture weigh 300 Gm. [old form 30 oz. av.].

Ferric Hydroxide, thus prepared, is a brownish-red magma, wholly soluble in hydrochoric acid without effervescence.

When Ferric Hydroxide is to be made in haste, for use as an antidote, the washing may be performed more quickly, though less perfectly, by transferring the precipitate at once to a wet muslin strainer, pressing forcibly with the hands, until no more liquid passes, and then adding enough Water to make the whole weigh about 300 Gm. [old form 30 oz. av.].

NOTE.—The ingredients for preparing Ferric Hydroxide as an antidote should always be kept on hand in bottles containing, respectively, 200 Cc. [old form 6 fl. oz.] of the Solution of Ferric Sulphate, and 276 Cc. [old form 8¼ fl. oz.] of Ammonia Water.

The reaction is as follows :

$$\underset{\text{Ferric Sulphate}}{Fe_2 3SO_4} + \underset{\text{Ammonium Hydroxide}}{6NH_4HO} = \underset{\text{Ferric Hydroxide}}{2Fe(OH)_3} + \underset{\text{Ammonium Sulphate}}{3(NH_4)_2SO_4}$$

Ammonia water is preferred as the precipitant, because an excess is easily detected by the odor, and the salt formed is readily washed out.

Uses.—This compound is used as the basis in preparing several iron salts, citrate, tartrate, etc., and also as the antidote to poisoning by arsenic. For the latter purpose it should be administered freely. It acts by producing insoluble ferrous arsenate.

$$\underset{\text{Ferric Hydroxide}}{4Fe(OH)_3} + \underset{\text{Arsenic Trioxide}}{As_2O_3} = \underset{\text{Ferrous Arsenate}}{Fe_3(AsO_4)_2} + \underset{\text{Ferrous Hydroxide}}{Fe(HO)_2} + \underset{\text{Water}}{5H_2O}$$

It should never be kept on hand, as it decomposes even when kept under water; the ingredients should always be kept already weighed out, placed in suitable bottles, *and in an accessible and well known place in the store*, so that if wanted quickly for an antidote it can be made without the unnecessary loss of a moment's time.

FERRI HYDROXIDUM CUM MAGNESII OXIDO. U.S. Ferric Hydroxide with Magnesium Oxide

[FERRI OXIDUM HYDRATUM CUM MAGNESIA, PHARM. 1890 ARSENIC ANTIDOTE FERRIC HYDRATE WITH MAGNESIA]

	Metric	Old form
* **Solution of Ferric Sulphate**	**40 Cc.**	1 fl. oz 3 fl. dr.
Magnesium Oxide	**10 Gm.**	154 grains
Water, a sufficient quantity		

Mix the Solution of Ferric Sulphate with 125 Cc. [old form $3\frac{3}{4}$ fl. oz.] of Water, and keep the liquid in a large, well-stoppered bottle. Rub the Magnesium Oxide with cold Water to a smooth and thin mixture, transfer this to a bottle capable of holding about 1000 Cc. [old form 2 pints], and fill it with Water to about three-fourths of its capacity. When the preparation is wanted for use, shake the Magnesium Oxide mixture to a homogeneous, thin magma, add it gradually to the diluted Solution of Ferric Sulphate, and shake them together until a uniform, smooth mixture results.

NOTE.—For the rapid preparation of this antidote to arsenical poisoning, the diluted Solution of Ferric Sulphate, and the mixture of Magnesium Oxide with Water, should always be kept on hand, in separate bottles, ready for immediate use.

Uses.—This preparation furnishes a ready and efficient antidote against arsenic poisoning. Ferric hydroxide is produced when the mixture of magnesium oxide is added to the diluted solution of ferric tersulphate, and, as the magnesium oxide is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. It contains in addition magnesium sulphate and hydroxide. It has been shown that no soluble compound with arsenic is formed when it is used as an antidote; the presence of the magnesium salts, from a therapeutical point of view, is not objectionable, and it is preferred to ferric hydroxide.

FERRI HYPOPHOSPHIS. U. S. Ferric Hypophosphite

$Fe(PH_2O_2)_3 = 249.09$

It should contain not less than 98 percent. of pure Ferric Hypophosphite $[(PH_2O.O)_3Fe]$, and should be kept in well-stoppered bottles.

Preparation.—This is among the hypophosphites brought into notice in consequence of their recommendation by Dr. Churchill in the treatment of phthisis, in which they were thought to be useful by the introduction of phosphorus into the system. This particular salt may be considered preferable to others when a marked condition of anæmia indicates a deficiency of iron in the tissues. It may be made by the action of hypophosphorous acid on ferrous carbonate formed by precipitation from ferrous sulphate; but, as some difficulty has been found in obtaining this acid perfectly pure, preference has been given to the plan of double decomposition. This salt may be made by causing ferrous sulphate and calcium hypophosphite to react on each other in molecular proportions represented by 480 grains of crystallized ferrous sulphate and 326 grains of commercial hypophosphite,—in the latter an allowance of 10 percent. being made for impurities ordinarily found in that salt. These quantities will yield 320 grains of ferric hypophosphite, and the reaction will be represented by the following formula :

$$\underset{\substack{\text{Calcium}\\\text{Hypophosphite}}}{Ca(H_2PO_2)_2} + \underset{\substack{\text{Ferrous}\\\text{Sulphate}}}{FeSO_4} = \underset{\substack{\text{Calcium}\\\text{Sulphate}}}{CaSO_4} + \underset{\substack{\text{Ferrous}\\\text{Hypophosphite}}}{Fe(H_2PO_2)_2}$$

Calcium sulphate is precipitated, and ferrous hypophosphite is held in solution. In this condition the salt is a ferrous compound ; but on evaporation the ferrous salt becomes ferric, and acquires the properties detailed in the Pharmacopœia.

Official Description.—A white, or grayish-white powder ; permanent in the air.

Odor and Taste.—Odorless and nearly tasteless.

Solubility.—*Water.* In 2300 parts at 25° C. (77° F.), and in 1200 parts of boiling water ; more readily in the presence of hypophosphorous acid, or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution.

Tests for Identity.—When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and, on complete ignition, leaves a residue of ferric pyrophosphate.

Ferric Hypophosphite is readily oxidized by nitric acid or other oxidizing agents.

Impurities and Tests for Impurities.—*Carbonate.* If to 1 Gm. of the salt 10 Cc. of acetic acid be added, no effervescence should occur.

If the mixture be subsequently heated to boiling, the filtrate should respond to the following tests :

The addition of a few drops of silver nitrate T.S. to a portion of the filtrate should, upon warming, cause a brown to black coloration or precipitate. If another portion of the filtrate be added drop by drop to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed upon gently heating.

Calcium. Another portion of the cold filtrate should afford no turbidity with ammonium oxalate T.S.

Phosphate. If 0.5 Gm. of the salt be boiled with 10 Cc. of potassium hydroxide T.S., a reddish-brown precipitate will be produced ; and if to the filtrate from the latter, slightly acidulated with hydrochloric acid, magnesia mixture T.S. be added, and subsequently an excess of ammonia water, no crystalline precipitate should be produced.

Heavy metals. If 1 Gm. of the salt be dissolved in about 25 Cc. of boiling water by the aid of sufficient hydrochloric acid, added drop by drop, then a slight excess of ammonia water added, the filtrate from the reddish-brown precipitate should be colorless, and, after acidulating with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—Ferric hypophosphite is given in anæmia and in cases of defective nerve nutrition ; it is administered in the form of pills, powders, or syrup. The dose is from three to ten grains (0.2 to 0.6 Gm.).

SYRUPUS FERRI IODIDI. U.S. Syrup of Ferrous Iodide

A syrupy liquid containing about 5 percent., by weight, of Ferrous Iodide [$FeI_2 = 307.30$], or about 6.74 Gm. in 100 Cc.

This syrup is prepared by forming a solution of ferrous iodide by acting on iron wire with iodine in the presence of water ; the green solution of ferrous iodide is then protected by its addition to sugar, and the syrup is poured into small, well-stoppered bottles which are exposed to daylight. A small amount of diluted hypophosphorous acid is added to aid in its preservation. The object of exposing the syrup to daylight is to prevent the separation of free iodine, to which the irritant action is due, the syrup being prone to decomposition and discoloration from this separation; when iodine is diffused through water and is exposed to light, colorless hydriodic acid is formed, and this is measurably protected from change through the intervention of the syrup. (See Syrupus Acidi Hydriodici, page 290.)

Official Description.—A transparent, pale green, or yellowish green liquid.
Taste and Reaction.—Sweet, strongly ferruginous taste, and an acid reaction.
Specific Gravity.—About 1.349 at 25° C. (77° F.).
Test for Identity.—On adding a few drops of potassium ferricyanide T.S. to a small portion of the diluted Syrup a blue precipitate will be produced.
Impurity and Test.—*Free iodine.* If mixed with a little starch T.S., and afterwards with a few drops of chlorine water, the syrup will acquire a deep blue color. This color should not be produced in the Syrup by starch T.S. alone.
Quantitative Test.—If 10 Gm. of Syrup of Ferrous Iodide be diluted with distilled water to measure 100 Cc., and 15.4 (15.36) Cc. of the solution be mixed with 15 Cc. of water, 6 Cc. of tenth-normal silver nitrate V.S., and 2 Cc. each of diluted nitric acid and ferric ammonium sulphate T.S., then, after thoroughly shaking the mixture, not more than 1 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 1 percent. of Ferrous Iodide).

Uses.—The dose of this syrup is from ten to thirty minims (0.6 to 2 Cc.); it should be largely diluted, and sucked through a glass tube, to protect the teeth from injury.

PILULÆ FERRI IODIDI. U.S. Pills of Ferrous Iodide

The liability to decomposition of ferrous iodide has led to various forms of administration which will present it unaltered. The official pills of ferrous iodide are directed to be coated with an ethereal solution of tolu to preserve them from change. The pills contain ferrous iodide, sugar, extract of glycyrrhiza, glycyrrhiza, and acacia. There is in each pill nearly one grain of ferrous iodide. Ferrous iodide is a valuable salt in diseases attended with anæmia which require the use of an alterative. The dose is one or two pills. (See Part V.)

FERRI PHOSPHAS SOLUBILIS. U.S. Soluble Ferric Phosphate

It should contain Ferric Phosphate corresponding in amount to not less than 12 percent. of metallic iron, and should be kept in amber-colored, well-stoppered bottles, protected from light.

No process is given in the U. S. P. (8th Rev.) for this scaled salt; the process of the U. S. P. 1890 is appended.

	Metric	Old form
Ferric Citrate	50 Gm.	10 oz. av.
Sodium Phosphate, uneffloresced	55 Gm.	11 oz. av.
Distilled Water	100 Cc.	19 fl. oz.

Dissolve the Ferric Citrate in the Distilled Water by heating on a water bath. To this solution add the Sodium Phosphate, and stir constantly until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

This scaled salt is very different from the insoluble slate-colored powder of iron phosphate formerly official. It is not a definite chemical compound, but is sometimes termed sodio-ferric citro-phosphate. It greatly resembles the official ferric pyrophosphate.

Official Description.—Thin, bright green, transparent scales. The salt is permanent in dry air when excluded from light, but when unprotected soon becomes dark and discolored.

Odor, Taste, and Reaction.—Without odor, and having an acidulous, slightly saline taste; slightly acid reaction.

Solubility.—*Water.* Freely and completely soluble.

Alcohol. Insoluble.

Tests for Identity.—The addition of ammonia water to the aqueous solution of the salt produces a reddish-brown color.

If soluble Ferric Phosphate be boiled with potassium hydroxide T.S., it affords a brownish-red precipitate without evolving ammonia.

Dissolve 0.1 Gm. of the salt in 2 Cc. of warm water, add 5 Cc. of potassium hydroxide T.S., boil and filter. Neutralize the filtrate with hydrochloric acid, add 2 Cc. of magnesia mixture T.S. and ammonia water in slight excess. A white, crystalline precipitate is produced, which, if well washed on a filter, is turned yellow by silver nitrate T.S.

To 1 Gm. of the salt dissolved in 10 Cc. of water, add 15 Cc. or a slight excess of boiling potassium hydroxide T.S., and, after thoroughly mixing, filter. The filtrate, after strongly acidulating with hydrochloric acid and adding 10 Cc. of magnesia mixture T.S., followed by a slight excess of ammonia water, will afford an abundant, white, crystalline precipitate.

Quantitative Test.—If 0.555 Gm. of the salt be dissolved in 10 Cc. of water, in a glass-stoppered flask having a capacity of about 100 Cc., and 2 Cc. of hydrochloric acid and 40 Cc. of water added, and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 12 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This is a mild and safe ferruginous tonic. It is given in doses of four to ten grains (0.2 to 0.6 Gm.).

FERRI PYROPHOSPHAS SOLUBILIS. U.S. Soluble Ferric Pyrophosphate

It should contain Ferric Pyrophosphate corresponding in amount to not less than 10 percent. of metallic iron, and should be kept in amber-colored, well-stoppered bottles, protected from light.

No process is given for this scaled salt in the U. S. P. (8th Rev.); the process of the U. S. P. 1890 is appended.

	Metric	Old form
Ferric Citrate	50 Gm.	8 oz. av.
Sodium Pyrophosphate, uneffloresced	50 Gm.	8 oz. av.
Distilled Water	100 Cc.	16 fl. oz.

Dissolve the Ferric Citrate in the Distilled Water, by heating on a water-bath. To this solution add the Sodium Pyrophosphate, and stir constantly until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

This compound is a mixture of several salts,—sodio-ferric pyrophosphate, sodio-ferric citrate, and ferric citrate. It differs from the salt official in 1870, which was the insoluble ferric pyrophosphate, $Fe_43P_2O_7$, dissolved in solution of ammonium citrate; the ammonium salt is less stable than the sodium compound, being slowly decomposed on exposure to the air, and the process yielded an unsatisfactory product.

Official Description.—Thin, apple-green, transparent scales. The salt is permanent in dry air, when excluded from light, but when unprotected, soon becomes discolored.

Odor, Taste, and Reaction.—Without odor; acidulous, slightly saline taste; slightly acid reaction.

Solubility.—*Water.* Freely and completely soluble.

Alcohol. Insoluble.

Tests for Identity.—If Soluble Ferric Pyrophosphate be boiled with potassium hydroxide T.S., it affords a brownish-red precipitate without evolving the odor of ammonia.

If 0.1 Gm. of the salt be fused with 0.1 Gm. each of potassium nitrate and sodium carbonate, and the residue boiled with 10 Cc. of distilled water and filtered, the filtrate, after being rendered nearly, but not quite, neutral with highly diluted nitric acid, should yield a yellow precipitate upon the addition of silver nitrate T.S.

Quantitative Test.—If 0.555 Gm. of the salt be dissolved in 10 Cc. of water, in a glass-stoppered flask having a capacity of about 100 Cc. and 8 Cc. of hydrochloric acid and 40 Cc. of water added, and if, after the addition of 2 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 10 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron).

Uses.—This is one of the best of the mild ferruginous preparations. It is very largely used on account of its solubility and the ease with which it can be administered either in pills or in solution. The dose is two to five grains (0.12 to 0.3 Gm.).

FERRI SULPHAS. U.S. Ferrous Sulphate

$FeSO_4 + 7H_2O = 276.01$

[IRON PROTOSULPHATE]

It should contain not less than 99.5 percent. of pure Ferrous Sulphate [$SO_2.O_2Fe + 7H_2O$] ; the crystals should not be effloresced, and should be kept in well-stoppered bottles.

Preparation.—This salt is rarely made by the pharmacist, because the commercial article is sold at a very low price. The following is a formerly official British process :

Take of Iron Wire, 4 oz. av. ; Sulphuric Acid, 4 fl. oz. [Imperial measure] ; Distilled Water, 1½ pints [Imp. meas.]. Pour the Water on the Iron placed in a porcelain dish, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and be preserved in a stoppered bottle.

The salt is a by-product in the manufacture of hydrogen, the following being the reaction :

$$\underset{\text{Iron}}{Fe_2} + \underset{\substack{\text{Sulphuric}\\ \text{Acid}}}{2H_2SO_4} = \underset{\substack{\text{Ferrous}\\ \text{Sulphate}}}{2FeSO_4} + \underset{\text{Hydrogen}}{4H}$$

Official Description.—Large, pale bluish-green, monoclinic prisms ; efflorescent in dry air. On exposure to moist air, the crystals rapidly oxidize, and become coated with brownish-yellow, basic ferric sulphate.

Odor, Taste, and Reaction.—Without odor ; saline, styptic taste ; acid reaction.

Solubility.—*Water.* In 0.9 part at 25° C. (77° F.), and in 0.3 part of boiling water.

Alcohol. Insoluble.

Tests for Identity.—When slowly heated to 115° C. (239° F.), the crystals disintegrate, and lose 38.87 percent. of their weight (6 molecules of water of crystallization).

The aqueous solution of the salt, even when highly diluted, gives with potassium ferricyanide T.S. a blue color or precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid.

Impurities and Tests for Impurities.—*Heavy metals.* If 1 Gm. of the salt be dissolved in about 25 Cc. of water, containing 1 Cc. of diluted sulphuric acid, the solution heated to boiling, oxidized with nitric acid, and then mixed with a slight excess of ammonia water, the filtrate from the reddish-brown precipitate produced should be colorless, and, after acidulating with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Salts of the alkali metals. If another portion of the salt be oxidized and precipitated as directed above, the filtrate, on evaporation to dryness and ignition, should not leave any weighable residue.

Free acid. If 1 Gm. of Ferrous Sulphate, in small fragments, be agitated during four or five minutes with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus paper.

Quantitative Test.—If 1.38 Gm. of the salt, in uneffloresced crystals, be dissolved in about 25 Cc. of diluted sulphuric acid, not less than 49.75 Cc. of tenth-normal potassium permanganate V.S. should be required to impart to the liquid a permanent pink color (each Cc. of the tenth-normal potassium permanganate V.S. indicating 2 percent. of crystallized Ferrous Sulphate).

Uses.—This is a very astringent iron salt. When used internally, the exsiccated or granulated salt is preferred. The impure ferrous sulphate, called *copperas*,[1] is used as a disinfectant. The dose of the sulphate is one to three grains (0.065 to 0.2 Gm.).

FERRI SULPHAS EXSICCATUS. U.S. Exsiccated Ferrous Sulphate

[DRIED FERROUS SULPHATE]

	Metric	Old form
* **Ferrous Sulphate,** in coarse powder	100 Gm.	25 oz. av.

Allow the salt to effloresce at a temperature of about 40° C. (104° F.), in dry air, and then heat it in a porcelain dish, on a water-bath, constantly stirring, until the product weighs from 64 to 65 Gm. [old form 16 oz. av.]. Lastly, reduce the residue to a fine powder, and transfer it at once to perfectly dry, well-stoppered bottles.

A grayish-white powder, slowly but completely soluble in water, and conforming to the reactions and tests given under *Ferri Sulphas*.

This process does not deprive the ferrous sulphate of all of its water of crystallization, about 15 percent. being retained. One hundred parts of crystallized sulphate yield about 64 percent. of the exsiccated salt.

Uses.—Exsiccated ferrous sulphate is a grayish-white powder, and is principally used in making pills, the crystallized sulphate being unfitted for the purpose on account of the large proportion of water that it contains. Five grains of the crystals are represented by three grains of the exsiccated sulphate. It is used in the official pills of aloes and iron.

FERRI SULPHAS GRANULATUS. U.S. Granulated Ferrous Sulphate

$FeSO_4 + 7H_2O = 276.01$

[FERRI SULPHAS PRECIPITATUS, U. S. 1880 PRECIPITATED FERROUS SULPHATE]

	Metric	Old form
* **Ferrous Sulphate,** in coarse powder	100 Gm.	4 oz. av.
Distilled Water	100 Cc.	4 fl. oz.
Diluted Sulphuric Acid	5 Cc.	1½ fl. dr.
Alcohol	25 Cc.	1 fl. oz.

Dissolve the Ferrous Sulphate in the Distilled Water previously heated to boiling, add the Diluted Sulphuric Acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain dish, on a sand-bath, until it weighs 150 Gm. [old form 6 oz. av.], and then cool it quickly, with constant stirring. Transfer the product to a glass funnel stopped with a plug of purified cotton, and, when it has thoroughly drained, pour upon it the Alcohol. When this has also drained, spread the crystalline powder on bibu-

---

[1] This unfortunate synonym, "*copperas*," has led to a great many errors, through the impression that this salt must contain copper. It is often confounded with the poisonous salt copper sulphate, or blue vitriol, and they have been substituted for each other.

lous paper, dry it quickly at the ordinary temperature, and transfer it at once to perfectly dry, well-stoppered bottles.

Granulated Ferrous Sulphate is a very pale bluish-green, crystalline powder, which should conform in every respect to the reactions and tests given under *Ferri Sulphas.*

Ferrous sulphate is insoluble in alcohol; hence, if a strong aqueous solution be poured into alcohol, it is precipitated in the form of a granular crystalline powder, and this method was used in the U. S. P. 1880 for preparing this salt. The processes of the U. S. P. 1890 and U. S. P. (8th Rev.) differ from that formerly official in that the sulphate is not precipitated but granulated, and subsequently washed with alcohol to free it from impurities.

Uses.—Granulated ferrous sulphate should be used in preference to the large crystals at the prescription counter; the soluble impurities are washed out by the alcohol. It is much less liable to oxidation and change than the ordinary crystallized sulphate.

LIQUOR FERRI ET AMMONII ACETATIS. U.S. Solution of Iron and Ammonium Acetate

[BASHAM'S MIXTURE]

	Metric	Old form
* **Tincture of Ferric Chloride**	40 Cc.	4 fl. dr.
Diluted Acetic Acid	60 Cc.	6 fl. dr.
Solution of Ammonium Acetate	500 Cc.	6¼ fl. oz.
Aromatic Elixir	120 Cc.	1½ fl. oz.
Glycerin	120 Cc.	1½ fl. oz.
Water, a sufficient quantity,		
To make	1000 Cc.	12½ fl. oz.

To the Solution of Ammonium Acetate (which should not be alkaline) add, successively, the Diluted Acetic Acid, the Tincture of Ferric Chloride, the Aromatic Elixir, and the Glycerin, and, lastly, enough Water to make the product measure 1000 Cc. [old form 12½ fl. oz.].

This preparation should be freshly made when wanted.

This solution was improved in the U. S. P. 1890 by the addition of glycerin, and in the 8th Decennial Revision, by doubling the strength of the important ingredients. It is not intended to be a permanent preparation, and in time will decompose. Some pharmacists prefer to keep all the ingredients mixed together in a shop bottle, except the tincture of ferric chloride, and, when called for, add the proper quantity of the tincture to the quantity to be dispensed. In this way time is saved, and a fresh preparation always furnished.

This is a mild ferruginous solution, of very pleasant taste, and is often known as Basham's mixture. It is given in doses of two fluidrachms to one-half fluidounce (8 to 16 Cc.).

LIQUOR FERRI SUBSULPHATIS. U.S. Solution of Ferric Subsulphate

[MONSEL'S SOLUTION SOLUTION OF BASIC FERRIC SULPHATE]

An aqueous solution of variable chemical composition, containing an amount of basic ferric sulphate corresponding to not less than 13.57 percent. of metallic iron.

	Metric	Old form
* **Ferrous Sulphate,** in clear crystals	675 Gm.	16 oz. av. 628 gr.
Sulphuric Acid	65 Gm.	7 fl. dr.
Nitric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	1000 Gm.	1 pint

Add the Sulphuric Acid to 500 Cc. [old form 7 fl oz.] of Distilled Water in a capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add 70 Gm. [old form 1 fl. oz. 100 min.] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. If, after the Ferrous Sulphate has been dissolved, the solution is of a black color, add Nitric Acid, a few drops at a time, with heating and stirring, until it no longer causes red fumes to be evolved; then boil the Solution until it assumes a ruby red color and is free from nitric acid. Lastly, add enough Distilled Water to make the product weigh 1000 Gm. [or measure, old form, 1 pint]. Filter, if necessary. Keep it in well-stoppered bottles, in a moderately warm place (not under 22° C. or 71.6° F.), protected from light.

This solution sometimes crystallizes, forming a semisolid, whitish mass. When this occurs, the application of a gentle heat to the bottle will restore the liquid condition.

NOTE.—Solution of Ferric Subsulphate is to be dispensed when Solution of Persulphate of Iron has been prescribed by the physician.

When ferrous sulphate is added to a hot mixture of nitric and sulphuric acids, a copious evolution of reddish-yellow vapors of nitrogen tetroxide takes place, and the iron assumes a blackish tint, due to the formation of a compound of the ferrous sulphate with the nitric oxide. This black color disappears under the influence of heat, and, when effervescence ceases, the dark reddish-brown liquid is left which is widely known as *Monsel's Solution.*

Official Description.—A dark reddish-brown liquid.

Odor, Taste, and Reaction.—Odorless or nearly so; acid, strongly styptic taste; acid reaction.

Specific Gravity.—About 1.548 at 25° C. (77° F.).

Solubility.—*Water.* Miscible in all proportions, without decomposition.

Alcohol. Miscible in all proportions, without decomposition.

Tests for Identity.—The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S.

On slowly mixing 2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, a semi-solid white mass should separate on standing (difference from *tersulphate*).

Impurities and Tests for Impurities.—*Nitric acid.* On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution (about 1 in 10), the crystal should not become brown, nor should a brownish-black color develop around it.

Ferrous salt. If to a diluted portion of the Solution (1 in 20), a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced; it should not at once turn green or greenish-blue.

Quantitative Test.—If 10 Gm. of the Solution be diluted to measure 100 Cc., and 11.1 Cc. of this be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at the temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require not less than 27.2 (27.15) Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron).

Uses.—This preparation is probably the most valuable official styptic solution. It is less irritating than the solution of ferric sulphate, owing to the smaller proportion of sulphuric acid. It is used externally in stopping hemorrhages, and internally in doses of three to six minims (0.2 to 0.4 Cc.), largely diluted with water.

LIQUOR FERRI TERSULPHATIS. U. S. Solution of Ferric Sulphate

An aqueous solution, which should contain about 36 percent. of normal Ferric Sulphate [$Fe_2(SO_2.O_2)_3 = 397.05$], corresponding to not less than 10 percent. of metallic iron.

	Metric	Old form
* **Ferrous Sulphate,** in clear crystals	500 Gm.	11 oz. av. 418 gr.
Sulphuric Acid	96 Gm.	1 fl. oz. 103 min.
Nitric Acid,		
Distilled Water, each, a sufficient quantity,		
To make	1000 Gm.	1 pint

Add the Sulphuric Acid to about 250 Cc. [old form 3¾ fl. oz.] of Distilled Water in a capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add 56 Gm. [old form 7 fl. dr.] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the Ferrous Sulphate is dissolved, if the solution has acquired a black color, add Nitric Acid, a few drops at a time, heating and stirring until it no longer causes red fumes to be evolved, and the Solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid. Lastly, add enough Distilled Water to make the product weigh 1000 Gm. [or measure, old form, 1 pint]. Filter, if necessary.

This solution differs from the solution of ferric subsulphate merely in containing a larger proportion of sulphuric acid. It has the sp. gr. 1.432, and is a solution of the *true* persulphate $Fe_2(SO_4)_3$, or normal ferric sulphate. The strength of this solution was increased in the U. S. P. (8th Rev.). The U. S. P. 1890 contained an amount of metallic iron corresponding to 8 percent.; the present Pharmacopœia contains 10 percent. Solution of persulphate of iron is the name under which Monsel's solution is erroneously prescribed. The latter is a solution of a subsalt, $Fe_4O(SO_4)_5$. The reaction for solution of ferric sulphate is as follows:

$$\underset{\substack{\text{Ferrous}\\\text{Sulphate}}}{6FeSO_4} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{3H_2SO_4} + \underset{\substack{\text{Nitric}\\\text{Acid}}}{2HNO_3} = \underset{\substack{\text{Ferric}\\\text{Sulphate}}}{3Fe_23SO_4} + \underset{\substack{\text{Nitrogen}\\\text{Dioxide}}}{2NO} + \underset{\text{Water}}{4H_2O}$$

Official Description.—A dark reddish-brown liquid.

Odor, Taste, and Reaction.—Almost odorless; acid, strongly styptic taste; acid reaction.

Specific Gravity.—From 1.430 to 1.450 at 25° C. (77° F.).

Solubility.—Miscible with water and alcohol, in all proportions, without decomposition.

Tests for Identity.—The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S.

On slowly mixing 2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, no solid white mass should separate on standing (difference from *subsulphate*).

Impurities and Tests for Impurities.—*Nitric acid.* On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution (about 1 in 10), the crystal should not become brown, nor should a brownish-black color develop around it.

Ferrous salt. If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue.

Quantitative Test.—If 1.11 Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require not less than 20 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron).

Uses.—This solution is largely used in pharmacy for preparing ferric hydroxide by precipitation with ammonia water. From this many of the iron salts and solutions are made. It is not used medicinally to any extent, the solution of the subsulphate being preferred.

Chromium. Cr; 51.7

Chromium occurs in nature as chrome-iron ore, deposits of which are found in Southeastern Pennsylvania. This metal is brittle, of a grayish-white color, and very hard, being capable of scratching glass. It forms five compounds with oxygen: 1. Monoxide, or *Chromous oxide*, CrO. 2. *Trichromic tetroxide*, Cr_3O_4. 3. Sesquioxide, or *chromic oxide*, Cr_2O_3. 4. Dioxide, CrO_2. 5. *Chromium trioxide*, CrO_3. The latter alone and its salts are of pharmaceutical interest.

Tests for Chromium Salts

1. Ammonium sulphide precipitates from solutions of chromium salts a greenish precipitate of chromic hydroxide.

2. Sodium or potassium hydroxide also produces a precipitate of chromic hydroxide, soluble in excess.

3. Soluble lead salts produce yellow precipitates of lead chromate (chrome yellow).

Official Salts containing Chromium

Official Name	Preparation
Chromii Trioxidum	Made by decomposing potassium dichromate with sulphuric acid
Potassii Dichromas	Made by removing one-half of the potassium from potassium chromate with sulphuric acid, evaporating and crystallizing (see page 524)

Unofficial Salts of Chromium

Chromii Bromidum, Cr_2Br_6 Chromium Bromide	By passing bromine vapor over an ignited mixture of chromic oxide with charcoal and starch paste
Chromii Dichloridum, $CrCl_2$ Chromium Dichloride	By passing dry chlorine gas over a red-hot mixture of charcoal and chromic oxide
Chromii Fluoridum, Cr_2Fl_6 Chromium Fluoride	By treating chromic oxide, dried, but not ignited, with excess of hydrofluoric acid, and heating the dried mass very strongly in a platinum crucible
Chromii Iodidum, Cr_2I_6 Chromium Iodide	By treating silver chromate with hydriodic acid and alcohol
Chromii Sulphas, $Cr_2(SO_4)_3 + 5H_2O$ Chromium Sulphate (Green)	By dissolving chromic oxide in strong sulphuric acid at a temperature between 50° and 60° C.

CHROMII TRIOXIDUM. U.S. Chromium Trioxide

CrO_3 = 99.34

[Acidum Chromicum, Pharm. 1890 Chromic Acid Chromic Anhydride]

It should contain not less than 90 percent. of pure Chromium Trioxide (chromic acid anhydride). It should be kept in glass-stoppered bottles, and great caution should be observed to avoid bringing it in contact with organic substances, such as cork, tannic acid, sugar, alcohol, collodion, etc., as serious accidents are liable to result.

Preparation.—Chromium trioxide, or, as it is usually called, chromic acid, is readily obtained by mixing one hundred measures of a cold saturated solution of potassium dichromate with one hundred and fifty measures of sulphuric acid, and allowing the mixture to cool. The sulphuric acid unites with the potassium, and sets free the chromium trioxide, which is deposited in crystals. The mother liquor having been poured off, these are transferred to a glass funnel, and the mother liquor displaced by nitric acid; they are then placed upon a tile or a clean, dry pressed brick to drain, covered with a glass bell jar.

$$\underset{\substack{\text{Potassium}\\\text{Dichromate}}}{K_2Cr_2O_7} + \underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} = \underset{\substack{\text{Chromium}\\\text{Trioxide}}}{2CrO_3} + \underset{\substack{\text{Acid Potassium}\\\text{Sulphate}}}{2KHSO_4} + \underset{\text{Water}}{H_2O}$$

Official Description.—Small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic lustre; destructive to animal and vegetable tissues; deliquescent in moist air.

Odor.—Odorless.

Solubility.—*Water.* Very soluble, forming an orange-red solution.

Other solvents. When brought in contact with alcohol, ether, glycerin, and other organic solvents, decomposition takes place, sometimes with dangerous violence.

Tests for Identity.—When Chromium Trioxide is heated, its color darkens, and finally becomes black, but it is restored on cooling. At 192° to 193° C. (377.6° to 379.4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating, leaves a residue of pure chromic oxide, which should yield nothing soluble in water.

When warmed with hydrochloric acid, chlorine is evolved.

Impurity and Test.—*Sulphuric acid.* A solution of 1 Gm. of Chromium Trioxide in 100 Cc. of water, previously acidulated with a few Cc. of hydrochloric acid, should not be rendered turbid on the addition of 1 Cc. of barium chloride T.S.

Quantitative Test.—If 1 Gm. of Chromium Trioxide be dissolved in 100 Cc. of water, then 8.3 Cc. (8.28 Cc.) of this solution, when measured into a glass-stoppered bottle (of about 200 Cc. capacity), mixed with 2 Cc. of hydrochloric acid and about 1 Gm. of potassium iodide, after securely closing and shaking for a few minutes, should require, after diluting with 100 Cc. of water and adding 5 Cc. of starch T.S., not less than 22.5 Cc. of tenth-normal sodium thiosulphate V.S. to change the deep blue color to a light green (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 4 percent. of pure Chromium Trioxide).

Uses.—Chromium trioxide is a powerful caustic and antiseptic; it parts with its combined oxygen with great facility. It is a very effective caustic in destroying warty growths. It is not used internally.

POTASSII DICHROMAS. U.S. Potassium Dichromate

For a description of this official chromium salt, see page 524.

CHAPTER XLV

NICKEL, COBALT, AND TIN

Ni ; 58.3. Co ; 58.56. Sn ; 118.1

None of these metals nor any of their compounds are considered of sufficient medicinal importance to give them a place in the U. S. Pharmacopœia. Their salts are sometimes used medicinally, and several are among the official reagents. Two of the metals, nickel and tin, are important in many respects, particularly in the arts.

Nickel. Ni ; 58.3

This metal is found in magnetic pyrites in Pennsylvania ; also as arsenic or *kupfernickel* in Germany and Sweden, and as a silicate in New Caledonia. Its specific gravity is 8.9. It is a white, malleable metal, and forms with copper a valuable alloy, known as German silver. This alloy is also used for making coins. Salts of nickel are very largely employed in electroplating, and some of them have come into use as medicines ; the Latin name of the metal is *Niccolum.*

Tests for Compounds of Nickel

1. Ammonium sulphide produces with a solution of a nickel salt a black precipitate (sulphide), insoluble in diluted hydrochloric acid, but soluble in hot nitric acid.

2. Potassium or sodium hydroxide produces with nickel salts pale green precipitates of hydroxide insoluble in an excess.

3. Potassium cyanide produces a green precipitate with a solution of a nickel salt, soluble in an excess, but reprecipitated by hydrochloric acid.

Unofficial Salts of Nickel

Niccoli Bromidum, $NiBr_2$ Nickel Bromide	By dissolving nickel carbonate in hydrobromic acid, concentrating, then crystallizing
Niccoli Carbonas, $NiCO_3$ Nickel Carbonate	By heating nickel chloride with an alkaline carbonate in sealed tubes and collecting the powder
Niccoli Chloridum, $NiCl_2$ Nickel Chloride	By heating nickel filings to low redness in a stream of chlorine
Niccoli Cyanidum, $Ni(CN)_2$ Nickel Cyanide	By adding to a solution of potassium cyanide a solution of any nickel salt in slight excess and collecting the precipitate
Niccoli Sulphas, $NiSO_4+7H_2O$ Nickel Sulphate	By dissolving pure nickel carbonate in diluted sulphuric acid, concentrating the solution, then crystallizing

Cobalt. Co ; 58.56

This metal is usually found associated with arsenical ores. It is white, tough, and brittle, unalterable in the air, and strongly magnetic. Sp. gr. 8.5. It forms two classes of salts, cobaltous and cobaltic, in this respect resembling iron. The native ore *skutterudite*, $CoAs_3$, and other cobalt minerals containing arsenic, are often sold in commerce under the name of *flystone*. It is used as a fly-poison by breaking it into small fragments and mixing them with sweetened water. The *chloride* and *sulphocyanate* have been used to make *ba-*

rometer paper, by dipping ordinary white paper into a solution and drying it; when dry the color is blue, but an increase of moisture in the air changes the color to pink. Salts of cobalt are used to give glass a blue color.

Cobalt forms no official salts, and none of the unofficial salts are of pharmaceutical interest.

Tests for Salts of Cobalt

1. Ammonium sulphide produces in a solution of a cobaltous salt a black precipitate (sulphide), insoluble in diluted hydrochloric acid.

2. Solution of potassium hydroxide produces with a solution of a cobaltous salt a blue precipitate, changing by heat first to a violet and subsequently to a red color.

3. Potassium cyanide produces a yellowish-brown precipitate, soluble in an excess; the clear solution after being boiled does not afford a precipitate with hydrochloric acid (difference from nickel salts).

Tin. Sn; 118.1

The sulphide and oxide are the forms in which tin is usually found. Tin is a valuable white metal, of a silvery color, which, when bent, emits a peculiar crackling sound, termed the "cry of tin." Its specific gravity is 7.25. It forms two classes of compounds, called *stannous* and *stannic* salts. These are not used to any extent in medicine or pharmacy, but are of great importance in the arts.

Tests for Compounds of Tin

1. Potassium or sodium hydroxide produces in a solution of a salt of tin a white precipitate (hydroxide), soluble in an excess.

2. Ammonia water produces a white precipitate (hydroxide) with a solution of a stannous salt, nearly insoluble in an excess. The same reagent with a stannic salt produces a similar white precipitate (hydroxide), slightly soluble in an excess.

3. Ammonia sulphide produces in solutions of stannous salts a brownish-black precipitate, soluble in an excess (if an excess of sulphur be present in the reagent). The yellow sulphide is precipitated from this solution on the addition of an acid. Ammonium sulphide with stannic salts produces a yellow precipitate, soluble in an excess.

4. Mercuric chloride in contact with stannous salts is reduced to mercurous chloride or metallic mercury; no change occurs when it is added to stannic salts.

Unofficial Salts of Tin

Stanni Chloridum, $SnCl_2 + 2H_2O$ Stannous Chloride (tin salt)	By dissolving tin in hot hydrochloric acid
Stanni Sulphidum, SnS Stannous Sulphide	By passing hydrogen sulphide gas into a solution of stannic chloride
Sodii Stannas, Na_2SnO_3 Sodium Stannate	By boiling tin ore with solution of sodium hydroxide
Acidum Stannicum, $SnO_2 + 2H_2O$ Stannic Acid	By precipitating a solution of an alkaline stannate with an acid
Acidum Metastannicum, $5SnO_2 + 10H_2O$ Metastannic Acid	By acting on tin with nitric acid

CHAPTER XLVI

LEAD, COPPER, SILVER, AND MERCURY

Pb; 205.35. Cu; 63.1. Ag; 107.12. Hg; 198.5

THIS group embraces four well known metals, which furnish compounds of great value as medicines. They are allied to one another chemically, although they differ greatly in their physical properties.

Lead. Pb; 205.35

Lead is obtained from the native sulphide, *galena*, by roasting in a reverberatory furnace. It is often associated with silver. It is a heavy, soft, bluish metal, with a specific gravity of 11.37. Lead forms five compounds with oxygen: 1. Suboxide, Pb_2O. 2. Monoxide, PbO. 3. Sesquioxide, Pb_2O_3. 4. Dioxide, PbO_2. 5. Triplumbic tetroxide, Pb_3O_4.

Tests for Compounds of Lead

1. Hydrogen sulphide or ammonium sulphide precipitates the insoluble black sulphide from salts of lead.
2. Sulphuric acid or a sulphate causes the precipitation of the white sulphate, insoluble in nitric acid.
3. The alkaline carbonates (sodium, potassium, and ammonium) precipitate lead carbonate, insoluble in an excess.

Poisonous Properties of Lead and its Compounds

Pure water dissolves appreciable quantities of lead through the formation of a slightly soluble hydroxide or carbonate. If traces of sulphates or chlorides be present in the water, an insoluble coating is formed on the surface of the metal, which protects it from further decomposition. Lead pipes and lead tanks for containing drinking water should be used with care (see U. S. Dispensatory, 18th edition, page 1059).

Official Salts and Preparations of Lead

Official Name	Preparation
Plumbi Acetas	Made by treating lead oxide with acetic acid, evaporating, and crystallizing
Liquor Plumbi Subacetatis	By boiling aqueous solution of lead acetate with lead oxide
Plumbi Subacetatis Dilutus	By diluting 40 Gm. of solution of lead subacetate with 960 Gm. of distilled water
Ceratum Plumbi Subacetatis	By mixing 20 Gm. of solution of lead subacetate, 20 Gm. of wool-fat, 20 Gm. of paraffin, 38 Gm. of white petrolatum, and 2 Gm. of camphor
Plumbi Iodidum	By double decomposition between lead nitrate and potassium iodide
Nitras	By treating lead oxide with diluted nitric acid, evaporating, and crystallizing
Oxidum	By roasting lead ore in reverberatory furnaces
Unguentum Diachylon	By diluting lead plaster with olive oil and adding a little oil of lavender
Emplastrum Plumbi	By mixing solutions of castile soap and lead acetate, collecting and washing precipitate

Unofficial Salts and Preparations of Lead

Plumbi Bromidum, $PbBr_2$ Lead Bromide	By making separate solutions of lead acetate and potassium bromide, mixing them, and collecting the precipitate
Plumbi Carbonas, $(PbCo_3)_2Pb(OH)_2$ Lead Carbonate	By acting on metallic lead with fumes of acetic acid and decaying matter
Plumbi Chloridum, $PbCl_2$ Lead Chloride	By dissolving lead acetate in water and adding hydrochloric acid, then collecting the precipitate
Plumbi Chloris, $Pb(ClO_2)_2$ Lead Chlorite	By making separate solutions of lead nitrate and neutral calcium chlorite, mixing them, and collecting the precipitate
Plumbi Chromas, $PbCrO_4$ Lead Chromate	By making separate solutions of lead nitrate and potassium dichromate, mixing them, and collecting the precipitate
Plumbi Dioxidum, PbO_2 Lead Dioxide	By treating red lead with diluted nitric acid and collecting the insoluble powder
Plumbi Hydroxidum Lead Hydroxide	By mixing solutions of lead acetate and sodium hydroxide and collecting the precipitate
Plumbi Oxidum Rubrum, Pb_3O_4 Red Lead Oxide	By heating massicot to near 450° C. (840° F.); it gradually combines with the oxygen of the air, which converts it into red lead
Plumbi Saccharas Lead Saccharate	By saturating a solution of saccharic acid in water with freshly precipitated lead carbonate gradually added
Plumbi Sulphas, $PbSO_4$ Lead Sulphate	By dissolving lead nitrate in water and adding sulphuric acid, then collecting the precipitate
Plumbi Tannas Lead Tannate	By adding a solution of tannin to one of lead acetate and collecting the precipitate

PLUMBI ACETAS. U.S. Lead Acetate

$$Pb(C_2H_3O_2)_2 + 3H_2O = 376.15$$

[SUGAR OF LEAD]

It should contain not less than 99.5 percent. of pure Lead Acetate $[(CH_3.COO)_2Pb + 3H_2O]$, and should be kept in well-stoppered bottles.

Preparation.—This important salt is made by adding lead oxide to acetic acid and gently heating the mixture until combination takes place.

$$\underset{\text{Lead Oxide}}{PbO} + \underset{\text{Acetic Acid}}{2HC_2H_3O_2} = \underset{\text{Lead Acetate}}{Pb(C_2H_3O_2)_2} + \underset{\text{Water}}{H_2O}$$

The commercial salt is unfit for pharmaceutical uses; it is not expected to be pure, and usually contains both carbonate and oxide. The official salt is thus described:

Official Description.—Colorless, shining, transparent, monoclinic prisms or plates, or heavy, white, crystalline masses, or granular crystals. Efflorescent, and absorbing carbon dioxide on exposure to the air.

Odor, Taste, and Reaction.—Faintly acetous odor; sweetish, astringent, afterwards metallic taste; neutral or slightly alkaline reaction.

Solubility.—*Water.* In 2 parts at 25° C. (77° F.); in 0.5 part of boiling water.

Alcohol. In 30 parts at 25° C. (77° F.); in 1 part of boiling alcohol.

Tests for Identity.—When heated to 40° C. (104° F.), the salt loses its water of crystallization (14.26 percent.). When heated rapidly to 75° C. (167° F.) it fuses in its water of crystallization, and at a higher temperature is converted into a pulverulent basic salt which fuses at about 280° C. (536° F.) with continued loss of acetic acid, finally decomposing with the evolution of carbon dioxide and acetone, leaving a residue of finely divided metallic lead mixed with oxide and carbonate.

On heating the salt with sulphuric acid, vapors of acetic acid are evolved.

The aqueous solution of Lead Acetate has a neutral or slightly alkaline reaction, and yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid.

Impurities and Tests for Impurities.—*Limit of carbonate.* A solution of the salt (1 in 10), prepared with water which has been recently boiled, should be clear, or only slightly opalescent.

Iron and copper. The above solution should yield, with potassium ferrocyanide T.S., a pure white precipitate.

Limit of zinc and iron. If to the aqueous solution of the salt (1 in 10), hydrochloric acid be added until no further precipitate is produced, the remainder of the lead removed from the filtrate by hydrogen sulphide, and the liquid filtered, a portion of the second filtrate should not, upon the addition of ammonia water, yield more than a slight precipitate.

Limit of salts of the alkali metals, and those of magnesium, calcium, zinc and iron. If another portion of the filtrate be evaporated to dryness, it should not leave more than a slight residue after gentle ignition.

Uses.—Lead acetate is a valuable astringent and sedative; it is used both internally and externally. The dose is from one to three grains (0.065 to 0.2 Gm.). Its solution in water is turbid, due to the formation of a trace of carbonate through the carbonic acid present in the water; diluted acetic acid dissolves this precipitate.

LIQUOR PLUMBI SUBACETATIS. U.S. Solution of Lead Subacetate

[GOULARD'S EXTRACT]

An aqueous liquid, which should contain in solution not less than 25 percent of Lead Subacetate [approximately $Pb_2O(CH_3.COO)_2 = 543.74$].

	Metric	Old form
* **Lead Acetate**	180 Gm.	3 oz. av. 313 gr.
Lead Oxide	110 Gm.	2 oz. av. 18 gr.
Distilled Water, a sufficient quantity,		
To make	1000 Gm.	1 pint

To the finely powdered Lead Oxide contained in a porcelain dish, of about 1000 Cc. [old form 2 pints] capacity, add slowly and in portions, with constant stirring, the Lead Acetate which has been previously dissolved in 700 Cc. [old form 11½ fl. oz.] of boiling Distilled Water, and boil the liquid for half an hour, with occasional stirring. Finally, when cool, filter the Solution, and add sufficient Distilled Water, which has been previously boiled and cooled, to make the finished product weigh 1000 Gm. [or measure, old form, 1 pint]. Keep the Solution in well-stoppered bottles.

The object of this process is to furnish a concentrated solution of a lead compound containing a small proportion of acetic acid. The "subacetate" is not a definite salt, but as found in the official solution it is a mixture of oxyacetates, produced by boiling the normal acetate in water in contact with the oxide.

$$\underset{\text{Lead Oxide}}{3PbO} + \underset{\text{Lead Acetate}}{3Pb(C_2H_3O_2)_2} = \underbrace{Pb_3O(C_2H_3O_2)_4 + Pb_3O_2(C_2H_3O_2)_2}_{\text{Lead Oxyacetates}}$$

Official Description.—A clear, colorless liquid. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate.

Odor, Taste, and Reaction.—Odorless; sweetish, astringent taste; alkaline reaction.

Specific Gravity.—About 1.235 at 25° C. (77° F.).

Tests for Identity.—When Solution of Lead Subacetate is added to a solution of acacia, it produces a dense, white precipitate (distinction from *normal lead acetate*).

In other respects the Solution conforms to the reactions and tests for an aqueous solution of lead acetate given under *Plumbi Acetas*.

Quantitative Test.—If 10 Gm. of the Solution be diluted with distilled water, which has been previously boiled and cooled, to measure 100 Cc., and 13.6 (13.594) Cc. of this be added to 35 Cc. of tenth-normal oxalic acid V.S., contained in a graduated cylinder, and, after thoroughly shaking, the mixture be diluted with distilled water to measure 50 Cc., and again well shaken, then, after the precipitate has settled, 10 Cc. of the clear solution, after diluting with about 50 Cc. of water and adding 5 Cc. of sulphuric acid, should require not more than 2 Cc. of tenth-normal potassium permanganate V.S. to produce a permanent pink tint (each Cc. of tenth-normal oxalic acid V.S. required for the precipitation of the 13.6 Cc. of the diluted Solution, corresponding to 1 percent. of Lead Subacetate).

Uses.—This solution, which is frequently termed *Goulard's Extract*, is sedative and astringent; it is employed externally as an application to inflamed surfaces.

LIQUOR PLUMBI SUBACETATIS DILUTUS. U.S. Diluted Solution of Lead Subacetate

[LEAD WATER]

An aqueous liquid, which should contain about 1 percent. of Lead Subacetate.

	Metric	Old form
* **Solution of Lead Subacetate**	**40 Gm.**	1 fl. oz. 20 min.
Distilled Water, a sufficient quantity,		
To make	**1000 Gm.**	2 pints

Mix the Solution of Lead Subacetate with enough Distilled Water, previously boiled and cooled, to make the product weigh 1000 Gm. [old form 2 pints]. Keep the Solution in well-stoppered bottles.

This solution will be opalescent, through the formation of a trace of carbonate, if the distilled water used has not been recently boiled and cooled, the object of which is to deprive the water of carbonic acid gas. The addition of a few drops of acetic acid clears the solution by dissolving the precipitate; but, as many serious errors have occurred through the internal use by patients of *lead* water in mistake for *lime* water, it is a good practice to dispense lead water in a slightly opalescent condition and lime water always as a transparent liquid, and, as an additional safeguard, to use blue poison bottles for the lead water.

Uses.—Lead water is used as a soothing application to inflamed surfaces.

CERATUM PLUMBI SUBACETATIS. U.S. Cerate of Lead Subacetate

[GOULARD'S CERATE]

This cerate is made by mixing 20 Gm. of solution of lead subacetate with 20 Gm. of melted wool-fat, and then adding 38 Gm. of white petrolatum and 20 Gm. of paraffin melted together, and in which 2 Gm. of camphor has been dissolved, mix the whole thoroughly as it cools. It possesses the sedative and astringent properties of the lead solution. It may be prevented from assuming a yellow color by the addition of a trace of acetic acid. (See Part V.)

PLUMBI IODIDUM. U.S. Lead Iodide

$PbI_2 = 457.15$

It should contain not less than 99 percent. of pure Lead Iodide, and should be kept in well-stoppered bottles, protected from light.

Preparation.—This Iodide may be made by a formerly official British process:

Take of Nitrate of Lead, Iodide of Potassium, each, 4 oz. av.; Distilled Water, a sufficiency. Dissolve the Nitrate of Lead, by the aid of heat, in a pint and a half, and the Iodide of Potassium in half a pint, of the Water, and mix the solutions. Collect the precipitate on a filter, wash it with Distilled Water, and dry it at a gentle heat.

This is an instance of double decomposition, lead iodide and potassium nitrate being formed. The nitrate is preferred to the acetate, because lead iodide is more soluble in solution of potassium acetate than in that of potassium nitrate.

$$\underset{\text{Potassium Iodide}}{2KI} + \underset{\text{Lead Nitrate}}{Pb2NO_3} = \underset{\text{Lead Iodide}}{PbI_2} + \underset{\text{Potassium Nitrate}}{2KNO_3}$$

Official Description.—A heavy, bright yellow powder; permanent in the air.
Odor and Taste.—Odorless and tasteless.
Solubility.—*Water.* In about 1300 parts at 25° C. (77° F.), and in about 200 parts of boiling water, separating from the latter solution on cooling in brilliant, golden-yellow crystalline laminæ.
Alcohol. Very slightly soluble.
Other solvents. Soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the alkali acetates, of potassium iodide, and of sodium thiosulphate, and in a hot solution of ammonium chloride.
Test for Identity.—When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide.
Impurities and Tests for Impurities.—*Chromate and other insoluble foreign salts.* If 1 Gm. of the salt be triturated with 2 Gm. of ammonium chloride and 2 Cc. of water, a nearly white mixture will result. If this be transferred to a test-tube, and heated in a water-bath for a few minutes, a clear and almost colorless solution should be formed. On cooling this solution, a solid mass of nearly colorless, fine, silky crystals will be produced, and on adding water or diluted sulphuric acid to this mass, yellow Lead Iodide will separate.
Limit of nitrate. Add 0.1 Gm. of the salt to 5 Cc. of water, and heat the mixture until it boils; cool the liquid and filter it into a test-tube of about 40 Cc. capacity, then add 5 Cc. of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire, insert in the upper portion of the test-tube a pledget of purified cotton, and over the mouth, place a piece of moistened red litmus paper; then if the tube be heated on a water-bath for fifteen minutes, no blue coloration of the paper should be discernible.
Acetate. If 1 Gm. of Lead Iodide be boiled for a few minutes with 20 Cc. of water, the mixture then cooled and filtered, and the lead removed from the filtrate by hydrogen sulphide, a portion of the second filtrate, after boiling to drive off hydrogen sulphide and carefully neutralizing with ammonia water, should not be colored red by a drop of ferric chloride T.S.
Soluble foreign salts. Another portion of this filtrate, if evaporated to dryness, should leave no residue.

Uses.—Lead iodide may be given internally in doses of one to three grains (0.065 to 0.2 Gm.). It is principally used externally in the form of a 10 percent. ointment.

PLUMBI NITRAS. U.S. Lead Nitrate

$Pb(NO_3)_2 = 328.49$

It should contain not less than 99.5 percent. of pure Lead Nitrate [$(NO_2.O)_2Pb$], and should be kept in well-closed vessels.

Preparation.—This salt may be easily made by adding lead oxide to equal parts of nitric acid and water, heating the mixture until solution is effected, and, after filtering, evaporating the solution of lead nitrate and crystallizing.

Official Description.—Colorless, transparent, octahedral crystals, when obtained by the spontaneous evaporation of cold solutions, or white, nearly opaque crystals, when formed by the cooling of hot solutions; permanent in the air.
Odor, Taste, and Reaction.—Odorless; sweetish, astringent, afterwards metallic taste; acid reaction.
Solubility.—*Water.* In 1.85 parts at 25° C. (77° F.); in 0.75 part of boiling water.
Alcohol. Almost insoluble.
Tests for Identity.—When strongly heated, the salt decrepitates, emits nitrous vapors, and finally leaves a residue of lead oxide.
It yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid.

Impurities and Tests for Impurities.—*Copper and iron.* The aqueous solution of the salt (1 in 10) should give, with potassium ferrocyanide T.S., a pure white precipitate.

Limit of zinc and iron. If hydrochloric acid be added to the aqueous solution of the salt (1 in 10) until no further precipitate is produced, and the remainder of the lead be removed from the filtrate by hydrogen sulphide, a portion of the second filtrate should not yield more than a slight precipitate upon the addition of ammonia water.

Limit of salts of the alkalies and those of magnesium, calcium, zinc, and iron. Another portion of this filtrate, when evaporated to dryness, should not leave more than a slight residue after gentle ignition.

Uses.—Lead nitrate is used in solution principally as an external application to excoriated surfaces.

PLUMBI OXIDUM. U.S. Lead Oxide

$PbO = 221.23$

[LITHARGE]

It should contain not less than 96 percent. of pure Lead Oxide, and should be kept in well-closed vessels.

Preparation.—Litharge is lead oxide which has been rendered semicrystalline by incomplete fusion. Almost all the litharge of commerce is obtained as a secondary product in the process for extracting silver from argentiferous galenas. After extracting the lead from the ore, the alloy is calcined in the open air, whereby the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains unchanged.

Red lead is a higher oxide, Pb_3O_4; 683.04, and is made by sprinkling hot litharge with water, powdering and drying it, and then heating it out of contact with air. Litharge is officially described as follows:

Official Description.—A heavy, yellowish or reddish-yellow powder, or minute scales. On exposure to the air it slowly absorbs moisture and carbon dioxide.

Odor, Taste, and Reaction.—Odorless and tasteless; faintly alkaline reaction.

Solubility.—*Water.* Almost insoluble.

Alcohol. Insoluble.

Other solvents. In acetic or diluted nitric acid and in warm solutions of the fixed alkali hydroxides.

Tests for Identity.—When heated, the Oxide assumes a brownish-red color, becoming yellow again on cooling; it fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead.

The solution in diluted nitric acid, which should be colorless, when nearly neutralized by ammonia water yields with hydrogen sulphide T.S. a black precipitate, with potassium iodide T.S. a yellow one, and with diluted sulphuric acid a white precipitate, the latter two being soluble in a strong solution of sodium hydroxide.

Impurities and Tests for Impurities.—*Limit of silicates, barium sulphate, etc.* Lead Oxide should be soluble in diluted nitric acid, with but little effervescence (limit of *carbonate*), and without the development of the odor of nitrous acid (absence of *lead*), leaving not more than a trifling residue.

Limit of copper. If from the solution in diluted nitric acid the lead be precipitated by sulphuric acid, the filtrate, after the addition of an excess of ammonia water, should not assume more than a slight bluish tint.

Limit of iron. Nor should the above solution yield more than traces of a reddish-brown precipitate

More than 4 percent. of insoluble impurities. If 5 Gm. of the Oxide contained in a small flask be shaken with 5 Cc. of water, then 20 Cc. of acetic acid added, and the mixture boiled for a few minutes and filtered, the insoluble residue, when well washed and dried, should not weigh more than 0.2 Gm.

Limit of soluble impurities. If, to the mixed filtrate and washings obtained in the last test, hydrochloric acid be added until no further precipitate be produced, the remainder of the lead removed from the filtrate by hydrogen sulphide, and the liquid filtered, the second filtrate, upon evaporation to dryness, should not yield a residue weighing more than 0.050 Gm.

Limit of carbonate and of moisture. When strongly heated in a porcelain crucible, the Oxide should not lose more than 4 percent. of its weight.

Uses.—Lead Oxide is used by manufacturers in making lead plaster, but in the U. S. P. (8th Rev.) the process of making lead plaster was changed (see below).

EMPLASTRUM PLUMBI. U. S. Lead Plaster

[Diachylon Plaster]

This compound of lead is now officially made by adding a solution of lead acetate to a solution of castile soap, whereby lead oleo-palmitate is precipitated and sodium acetate remains in solution. The precipitate is thoroughly washed, by kneading with warm water, and formed into cylindrical rolls. (See Part V.)

The official process in the U. S. P. 1890, and which has long been in use, consists of boiling lead oxide with olive oil and water, whereby the lead enters into combination with the fatty acids of the oil. (See Glycerinum.) It is used as the basis of many plasters.

UNGUENTUM DIACHYLON. U.S. Diachylon Ointment

This ointment is simply lead plaster diluted with olive oil to the consistence of an ointment and slightly perfumed with oil of lavender flowers. (See Unguenta.) It is used externally in several skin diseases.

Copper. Cu ; 63.1

Copper is found naturally in its metallic condition, also as a sulphide or oxide, and as a sulphate, carbonate, phosphate, or arsenate. It is a brilliant metal, of a red color, having a specific gravity of 8.92 to 8.95. It forms two oxides : 1. Red cuprous oxide, Cu_2O. 2. Black cupric oxide, CuO.

Tests for Compounds of Copper

1. Hydrogen sulphide or ammonium sulphide produces a black precipitate of cupric sulphide.
2. Ammonia water produces in concentrated solutions of copper salts a pale blue precipitate of cupric hydroxide, in dilute solutions a deep blue coloration.
3. Potassium ferrocyanide produces a reddish-brown precipitate of cupric ferrocyanide.
4. A bright surface of metallic iron or zinc immersed in an acidulated solution of a copper salt is coated with metallic copper.
5. Copper salts color the flame of an alcohol lamp or Bunsen burner green.

Official Salt of Copper

Official Name	Preparation
Cupri Sulphas	By treating copper with diluted sulphuric acid, evaporating the solution, and crystallizing

Unofficial Salts of Copper

Cupri Acetas, $Cu(C_2H_3O_2)_2 + H_2O$ Copper Acetate	By treating copper with acetic acid and purifying the product by crystallization
Cupri Arsenas, $Cu_3As_2O_8 + 4H_2O$ Copper Arsenate	By adding a solution of copper sulphate to a solution of disodic arsenate, and collecting and drying the precipitate
Cupri Bromidum, $CuBr_2$ Copper Bromide	By evaporating a solution of cupric oxide in aqueous hydrobromic acid, and fusing the residue at a gentle heat

Unofficial Salts of Copper—*Continued*

Cupri Citras Copper Citrate	By heating a solution of cupric acetate with citric acid and setting aside to crystallize
Cupri Nitras, $Cu(NO_3)_2$ Copper Nitrate	By dissolving metallic copper in nitric acid and concentrating the solution, then crystallizing
Cupri Oxidum, CuO Copper Oxide	By continued ignition of copper in contact with air
Cupri Subacetas, $Cu(HO)_2.Cu(C_2H_3O_2)_2$ Verdigris	Made by acting on sheets of copper with acetic acid
Cupri Tartras Copper Tartrate	By adding a solution of neutral potassium tartrate to a solution of cupric sulphate and collecting the precipitate

CUPRI SULPHAS. U.S. Copper Sulphate

$$CuSO_4 + 5H_2O = 247.85$$

It should contain not less than 99.5 percent. of pure Copper Sulphate [$SO_2.O_2Cu + 5H_2O$].

Preparation.—This salt is economically made by acting on scrap copper with diluted sulphuric acid, heating, evaporating the solution, and crystallizing.

Official Description.—Large, transparent, deep blue, triclinic crystals; slowly efflorescent in dry air.

Odor, Taste, and Reaction.—Odorless; nauseous, metallic taste. The aqueous solution (1 in 20) has a blue color, and shows an acid reaction with blue litmus paper.

Solubility.—*Water.* Soluble in about 2.2 parts at 25° C. (77° F.), and in 0.5 part of boiling water.

Alcohol. In 400 parts at 25° C. (77° F.).

Other solvents. In 3.5 parts of glycerin at 25° C. (77° F.).

Tests for Identity.—When heated to 30° C. (86° F.), the salt loses 2 of its 5 molecules of water (14.43 percent.), and is converted into a pale blue, amorphous powder. Two more molecules of water are lost at 100° C. (212° F.), while the fifth is retained until 200° C. (392° F.) is reached, when a white, anhydrous powder remains (63.9 percent. of the original weight). At a still higher temperature, sulphur dioxide and oxygen are given off, and a residue of black cupric oxide is left.

If a drop of the solution be placed upon a bright piece of iron, a red film of metallic copper will be produced.

With potassium ferrocyanide T.S. the solution yields a deep reddish-brown precipitate.

Barium chloride T.S. produces in the solution a white precipitate, insoluble in hydrochloric acid.

If ammonia water be added to the solution, drop by drop, a pale blue precipitate of cupric hydroxide is formed, which redissolves in an excess of ammonia water, forming a deep azure-blue solution.

Impurities and Tests for Impurities.—*Limit of iron, aluminum, etc.* If hydrogen sulphide gas be passed through 10 Cc. of the aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, until all of the copper is precipitated as sulphide, one-half of the colorless filtrate should not be colored or rendered turbid upon the addition of ammonia water, nor should the remaining portion of the filtrate yield, upon evaporation and ignition, a weighable residue.

Heavy metals. If the aqueous solution of the salt (1 in 20) be heated to boiling with an excess of sodium hydroxide T.S., until all of the copper has been converted into black cupric oxide, it will yield a colorless filtrate, which, after acidulation with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Uses.—Copper sulphate, called commercially *blue vitriol*, is used internally as an emetic, in doses of four grains (0.25 Gm.); as an astringent or tonic, from one-fifth to one-half grain (0.01 to 0.03 Gm.) is given. It is used as an injection in gonorrhœa and other diseases, and also as a stimulant wash, and in substance as an escharotic.

Silver. Ag; 107.12

Silver is found in the metallic state, but usually as a sulphide, and associated with lead sulphide, or *galena*.

Silver is a brilliant white metal, very malleable and ductile, having a specific gravity of 10.4 to 10.5. It forms but one oxide, Ag_2O.

Tests for Silver Salts

1. Hydrochloric acid or any soluble chloride produces with a soluble salt of silver a characteristic, curdy, white precipitate of silver chloride, which is insoluble in hot nitric acid, but soluble in ammonia water.

2. Hydrogen sulphide or ammonium sulphide produces a black precipitate of silver sulphide.

3. Caustic alkalies produce a brown precipitate of silver oxide.

Official Salts and Preparations of Silver

Official Name	Preparation
Argenti Cyanidum	By passing hydrocyanic acid gas into solution of silver nitrate
Nitras	By treating metallic silver with nitric acid, evaporating the solution, and crystallizing
Nitras Fusus	By fusing and moulding silver nitrate
Nitras Mitigatus	By fusing together 30 parts of silver nitrate and 60 parts potassium nitrate
Oxidum	By precipitating solution of silver nitrate with solution of potassium hydroxide

Unofficial Salts of Silver

Argenti Acetas, $AgC_2H_3O_2$ Silver Acetate	By adding a solution of silver nitrate to a solution of sodium acetate, then collecting and drying the precipitate
Argenti Bromidum, AgBr Silver Bromide	By adding to a solution of silver nitrate a solution of potassium bromide, then collecting and drying the precipitate
Argenti Chloridum, AgCl Silver Chloride	By adding to a solution of silver nitrate hydrochloric acid as long as a precipitate is produced, then collecting and drying the precipitate
Argenti Chromas, Ag_2CrO_4 Silver Chromate	By adding a solution of neutral potassium chromate to a solution of silver nitrate, then collecting and drying the precipitate
Argenti Iodidum, AgI Silver Iodide	By double decomposition between potassium iodide and silver nitrate
Argenti Lactas, $AgC_3H_5O_3 + H_2O$ Silver Lactate	By boiling silver carbonate with lactic acid, and collecting and drying the precipitate
Argenti Oxalas, $Ag_2C_2O_4$ Silver Oxalate	By adding a solution of oxalic acid to a solution of silver nitrate, and collecting and drying the precipitate
Argenti Phosphas, Ag_3PO_4 Silver Phosphate	By adding a solution of silver nitrate to a solution of sodium phosphate, and collecting and drying the precipitate
Argenti Sulphas, Ag_2SO_4 Silver Sulphate	By adding a solution of silver nitrate to a solution of sodium sulphate, and collecting and drying the precipitate

ARGENTI CYANIDUM. U.S. *Silver Cyanide*

$AgCN = 132.96$

It should contain not less than 99.9 percent. of pure Silver Cyanide, corresponding to 80.48 percent. of metallic silver. It should be kept in dark amber-colored vials, protected from light.

Preparation.—Silver cyanide is easily prepared by passing hydrocyanic acid gas into a solution of silver nitrate, or by mixing solutions of potassium cyanide and silver nitrate.

$$\underset{\substack{\text{Silver}\\\text{Nitrate}}}{AgNO_3} + \underset{\substack{\text{Potassium}\\\text{Cyanide}}}{KCN} = \underset{\substack{\text{Silver}\\\text{Cyanide}}}{AgCN} + \underset{\substack{\text{Potassium}\\\text{Nitrate}}}{KNO_3}$$

Official Description.—A white powder, permanent in dry air, but gradually turning brown on exposure to light.

Odor and Taste.—Without odor or taste.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents. Insoluble in cold nitric acid; soluble in boiling nitric acid with evolution of hydrocyanic acid; also soluble in ammonia water, sodium thiosulphate T.S., and potassium cyanide T.S.

Quantitative Test.—When heated in a porcelain crucible the salt fuses, gives off cyanogen gas, and, on ignition, leaves a residue of metallic silver amounting to 80.48 percent of its original weight.

Uses.—This salt was made official to use in the extemporaneous preparation of hydrocyanic acid. (See Acidum Hydrocyanicum Dilutum.)

ARGENTI NITRAS. U.S. Silver Nitrate

$AgNO_3 = 168.69$

It should contain not less than 99.9 percent. of pure Silver Nitrate, and should be kept in dark amber-colored vials, protected from light.

Preparation.—This valuable salt may be made by a former official process:

Take of Silver, in small pieces, 2 oz. troy; Nitric Acid, 2½ oz. troy; Distilled Water, a sufficient quantity. Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapors cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stoppered bottle. By evaporating the mother water, more crystals may be obtained.

The silver employed is usually coin, and this always contains copper; hence, copper nitrate is present, which is known by the bluish color of the solution. By evaporating the solution and fusing the residue the copper salt is decomposed and the insoluble copper oxide produced; by solution and filtration this is separated, and the purified solution of silver nitrate is evaporated and crystallized.

$$\underset{\text{Silver}}{Ag_3} + \underset{\substack{\text{Nitric}\\\text{Acid}}}{4HNO_3} = \underset{\substack{\text{Silver}\\\text{Nitrate}}}{3AgNO_3} + \underset{\substack{\text{Nitrogen}\\\text{Monoxide}}}{NO} + \underset{\text{Water}}{2H_2O}$$

Official Description.—Colorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in the presence of organic matter.

Odor, Taste, and Reaction.—Without odor, but having a bitter, caustic, and strongly metallic taste; neutral reaction.

Solubility.—*Water.* In 0.54 part at 25° C. (77° F.); in 0.1 part of boiling water.

Alcohol. In 24 parts at 25° C. (77° F.); in 5 parts boiling Alcohol.

Tests for Identity.—When heated in a porcelain crucible to about 200° C. (392° F.), the salt melts, forming a faintly yellow liquid, which, on cooling, congeals to a pure white, crystalline mass. At a higher temperature it is gradually decomposed with evolution of nitrous vapors.

Impurities and Tests for Impurities.—*Copper.* An aqueous solution of the salt yields, with hydrochloric acid, a white precipitate, which is readily dissolved by ammonia water, the liquid not acquiring a blue color.

Lead. If 5 Cc. of an aqueous solution of the salt (1 in 10) be mixed with 20 Cc. of hot diluted sulphuric acid, and heated to boiling, no turbidity should be perceptible, and upon standing, no white precipitate should be deposited.

Limit of foreign salts. If a portion of an aqueous solution (1 in 10) be completely precipitated by hydrochloric acid, filtered, and the filtrate evaporated to dryness, not more than 0.1 per cent. of residue should remain.

Quantitative Test.—If 0.5 Gm. of Silver Nitrate, dissolved in 10 Cc. of distilled water, be well mixed with 30 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 0.4 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color.

Uses.—Silver nitrate is used externally as a caustic and escharotic; internally, it is given in gastritis and diarrhœa, in doses of one-fifth to one-half grain (0.01 to 0.03 Gm.).

ARGENTI NITRAS FUSUS. U.S. Moulded Silver Nitrate

[Fused Silver Nitrate Lunar Caustic Toughened Caustic]

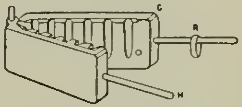
It should contain not less than 94.8 percent. of pure Silver Nitrate.

	Metric	Old form
* **Silver Nitrate**	**100 Gm.**	1 oz. av.
Hydrochloric Acid	**4 Gm.**	16 minims

To the Silver Nitrate, contained in a porcelain dish, add the Hydrochloric Acid, and melt the mixture at as low a temperature as possible. Stir well, and pour the melted mass into suitable moulds. It should be kept in dark amber-colored vials, protected from light.

When pure fused silver nitrate is cooled, the mass is very brittle, but the addition of hydrochloric acid produces sufficient silver chloride to toughen it, so that the cast cones or sticks will not break so easily. In order to keep the sticks from becoming discolored during the casting process, it is advisable to add a little diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. Fig. 445 illustrates the silver moulds used in moulding the cones.

Fig. 445



Caustic cone mould

Official Description.—A white, hard solid, generally in the form of pencils or cones of a fibrous fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter.

Odor, Taste, and Reaction.—Odorless; bitter, caustic, and strongly metallic taste; neutral reaction.

Solubility.—*Water.* Soluble, with the exception of about 5 percent. of silver chloride, in 0.54 part at 25° C. (77° F.); in 0.1 part of boiling water. The portion left undissolved by water should be completely soluble in ammonia water.

Alcohol. In 24 parts at 25° C. (77° F.); in 5 parts of boiling alcohol.

Tests for Identity.—A clear, aqueous solution of Moulded Silver Nitrate, decanted from the insoluble portion, should be neutral to litmus paper, and should respond to the tests of identity and purity stated under *Argenti Nitras.*

Quantitative Test.—If 0.5 Gm. of Moulded Silver Nitrate, dissolved as completely as possible in 10 Cc. of water, be thoroughly mixed with 30 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 1.9 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color.

Uses.—Moulded silver nitrate is used as an escharotic; a good caustic holder may be made from a glass stirring rod of the same diameter as the cone by joining it to the cone with a short length of rubber tubing. The cone may be protected from the action of the air by slipping over it another short length of rubber tubing, having a very short piece of glass rod in the other end as a stopper.

Death has resulted more than once through the careless use of silver nitrate in cauterizing the throat, the cone having slipped out of the fingers and then been swallowed by the patient.

ARGENTI NITRAS MITIGATUS. U.S. Mitigated Silver Nitrate

[ARGENTI NITRAS DILUTUS, PHARM. 1890 DILUTED SILVER NITRATE MITIGATED CAUSTIC]

It should contain not less than 33.3 percent. of pure Silver Nitrate.

	Metric	Old form
* **Silver Nitrate**	**30 Gm.**	1 oz. av.
Potassium Nitrate	**60 Gm.**	2 oz. av.

Melt the salts together in a porcelain crucible, at as low a temperature as possible, stirring the melted mass well until it flows smoothly. Then pour it into suitable moulds. It should be kept in dark amber-colored vials, protected from light.

Official Description.—A white, hard solid, generally in the form of pencils or cones of a finely granular fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter.

Odor, Taste, and Reaction.—Odorless; caustic, metallic taste; neutral reaction.

Solubility.—Each of its constituents retains the solubility in water and in alcohol stated respectively under *Argenti Nitras* and *Potassii Nitras*.

Tests for Identity.—An aqueous solution of Mitigated Silver Nitrate yields with a slight excess of hydrochloric acid a white precipitate, which is readily soluble in ammonia water. The filtrate from this precipitate, when evaporated to dryness, yields a white residue which is completely soluble in water, and this solution, when concentrated, affords a white, crystalline precipitate with sodium bitartrate T.S.

If 1 drop of diphenylamine T.S. be mixed with 5 Cc. of an aqueous solution of the salt in a test-tube, and sulphuric acid be carefully poured in, so as to form a separate layer, a blue color will appear at the line of contact.

Impurities and Test.—*Copper.* If to an aqueous solution of Mitigated Silver Nitrate a slight excess of ammonia water be added, it should neither assume a blue color.

Lead and bismuth. Nor show any turbidity.

Quantitative Test.—If 1 Gm. of Mitigated Silver Nitrate, dissolved in 10 Cc. of water, be well mixed with 20 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 0.3 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color.

Uses.—The object of this preparation is to provide a fused silver nitrate, which may often be useful where the undiluted caustic might prove too severe in its action. This preparation is used only externally. It is similar in its action to the moulded nitrate, but less energetic.

ARGENTI OXIDUM. U.S. Silver Oxide

$Ag_2O = 230.12$

It should contain 99.8 percent. of pure Silver Oxide, corresponding to not less than 92.9 percent. of pure metallic silver, and should be kept in dark amber-colored vials. Silver Oxide should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia.

Preparation.—This salt may be made by a former official process: Take of Nitrate of Silver, 4 oz. troy; Distilled Water, half a pint; Solution of Potassa, $1\frac{1}{2}$ pints, or a sufficient quantity. Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well-stoppered bottle protected from the light.

$$\underset{\substack{\text{Silver}\\\text{Nitrate}}}{2AgNO_3} + \underset{\substack{\text{Potassium}\\\text{Hydroxide}}}{2KHO} = \underset{\substack{\text{Silver}\\\text{Oxide}}}{Ag_2O} + \underset{\substack{\text{Potassium}\\\text{Nitrate.}}}{2KNO_3} + \underset{\text{Water}}{H_2O}$$

Official Description.—A heavy, dark brownish-black powder, liable to reduction by exposure to light.

Odor, Taste, and Reaction.—Odorless; metallic taste; alkaline reaction.

Solubility.—*Water.* Very slightly. *Alcohol.* Insoluble.

Tests for Identity.—When heated in a porcelain crucible to about 250° to 300° C. (482° to 572° F.), it is rapidly decomposed, with the evolution of oxygen, leaving a residue of metallic silver. The solution of the Oxide in nitric acid should be colorless, and should respond to the reactions and tests stated under *Argenti Nitras.*

Impurity and Test for Impurity.—*Carbonate.* It is readily soluble in nitric acid without effervescence.

Limit of Chloride.—If 0.2 Gm. of the Oxide be dissolved in a mixture of 1 Cc. of nitric acid and 2 Cc. of distilled water, 10 Cc. of ammonia water added, and the liquid diluted to 60 Cc., then 10 Cc. of this solution should not immediately become cloudy upon the addition of 1 Cc. of nitric acid.

Quantitative Test.—If 0.5 Gm. of the Oxide be ignited in a porcelain crucible, it should yield not less than 0.464 Gm. of pure metallic silver.

Uses.—Silver oxide is used as a substitute for silver nitrate, being much less caustic than the latter, and better suited for internal use. It is owing to the facility with which it parts with its oxygen that silver oxide should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia. The dose is one grain (0.065 Gm.).

Gelatin capsules are well fitted for dispensing this compound. With most excipients decomposition ensues, and the pills have been known to explode with some violence.

Mercury. Hg; 198.5

Mercury, or quicksilver, is found most abundantly as sulphide, or *cinnabar;* the principal mines are in Spain and California. It is a brilliant, silver-white metal, liquid above —40° C. (—40° F.), and having the specific gravity 13.5584. Mercury forms two series of compounds,—*mercurous,* and *mercuric.* It is used more largely in medicine in the metallic state than any other element.

Tests for Compounds of Mercury

1. Ammonium sulphide or hydrogen sulphide, in excess, produces a black precipitate (sulphide) in solutions of salts of mercury.
2. Potassium iodide produces with mercurous salts a green precipitate of mercurous iodide, or with mercuric salts a red precipitate of mercuric iodide, soluble in excess.
3. With hydrochloric acid or soluble chlorides a white precipitate of mercurous chloride is produced with mercurous salts, while with mercuric salts no precipitation occurs.
4. A plate of copper or a solution of stannous chloride, in excess, precipitates the metal from its soluble combinations.

Official Preparations of Mercury

Preparations of the Metal

Official Name	Preparation
Hydrargyrum cum Creta	By extinguishing 38 Gm. of mercury with 10 Gm. of clarified honey and 57 Gm. of prepared chalk
Emplastrum Hydrargyri	By extinguishing 30 Gm. of mercury with 1 Gm. of oleate of mercury, and incorporating with 10 Gm. of hydrous wool-fat and sufficient melted lead plaster to make 100 Gm.
Massa Hydrargyri	By extinguishing 33 percent. of mercury with honey of rose and glycerin, and then adding powdered glycyrrhiza and powdered althea
Unguentum Hydrargyri	By extinguishing 500 Gm. of mercury with 20 Gm. of oleate of mercury, then adding sufficient melted benzoinated lard and prepared suet to make 1000 Gm.
Hydrargyri Dilutum	By mixing 670 Gm. of mercurial ointment with 330 Gm. of petrolatum

Salts of Mercury and their Preparations

Hydrargyrum Ammoniatum	By precipitating solution of mercuric chloride with ammonia water
Unguentum Hydrargyri Ammoniati	By incorporating 10 Gm. of ammoniated mercury with 50 Gm. of white petrolatum and 40 Gm. of hydrous wool-fat
Hydrargyri Chloridum Corrosivum	By subliming mercuric sulphate with sodium chloride
Chloridum Mite	By subliming mercuric sulphate and mercury with sodium chloride
Iodidum Rubrum	By double decomposition between mercuric chloride and potassium iodide
Iodidum Flavum	By precipitating an acid solution of mercurous nitrate with potassium iodide
Oxidum Flavum	By precipitating solution of mercurous chloride with sodium hydroxide
Unguentum Hydrargyri Oxidi Flavi	By incorporating 10 Gm. of yellow mercuric oxide, after trituration with 10 Gm. of water, with 40 Gm. of hydrous wool-fat and 40 Gm. of petrolatum
Oleatum Hydrargyri	By dissolving 25 Gm. of yellow mercuric oxide in 75 Gm. of oleic acid
Hydrargyri Oxidum Rubrum	By decomposing mercuric nitrate by heat
Unguentum Hydrargyri Oxidi Rubri	By incorporating 10 Gm. of red mercuric oxide, after trituration with 10 Gm. of water, with 40 Gm. of hydrous wool-fat and 40 Gm. of petrolatum
Liquor Hydrargyri Nitratis	By dissolving 40 Gm. of red mercuric oxide in 45 Gm. of nitric acid and 15 Gm. of water
Unguentum Hydrargyri Nitratis	By treating lard with nitric acid, and then incorporating a solution of mercuric nitrate

Unofficial Salts of Mercury

Hydrargyri Acetas Mercuric Acetate	By dissolving mercuric oxide in acetic acid, filtering, concentrating, and crystallizing
Hydrargyri Arsenas Mercuric Arsenate	By adding a solution of arsenic acid to a solution of mercuric nitrate, and collecting the precipitate
Hydrargyri Bromidum, $HgBr_2$ Mercuric Bromide	By dissolving mercuric oxide in hot aqueous hydrobromic acid, filtering and concentrating, then crystallizing
Hydrargyri Carbonas, Hg_2CO_3 Mercurous Carbonate	By precipitating a solution of mercurous nitrate with acid potassium carbonate
Hydrargyri Chloras, $Hg(ClO_3)_2 + H_2O$ Mercuric Chlorate	By dissolving mercuric oxide in warm chloric acid, filtering and concentrating, then crystallizing
Hydrargyri Chromas, $HgCrO_4$ Mercuric Chromate	By boiling equal parts of chromium trioxide and yellow mercuric oxide in water, and collecting crystals
Hydrargyri Cyanidum, $Hg(CN)_2$ Mercuric Cyanide	By passing hydrocyanic acid into a vessel containing mercuric oxide with water
Hydrargyri Lactas, $(Hg_2)_2(C_3H_5O_3)_2 + 2H_2O$ Mercurous Lactate	By mixing boiling solutions of sodium lactate and mercurous nitrate, and collecting the precipitate
Hydrargyri Subsulphas Flavus, $Hg(HgO)_2SO_4$ Yellow Mercuric Subsulphate	By adding mercuric sulphate to boiling water
Hydrargyri Sulphidum Nigrum, HgS Black Mercuric Sulphide Ethiops Mineral	By rubbing together equal parts of mercury and sulphur
Hydrargyri Sulphidum Rubrum, HgS Red Mercuric Sulphide Vermilion	By fusing and subliming mercury and sulphur
Hydrargyri Nitras, $Hg_2(NO_3)_2 + 2H_2O$ Mercurous Nitrate	By mixing 4 parts mercury, 3 parts nitric acid, 1 part water, and after twenty-four hours collecting the crystals
Hydrargyri Sulphas, $HgSO_4$ Mercuric Sulphate	By heating 10 oz. mercury with 6 fl. oz. sulphuric acid, in a porcelain vessel, and stirring constantly until a white salt is obtained

HYDRARGYRUM. U.S. Mercury

$Hg = 198.50$

[QUICKSILVER]

It should contain not less than 99.9 percent. of pure metallic Mercury, and should be kept in strong, well-stoppered bottles.

Mercury for pharmaceutical uses should be pure. To separate mechanical impurities, moisture, or small quantities of oxide, mercury may be filtered by collecting it in a sound piece of chamois leather and, gathering the corners together, forcibly squeezing the particles through the pores of the leather. But distillation is preferable in most cases to purify the metal effectually, which may be accomplished by a process formerly official in the British Pharmacopœia, as follows:

Take of Mercury, 3 pounds [avoirdupois]; Hydrochloric Acid, 3 fluidrachms; Distilled Water, a sufficiency. Place the Mercury in a glass retort or iron bottle, and, applying heat, cause two pounds and a half of the metal to distil over into a flask employed as a receiver. Boil on this for five minutes the Hydrochloric Acid diluted with 9 fluidrachms of Distilled Water, and having, by repeated affusions of Distilled Water and decantations, removed every trace of acid, let the mercury be transferred to a porcelain capsule, and dried first by filtering paper, and finally on a water-bath.

Official Description.—A shining, silver-white metal.

Odor, Taste, and Reaction.—Odorless; tasteless.

Specific Gravity.—13.535 at 25° C. (77° F.).

Solubility.—Insoluble in the ordinary solvents, also in concentrated hydrochloric acid, and, at ordinary temperatures, in sulphuric acid; but it dissolves in the latter when boiled with it, and is readily and completely soluble in nitric acid.

Tests for Identity.—It is liquid at ordinary temperatures and easily divisible into spherical globules; but when cooled to —39.38° C. (—38.88° F.), it forms a ductile, malleable mass.

At ordinary temperatures it volatilizes very slowly, more rapidly as the temperature increases, and at 357.25° C. (675.05° F.) it boils and is completely volatilized, yielding a colorless, very poisonous vapor, and no appreciable residue.

When globules of Mercury are dropped upon white paper, they should roll about freely, retaining their globular form, and leaving no streaks or traces.

It should be perfectly dry and present a bright surface even after agitation in contact with air.

Impurity and Test.—*More than slight traces of foreign metals.* On boiling 5 Gm. of Mercury with 5 Cc. of water and 4.5 Gm. of sodium thiosulphate, in a test-tube, for about one minute, the Mercury should not lose its lustre, and should not acquire more than a slightly yellowish shade.

Uses.—When mercury is administered in a finely divided condition, as in blue mass, or in mercury with chalk, it exerts an action upon the liver, which is termed alterative. This action is possessed by some of its salts.

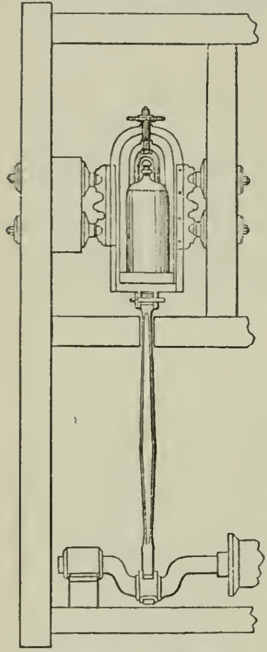
MASSA HYDRARGYRI. U. S. Mass of Mercury

	Metric	Old form
* **Mercury**	33 Gm.	5 oz. av. 122 gr.
Glycyrrhiza, in No. 60 powder	10 Gm.	1 oz. av. 263 gr.
Althæa, in No. 60 powder	15 Gm.	2 oz. av. 175 gr.
Glycerin	9 Gm.	1 oz. av. 193 gr.
Honey of Rose	33 Gm.	5 oz. av. 122 gr.
To make	100 Gm.	16 oz. av.

Triturate the Mercury with the Honey of Rose until it is extinguished and globules of Mercury are no longer visible under a lens magnifying ten diameters. Add the Glycerin, then the Glycyrrhiza and Althaea gradually, and continue the trituration until the mass is homogeneous. Keep the product in well-closed containers. (For tests see Part V.)

By using this formula the pharmacist is enabled to make blue mass extemporaneously with very little labor. The mass should not be *forcibly pressed,* or the globules of mercury will run together, and will grow larger instead of smaller.

Fig. 446



Squibb's mercurial shaker

Uses.—The object of this preparation is to furnish mercury in a finely divided condition. It is given in small doses to produce salivation, and in doses of three to ten grains (0.2 to 0.6 Gm.) as an alterative or purgative.

Fig. 446 illustrates the mercurial shaker invented by Dr. Squibb. It consists of a stout wooden frame to which is attached a metal cage for holding a strong glass gallon bottle; this is held in place by a cup-shaped screw clamp which rests on a cloth collar placed around the top of the bottle above the shoulder; the sides of the cage move in guides which are bolted to the wooden frame. A vertical shaft operated by the horizontal shaft at the bottom communicates an "up and down" motion to the bottle, and, when speeded properly, the mercury and a mixture containing honey in the bottle is thrown from the top to the bottom rapidly, and the mercury is thus quickly extinguished. The mixture is afterwards incorporated with the powders, placed in a large vessel, and the mass is finished. In making mercurial ointment, the mercury is placed in the bottle holding the lard, and both are shaken together; the mixture is afterwards mixed with the melted suet. This process of extinguishing mercury is termed "succussion."

HYDRARGYRUM CUM CRETA. U.S. Mercury with Chalk

[Gray Powder]

	Metric	Old form
* **Mercury**	38 Gm.	166 grains
Clarified Honey	10 Gm.	44 grains
Prepared Chalk	57 Gm.	248 grains
Water, a sufficient quantity,		
To make	100 Gm.	1 oz. av.

Weigh the Mercury and Clarified Honey successively into a strong bottle of the capacity of 100 Cc. [old form 1 fl. oz.], and add 2 Cc. [old form 10 minims] of Water. Cork the bottle, and shake it for about half an hour at a time, until the aggregate time of shaking reaches ten hours, or until the globules of Mercury are no longer visible under a lens magnifying *four diameters.* The shaking may be more conveniently performed by mechanical means. Rub the Prepared Chalk with Water, in a mortar, to a thick, creamy paste, and, having added the contents of the bottle, washing the last portions in with a little Water, triturate the whole to a uniform mixture.

Finally, dry the mixture, first between ample layers of bibulous paper, and afterwards in a dish at the ordinary temperature, until it weighs 100 Gm. [old form 1 oz. av.]. Then reduce it to a uniform powder, without trituration, and keep it in well-stoppered bottles, protected from light.

The intention here is to furnish mercury in a finely divided condition in the form of a powder. The above process is a very tedious one. In Matter's process, fifty-three grains of powdered acacia are mixed with fifty-three grains of chalk, enough water added to form a thin paste, and one hundred and sixty-seven grains of mercury added and triturated until extinguished. One hundred and sixty-five grains of chalk are made into a paste with water, and added to it, and the water evaporated from the mixture in a water-bath ; it is rubbed to powder when dry.

Official Description.—A light gray, rather damp powder, free from grittiness.

Odor and Taste.—Without odor ; slightly sweetish taste.

Impurities and Tests for Impurities.—*Limit of mercurous oxide.* If a portion of the powder be digested with warm acetic acid, the chalk is dissolved with effervescence, leaving a residue of finely divided mercury. The filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid.

Limit of mercuric oxide. If 0.1 Gm. of the powder be digested with 20 Cc. of warm diluted hydrochloric acid, the filtrate should not be affected by hydrogen sulphide T.S.

Uses.—Mercury with chalk is a mild mercurial, frequently given to children. It should be free from mercurous or mercuric oxide ; through exposure to air old specimens frequently contain both. The dose is four to ten grains (0.25 to 0.6 Gm.).

UNGUENTUM HYDRARGYRI. U.S. Mercurial Ointment

This ointment is made by extinguishing 500 Gm. of mercury with 20 Gm. of oleate of mercury ; the mixture is then incorporated with 250 Gm. of benzoinated lard and 230 Gm. of prepared suet, melted together. (See Unguenta.) The object of this process is to furnish finely divided mercury in a convenient form for external administration. The ointment is largely used, and the extemporaneous process furnishes a satisfactory preparation.

UNGUENTUM HYDRARGYRI DILUTUM. U.S. Blue Ointment

This ointment is made by mixing 670 Gm. of mercurial ointment with 330 Gm. of petrolatum, thus producing a 33⅓ percent. mercurial ointment. A demand for a weaker mercurial preparation for external use has warranted the introduction of this diluted ointment into the U. S. Pharmacopœia (8th Revision). Its properties are the same as the official mercurial ointment, although less active. (See Unguenta.)

EMPLASTRUM HYDRARGYRI. U.S. Mercurial Plaster

This plaster contains 30 Gm. of finely divided mercury extinguished in 1 Gm. of oleate of mercury and incorporated with 10 Gm. of hydrous wool-fat and 59 Gm. of melted lead plaster, the whole being thoroughly mixed while cooling. (See Emplastra.) Its uses are the same as those of the ointment, metallic mercury in a finely divided condition being present in both, the only difference being in the form of the preparations.

HYDRARGYRUM AMMONIATUM. U.S. Ammoniated Mercury

$HgNH_2Cl = 249.61$

[WHITE PRECIPITATE]

It should contain not less than 78 percent. nor more than 80 percent. of metallic mercury.

	Metric	Old form
* **Corrosive Mercuric Chloride,** in powder	**100 Gm.**	1 oz. av.
Ammonia Water,		
Distilled Water, each, a sufficient quantity		

Dissolve the Corrosive Mercuric Chloride in 2000 Cc. [old form 20 fl. oz.] of warm Distilled Water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into 150 Cc. [old form 1½ fl. oz.] of Ammonia Water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of 400 Cc. [old form 4 fl. oz.] of Distilled Water and 20 Cc. [old form 1½ fl. dr.] of Ammonia Water. Finally, dry the precipitate between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light.

In this process the ammonium of one-half of the ammonium chloride, which is formed upon mixing the solutions, has two of its hydrogen atoms replaced by one atom of bivalent mercury, NH_4Cl becoming NH_2HgCl.

$$\underset{\text{Mercuric Chloride}}{HgCl_2} + \underset{\text{Water of Ammonia}}{2NH_4HO} = \underset{\text{Ammonium Chloride}}{NH_4Cl} + \underset{\text{Mercurammonium Chloride}}{NH_2HgCl} + \underset{\text{Water}}{2H_2O}$$

Official Description.—White, pulverulent pieces, or a white, amorphous powder; permanent in the air.

Odor and Taste.—Without odor; earthy, afterwards styptic and metallic taste.

Solubility.—Insoluble in water or in alcohol. By prolonged washing with water it is gradually decomposed, assuming a yellow color, and becoming converted into a basic salt. Readily soluble in warm hydrochloric, nitric, or acetic acid, and in a cold solution of ammonium carbonate. Also completely soluble in a cold solution of sodium thiosulphate, with the evolution of ammonia; when this solution is heated for a short time, red mercuric sulphide is separated, which, on protracted boiling, turns black.

Tests for Identity.—At a temperature below a red heat Ammoniated Mercury is decomposed without fusion, and at a red heat it is wholly volatilized.

When heated with potassium hydroxide T.S., the salt turns yellow, and evolves vapor of ammonia.

The solution of the salt in diluted nitric acid gives with potassium iodide T.S. a red precipitate, and with silver nitrate T.S. a white precipitate.

Impurities and Tests for Impurities.—*Carbonate.* The salt should be soluble in hydrochloric acid without effervescence.

Mercurous salt. And without leaving a residue.

Foreign salts, metals, and arsenic. The solution of 0.5 Gm. of Ammoniated Mercury in 2 Cc. of hydrochloric acid diluted with water to 25 Cc. should not respond to the tests for *foreign salts, metals*, and *arsenic*, as described under *Hydrargyri Chloridum Mite.*

Uses.—This compound of mercury is not used internally; it is applied externally in the form of ointment.

UNGUENTUM HYDRARGYRI AMMONIATI. U.S. Ointment of Ammoniated Mercury

This ointment is made by incorporating 10 Gm. of ammoniated mercury with 50 Gm. of white petrolatum and 40 Gm. of hydrous wool-fat. It is a valuable application in certain forms of eczema and psoriasis and other skin diseases. (See Unguenta.)

HYDRARGYRI CHLORIDUM CORROSIVUM. U.S. Corrosive Mercuric Chloride

$HgCl_2 = 268.86$

[BICHLORIDE OF MERCURY CORROSIVE SUBLIMATE MERCURIC CHLORIDE]

It should contain not less than 99.5 percent. of pure Mercuric Chloride, and be kept in well-stoppered bottles.

Preparation.—This important mercuric salt may be made by the former official process, as follows:

Take of Mercury, 24 oz; Sulphuric Acid, 36 oz.; Chloride of Sodium, 18 oz. Boil the Mercury with the Sulphuric Acid, by means of a sand-bath, until a dry white mass is left. Rub this, when cold, with the Chloride of Sodium in an earthenware mortar; then sublime with a gradually increasing heat.

By boiling sulphuric acid in excess with mercury to dryness a white salt (mercuric sulphate) is formed, according to the reaction:

$$\underset{\text{Sulphuric Acid}}{2H_2SO_4} + \underset{\text{Mercury}}{Hg} = \underset{\text{Mercuric Sulphate}}{HgSO_4} + \underset{\text{Sulphurous Acid}}{SO_2} + \underset{\text{Water}}{2H_2O}$$

When this is mixed with sodium chloride, and the mixture exposed to a subliming heat, decomposition takes place, according to the reaction:

$$\underset{\text{Mercuric Sulphate}}{HgSO_4} + \underset{\text{Sodium Chloride}}{(NaCl)_2} = \underset{\text{Sodium Sulphate}}{Na_2SO_4} + \underset{\text{Mercuric Chloride}}{HgCl_2}$$

The mercuric chloride thus formed sublimes, and the sodium sulphate remains behind.

This chloride is always sublimed in masses, to distinguish it from mercurous chloride, or calomel, which is in powder.

Official Description.—Heavy, colorless, rhombic crystals, or crystalline masses; permanent in the air.

Odor, Taste, and Reaction.—Odorless; acrid and persistent metallic taste. The aqueous solution reddens blue litmus paper, but becomes neutral to litmus paper upon the addition of sodium chloride.

Solubility.—*Water.* When in fine powder, it is soluble in 13 parts at 25° C. (77° F.), and in 2 parts of boiling water.

Alcohol. When in fine powder, soluble in three parts of alcohol at 25° C. (77° F.), and in 1.2 parts of boiling alcohol.

Other solvents. When in fine powder, soluble in about 14 parts of glycerin at 25° C. (77° F.).

Tests for Identity.—If 1 Gm. of finely powdered Mercuric Chloride be dissolved in 10 Cc. of alcohol or 20 Cc. of water, it should leave not more than 0.005 Gm. of residue.

It fuses at 265° C. (509° F.) to a colorless liquid, and at about 300° C. (572° F.) it volatilizes in dense, white vapors, leaving no appreciable residue.

With ammonia water the aqueous solution of the salt yields a white precipitate; with an excess of hydrogen sulphide a black one; with potassium iodide T.S. a red one, soluble in an excess of the reagent; and with silver nitrate T.S. a white precipitate, insoluble in nitric acid.

Impurities and Tests for Impurities.—*Foreign salts.* If to 0.5 Gm. of Mercuric Chloride, dissolved in 20 Cc. of water, 5 Cc. of hydrochloric acid be added, and the solution be completely saturated with hydrogen sulphide, allowed to stand for several hours in a well-corked flask until the precipitate has subsided, and then filtered, the filtrate should be colorless and leave no weighable residue upon evaporation.

Arsenic. If the precipitate obtained in the preceding test, after washing with about 100 Cc. of water and draining, be rinsed into a beaker with about 20 Cc. of water, and then 5 Cc. of stronger ammonia water added, and if after covering and digesting the mixture for about 15 minutes on a bath of boiling water, it be rinsed upon a filter and washed with a little water, the filtrate and washings after evaporating to dryness, moistening with 6 drops of nitric acid, and again drying, should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of foreign metals. If the precipitated sulphide remaining upon the filter be treated with diluted nitric acid (1 in 4), warmed, and then filtered, the filtrate should leave no weighable residue upon evaporation and gentle ignition.

Uses.—Pharmaceutically, mercuric chloride is used in several preparations to furnish the mercury in the compounds. Medicinally, as an alterative, it is one of the most valuable internal remedies in syphilis and chronic rheumatism, the dose being one-twentieth of a grain (0.003 Gm.). Externally, it is used as a stimulant and escharotic. Recently it has been very extensively employed in antiseptic surgery. It is undoubtedly the most powerful antiseptic available, the only serious disadvantage being the necessity for great care on account of its poisonous properties. The antidote to poisoning by corrosive sublimate is the free use of white of egg, milk, or other albuminous liquids, followed by an emetic.

HYDRARGYRI CHLORIDUM MITE. U.S. Mild Mercurous Chloride

$HgCl = 233.68$

[CALOMEL MERCUROUS CHLORIDE PROTOCHLORIDE OF MERCURY SUBCHLORIDE OF MERCURY]

It should contain not less than 99.5 percent. of pure Mercurous Chloride, and be kept in dark amber-colored bottles.

Preparation.—The former official process may be used to prepare mercurous chloride, as follows:

Take of Mercury, 48 oz.; Sulphuric Acid, 36 oz.; Chloride of Sodium, 18 oz.; Distilled Water, a sufficient quantity. Boil, by means of a sand bath, 24 oz. of the Mercury with the Sulphuric Acid, until a dry, white mass is left. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and, having rubbed it with the other ingredients until globules of Mercury cease to be visible, sublime the mixture into a large chamber so that the sublimate may fall in powder. Wash the sublimed matter with boiling Distilled Water, until the washings afford no precipitate with water of ammonia, and dry it.

In this preparation mercuric sulphate is first made; this is then triturated with a quantity of mercury equal to that used in forming it; mercurous sulphate is produced, and when this is mixed with sodium chloride and sublimed, mercurous chloride is produced as a fine white sublimate, and sodium sulphate remains behind.

$$\underset{\substack{\text{Sulphuric}\\\text{Acid}}}{2H_2SO_4} + \underset{\text{Mercury}}{Hg} = \underset{\substack{\text{Mercuric}\\\text{Sulphate}}}{HgSO_4} + \underset{\substack{\text{Sulphurous}\\\text{Acid}}}{SO_2} + \underset{\text{Water}}{2H_2O}$$

$$\underset{\substack{\text{Mercuric}\\\text{Sulphate}}}{HgSO_4} + \underset{\text{Mercury}}{Hg} = \underset{\substack{\text{Mercurous}\\\text{Sulphate}}}{Hg_2SO_4}$$

$$\underset{\substack{\text{Mercurous}\\\text{Sulphate}}}{Hg_2SO_4} + \underset{\substack{\text{Sodium}\\\text{Chloride}}}{2NaCl} = \underset{\substack{\text{Mercurous}\\\text{Chloride}}}{2HgCl} + \underset{\substack{\text{Sodium}\\\text{Sulphate}}}{Na_2SO_4}$$

Official Description.—A white, impalpable powder, becoming yellowish-white on being triturated with strong pressure, and showing only small, isolated crystals when viewed under a lens having a magnifying power of one hundred diameters. Permanent in the air.

Odor and Taste.—Odorless and tasteless.

Solubility.—*Water.* Insoluble.

Alcohol. Insoluble.

Other solvents.—Insoluble in ether and cold dilute acids.

Tests for Identity.—When strongly heated, Mercurous Chloride is volatilized without fusion or the evolution of brown vapors, leaving no appreciable residue.

In contact with calcium hydroxide T.S., or with solutions of alkali hydroxides, or with ammonia water, the salt is blackened.

When heated with dried sodium carbonate in a dry glass tube, it yields a sublimate of metallic mercury.

Impurities and Tests for Impurities.—*Heavy Metals.* If 1 Gm. of the salt be shaken with 10 Cc. of water or alcohol, and the mixture filtered, neither of the filtrates should respond to the Time-Limit Test for *heavy metals* (see U. S. P. Test No. 121, Chap. LXII).

Soluble impurities. Nor should any appreciable residue be left on evaporation.

Mercuric chloride. If 2 Gm. of the salt be shaken with 20 Cc. of ether, filtered, the filtrate evaporated, and 10 Cc. of distilled water added, not more than a slight opalescence should result upon the addition of silver nitrate T.S. to 5 Cc. of the filtrate, and no change in color should be produced upon adding a few drops of ammonium sulphide T.S. to the remainder.

Distinction from, and absence of, ammoniated mercury. On heating a portion of the salt in a test-tube with potassium hydroxide T.S., it should not evolve ammonia; and if another portion be shaken with acetic acid, and filtered, the filtrate should not be affected by hydrogen sulphide T.S., nor by silver nitrate T.S.

Foreign salts. If to 0.5 Gm. of Mercurous Chloride contained in a small beaker, 5 Cc. of nitric acid be added, and the mixture evaporated to dryness on a water-bath, and if, after dissolving the residue in about 25 Cc. of distilled water and 5 Cc. of hydrochloric acid, the solution be completely saturated with hydrogen sulphide, and allowed to stand for several hours in a well-corked flask, until the precipitate has subsided, and then filtered, the filtrate should be colorless and leave no weighable residue upon evaporation and gentle ignition.

Arsenic. If the precipitate obtained in the preceding test, after washing with about 100 Cc. of water, and draining, be rinsed into a beaker with about 20 Cc. of water and then 5 Cc. of stronger ammonia water added, and if, after covering and digesting the mixture for about 15 minutes on a water-bath, it be rinsed upon a filter and washed with a little water, the filtrate and washings, after evaporating to dryness, moistening with 6 drops of nitric acid, and again drying, should not respond to the Modified Gutzeit's Test for *arsenic* (see U. S. P. Test No. 17, Chap. LXII).

Limit of foreign metals. If the precipitated sulphide remaining upon the filter be treated with diluted nitric acid (1 in 4), warmed, and then filtered, the filtrate should leave no weighable residue upon evaporation and gentle ignition.

Uses.—Calomel is largely used as an hepatic stimulant and alterative; it is also purgative, and, in large doses, sedative. It is given in doses of one-half grain to twenty grains (0.03 to 1.3 Gm.). Care must be exercised in prescribing calomel with other remedies that the chemical action does not produce corrosive sublimate.

HYDRARGYRI IODIDUM FLAVUM. U. S. Yellow Mercurous Iodide

$HgI = 324.40$

[GREEN IODIDE OF MERCURY MERCUROUS IODIDE PROTIODIDE OF MERCURY, YELLOW IODIDE OF MERCURY]

It should contain not less than 99.5 percent. of pure Mercurous Iodide.

	Metric	Old form
* **Mercury**	50 Gm.	1 oz. av. 293 gr.
Nitric Acid,		
Potassium Iodide,		
Distilled Water, each, a sufficient quantity		

Mix 20 Cc. [old form 5 fl. dr.] each, of Nitric Acid and Distilled Water, and, when the liquid is cold, pour it upon the Mercury contained in a glass beaker. Set the mixture aside in a dark place, and keep it at a temperature between 25° and 30° C. (77° and 86° F.),

with occasional agitation, until the reaction ceases and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother liquor, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark place. When the salt is dry dissolve 40 Gm. [old form 584 grains] of it in 650 Cc. [old form 20½ fl. oz.] of Distilled Water to which 6 Cc. [old form 92 minims] of Nitric Acid have previously been added. Having prepared a solution of 16 Gm. [old form 233 grains] of Potassium Iodide in 32 Cc. [old form 1 fl. oz.] of Distilled Water, slowly pour the solution of Potassium Iodide into the solution of Mercurous Nitrate, with constant stirring, which should be continued for fifteen minutes, allow the precipitate to subside, decant the supernatant liquid, and wash the precipitate by decantation with ten successive portions of 500 Cc. [old form 1 pint] each of Distilled Water. Finally, transfer the precipitate to a filter, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 40° C. (104° F.), and keep it in dark amber-colored vials, with the least possible exposure to light.

Instead of weighing off 40 Gm. [old form 584 grains] of the Mercurous Nitrate as above directed, the whole of the crystallized salt may be taken and the amount of Potassium Iodide, etc., adjusted to the proportions given above.

Official Description.—A bright yellow, amorphous powder. By exposure to light it becomes darker, in proportion as it undergoes decomposition into metallic mercury and mercuric iodide.

Odor and Taste.—Odorless and tasteless.

Solubility.—*Water.* Almost insoluble.
Alcohol. Wholly insoluble.
Other solvents. Wholly insoluble in ether.

Tests for Identity.—When slowly and moderately heated, it assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is volatilized, leaving not more than 0.05 percent. of residue.

When Mercurous Iodide is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved.

In contact with a solution of potassium iodide, the salt is decomposed into mercuric iodide, which dissolves, and metallic mercury, which remains undissolved.

Impurity and Test.—*More than traces of mercuric iodide.* If 0.5 Gm. of the salt be shaken with 10 Cc. of alcohol and the mixture allowed to stand and then filtered, a portion of the perfectly clear filtrate should be scarcely affected by hydrogen sulphide T.S., nor should it produce more than a very faint, transient opalescence when dropped into water; and if 5 Cc. of the filtrate be evaporated on a white porcelain surface, not more than a very faint, red stain should remain.

Uses.—Yellow mercurous iodide is used as an alterative. It is better adapted for internal administration than the red iodide, because it is milder. The dose is from one-fifth to one grain (0.01 to 0.065 Gm.).

HYDRARGYRI IODIDUM RUBRUM. U.S. Red Mercuric Iodide

$HgI_2 = 450.30$

[Biniodide of Mercury Mercuric Iodide Red Iodide of Mercury]

It should contain not less than 98.5 percent. of pure Mercuric Iodide.

	Metric	Old form
* **Corrosive Mercuric Chloride**	40 Gm.	1 oz. av. 148 gr.
Potassium Iodide	50 Gm.	1 oz. av. 293 gr.
Distilled Water, a sufficient quantity		

Dissolve the Corrosive Mercuric Chloride and the Potassium Iodide, each, in 800 Cc. [old form 25½ fl. oz.] of Distilled Water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, with constant and very active stirring, into 2000 Cc. [old form 4 pints] of Distilled Water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings give not more than a slight opalescence with silver nitrate test solution. Finally, dry it, in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.), and keep it in well-stoppered bottles, protected from light.

In this process mercuric iodide and potassium chloride are formed by double decomposition.

$$\underset{\substack{\text{Mercuric}\\\text{Chloride}}}{HgCl_2} + \underset{\substack{\text{Potassium}\\\text{Iodide}}}{2KI} = \underset{\substack{\text{Mercuric}\\\text{Iodide}}}{HgI_2} + \underset{\substack{\text{Potassium}\\\text{Chloride}}}{2KCl}$$

As mercuric iodide is soluble in solutions both of mercuric chloride and of potassium iodide, it is not profitable to use an excess of either. It may be obtained in handsome crystals by dissolving it in hot hydrochloric acid to saturation and allowing the solution to cool slowly.

Official Description.—A scarlet-red, amorphous powder; permanent in the air.

Odor and Taste.—Odorless; tasteless.

Solubility.—*Water.* Almost insoluble.

Alcohol. In 116 parts at 25° C. (77° F.), and in 15 parts of boiling alcohol.

Other solvents. In 85 parts of ether and 1340 parts of chloroform at 25° C. (77° F.); also in solutions of the soluble iodides, mercuric chloride, sodium thiosulphate, and hot solutions of the alkali chlorides.

Tests for Identity.—When heated to about 150° C. (302° F.), the salt becomes yellow, but again assumes a red color on cooling; at 253° C. (487.4° F.) it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass, and at higher temperatures is finally volatilized, leaving not more than 0.05 percent. of residue.

On heating the salt with potassium hydroxide T.S., and adding a little sugar of milk, metallic mercury is precipitated.

Mercuric chloride. A saturated solution of Mercuric Iodide in hot alcohol should, after cooling, be colorless; and when diluted with an equal volume of water, the solution should not redden blue litmus paper.

Limit of soluble chlorides or iodides. If about 0.5 Gm. of Mercuric Iodide be thoroughly agitated with 10 Cc. of distilled water, the filtered liquid should not become more than slightly colored by hydrogen sulphide T.S., nor give more than a slight opalescence with silver nitrate T.S.

Uses.—This iodide is used internally in the treatment of syphilis, in doses of one-twentieth of a grain (0.003 Gm.); it is frequently given in pill form combined with potassium iodide. Externally, it is often used in the form of an ointment, of the strength of sixteen grains in an ounce of simple ointment.

HYDRARGYRI OXIDUM FLAVUM. U.S. Yellow Mercuric Oxide

$HgO = 214.38$

It should contain not less than 99.5 percent. of pure Yellow Mercuric Oxide.

	Metric	Old form
***Corrosive Mercuric Chloride**	100 Gm.	1460 grains
Sodium Hydroxide	40 Gm.	584 grains
Distilled Water, a sufficient quantity		

Dissolve the Corrosive Mercuric Chloride in 1000 Cc. [old form 2 pints] of warm Distilled Water, and filter the solution. Dissolve the Sodium Hydroxide (which should contain at least 90 percent. of pure, anhydrous sodium hydroxide) in 1000 Cc. [old form 2 pints] of cold Distilled Water, and into this solution pour gradually, and with constant stirring, the solution of Corrosive Mercuric Chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the addition and decantation of portions of Distilled Water, using 1000 Cc. [old form 2 pints] of Water each time. Collect the precipitate on a strainer, and continue the washing with warm Distilled Water, until a small portion of the washings, when poured on a little mercuric chloride test solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light.

$$\underset{\substack{\text{Mercuric}\\ \text{Chloride}}}{HgCl_2} + \underset{\substack{\text{Sodium}\\ \text{Hydroxide}}}{2NaHO} = \underset{\substack{\text{Mercuric}\\ \text{Oxide}}}{HgO} + \underset{\substack{\text{Sodium}\\ \text{Chloride}}}{2NaCl} + \underset{\text{Water}}{H_2O}$$

Official Description.—A light orange-yellow, amorphous, heavy, impalpable powder; permanent in the air, but turning darker on exposure to light.

Odor, Taste, and Reaction.—Odorless; somewhat metallic taste; when moistened with hot water, it should not turn red litmus paper blue.

Solubility.—*Water.* Almost insoluble.

Alcohol. Insoluble.

Other solvents. Readily and completely in diluted hydrochloric or nitric acid, forming colorless solutions.

Tests for Identity.—When moderately heated, Yellow Mercuric Oxide assumes a red color. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving not more than 0.1 percent. of residue.

If 0.5 Gm. of Yellow Mercuric Oxide be digested on a water-bath, for fifteen minutes, with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will be converted into white mercuric oxalate (distinction from *red mercuric oxide*).

Impurities and Tests for Impurities.—*Limit of chlorides.* On dissolving 0.1 Gm. of the Oxide in 10 Cc. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate T.S.

The solution of 0.5 Gm. of the Oxide in a mixture of 2 Cc. of hydrochloric acid and 25 Cc. of water, should not respond to the tests for *foreign salts*, *metals*, or *arsenic*, as described under *Hydrargyri Chloridum Mite.*

Uses.—Yellow mercuric oxide is used in making the oleate of mercury and in the official ointment; it is employed only externally.

UNGUENTUM HYDRARGYRI OXIDI FLAVI. U.S. Ointment of Yellow Mercuric Oxide

This preparation is made by incorporating 10 Gm. of yellow mercuric oxide after thorough trituration with 10 Gm. of water, with 40 Gm. of hydrous wool-fat and 40 Gm. of petrolatum. Its uses are the same as those of the ointment of red mercuric oxide. (See Unguenta.)

OLEATUM HYDRARGYRI. U.S. Oleate of Mercury

This oleate is made by dissolving 25 Gm. of dried yellow mercuric oxide in 75 Gm. of oleic acid. The yellow mercuric oxide is first triturated with 25 Cc. of water, the oleic acid added and the water evaporated with the aid of a gentle heat. It is best to avoid much heat in making this preparation, to prevent partial decomposition and separation of metallic mercury; in time this change slowly takes place, even when the directions have been strictly followed (see page 325).

HYDRARGYRI OXIDUM RUBRUM. U.S. Red Mercuric Oxide

$HgO = 214.38$

[RED PRECIPITATE]

It should contain not less than 99.5 percent. of pure Red Mercuric Oxide, and should be kept in well-stoppered bottles, protected from light.

Preparation.—This oxide may be made by a former official process, as follows:

Take of Mercury, 36 oz.; Nitric Acid, 24 oz.; Water, 2 pints. Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapors cease to rise.

Mercuric nitrate is first formed, and this is decomposed by heat.

$$\underset{\text{Mercuric Nitrate}}{2Hg(NO_3)_2} = \underset{\text{Mercuric Oxide}}{2HgO} + \underset{\text{Nitrogen Dioxide}}{4NO_2} + \underset{\text{Oxygen}}{O_2}$$

Official Description.—Heavy, orange-red, crystalline scales, or a crystalline powder, becoming more yellow the finer it is divided; permanent in the air.

Odor and Taste.—Odorless; somewhat metallic taste.

Solubility.—*Water.* Almost insoluble.

Alcohol. Insoluble.

Other solvents. Readily soluble in diluted nitric acid, forming a clear solution, or in hydrochloric acid (1 in 10) with faint opalescence.

Tests for Identity.—When heated to about 400° C. (752° F.), Red Mercuric Oxide becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no appreciable residue.

If 0.5 Gm. be digested on a water bath with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will not change color within two hours (distinction from *yellow mercuric oxide*).

Impurities and Tests for Impurities.—*Nitrate.* If 1 Gm. of Red Mercuric Oxide be mixed with 5 Cc. of water, and 2 Cc. of sulphuric acid added, the mixture cooled, and 2 Cc. of ferrous sulphate T.S. be carefully poured upon it, no brown zone should be developed at the line of contact upon standing.

Limit of chlorides. On dissolving 0.1 Gm. of the Oxide in 10 Cc. of diluted nitric acid, the resulting solution should be clear, and should not produce more than a slight opalescence with silver nitrate T.S.

Foreign salts, metals, or arsenic. The solution of 0.5 Gm. of the Oxide in a mixture of 2 Cc. of hydrochloric acid and 25 Cc. of water, should not respond to the tests for *foreign salts, metals,* or *arsenic,* as described under *Hydrargyri Chloridum Mite.*

Uses.—Red mercuric oxide has the same chemical composition as the yellow oxide. It is used in the form of ointment for inflamed eyelids, in skin diseases, and for destroying body vermin.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. U.S. Ointment of Red Mercuric Oxide

This preparation, usually known as *red precipitate ointment,* is made by incorporating 10 Gm. of red mercuric oxide, after thorough trituration with 10 Cc. of water, with 40 Gm. of hydrous wool fat and 40 Gm. of petrolatum. (See Unguenta.) It is used as a stimulating application to indolent sores and in blepharitis.

LIQUOR HYDRARGYRI NITRATIS. U.S. Solution of Mercuric Nitrate

A liquid, which should contain about 60 percent. of Mercuric Nitrate $[Hg(NO_2.O)_2 = 321.64]$, and about 11 percent. of free nitric acid.

	Metric	Old form
*** Red Mercuric Oxide**	**40 Gm.**	6 oz. av. 425 gr.
Nitric Acid	**45 Gm.**	5 fl. oz. 160 min.
Distilled Water	**15 Gm.**	2 fl. oz. 239 min.
To make	**100 Gm.**	8 fl. oz.

Mix the Nitric Acid with the Distilled Water, and dissolve the Red Mercuric Oxide in the mixture. Keep the product in glass-stoppered bottles.

Official Description.—A clear, nearly colorless, heavy liquid.

Odor and Reaction.—Faint odor of nitric acid; strongly acid reaction.

Specific Gravity.—About 2.086 at 25° C. (77° F.).

Tests for Identity.—On evaporating a few drops of the Solution in a porcelain dish, a white residue is left, which, on being heated, becomes successively yellow, red, and brown, and is finally completely volatilized.

On a bright surface of copper, the Solution deposits a coating of metallic mercury.

The Solution, diluted with water, yields with potassium hydroxide T.S. a yellow precipitate; and with potassium iodide T.S. a bright red one, soluble in an excess of the reagent.

A clear crystal of ferrous sulphate dropped into the Solution rapidly acquires a brown color, and becomes surrounded by a brownish-black zone.

Impurity and Test.—*Mercurous salt.* No precipitation or cloudiness should occur in the Solution on the addition of water, or of diluted hydrochloric acid.

Uses.—This is a corrosive liquid, used principally to cauterize malignant ulcerations, cancers, etc. It is never given internally.

UNGUENTUM HYDRARGYRI NITRATIS. U.S. Ointment of Mercuric Nitrate

This important ointment is made by heating 760 Gm. of lard to a temperature of 105° C. (221° F.), withdrawing the heat, and then adding gradually 70 Gm. of Nitric Acid, and, after the reaction has moderated, continuing the heat until effervescence ceases, and then allowing the mixture to cool to about 40° C. (104° F.); then dissolving 70 Gm. of mercury in 105 Gm. of nitric acid with the aid of sufficient heat, and adding this solution to the ointment before it has become entirely cold. When nitric acid is added to lard oil under the above circumstances, the *olein* of the oil is converted into elaïdin, and the color changes to a deep orange; this, upon stirring and cooling, becomes lighter, and it has received the name of *citrine ointment.* It is used in various skin diseases and in inflammation of the eyelids. (See Unguenta.)

CHAPTER XLVII

ANTIMONY, ARSENIC, AND BISMUTH

Sb ; 119.3. As; 74.4. Bi ; 206.9

THESE three metals, which have the Latin names Antimonium, Arsenium, Bismuthum, form a group which presents several analogies. Arsenic is regarded by a number of chemists as not metallic, and on account of some of its chemical relations it is classed by them with the non-metallic elements, but in some of its physical properties, notably its lustre, specific gravity, etc., it closely resembles the metals, and it is therefore considered in the group with antimony and bismuth.

Antimony (Stibium). Sb ; 119.3

This metal is found in nature in a free state, and as a sulphide, oxide, or oxysulphide. The native sulphide is the chief source of the metal, and roasting with iron and sodium sulphide is the process generally resorted to for obtaining it. It is a brittle, brilliant metal, of a lamellated texture, of a silver-white color when pure, but bluish-white as it occurs in commerce. When rubbed between the fingers, it imparts a sensible odor. Its specific gravity is 6.7, and its fusing point 425° C. (797° F.), or about a red heat. It forms three combinations with oxygen,—*antimony trioxide* (antimonous oxide), Sb_2O_3; *antimony tetroxide*, Sb_2O_4 (by some considered to be an antimonate of the teroxide of antimony, Sb_4O_8) ; and *antimony pentoxide* (antimonic oxide), Sb_2O_5. The first of these unites with water to form antimonous acid, the salts of which are called *antimonites;* the third unites with water to form antimonic acid, the salts of which are called *antimonates.*

Tests for Salts of Antimony

1. If hydrogen sulphide be added to an acidified solution of salt of antimony, an orange-red precipitate of sulphide will be produced. This is soluble in ammonium sulphide, but is again precipitated upon the addition of an acid.

2. If hydrochloric acid be added to the sulphide, so as to form a strong solution of antimonous chloride, and this be mixed with water, a white precipitate of oxychloride will be produced.

3. Zinc and iron precipitate antimony as a black powder from its solutions ; copper precipitates it as a metallic film: this may be dissolved by potassium permanganate, and this solution will yield antimony sulphide with hydrogen sulphide.

Official Salt and Preparation of Antimony

Official Name	Preparation
Antimonii et Potassii Tartras Tartar Emetic	By boiling antimonous oxide and acid potassium tartrate together with water, evaporating, and crystallizing
Vinum Antimonii	Four Gm. antimony and potassium tartrate, 65 Cc. distilled water, 175 Cc. alcohol, and sufficient white wine to make 1000 Cc.

Unofficial Salts and Preparations of Antimony

Antimonii Bromidum, $SbBr_3$ Antimony Bromide	By adding dry antimony to bromine contained in a retort, agitating until the combination is complete, then purifying by distillation, and collecting the crystals
Antimonii Fluoridum, $SbFl_3$ Antimony Fluoride	By placing antimony and mercury fluoride in a retort, distilling, and collecting the white mass
Antimonii Iodidum, SbI_3 Antimony Iodide	By direct combination of the elements
Antimonii Oxidum, Sb_2O_3 Antimony Oxide. U. S. P. 1890	By adding antimonous chloride to water, and treating the oxychloride formed with ammonia water
Antimonii Oxysulphidum, Sb_2S_3 and Sb_2O_3 Antimony Oxysulphide	By boiling 1 part black antimony with 250 parts water containing 23 parts sodium carbonate, filtering, and collecting the precipitate
Antimonii Pentasulphidum Antimony Pentasulphide	By adding 70 parts crystallized sodium carbonate to 250 parts water and boiling; then mixing with 26 parts lime and 80 parts water; lastly, adding 36 parts levigated antimony sulphide and 7 parts sublimed sulphur, boiling until the gray color disappears, filtering, and then crystallizing
Antimonii Sulphas, $Sb_2(SO_4)_3$ Antimony Sulphate	By boiling antimony with strong sulphuric acid, and collecting the white mass
Antimonii Sulphidum, Sb_2S_3 Antimony Sulphide. U. S. P. 1890	By purifying antimony ore by fusion
Antomonii Sulphidum Purificatum, Sb_2S_3 Purified Antimony Sulphide. U. S. P. 1890	By macerating antimonous sulphide with water containing a trace of ammonia water
Antimonium Sulphuratum Sulphurated Antimony. (Kermes Mineral). U. S. P. 1890	By boiling antimonous sulphide with solution of sodium hydroxide and adding sulphuric acid to the hot solution
Pilulæ Antimonii Compositæ Compound Pills of Antimony (Plummer's Pills). U. S. P. 1890	Made by forming a mass of 4 Gm. each sulphurated antimony, mild mercurous chloride, and guaiac with the aid of castor oil, and dividing the mass into 100 pills. Used in secondary syphilis and various skin diseases
Pulvis Antimonialis Antimonial Powder (James's Powder). U. S. P. 1890	Made by mixing 33 Gm. of antimony oxide with 67 Gm. of precipitated calcium phosphate. Used as a diaphoretic in doses of three to five grains (0.2 to 0.3 Gm.)

ANTIMONII ET POTASSII TARTRAS. U. S. Antimony and Potassium Tartrate

$$2K(SbO)C_4H_4O_6 + H_2O = 659.80$$

[TARTARATED ANTIMONY TARTAR EMETIC]

It should contain not less than 99.5 percent. of pure Antimony and Potassium Tartrate $[2C_2H_2(OH)_2(COOK)COOSbO + H_2O]$.

This, the most important antimonial compound, may be made by a former official process, as follows:

Take of Oxide of Antimony, in very fine powder, 2 oz.; Bitartrate of Potassium, in very fine powder, 2½ oz.; Distilled Water, 18 fl. oz. To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stoppered bottle. By further evaporation the mother water may be made to yield more crystals, which should be purified by a second crystallization.

Like potassium and sodium tartrate, this is a double salt. Two replaceable hydrogen atoms of tartaric acid $(H_2C_4H_4O_6)$ are substituted by one of antimonyl (SbO) and one of potassium (K). The group (SbO) is hypothetical.

$$\underset{\text{Acid Potassium Tartrate}}{2KHC_4H_4O_6} + \underset{\text{Antimonous Oxide}}{Sb_2O_3} = \underset{\text{Antimony and Potassium Tartrate}}{2KSbOC_4H_4O_6} + \underset{\text{Water}}{H_2O}$$

Official Description.—Colorless, transparent crystals of the rhombic system, becoming opaque and white on exposure to air, or a white, granular powder.

Odor, Taste, and Reaction.—Without odor; sweet, afterwards disagreeable, metallic taste; slightly acid reaction.

Solubility.—*Water.* In 15.5 parts at 25° C. (77° F.); in 3 parts of boiling water.

Alcohol. Insoluble in alcohol, which precipitates it from its aqueous solution in the form of a crystalline powder.

Tests for Identity.—When heated to 110° C. (230° F.) in a vacuum, the salt loses its water of crystallization (2.71 percent.). When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue having an alkaline reaction.
