(*U. S. P.*). The deep red color is that of ferric acetate ($Fe_2[C_2H_3O_2]_6$), and the precipitate is basic ferric acetate ($Fe_2[OH]_2[C_2H_3O_2]_4$). "If a non-luminous flame be colored by the introduction of the salt, and viewed through a blue glass, the yellow color should entirely disappear, no red color taking its place (absence of potassium). If to 5 Cc. of the aqueous solution (1 in 20), slightly acidulated with acetic acid, an equal volume of hydrogen sulphide T.S. be added, no color or turbidity should appear, either at once (absence of arsenic, lead, zinc, etc.), or after adding ammonia water in slight excess (absence of iron, etc.)"—(*U. S. P.*). The *German Pharmacopœia* directs that 20 Cc. of the solution (1 in 20) should not be altered by the addition of 0.5 Cc. of solution of potassium ferrocyanide (absence of iron, copper, etc.). "The aqueous solution, acidulated with acetic acid, should not be rendered turbid by ammonium oxalate T.S. (absence of calcium). If a solution of 1 Gm. of the salt in 50 Cc. of water be slightly acidulated with nitric acid, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If to a solution of 2 Gm. of the salt in 10 Cc. of water, acidulated with hydrochloric acid, 0.1 Cc. of barium chloride T.S. be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate)"—(*U. S. P.*). To test for the possible presence of sodium formiate, Hager (*Handbuch der Pharm. Praxis*, 1886) recommends to boil the aqueous solution with addition of silver nitrate solution. A reduction to metallic silver takes place if sodium formiate is present. "If 1.36 Gm. of sodium acetate be completely decomposed at a red heat, and the residue dissolved in water, it should require, for complete neutralization, 10 Cc. of normal sulphuric acid (corresponding to 100 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Acetate of sodium possesses the diuretic properties of acetate of potassium, but in a feebler degree, but it has the advantage over the potassium salt, in not being deliquescent. Moreover, being milder, it is less apt to provoke gastric disturbances. Its dose is from 20 grains to 1 or 2 drachms, largely diluted with water. Larger doses, and sometimes even 1 drachm of it, proves laxative.

SODII ARSENAS (U. S. P.)—SODIUM ARSENATE.

FORMULA: $Na_2HAsO_4+7H_2O$. MOLECULAR WEIGHT: 311.46.

SYNONYMS: *Sodii arsenias* (*Pharm.*, 1880), *Sodium arseniate*, *Arseniate of soda*, *Sodæ arsenias*, *Arsenias natricus*, *Arsenias sodicus*, *Natrium arsenicum*, *Arsenate of soda*.

"Sodium arsenate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—This salt is prepared by melting in a clay crucible arsenic trioxide (*arsenous anhydride*), dried sodium carbonate and sodium nitrate, lixiviating the product of fusion with water and allowing to crystallize (see detailed directions in *Br. Pharm.*, 1885). Or, arsenic trioxide may be dissolved in solution of sodium hydroxide, the solution evaporated to dryness and the mass fused with sodium nitrate. This avoids volatilization of the noxious arsenic trioxide. The fused mass contains *sodium pyro-arsenate* ($Na_4As_2O_7$), analogous to sodium pyrophosphate ($Na_4P_2O_7$), but dissolves in water with formation of the *ortho-arsenate* as follows: $Na_4As_2O_7+H_2O=2AsO_4HNa_2$. This arsenate of sodium is used to some extent in medicine, as in the preparation of *Liquor Sodii Arsenitis*, but is more largely used as a clearing agent after the use of mordants in calico-printing. The *British Pharmacopœia* (1898) recognizes the anhydrous salt Na_2HAsO_4, obtained by exposing crystallized sodium arsenate to a temperature of 148.9° C. (300° F.).

Description and Tests.—Sodium arsenate is described by the *U. S. P.* as occurring in "colorless, transparent, monoclinic prisms, odorless, and having a mild, alkaline taste (the salt is very poisonous). Efflorescent in dry air, and somewhat deliquescent in moist air. Soluble in 4 parts of water at 15° C. (59° F.), and very soluble in boiling water; very sparingly soluble in cold, but soluble in 60 parts of boiling alcohol. When gently heated, the salt loses 5 molecules of water (28.8 per cent), and is converted into a white powder. At 148° C. (298.4° F.) the rest of the water of crystallization is lost, the salt fuses, and at a red heat is converted into pyro-arsenate. It imparts an intense, yellow color to a non-luminous flame"—(*U. S. P.*). Curtmann and Power state that "the salt with 7 molecules of water does not readily effloresce, while that with 12 molecules, which is generally sold, effloresces readily. The salt does not lose the remainder of its water at 148° C., but only 2 molecules. The rest is lost at about 690° C. (1274° F.), or at a bright-red heat. Below 30° C. (86° F.) the salt crystallizes with 12 molecules of water, of which 5 are lost spontaneously. Above 33° C. (91.4° F.), crystals form with 7 molecules" (*Digest of Criticisms on the U. S. P.*, Part II, 1898). "The aqueous solution (1 in 20) of the salt yields a white precipitate with barium chloride T.S., or with calcium chloride T.S., and a dark-red precipitate with silver nitrate T.S., all of which precipitates are soluble in nitric acid"—(*U. S. P.*). These precipitates are the arsenates of the metals named, and are analogous to the corresponding phosphates. Sodium arsenate also forms a characteristic crystalline ammonium-magnesium salt ($AsO_4NH_4Mg+6H_2O$), isomorphous with the corresponding ammonium-magnesium phosphate (see *Magnesii Sulphas*). "If 0.5 Cc. of the aqueous solution (1 in 20) be mixed with 2 Cc. of hydrochloric acid, and a drop of this mixture be placed upon a bright piece of copper-foil, upon applying a gentle heat, a dark steel-gray film will be deposited from the drop upon the copper"—(*U. S. P.*). This is Reinsch's test for arsenic; the gray film consists of this element. "If to 2 Cc. of the aqueous solution (1 in 20) 5 Cc. of decinormal silver nitrate V.S. be added, and the precipitate redissolved by excess of ammonia water, no black precipitate of reduced silver should appear on boiling (absence of arsenite). If to 5 Cc. of the aqueous solution 1 Cc. of ammonium sulphide T.S. be added, no turbidity or coloration should appear (absence of lead, copper, iron, etc.)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The uses of this salt are similar to those of arsenous acid and Fowler's solution. It is claimed to be less irritating than the latter and less likely to produce arsenical phenomena. It is but little employed, however, and chiefly in the form of *Liquor Sodii Arsenatis*. It has been used with success in nervous affections, as *chorea*, and is asserted useful in *saccharine diabetes*. It may be used hypodermatically in doses of from $\frac{1}{20}$ to $\frac{1}{8}$ grain; internally in double these doses. *Antiasthmatic cigarettes* are made from paper which has been saturated with an aqueous solution (1 in 30) of sodium arsenate and dried.

SODII BENZOAS (U. S. P.)—SODIUM BENZOATE.

FORMULA: $NaC_7H_5O_2$. MOLECULAR WEIGHT: 143.71.

SYNONYMS: *Benzoas sodicus, Natrium benzoicum, Sodæ benzoas, Benzoate of soda.*

"Sodium benzoate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Take of pure benzoic acid (made from gum benzoin), 8 parts; bicarbonate of sodium, 5½ parts; distilled water, 6 parts. Mix the benzoic acid, with the distilled water, in a capacious porcelain capsule; raise the temperature, by means of a water-bath, to 65.5° C. (150° F.), then add the bicarbonate of sodium, stirring constantly with a porcelain spatula. When a clear solution is produced, and effervescence ceases, filter; then evaporate the filtrate upon a water-bath, with constant stirring, until a dry salt is obtained. The yield will be 12 parts. The reaction takes place according to the equation $C_6H_5.COOH+NaHCO_3=C_6H_5COONa+H_2O+CO_2$. Instead of bicarbonate of sodium, the carbonate or the hydroxide may be employed. Benzoate of sodium came into use during the latter part of 1879.

Description.—As obtained by the above process, sodium benzoate is a "white, amorphous powder, odorless, or having a faint odor of benzoin, and a sweetish, astringent taste. Permanent in the air"—(*U. S. P.*). When allowed to crystallize, the salt has the composition $C_7H_5O_2Na+H_2O$, but loses its water by efflorescence. The anhydrous salt is "soluble, at 15° C. (59° F.), in 1.8 parts of water, and in 45 parts of alcohol; in 1.3 parts of boiling water, and in 20 parts of boiling alcohol"—(*U. S. P.*). Benzoate of sodium is insoluble in ether and chloroform. "When heated, the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intense yellow color. The aqueous solution is neutral to litmus paper"—(*U. S. P.*).

Tests.—"If a few drops of ferric chloride T.S. be added to an aqueous solution of the salt, a flesh-colored precipitate will be deposited. If 5 Cc. of diluted nitric acid be added to a solution of 1 Gm. of the salt in 10 Cc. of water, a white precipitate of benzoic acid will be produced, which, after being thoroughly washed, should conform to the test of purity given under *Acidum Benzoicum*"—(*U. S. P.*). Especially should it not have a urinous odor, which would indicate that hippuric acid was the source of the benzoic acid employed. "The filtrate from the precipitated benzoic acid should not be rendered turbid by silver nitrate T.S. (absence of chloride), nor by barium chloride T.S. (absence of sulphate). Five Cc. of the aqueous solution (1 in 20) should not give a precipitate with 0.5 Cc. of sodium cobaltic nitrite T.S. (limit of potassium). If to 5 Cc. of the aqueous solution (1 in 20) an equal volume of hydrogen sulphide T.S. be added, no coloration or turbidity be perceptible, either before or after the addition of 1 Cc. of ammonia water (absence of lead, iron, etc.). If 2 Gm. of sodium benzoate be ignited in a porcelain capsule until most of the carbonaceous matter is destroyed, and the residue be then dissolved in 20 Cc. of water, it should require for complete neutralization not less than 13.9 Cc. of normal sulphuric acid (corresponding to at least 99.8 per cent of the pure salt), methyl-orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Benzoate of sodium was introduced into therapeutics as an antipyretic and a decided antiseptic. It is said to reduce *fever* less rapidly than quinine, and more permanently. It has been employed not only as a prophylactic against *diphtheria*, but likewise as a curative agent. It has also been used with variable success in *pharyngitis* and *tonsillitis.* In Germany, many cases of this disease have been recorded, in which it proved successful. Klebs and Hoffmann have derived great benefit from its administration in *erysipelas*, in *albuminuria*, and in some cases of *acute rheumatism.* Petersen succeeded in recovering a patient from an almost hopeless *puerperal fever*, giving it in daily doses of 154 grains in solution; he advises its further trial. More recently it has been recommended in *malarial, infectious*, and *eruptive fevers.* Dr. J. B. Berkhart reports the cure of a case of *syphilitic lupus* from its use. Partzersky, of Moscow, reports the drug a specific in *uræmic poisoning*, as under his administration of it, it promptly controlled the headache, pupillary dilatation, albuminuria, and convulsions of 10 cases of *nephritis*, 3 of which were of the interstitial variety, and the balance of the parenchymatous form. Webster (*Dynam. Therap.*) suggests its remembrance in the *albuminuria of pregnancy.* From the statements made by many physicians who have experimented with this agent, it appears to have valuable therapeutical properties. The salt prepared with the natural benzoic acid should only be employed. Its dose varies from 10 to 20 grains, in solution, repeated every 1, 2, or 4 hours; large doses, even when continued for a long time, give rise to no unpleasant after-effects. A 5 per cent solution of this salt, inhaled into the lungs, has been advised in the treatment of *phthisis* (Rokitansky); no confidence can be placed in its inhalation as a remedial means in this disease. By inhalation or atomization, it is of service in fetid *catarrhal* and *bronchial discharges.*

Related Preparations.—POTASSII BENZOAS. Formula: $KC_7H_5O_2.3H_2O$. Molecular Weight: 213.62. Potassium benzoate is prepared like the corresponding sodium salt, employing benzoic acid (10 parts) and potassium bicarbonate (8.2 parts). The yield is 17.5 parts. It crystallizes, though not readily, in small, efflorescent lamellæ, easily dissolved by water or alcohol.

SODII SULPHOBENZOAS, *Sodium sulphobenzoate* ($C_6H_4[NaSO_3]COONa$).—Twenty-five grains of this salt in a pint of water, is claimed by Heckel as a superior and non-poisonous antiseptic for use upon *wounds.*

SODII BORO-BENZOAS (N. F.), *Sodium boro-benzoate.*—"Sodium borate, in fine powder, 3 parts; sodium benzoate, 4 parts. Mix them intimately"—(*Nat. Form.*, 1st ed.).

SODII BICARBONAS (U. S. P.)—SODIUM BICARBONATE.

FORMULA: $NaHCO_3$. MOLECULAR WEIGHT: 83.85.

SYNONYM: *Bicarbonate of soda, Baking soda, Acid sodium carbonate, Sodium hydrocarbonate, Bicarbonas sodicus, Natrium carbonicum acidulum, Sodæ bicarbonas, Sodium hydrogen carbonate.*

"Sodium bicarbonate should be kept in well-closed vessels, and in a cool place"—(*U. S. P.*).

Preparation.—Sodium bicarbonate may be prepared by allowing crystallized sodium carbonate ($Na_2CO_3+10H_2O$) to lie in contact with carbonic acid gas, evolved from marble or limestone by means of hydrochloric acid. The gas is rapidly absorbed by the salt with formation of bicarbonate, as follows: $Na_2CO_3+10H_2O+CO_2=2NaHCO_3+9H_2O$. The bicarbonate being much less soluble in water than the monocarbonate, the excess of the latter is removed by washing with cold water. By this method sodium bicarbonate may be prepared both on a small and a large scale. The largest quantities of the salt are made by the Solvay or ammonia-soda process, which is that pursued in the Syracuse (N.Y.) Soda Works, as well as in England and partly on the continent of Europe. It consists in saturating a mixture of sodium chloride (common salt) and aqueous ammonia with carbonic acid gas under pressure. Sodium bicarbonate being with difficulty soluble, precipitates, while ammonium chloride remains in solution. The reaction takes place as follows: $NaCl+NH_3+CO_2+H_2O=NaHCO_3+NH_4Cl$. This process is also carried further, namely, to the manufacture of neutral sodium carbonate (see *Sodii Carbonas*).

Description.—The salt, as required by the *U. S. P.*, must contain at least 98.6 per cent of bicarbonate. The *U. S. P.* (1880) admitted, in addition to the pure compound, a commercial salt (of 95 per cent purity) under the name *Sodii Bicarbonas Venalis*. A bicarbonate used in baking powder, as a substitute for commercial potassium bicarbonate (*sal aëratus*, which see), has been called *Soda sal aëratus*. The sodium bicarbonate now official is "a white, opaque powder, odorless, and having a cooling, mildly alkaline taste. Permanent in dry, but slowly decomposed in moist air. Soluble in 11.3 parts of water at 15° C. (59° F.); above that temperature the solution loses carbon dioxide, and at a boiling heat the salt is entirely converted into normal carbonate. Insoluble in alcohol and in ether. When heated, the salt is decomposed into normal carbonate, water, and carbon dioxide, and finally, at 100° C. (212° F.), loses about 36.3 per cent of its weight. At a bright-red heat it melts. To a non-luminous flame, it imparts an intense yellow color. The solution, when freshly prepared with cold, distilled water, without shaking, gives a very faint alkaline reaction with litmus paper. The alkalinity increases by standing, agitation, or increase of temperature. With acids, the solution effervesces strongly"—(*U. S. P.*). Bicarbonate of sodium is, therefore, incompatible with acids, acid salts, also with lime-water, ammonium chloride, and the salts of heavy metals. Sulphate of magnesium does not decompose it, but precipitates with not too dilute a solution of monocarbonate.

Tests.—Sodium carbonate is usually quite pure. It is liable to contain traces of sodium chloride, ammonium bicarbonate, potassium salts, etc., and always contains a small percentage of normal carbonate. The *U. S. P.* test, given below, makes allowance for about 1.76 per cent of sodium carbonate. The *German Pharmacopœia* allows 2 per cent. Its presence is due partly to insufficient saturation, or to loss of carbonic acid gas by exposure. The *U. S. P.* gives the following tests: "If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should yield a perfectly clear and colorless solution, leaving no residue. If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride T.S. (absence of sulphocyanate). If 1 Gm. of the salt be dissolved in 3 Cc. of acetic acid, it should yield no precipitate within an hour after being mixed with 0.5 Cc. of sodium cobaltic nitrite T.S. (limit of potassium). If 0.6 Gm. of the salt be dissolved, without agitation, in 10 Cc. of cold water, and 0.1 Cc. of normal sulphuric acid added, no red color should appear upon the addition of 2 drops of phenolphtalein T.S. (limit of normal carbonate)"—(*U. S. P.*). This test is based upon the conversion of normal sodium carbonate, which reddens phenolphtalein, into bicarbonate, which is neutral to this indicator. The following reaction takes place: $2Na_2CO_3+H_2SO_4=2NaHCO_3+Na_2SO_4$. Care must be taken that no carbonic acid gas escapes; for this reason, the employment of 50 Cc. of water in this test is recommended (C. E. Smith. *Digest of Criticisms on the U. S. P.*, Part II, 1898). The *U. S. P.* further directs: "If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the solution should not be rendered turbid by the addition of an equal volume of hydrogen sulphide T.S., either at once (absence of arsenic, etc.), or after the addition of ammonia water in slight excess (absence of iron, aluminum, etc.).

Five Cc. of the aqueous solution, acidulated with acetic acid, should not be rendered turbid by 0.5 Cc. of ammonium oxalate T.S. (absence of calcium). If 1.2 Gm. of sodium bicarbonate be dissolved in 10 Cc. of diluted nitric acid, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If 2.5 Gm. of the salt be dissolved in 11 Cc. of diluted hydrochloric acid, then 0.1 Cc. of nitric acid and 0.1 Cc. of barium chloride added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate, sulphite, and hyposulphite)"—(*U. S. P.*). The addition of nitric acid is made in order to convert the sulphite and hyposulphite into sulphate, which is then precipitated by barium chloride. "If sodium bicarbonate be heated in a test-tube, no ammonical vapor should be emitted"—(*U. S. P.*). If ammonia is evolved, white clouds are to be seen when a glass rod, moistened with hydrochloric acid, is held in the mouth of the test-tube. "To neutralize 0.85 Gm. of sodium bicarbonate should require not less than 10 Cc. of normal sulphuric acid (corresponding to at least 98.6 per cent of the pure salt), methyl-orange being used as indicator"—(*U. S. P.*). The *German Pharmacopœia* directs that 100 parts of the salt, previously dried over sulphuric acid, upon ignition, should not leave more than 63.8 parts of residue. This corresponds to the presence of 2 per cent of sodium carbonate, as stated above. The loss, upon ignition, consists in the escape of water and carbonic dioxide, according to the equation: $NaHCO_3 = Na_2CO_3 + CO_2 + H_2O$. Thus, 100 parts of the bicarbonate yield 63.095 parts of sodium carbonate, 10.714 parts of water, and 26.191 parts of carbonic dioxide. Mr. H. M. J. Schroeter (*Amer. Jour. Pharm.*, 1888, p. 602) records the analytical results obtained from 16 specimens of commercial sodium bicarbonate. He ignites a weighed quantity of the commercial salt in a combustion tube, determines the quantity of water and carbonic acid gas evolved; upon afterward determining the total quantity of carbonic acid gas present, the amount of moisture and the percentage of mono- and of bicarbonate may be calculated. (Also see formula by Prof. W. T. Wenzell, *ibid.*, 1894, p. 504.)

Action, Medical Uses, and Dosage.—Bicarbonate of sodium possesses properties similar to the bicarbonate of potassium, though less actively diuretic. It also resembles the carbonate of sodium in its action, but is much less irritating, and milder to the taste. It is an excellent antacid, and has been used in *urinary diseases*, attended with *uric acid formations;* but its use should not be continued too long after the removal of these formations, else deposits of the phosphates will occur. The bicarbonate is, however, less apt to produce this result than the carbonate of sodium, more especially when it is administered in carbonic acid water. It has also been recommended as a remedy in *croup*, *membranous sore throat*, *diphtheria*, *tonsillitis*, and to diminish the saccharine matter of *diabetic urine*. It is also useful in *suppression of urine* from *epithelial nephritis*. In *inflammatory diseases*, it is supposed to remove any abnormal increase of fibrin in the blood, and thus aid in effecting a solution of the disease. In *rheumatism*, particularly of the joints, with acid and heavily loaded renal secretions, acid perspiration, high fever, pallid mucous membranes, and white-coated tongue, sodium bicarbonate, both internally and locally, is a very useful agent. Large doses are required. Under such conditions, it is likewise valuable in many cases of *biliary calculi*. Taken after meals, sodium bicarbonate is useful as a palliative, and only as a palliative in *acid dyspepsia*, with cardialgia, sour eructations, flatulence, vomiting, and sour, fluid alvine discharges. Continued for a long time, as it frequently is by persons troubled with "sour stomach," it is apt to increase the difficulty and produce an incurable form of dyspepsia. It is a good agent to control excessive acidity in *fevers*, and a teaspoonful of the salt, in a glass of warm water, relieves *sick headache*, due to *gastric acidity*. In case there is deficient secretion of gastric juice, it should be given ½ hour before meals. *Flatulent colic* is quickly relieved by it, as is also *diarrhœa*, with acid, green discharges. Ten-grain doses, every 2 hours, in infusion of uva ursi, have given good results in *acute cystitis*.

Locally, a solution of sodium bicarbonate forms an exceedingly efficient application to *burns* and *scalds*, *poisoning by Rhus Toxicodendron*, and *pruritus vulvæ*, due to acid urine. It is useful in some forms of *indolent ulcers*. A weak solution has been injected in *gonorrhœa*. A dilute solution is valued to soften *ceruminous masses*, and in *inflammation of the external ear and attic*, and a 10 per cent solution is useful to remove the crusts which form in *ciliary blepharitis*. Large doses of sodium bicarbonate have recently been advised to break up *acute colds*, and the salt enters into the formation of several *catarrh* lotions. In powder, sodium bicarbonate has been recommended to be applied directly to the parts in *acute tonsillitis*, and, with an equal quantity of borax, is reputed to render *diphtheritic deposits* soft. A solution of it is frequently employed as a wash in *acid leucorrhœa*. The dose of bicarbonate of sodium is from 5 to 40 grains in a glass of common soda or carbonated water; the dose for children in proportion.

Specific Indications and Uses.—Pallid mucous membranes, with a filmy, white coat upon the tongue; acid dyspepsia; cardialgia; sour eructations; sour green diarrhœa; flatulent colic; rheumatic pain, with acid urine and sour sweat high fever and sour diarrhœa; uric acid deposits; sick headache, from sour stomach. Locally, to burns, scalds, and dermatitis venenata, and to pruritic states, from uric acid diathesis.

Related Preparations.—SODA POWDERS, or EFFERVESCING POWDERS, are prepared by placing in one paper tartaric acid, 25 grains, and in another bicarbonate of sodium, 30 grains. When to be used, they are dissolved in separate portions of water, to which some aromatic syrup may be added, and then mixed. Effervescence immediately ensues, during which the liquid is to be drank. It forms a cooling and slightly laxative draught, which is very agreeable and invigorating, especially in *fevers*. The effervescence is occasioned by the escape of carbonic acid gas, which is set free from the bicarbonate by the tartartic acid, which unites with the sodium, forming a tartrate of sodium.

BAKING POWDERS.—These are usually composed of sodium bicarbonate and an acid ingredient which, in contact with the former, decomposes it with evolution of carbonic acid gas. A method of making baking powder, long in use as such, is by mixing 2 (or 2½) parts of pure bitartrate of potassium and 1 part of bicarbonate of sodium.

SODII BICARBONAS SACCHARATUS (N. F.), *Saccharated sodium bicarbonate.*—"Sodium bicarbonate (*U. S. P.*), in very fine powder, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; sugar, in very fine powder, two hundred and fifty grammes (250 Gm. [8 ozs. av., 358 grs.]. Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles. *Note.*—This saccharate, when dissolved in water with an equal weight of saccharated citric acid (F. 5), or of saccharated tartaric acid (F. 8), will form a neutral solution, and it is introduced into the formulary for the convenient preparation of effervescent powders. This saccharate contains 75 per cent of sodium bicarbonate"—(*Nat. Form.*).

SODII BISULPHIS (U. S. P.)—SODIUM BISULPHITE.

FORMULA: $NaHSO_3$. MOLECULAR WEIGHT: 103.86.

SYNONYMS: *Sodæ bisulphis, Bisulphite of soda.*

"Sodium bisulphite should be kept in a cool place, in small, well-stoppered bottles, filled as full as possible"—(*U. S. P.*).

Preparation and Uses.—Bisulphite of sodium may be obtained by passing a current of sulphurous acid gas through a solution of 1 part of crystallized carbonate of sodium in 2 parts of water, until the acid is in excess, and then concentrating, being careful to exclude the air. The bisulphite forms 4-sided rectangular prisms on cooling. This salt is Chaudet's *leucogène*, and is employed in the arts for the purpose of bleaching wool, etc., and as an *antichlor*, instead of sodium hyposulphite (which see), to remove excess of chlorine when used in bleaching wood-pulp, paper, etc. It is likewise employed as a preservative for meats, eggs, etc., and as an antiferment. An important use is now made of this salt in the manufacture and purification of essential oils, owing to its property of forming crystallizable addition products with aldehydes and ketones, *e. g.*, cinnamic aldehyde, citral, etc. (see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, pp. 212, 221, 505, etc.).

Description and Tests.—"Opaque, prismatic crystals, or a granular powder, exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble, at 15° C. (59° F.), in 4 parts of water, and in 72 parts of alcohol; in about 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an acid reaction with litmus paper. On the addition of hydrochloric or sulphuric acid, the aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate T.S. and held over the escaping gas. If 1.2 Gm. of sodium bisulphite be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If 2.5 Gm. of sodium bisulphite be dissolved in 11 Cc. of diluted hydrochloric acid with the aid of sufficient heat to expel the sulphur dioxide, the solution should not be turbid (absence of hyposulphite). After adding to it 0.15 Cc. of barium chloride T.S., and removing the precipitate, if any, by filtration, a portion of the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate). If to 5 Cc. of the preceding filtrate an equal volume of hydrogen sulphide T.S. be added, no turbidity or coloration should occur (absence of arsenic, etc.). If 0.26 Gm. of sodium bisulphite be dissolved in 20 Cc. of water, recently boiled to expel air, and a little starch T.S. be added, at least 45 Cc. of decinormal iodine V.S. should be required to produce a permanent blue tint after agitation (corresponding to at least 90 per cent of pure sodium bisulphite)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt has been preferred by some physicians to the sodium hyposulphite, in the *vomitings* and *aphthous ulcerations* referred to under magnesium sulphite and sodium hyposulphite; it being remarked that when the hyposulphite is decomposed by the hydrochloric acid of the stomach, not only is sulphurous acid set free, but sulphur is precipitated which is not a desirable agent—that is not the case with the bisulphite. The dose of the bisulphite of sodium is from 10 to 60 grains.

SODII BORAS (U. S. P.)—SODIUM BORATE.

FORMULA: $Na_2B_4O_7+10H_2O$. MOLECULAR WEIGHT: 380.92.

SYNONYMS: *Borax*, *Boras sodicus*, *Sodium pyroborate*, *Sodium tetraborate*, *Natrium pyroboricum*, *Natrium biboricum* or *biboracicum*, *Sodæ biboras*, *Biborate of soda*, *Borate of soda*.

Source, History, and Preparation.—Borax occurs in nature in several forms; as crystallized crude borax it is found on the borders of various lakes in Persia and Thibet, and is obtained in large quantities also from the beds of the borax lakes of Nevada and California, as well as the sandy soils of these regions (see account by Arthur Robottom, *Amer. Jour. Pharm.*, 1887, pp. 80–86; also see *ibid.*, 1882, p. 472, and 1885, p. 304). That formerly imported from Asia by way of Venice and Holland, was called *tinkal* or *crude borax*, and required special methods of purification owing to its being coated with a fatty substance (see this *Dispensatory*, preceding edition). Native borax also occurs near Potosi (Peru). In the form of *boro-natrocalcite* or *tiza* (hydrated sodium-calcium borate) it is found in South America (Chili and Peru), and in Nevada and California and other countries. Considerable quantities of the borax of commerce are now prepared from boric acid, which in turn is derived either from the Tuscany occurrence (see *Acidum Boricum*), or from borate minerals (*boracite* [magnesium borate and magnesium chloride], *boro-natrocalcite*, *ulexine*, etc.) by decomposition with sulphuric or hydrochloric acids. In order to prepare borax, coarsely pulverized boric acid is added to solution of sodium carbonate, and the product allowed to crystallize. The crude borax is refined by crystallization from hot water with addition of some sodium carbonate. Another method of preparing borax consists in fusing together crude boric acid with a definite amount of sodium carbonate, dissolving in water, filtering and evaporating to crystallization.

Description and Tests.—Crystallized borax ($B_4O_7Na_2+10H_2O$), as usually obtained, crystallizes in the monoclinic system and is called *common* or *prismatic borax*, while *octohedral borax* ($B_4O_7Na_2+5H_2O$) crystallizes in the regular system, in octohedra, and is obtained by allowing a concentrated solution of borax in water to crystallize above 56° C. (132.8° F.). Prismatic borax, as required by the *U. S. P.*, occurs in "colorless, transparent, monoclinic prisms, or a white powder, inodorous, and having a sweetish, alkaline taste. Slightly efflorescent in warm, dry air. Soluble in 16 parts of water at 15° C. (59° F.), and in 0.5 part of boiling water; insoluble in alcohol. At 80° C. (176° F.) it is soluble in 1 part of glycerin"—(*U. S. P.*). Glycerin and other polyhydric alcohols, *e. g.*, sugars, react with borax, decomposing it into sodium metaborate ($Na_2B_2O_4$) and free boric acid; the liberation of the latter induces secondary reactions, *e. g.*, formation of ethers (see *Glycerinum*). "When heated, the salt at first loses part of its water, then melts, and, when further heated, swells up and forms a white, porous mass. At a red heat it loses all its water of crystallization (47.14 per cent), and fuses to a colorless glass. To a non-luminous flame it imparts an intense, yellow color"—(*U. S. P.*). The transparent mass formed when borax is fused is called *vitrified borax, glass of borax, borax-glass;* it is anhydrous borax ($Na_2B_4O_7$). Borax glass, melted in the flame of a blow-pipe, dissolves oxides of metals, some, *e. g.*, cobalt salts, with characteristic color, hence its use as a dry-way test for certain metallic salts. When borax is fused with sodium carbonate in equimolecular proportions, the fused mass upon crystallization from water yields crystals of *sodium metaborate* ($Na_2B_2O_4+8H_2O$). When borax is added to a mucilage it soon thickens it into a firm, tremulous jelly, which is soluble in syrup. A few drops of diluted acetic acid added to the mucilage or emulsion will prevent this action of borax.

Tests and Uses.—The following tests are characteristic for borax and boric acid: "The aqueous solution (1 in 20) colors red litmus paper blue, and yellow turmeric paper reddish-brown. After being acidulated with hydrochloric acid, the solution colors blue litmus paper red; yellow turmeric paper remains unchanged at first, but, on drying, becomes brownish-red, and this color is temporarily changed to bluish-black by moistening with ammonia water. If a drop of the solution of the salt in glycerin be held in the flame, a transient bright-green color will appear"—(*U. S. P.*). This coloration is due to a glycerin ether of boric acid. "If a slight excess of sulphuric acid be added to a hot, saturated, aqueous solution of the salt, shining, scaly crystals of boric acid will separate on cooling, which impart a green color to the flame of alcohol"—(*U. S. P.*).

Borax is rarely adulterated. In one instance, borax contained 20 per cent of phosphate of sodium. This was separated mechanically by exposing the salt to the heat of a drying-room for a few hours, when the phosphate effloresced and could be picked out and tested with the usual reagents.

The usual contaminations of borax are chlorides and sulphates which are rarely absent. The *U. S. P.* gives the following directions for the detection of impurities: "With 19 Cc. of water, 1 Gm. of the salt should yield a perfectly clear and colorless solution, leaving no residue. The aqueous solution (1 in 20) should not effervesce with acids (absence of carbonate). It should not be rendered turbid by ammonium sulphide T.S. (absence of iron, aluminum, etc.); nor after being acidulated with hydrochloric acid, by an equal volume of hydrogen sulphide T.S. (absence of arsenic, lead, etc.). When acidulated with acetic acid, the solution should not be rendered turbid by ammonium oxalate T.S. (absence of calcium). The aqueous solution (1 in 20) should not be rendered turbid by magnesia mixture (absence of phosphate). If 0.48 Gm. of the salt be dissolved in 15 Cc. of water, then 1 Cc. of diluted nitric acid and 0.2 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If 2.5 Gm. of the salt be dissolved in 50 Cc. of water, then 10 Cc. of diluted hydrochloric acid and 0.1 Cc. of barium chloride T.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted sulphuric acid by the aid of heat, and 3 drops of indigo T.S. be added, the blue color should not be discharged (absence of nitrate)"—(*U. S. P.*).

Borax is frequently used in the arts, being employed in the glazing of brick, tiling, earthenware utensils, etc., as well as the enameling of iron vessels. Meat packers consume large quantities of it. It is used as a flux in metallurgical manipulations, and is employed in laundries to impart a gloss to starched garments. Many toilet and medicinal soaps contain it. Borax, recrystallized, has been suggested as a possibly useful agent in standardizing volumetric acid solutions (see W. A. Puckner, *Pharm. Archives*, 1898, p. 182).

Action, Medical Uses, and Dosage.—In very large doses borax is a poison acting as a depressant upon the heart and spinal axis. In general its effects closely resemble those of boric acid. The chief toxic symptoms are mental depression, enfeebled heart action with either slow or rapid, but very weak, pulsation, reduced temperature, and an erythema accompanied with itching and tumefaction and followed by exfoliation of the skin; ecchymotic discolorations are sometimes observed, the respiration is disordered, the urine and fæces are involuntarily discharged and coma, followed by death, ensues. The mental faculties are usually active until near dissolution. Borax has been largely used as an antiseptic agent. Its action upon bacteria is said to be less pronounced than its power of preventing putrefactive changes (Sternberg).

The medicinal actions of borax are but imperfectly known. It is supposed to be a diuretic, refrigerant, antilithic, emmenagogue, and aphrodisiac. It has been found an excellent remedy in *renal diseases* and *gravel*, when uric acid is present in excess, and may be used in doses of from 20 to 40 grains, well diluted with water. It is rarely used as a parturient agent, yet there is no doubt that it exerts an action on the uterus. It has been successfully used in *amenorrhœa*, *dysmenorrhœa*, especially for the radical cure of the membranous form, in *uterine hemorrhage*, and to promote *parturition*, or expedite the delivery of the placenta. In such instances it has been used alone, or combined with other agents, as ergot, blue cohosh, cinnamon, etc. Ten grains given for a dose, and repeated 3 or 4 times a day for several days, have produced abortion, attended with pains all over the system, and excessive debility of the joints, which remained for several months in a greater or less degree. It is an aphrodisiac, and will excite the venereal appetite when taken internally; but its aphrodisiac effects are said to be more marked when a solution of it is injected into the rectum, and retained there 1 or 2 hours. A solution of 10 or 15 grains to the fluid ounce of water, injected, will, in 2 or 3 hours, produce a powerful venereal excitement. And if the strength of the solution be doubled, it will cause powerful erections, and several copious seminal emissions. These aphrodisiac effects, however, will often be found to fail with certain individuals. Small doses of borax (1 grain, 3 or 4 times a day) have been employed with asserted success in *sterility* where conception was prevented by leucorrhœal discharges. In nervous diseases borax has been used somewhat, particularly in *epilepsy*. The results, however, have not been such as to warrant the extravagant statements made in favor of it. Small doses of borax are especially valuable in the *summer disorders of children*, and in *fetid dysentery*. In the latter disorder an injection of solution of borax is also of value. For internal administration, Prof. J. M. Scudder, M. D., recommended teaspoonful doses of a solution of from 1 to 5 grains of borax "in *persistent sore mouth; dyspepsia*, with sense of constriction; gnawing pain; uneasy stools; frequent desire to pass urine, the last part of the discharge being muco-pus; dragging pain in the back, and *acrid leucorrhœa*" (*Spec. Med.*, p. 93).

In the strength of from 1 to 4 drachms to 1 pint of water, borax forms a good antiseptic wash and dressing for "*wounds, injuries*, and *surgical operations*." It is in extensive use as an external application in *aphthous* and *inflammatory conditions of the mouth and throat*, and in *scaly diseases of the skin*. A solution of 1 drachm in 5 fluid ounces of water, with a little sugar or honey, forms one of the best applications for use as a gargle in the early stage of *mercurial salivation*, and also in all varieties of *aphthous ulceration of the mouth and throat*. No remedy is more efficient in the *aphthous sore mouth of infants*. Equal parts of borax and loaf-sugar triturated together may be employed, sprinkling the mixture upon the sores several times a day. For older persons and especially for the *aphthous ulcerations of phthisis*: ℞ Borax, ʒiii; honey, ℥ss; infusion of sage, q. s. Oj. Apply freely (Locke). With myrrh and honey it is efficient in *sponginess of the gums*. It is a good remedy for *thrush* in infants and for *sore nipples* and *aphthous conditions of the vulva and vagina*. Borax ʒss to cold cream ʒss, forms a good application for *chilblains*, and both in lotion and ointment the salt is considered efficient for *falling of the hair*. In *liver spots* (*pityriasis versicolor*) a lotion of borax has also been found beneficial, as it has in *freckles*, and other *blemishes of the skin*, and alone or combined with morphine, it is an exceedingly soothing application in *pruritis vulvæ*. Combined with sugar it forms an excellent collyrium, and enters into several cooling or refrigerant lotions. Powdered borax blown into the nostrils will be found useful in many instances of *chronic catarrh*, and *chronic inflammation of the mucous membrane lining the nasal and faucial passages*. A wash of borax is frequently used in the same affections. It forms a useful injection for *gonorrhœa*, a bladder wash in *cystitis*, with unhealthy discharges, and a good dressing for the *bites of animals*. It is universally employed as an injection for *inflammatory states of the vagina*. In *leucorrhœa* it is best adapted where the secretion is glairy, colored, and profuse; a strong solution should be employed. Borax forms a good dry dressing for *chancroid*, and in solution is effective in the treatment of *bubo*. It forms a good wash in *diphtheria*, but of course is not curative. In aural practice it is used to soften *inspissated ceruminous masses*, and to cleanse the meatus and middle ear of pus, being even preferable to boric acid for the latter purpose. In *ocular disorders* it is used in removing corneal *opacites*, in *muco-purulent conjunctivitis*, *corneal ulceration*, and to remove the crusts in *ciliary blepharitis*. For use upon the eye it should be used of the strength of 5 grains to 1 fluid ounce of water. Sprinkled around libraries, pantries, etc., borax will be found effectual in driving away cockroaches and other insects. One drachm of borax dissolved in 2 fluid ounces of distilled vinegar, is said to be an excellent lotion for *ringworm of the scalp* (C.). The dose of borax is from 10 to 30 grains, dissolved in water, or in infusion of elm or flaxseed.

Specific Indications and Uses.—Uric acid diathesis; gravel; persistent sore mouth; dyspepsia, with feeling of constriction; gnawing pains, uneasiness at stool, urging to urinate, the discharge being finally of muco-pus; dragging pain in the back; acrid leucorrhœa. Locally in aphthous conditions of the mouth, throat, vulva and vagina; a wash for catarrhal discharges; leucorrhœa with glairy, colored, and copious discharge; pruritis vulvæ; freckles; a cleansing antiseptic.

Derivative of Borax.—Soluble Cream of Tartar, *Tartarus boraxatus*, *Cremor tartari solubilis*, is obtained by dissolving 3 parts of cream of tartar and 1 part of borax in 8 parts of water, boiling for 2 or 3 minutes, and filtering when cool. Upon evaporating the solution on a steam-bath, a gummy, acid mass is obtained, soluble in water. It absorbs moisture from the atmosphere and must be kept in a well-closed vessel, The *French Codex* (1884) employs boric acid, and gives the following directions: One part of crystallized boracic acid, 4 parts of powdered bitartrate of potassium, and 10 parts of water, are exposed, in a silver vessel, to ebullition with constant agitation, until evaporation has reduced the mixture to a thick mass; this mass is detached in portions, spread on plates, and dried in a heated stove at a temperature of 40° to 50° C. (104° to 122° F.). The dry product is then broken into pieces and preserved in well-closed bottles. It is soluble in water in all proportions. (As to the chemical composition of these preparations, see E. Jahns, *Archiv der Pharm.*, 1878, p. 224.)

SODII BROMIDUM (U. S. P.)—SODIUM BROMIDE.

Formula: NaBr. Molecular Weight: 102.76.

"Sodium bromide should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Sodium bromide may be prepared by the action of bromine upon solution of sodium hydroxide, evaporating the solution of sodium bromide and bromate to dryness, mixing the residue with charcoal, and igniting in a Hessian crucible, dissolving in water, and allowing to crystallize. Or, the salt may be obtained by double decomposition between solutions of sodium carbonate and ferrous bromide, as follows: $FeBr_2 + Na_2CO_3 = FeCO_3 + 2NaBr$ (compare *Potasii Bromidum*). From hot, concentrated solutions, the salt is obtained in anhydrous, cubical crystals; from solutions evaporating at ordinary temperatures, monoclinic prisms are formed, holding 2 molecules of water ($NaBr.2H_2O$). The anhydrous salt contains more bromine (77.62 per cent) than its corresponding potassium salt (67.13 per cent).

Description and Tests.—The *U. S. P.* describes sodium bromide as occurring in "colorless or white, cubical crystals, or a white, granular powder, odorless, and having a saline, slightly bitter taste. From air the salt attracts moisture without deliquescing. Soluble, at 15° C. (59° F.), in 1.2 parts of water, and in 13 parts of alcohol; in 0.5 part of boiling water, and in 11 parts of boiling alcohol. When heated to a bright-red heat, the salt melts, and, at a somewhat higher temperature, slowly volatilizes, without decomposition. To a non-luminous flame, it imparts an intense, yellow color. The aqueous solution is neutral, or at most very feebly alkaline, to litmus paper. If a few drops of chloroform be poured into 10 Cc. of the aqueous solution (1 in 20), then 1 Cc. of chlorine water added, and the mixture agitated, the liberated bromine will dissolve in the chloroform, imparting to it a yellow or brownish-yellow color, without a violet tint. The aqueous solution (1 in 20) should be clear and colorless, and should not be rendered turbid by sodium bitartrate T.S., nor by sodium cobaltic nitrite T.S. (limit of potassium); nor by ammonium oxalate T.S. (absence of calcium); nor by barium chloride T.S. (absence of sulphate). If the aqueous solution be slightly acidulated with hydrochloric acid, it should not be rendered turbid by the addition of an equal volume of hydrogen sulphide T.S., either at once (absence of arsenic, lead, etc.), or after adding ammonia water in slight excess (absence of iron, aluminum, etc.). If diluted sulphuric acid be dropped upon some of the powdered salt, no yellow color should appear at once (absence of bromate). If 5 Cc. of the aqueous solution (1 in 20) be mixed with a few drops of starch T.S., and then 0.5 Cc. of chlorine water added, no blue color should appear (absence of iodine). If 1 Gm. of the powdered salt be kept for 20 minutes at a temperature of 100° C. (212° F.), or slightly above it, it should not lose more than 0.03 Gm. in weight (limit of moisture). If 0.3 Gm. of the well-dried salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should not require more than 29.8 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to at least 97.29 per cent of the pure salt"—(*U. S. P.*). By this test, allowance is made for about 2.6 per cent of chloride.

Action, Medical Uses, and Dosage.—Sodium bromide is practically identical with the potassium salt in its effects upon the system, except in point of activity, being somewhat less of a nerve sedative and hypnotic. It has the advantage over potassium bromide in that it seldom occasions the dullness of mind and lethargy so common to the former, nor is its effect upon the nervous system so depressing. It has the further advantage of a pleasanter taste, and comparative freedom from the tendency to produce acneiform eruptions, fetid breath, and other symptoms of bromism. For the general purposes for which the bromides are indicated, it may be preferred to the potassic salt, except in severe cases of *epilepsy*, when the more powerful action of the latter will be required. In milder cases the sodium salt will answer, and it may be substituted in cases where the bromides are necessary, and yet the potassium compound can not be tolerated. It is especially to be preferred in the disorders of children. Like potassium bromide, a condition of plethora is the indication for it, and it is especially useful in *insomnia*, with excitement, from bodily and mental fatigue; the excitation of *delirium tremens*, *cardiac palpitations*, purely nervous, and the result of masturbation, sexual excesses, and the immoderate use of alcohol, tobacco, cigarettes, etc., and in the various phases of nervous irritability attending the climacteric. Dose, from 2 to 60 grains, and gradually increased, if necessary, to 120 grains. It should be well diluted with water.

Specific Indications and Uses.— Practically the same as for *Potassii Bromidum* (which see).

SODII CARBONAS (U. S. P.)—SODIUM CARBONATE.

FORMULA: $Na_2CO_3+10H_2O$. MOLECULAR WEIGHT: 285.45.

SYNONYMS: *Sal sodæ depuratus*, *Pure carbonate of sodium*, *Soda carbonas*, *Carbonas sodicus*, *Sal soda*, *Washing soda*, *Carbonate of soda*.

"Sodium carbonate should be kept in well-closed vessels"—(*U. S. P.*).

Source, Preparation, and History.—Carbonate of sodium exists in several mineral springs, in the alkali lakes of Egypt, Venezuela, Mexico, California, Wyoming, etc., and in the surface of certain soils in the form of an efflorescence, *e. g.*, near Tripoli, in north Africa, and Hungary. It is also to be found in the ashes of seaweeds and salt-marsh plants. The soda from Egypt is called *trona*, and is composed of carbonate and bicarbonate of sodium. *Barilla* and *kelp* are preparations from the ashes of marine plants; the former contains about 30 per cent of sodium carbonate. At one time 20.000 persons were engaged in the manufacture of kelp in the Orkneys and Hebrides Islands.

The two chief sources from which sodium carbonate is now made on a large scale, are *common salt* and the mineral *cryolite*, occurring in Greenland in large quantities. Common salt is converted into sodium carbonate by two different methods: (1) The *Leblanc* process (1794), and (2) the *ammonia-soda* process of Solvay (1861).

The LEBLANC PROCESS consists in converting the sodium chloride first into sodium sulphate (*salt-cake process*) by means of sulphuric acid, hydrochloric acid being obtained as a by-product, as follows: $2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$. The sulphate, being thoroughly dried, is intimately mixed with calcium carbonate (limestone) and coal in certain proportions. The mixture is then subjected to a strong heat in a reverberatory furnace (or in a large revolving drum; see illustration in Roscoe and Schorlemmer's *Chemistry*) until a pasty, dark mass is obtained, called *black soda-ash*. The chief constituents of the latter are water-soluble sodium carbonate (about 44 per cent) and insoluble calcium sulphide (about 30 per cent), and are formed as follows: $Na_2SO_4 + C_4 = Na_2S + 4CO$; $Na_2S + CaCO_3 = Na_2CO_3 + CaS$. When this mass is lixiviated, and the solution evaporated to dryness. the sodium carbonate is obtained as a white or gray compact substance which is called *soda-ash* or *white soda-ash*. The carbonate of sodium, or *sal soda*, of commerce, is obtained by dissolving the white soda-ash in water, separating the impurities by filtration or sedimentation, running the solution into vats, and allowing it to crystallize. This mode of manufacturing carbonate of sodium was formerly employed almost exclusively.

The SOLVAY PROCESS is that pursued in the United States. The bicarbonate obtained in this process (see *Sodii Bicarbonas*) is heated to redness, and the monocarbonate formed is dissolved in water and crystallized. The bicarbonate, when heated to dull-redness, is decomposed according to the equation: $2NaHCO_3 = Na_2CO_3 + H_2O + CO_2$.

From CRYOLITE ($Al_2Fl_6.6NaFl$), sal soda is obtained by mixing the finely-powdered mineral with chalk or with caustic lime, and heating to redness, short of fusion. Insoluble calcium fluoride and soluble sodium aluminate are formed as follows: $Al_2Fl_6.6FlNa + 6CaO = 6CaFl_2 + Al_2O_3.3Na_2O$. The sodium aluminate is dissolved in water, and decomposed by carbonic acid gas into insoluble aluminum hydroxide and soluble sodium carbonate, according to the equation: $Al_2O_3.3Na_2O + 3CO_2 + 3H_2O = Al_2(OH)_6 + 3Na_2CO_3$.

Description.—The ordinary form met with in commerce, under the names *sal soda* and *washing soda*, is the impure article, known as *Sodii Carbonas Venalis* (*Sal sodæ, Soda cruda*). When purified by repeated crystallization from hot water, it yields the pharmacopœial salt. The latter is described as occurring in "colorless, monoclinic crystals, odorless, and having a strongly alkaline taste. In dry air, the salt effloresces, and, if left exposed, soon loses about half of its water of crystallization (31.46 per cent of its weight), and becomes a white powder. Soluble in 1.6 parts of water at 15° C. (59° F.), and in 0.09 part at 38° C. (100.4° F.), and in 0.2 part of boiling water; insoluble in alcohol and in ether; soluble in 1.02 parts of glycerin. When heated to 32.5° C. (90.5° F.), the crystals fuse in their water of crystallization, and lose some water. At a higher temperature, the salt continues to lose water, until, at last, an anhydrous residue is left, corresponding to 37 per cent of the weight of the crystals. At a bright-red heat the anhydrous salt fuses. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an alkaline reaction with litmus paper, and effervesces strongly with acids. On treating the salt with 20 parts of water. a clear and colorless solution should be formed. and no insoluble residue should be left"—(*U.S.P.*). Its incompatibilities are acids. metallic and earthy salts, solutions of lime, bitartrate of potassium, chloride of ammonium. solutions of metallic salts. etc.

Tests.—Carbonate of sodium is distinguished from potassium carbonate by its disposition to effloresce, while the latter tends to absorb moisture. The potassium salt, in solution, may be readily identified by yielding a crystalline precipitate with an excess of tartaric acid. From sodium bicarbonate, the monocarbonate may be roughly distinguished by its greater solubility in water, by yielding a white precipitate with magnesium sulphate. and a reddish-brown one with corrosive sublimate. The *U. S. P.* ascertains the purity of sodium carbonate by the following tests: "If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride T.S. (absence of sulphocyanate). If to 5 Cc. of the aqueous solution, slightly supersaturated with hydrochloric acid, an equal volume of hydrogen sulphide T.S. be added, no turbidity should be produced, either before or after the addition of ammonia water in slight excess (absence of arsenic, lead, iron, aluminum, etc.). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of ammonium oxalate T.S. should produce no turbidity (absence of calcium). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of sodium cobaltic nitrite T.S. should not render it turbid within 1 hour (limit of potassium). If 1.2 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If 2.5 Gm. of the salt be dissolved in 10 Cc. of diluted hydrochloric acid, then 0.1 Cc. of nitric acid and 0.1 Cc. of barium chloride T.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate, sulphite, and hyposulphite). If the crystallized salt be heated in a test-tube, the vapor of ammonia should not be evolved. To neutralize 1 Gm. of anhydrous sodium carbonate (deprived of its water of crystallization by heat immediately before being weighed) should require not less than 18.7 Cc. of normal sulphuric acid (corresponding to not less than 98.9 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*). (For method of quantitative determination of monocarbonate, when mixed with bicarbonate, see *Sodii Bicarbonas;* for determination of carbonate in the caustic alkali, see *Potassa.*)

Action, Medical Uses, and Dosage.—In large doses, carbonate of sodium will prove very injurious, producing a softening and disorganization of the tissues of the stomach. In smaller ones, it acts as an antacid and diuretic. The antidotes to an improper dose are vegetable acids, as vinegar, lemon-juice, sour wine, solution of cream of tartar, citric or tartaric acids; sweet oil, largely administered, will also modify its destructive action. As a remedy it has been used in *gastric acidity*, in *urinary affections*, with *uric acid deposits*, *gastro-cephalagia* or *sick headache*, *pertussis*, *goitre*, *scrofula*, etc. It is usually preferred to the potassium salt on account of its more pleasant taste. As with all the alkaline carbonates, if too long employed, it may bring on phosphatic gravel through the alkalinity of the urine; on this account, the bicarbonates dissolved in carbonic acid water and taken, are preferable, as the excess of carbonic acid tends to keep the phosphates in solution. It has been found useful in some *cutaneous diseases*, used internally and applied locally, in solution, 15 or 20 grains or even more of the carbonate, to 2 fluid ounces of water; or a bath may be prepared of similar proportions. The skin disorders most benefited by it, are those of a dry or scaly character. The strength of the bath or lotion must be regulated according to their effects. It is regarded as less valuable in the *vesicular and pustular skin diseases*, in which, as a rule, the bath must be very much diluted. A weak solution is of service, locally, in *pruritis vulvæ*. Continued large doses of this salt have produced, in a very few days, marked symptoms of a scorbutic character. It is but little used at the present day. The dose of carbonate of sodium is from 5 to 20 grains, in well diluted solution.

SODII CARBONAS EXSICCATUS (U. S. P.)—DRIED SODIUM CARBONATE.

FORMULA: $Na_2CO_3 2H_2O$. MOLECULAR WEIGHT: 141.77.

SYNONYMS: *Sodii carbonas exsiccata*, *Dried carbonate of soda*.

Preparation—"Sodium carbonate, two hundred grammes (200 Gm.) [7 ozs. av., 247 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] Break the crystals into small fragments, and allow them to effloresce for several days in warm air, at a temperature not exceeding 25° C. (77° F.), until they are completely disintegrated, then dry the white powder at a temperature of about

45° C. (113° F.), until its weight is reduced to one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Pass the powder through a sieve, and preserve it in well-stoppered bottles"—(*U. S. P.*). The composition of the crystallized sodium carbonate being $Na_2CO_3+10H_2O$, a loss of 50 per cent of its weight results in a compound retaining a little over 3 molecules of water. By allowing the salt to effloresce at the moderate temperature directed (32.5° C. [90.5° F.]), a light and bulky powder is obtained. If the salt be heated so as to remove all its water of crystallization, as directed by the *British Pharmacopœia*, a denser, heavier, anhydrous product is formed.

Description and Tests.—"A loose, white powder, conforming to the reactions and tests given under *Sodii Carbonas*. To neutralize 1 Gm. of the salt should require not less than 13.8 Cc. of normal sulphuric acid (corresponding to about 73 per cent of anhydrous sodium carbonate), methyl orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Dried or anhydrous carbonate of sodium possesses properties similar to the crystallized carbonate. It is antacid and antilithic, and is useful in *urinary affections with excess of uric acid*. It may be given in powder or in pill, with extracts, soap, etc., though, on account of its irritant properties, these are bad forms of exhibition. It is better given very largely diluted with water. The dose is from 5 to 15 grains, rather less than the carbonate, on account of its loss of water of crystallization.

SODII CHLORAS (U. S. P.)—SODIUM CHLORATE.

FORMULA: $NaClO_3$. MOLECULAR WEIGHT: 106.25.

SYNONYMS: *Natrium chloricum*, *Chloras sodicus*.

"Sodium chlorate should be kept in glass-stoppered bottles, and *great caution* should be observed in handling the salt, as dangerous explosions are liable to occur when it is mixed with organic matters (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and either heated directly, or subjected to trituration or concussion"—(*U. S. P.*).

Preparation.—Sodium chlorate is obtained from potassium chlorate by double decomposition with sodium salts of such acids as will produce difficultly soluble potassium salts, *e. g.*, sodium fluosilicate, or sodium bitartrate (Wittstein). In the latter case, the following reaction takes place: $KClO_3+NaHC_4H_4O_6=NaClO_3+KHC_4H_4O_6$ (cream of tartar).

Description and Tests.—This salt parts with its oxygen so readily that the caution above given is exceedingly appropriate. The *U. S. P.* describes this body as occurring in "colorless, transparent crystals (principally regular cubes, with tetrahedral facets), or a crystalline powder, odorless, and having a cooling, saline taste. Permanent in dry air. Soluble, at 15° C. (59° F.), in 1.1 parts of water, and in about 100 parts of alcohol; in 0.5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 per cent of its weight), and finally leaves a residue of sodium chloride, readily soluble in water, and yielding, with silver nitrate T.S., a white, curdy precipitate, insoluble in nitric acid. To a non-luminous flame, it imparts an intense, yellow color"—(*U. S. P.*). Decomposition upon heat takes places as follows: $NaClO_3 = NaCl+O_3$. If a trace of organic matter—*e.g.*, potassium or sodium tartrate is present in the salt, some chlorine will also be given off, and the residue has an alkaline reaction (see *Tests*, below; and F. Holberg, *Amer. Jour. Pharm.*, 1886, p. 15). "The aqueous solution is neutral to litmus paper. When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color, and emits the odor of chlorine. A saturated, aqueous solution should not be rendered turbid by sodium bitartrate T.S. (limit of potassium). An aqueous solution of the residue left after igniting a portion of the salt, should not give an alkaline reaction with litmus paper (absence of tartrate). The aqueous solution (1 in 20), slightly acidulated with acetic acid, should not be rendered turbid by the addition of an equal volume of hydrogen sulphide T.S., either at once (absence of arsenic, lead, etc.), or after the addition of ammonia water in slight excess (absence of iron, aluminum, etc.). The aqueous solution (1 in 20) should not be rendered turbid by adding to it a few drops of ammonia water, and then sodium phosphate T.S. (absence of magnesium, etc.). The solution (1 in 20), slightly acidulated with acetic acid, should not be rendered turbid by ammonium oxalate T.S. (absence of calcium); nor by barium chloride T.S. (absence of sulphate); nor should silver nitrate T.S. produce in it more than a slight opalescence (limit of chloride) "—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The only advantage this salt has over the corresponding potassium chlorate, whose properties are identical, but stronger, is its greater solubility, so that stronger solutions may be employed. It is seldom used in medicine. Solutions of from 1 to 5 per cent may be used as a lotion or gargle. The dose ranges from 1 to 20 grains.

SODII CHLORIDUM (U. S. P.)—SODIUM CHLORIDE.

FORMULA: NaCl. MOLECULAR WEIGHT: 58.37.

SYNONYMS: *Common salt*, *Sea salt*, *Table salt*, *Sal culinare*, *Sal commune*, *Chloruretum sodicum*, *Muriate of soda*, *Sodæ murias*.

Source, History, and Preparation.—Chloride of sodium has been known and employed as an indispensable seasoner of food since the very origin of the human race. It exists in unlimited quantity in the waters of the ocean, which contain about 2½ per cent of chloride of sodium, with other mineral salts, and is also found in many mineral waters, springs, and lakes (Dead Sea in Palestine, Salt Lake in Utah). It is also met with in the solid form as cubical *Rock-salt* (*Fossil-salt*, *Gem-salt*, *Sal Gemmæ*, etc.) near Cardona in Spain, at Wieliczka in Poland, at Stassfurt in Germany, Reichenhall in Austria, in England, and many other parts of the globe. In the United States the salt wells of New York and Michigan furnish the greater portion of the salt in this country. Salt is contained in marine plants, and in animal fluids, *e. g.*, the blood, sweat, urine, etc. From sea water, the salt may be obtained by spontaneous evaporation in flat basins by exposure to sun and wind. This process is carried out in France, and along the borders of the Mediterranean, and the salt produced is the *sea salt* or *bay salt* of commerce. In countries with cold winters the brine is concentrated by freezing and removing the pure ice. The mother liquors from the manufacture of sea salt are rich in magnesium and potassium chlorides, sulphates, and bromides.

Salt from rock-salt deposits is obtained by mining, that from saline springs by evaporation in pans. In certain parts of Germany, preliminary evaporation of diluted salt solutions is effected by allowing the latter to trickle down over fagots formed into a high pile.

Description.—Chloride of sodium, upon slow evaporation, crystallizes in colorless, transparent cubes, but when rapidly evaporated, in hollow, 4-sided, pyramid-like bodies. At ordinary temperatures, salt does not crystallize with water; at a low temperature it crystallizes with 2, and at still lower temperature with 10 molecules of water. The *U. S. P.* describes sodium chloride as in "colorless, transparent, cubical crystals, or a white, crystalline powder, odorless, and having a purely saline taste. Permanent in dry air"—(*U. S. P.*). In a damp atmosphere, salt becomes moist, especially when it contains traces of magnesium or calcium chloride. Sodium chloride is "soluble in 2.8 parts of water at 15° C (59° F.), and in 2.5 parts of boiling water; almost insoluble in alcohol: insoluble in ether or chloroform"—(*U. S. P.*). It is also insoluble in concentrated hydrochloric acid. A solution of sodium chloride in water is precipitated when the solution is saturated with hydrochloric acid gas. "When heated, the salt decrepitates. At a red heat it fuses, and at a white heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution of the salt is neutral to litmus paper"—(*U. S. P.*). Sodium chloride is incompatible with nitric and sulphuric acids, with carbonate of potassium, nitrate of silver (see below), and mercurous oxide. Solutions containing salt should not be kept in galvanized iron vessels, owing to the solvent action of sodium chloride on zinc.

Tests.—The usual impurities in sodium chloride are salts of potassium, sulphates of sodium and calcium, and chlorides of calcium and magnesium, traces of bromides, iodides, and iron, the latter impurity due to the solvent action of impure brine upon the iron of the evaporating pan. The *U. S. P.* directs the following tests for solution of sodium chloride: "With silver nitrate T.S. the solution yields a white, curdy precipitate insoluble in nitric acid"—(*U. S. P.*). The precipitated silver chloride (AgCl) is soluble in aqueous ammonia. "No turbidity should be produced in 5 Cc. of the aqueous solution (1 in 20) by the addition of 0.5 Cc. of sodium cobaltic nitrite T.S. (limit of potassium). The aqueous solution, slightly acidulated with acetic acid, should not be rendered turbid by ammonium oxalate T.S. (absence of calcium); nor by barium chloride T.S. (absence of sulphate); nor by an equal volume of hydrogen sulphide T.S., either before or after addition of ammonia water in slight excess (absence of arsenic, lead, zinc, iron, aluminum, etc.). No turbidity should be produced in the aqueous solution by the addition of sodium phosphate T.S. and a few drops of ammonia water (absence of magnesium, etc.). If 2 Gm. of the finely powdered salt be digested for some hours with 25 Cc. of warm alcohol, and, after cooling, the undissolved salt be removed by filtration, then the filtrate evaporated to dryness and the residue dissolved in 1 Cc. of water and mixed with a few drops of starch T.S., the addition of chlorine water, drop by drop, should produce neither a blue nor a yellow tint (absence of iodide or bromide). If 0.195 Gm. of well-dried sodium chloride be dissolved in 10 Cc. of water, and the solution mixed with a few drops of potassium chromate T.S., it should require not less than 33.4 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to at least 99.9 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—From 2 to 4 drachms of chloride of sodium will purge, and sometimes vomit; and in still greater quantity it will induce free emesis without causing prostration. In smaller doses it is a mild irritant, alterative, and vermifuge. It is useful in all chronic diseases characterized by a pale color of the tongue with a white coat or fur. A teaspoonful or so of salt, swallowed without being in solution, will frequently check *hemorrhage from the lungs;* and for this purpose, as well as to act as an astringent in *diarrhœa* and *dysentery*, it has been combined with lemon juice, or a solution of citric acid. As a tonic or alterative it is very useful in *scrofula* and all *strumous diseases*. Used moderately as a condiment it improves the digestive powers, and corrects the disposition to generate *worms*. It should be freely eaten by strumous children, and those troubled with worms; it invigorates the digestive organs. It is serviceable as an antidote in *poisoning by nitrate of silver*. Certain kinds of *dyspepsia* are benefited by it. It is most beneficial in those cases in which the food decomposes in the stomach giving rise to *gastralgia*, *acidity*, *flatulence*, and *constipation* or *diarrhœa*. It exerts a salutary influence upon the system, even during health, when taken in very small quantity, but an undue amount of it used daily, does, undoubtedly, in many persons dispose to plethora and corpulency. Excessive doses, long continued, give rise to changes in the vocal cords, sore throat, constipation, or chronic diarrhœa, catarrh, abscesses, deposits, thins the blood, and give a pale waxy color to the individual. Skin affections with dryness of the cuticle, which sweats easily upon exertion, and dandruff, have also been attributed to the inordinate use of salt (*Ec. Med. Jour.*, 1895, p. 412). In the fact the symptoms of scurvy and those of the sodium chloride habit are very similar. In *spasms* of an epileptic or apoplectic character, the effects of intemperance, salt and mustard, 1 or 2 teaspoonfuls of each, given in warm water, every 10 or 15 minutes, until free emesis is produced, will be found the most efficient emetic. In these cases, counter-irritation may be produced by bastinadoing the feet, and after the vomiting, the patient may drink freely of good fresh milk. During the *cholera* of 1849–50–51, in Cincinnati, much benefit was derived from the following mixture: Black pepper, in powder, fine table salt, of each, 1 teaspoonful; vinegar, 5 teaspoonfuls; hot water, ½ tumblerful. Dose, 1 tablespoonful every 5, 10, or 15 minutes, as circumstances required. It speedily checked vomiting, abated the watery discharges, and removed the cramps. It succeeded in many cases, where every other means had failed (J. King). A small pinch of salt should occasionally be given to patients suffering with *fevers* and other complaints in which but little nourishment can be taken. As Dr. Scudder aptly remarks, attention to this matter "may be the difference between life and death." Salt should be added in small amounts to the food of bottle-fed children suffering from *infantile dyspepsia* and *cholera infantum*. Salt and bicarbonate of sodium combined are frequently used to allay *sour stomach* and check *sick headache;* sometimes the combination acts as a gentle emetic. A teaspoonful of salt in a glass of cold water taken before breakfast will often overcome *obstinate constipation*. The specific indications for its selection should be observed. A solution of salt or salt and mustard forms a good emetic in cases of *narcotic poisoning*. At one time salt was recommended as a remedy in *phthisis*, in which it is needless to say it proved a failure, and as a remedy for *intermittent fever*. If the stomach was loaded it was emptied with an emetic dose of the salt, administered during the apyrexia; if not, from 10 to 30 grains of the salt were given every 3 hours. The cases benefited were those in which the tongue was broad and pale, or natural in color, but easily pitted by the teeth. The entire absence of salt in the food, gives rise to a cachectic condition, and other morbid states, with the formation of an abundance of intestinal worms. Externally, salt in solution in water or whiskey, is a topical stimulant, frequently useful in *contusions*, *sprains*, and *glandular enlargements*. Hot salt bags are useful to allay *local pains*, as in *neuralgia*, *earache*, *toothache*, *colic*, *rheumatism*, and *dysmenorrhœa*. The external application of hot salt solutions by means of saturated compresses is often very effectual in relieving *visceral inflammations*, particularly *acute kidney affections*, *inflammation of brain*, *spinal cord*, *glands*, *pleura*, etc. *Rheumatic*, *traumatic*, or *tubercular forms of arthritis* are likewise benefited by its local application, hot or cold, as is most grateful to the patient. In powder or solution it has likewise proved efficient as an application in some *ophthalmic diseases*. In *muco-purulent conjunctivitis* a 1 per cent solution is very useful, and a solution of salt should be applied after the use of silver nitrate upon the ocular membranes. It is sometimes useful in *trachoma*. In aural practice a solution is useful in *inflammation of the attic and of the middle ear* resulting from *scarlet fever*, using it after the discharge has become established. It is also used for irrigating purposes after *mastoid operations*. In ear affections 1 drachm of salt should be dissolved in 1 pint of water. Added to injections it renders them more stimulating. Weak solutions are useful in *acute and chronic nasal catarrh*, *ozena*, and *pharyngitis* and *tonsillitis;* and stronger solutions may be used as a wash in *leucorrhœa*, *gleet*, *pruritis vulvæ*, *mercurial and indolent ulcers*, *bites*, *stings*, etc. A salt water enema is useful in *ascarides*, and when sufficiently strong may be used for its derivative effects in *cerebral congestion*.

Normal Saline Solution, *Physiological Salt Solution*.—This solution is now largely used after surgical operations in the treatment of *shock*, and particularly if much blood has been lost. It is composed of sodium chloride, 1 drachm; sodium bicarbonate, 15 grains; distilled water, 2 pints (*Amer. Text-book of Surgery*). In an emergency sodium chloride alone (1 drachm) may be dissolved in 1 pint of sterilized water. The following saline solution has also been advised: Calcium chloride, 4 grains; potassium chloride, 1½ grains; sodium chloride, 135 grains; sterilized water, 1 quart (*Amer. Text-book of Surgery*). These solutions are used in extreme emergencies, where death is imminent, by *transfusion* into the veins, or more generally, and in less severe cases, by *hypodermoclysis*, or injection into the subcutaneous areolar tissue, changing the point of injection as necessary and rubbing the parts continually to aid dispersion under the skin. Large quantities, 1 to 2 quarts, may be used, but smaller amounts, from 10 to 40 ounces, repeated as the effects of the solution begin to wane, are preferable. The injection should be used at about 104° F. to 112° F., according to method of introduction. High rectal enema (held in by means of a compress) of the same may be administered alone or in conjunction with the above methods. The use of the normal saline solution is considered the best and most reliable method of stimulation after *shock*, in *profuse hemorrhage*, *violent diarrhœas*, and in *Asiatic cholera*. Other indicated treatment must be followed at the same time, particularly the application of external heat. When employed by transfusion, care must be taken that no air passes into the vein. The apparatus required for the use of these solutions is a funnel with rubber tubing and needle attached. A pitcher and tube may be used like a siphon. All apparatus should be thoroughly sterilized.

The dose of salt as a tonic or alterative, is from 10 to 60 grains; as an enema, ½ to 1 ounce; as a cathartic, 2 to 4 drachms; as an emetic, ½ to 1 ounce.

Specific Indications and Uses.—Tongue broad and pale with white coat or fur; broad tongue, natural in color, but easily pitted by the teeth; poisoning by nitrate of silver.

Artificial Sea Water.—Artificial sea water, for a *vivarium* or *marine aquarium*, in which to keep marine animalcules, sea plants, diatoms, etc., is composed of chloride of sodium, 43¼ ounces; sulphate of magnesium, 7½ ounces; chloride of magnesium, 6 ounces; sulphate of calcium, 2¾ ounces; chloride of potassium, 1¼ ounces; bromide of magnesium, carbonate of calcium each, 21 grains; soft spring or rain water, 10 gallons. Mix. Dissolve and filter through a sponge in a glass funnel.

SODII CITRO-TARTRAS EFFERVESCENS.—EFFERVESCENT CITRO-TARTRATE OF SODIUM.

Synonyms: *Sodæ citro-tartras effervescens*, *Effervescent citro-tartrate of soda*.

Preparation.—This preparation is official in the *British Pharmacopœia*. "Take of sodium bicarbonate, in powder, 51 ounces (Imp.); tartaric acid, in powder, 27 ounces (Imp.); citric acid, in powder, 18 ounces (Imp.); refined sugar, in powder, 15 ounces (Imp.). Mix the powders thoroughly; place the mixture in a dish or pan of suitable form heated to between 93.3° and 104.4° C. (200° and 220° F.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 54.4° C. (130° F.). The product should weigh about 100 ounces"—(*Br. Pharm.*, 1898).

This preparation, when mixed with water, briskly effervesces with the escape of carbon dioxide. The same ingredients, merely mixed, readily decompose, but if prepared as described, the heat dispels all the water so that no reaction ensues until water is added to it. The preparation should be preserved in well-stoppered bottles.

Action, Medical Uses, and Dosage.—This combination is laxative and refrigerant, and is employed to reduce *fever*, cause *diaphoresis*, and to correct *excessive acidity*, for these purposes being sometimes used in *febrile* and *inflammatory states*, to allay nausea and vomiting, and in the acute forms of *rheumatism of the joints*, with excessively acid urine. Dose, 1 to 2 fluid drachms largely diluted with water.

SODII HYPOPHOSPHIS (U. S. P.)—SODIUM HYPOPHOSPHITE.

Formula: $NaPH_2O_2+H_2O$. Molecular Weight: 105.84.

Synonyms: *Hypophosphite of soda*, *Hypophosphis sodicus*, *Sodæ hypophosphis*, *Natrium hypophosphorosum*.

"Sodium hypophosphite should be kept in well-stoppered bottles"—(*U.S.P.*).

Preparation.—Hypophosphite of sodium is prepared by double decomposition between hypophosphite of calcium (see *Calcii Hypophosphis* and *Acidum Hypophosphorosum*) and crystallized carbonate of sodium. Take of hypophosphite of calcium, 6 ounces; crystallized carbonate of sodium, 10 ounces; water, a sufficient quantity. Dissolve the hypophosphite in 4 pints of water, and the carbonate in 1½ pints, mix the solutions, pour the mixture on a filter and wash the precipitate of carbonate of calcium, after draining with water, till the filtrate measures 6 pints. Evaporate this liquid carefully till a pellicle forms, and then stir constantly, continuing the heat until it granulates. In order to crystallize it, treat the granulated salt with alcohol of specific gravity 0.835, evaporate the solution until syrupy, and set it in a warm place to crystallize (Prof. W. Procter, Jr., 1858). The reaction is as follows: $Ca(PH_2O_2)_2+Na_2CO_3=CaCO_3+2NaPH_2O_2$. In a moist state, under exposure to sand-bath or even water-bath heat, neutral sodium hypophosphite has been known to explode with violence (see *Amer. Jour. Pharm.*, 1860, p. 87). Therefore great care should be taken in evaporating the solution that the temperature be kept below that of the boiling point of water. It is largely used in the preparation of *Syrup of the Hypophosphites*.

Description.—The *U. S. P.* demands this salt in "small, colorless, transparent, rectangular plates of a pearly lustre, or a white granular powder, odorless, and having a bitterish-sweet, saline taste. Very deliquescent on exposure to moist air.

Soluble, at 15° C. (59° F.), in 1 part of water, and in 30 parts of alcohol; in 0.12 part of boiling water, and in 1 part of boiling alcohol; slightly soluble in absolute alcohol; insoluble in ether. When heated in a test-tube, the salt at first loses its water of crystallization, and at about 200° C. (392° F.) it is decomposed, evolving hydrogen and hydrogen phosphide, which burn with a bright, yellow flame. Finally there is left a residue of sodium pyrophosphate and metaphosphate, sometimes mingled with a little red phosphorus. To a non-luminous flame the salt communicates an intense, yellow color. On triturating or heating sodium hypophosphite with nitrates, chlorates, or other oxidizing agents, it detonates violently. The aqueous solution is neutral to litmus paper"—(*U. S. P.*).

Tests.—Sodium hypophosphite is a strongly reducing agent. Thus, "a 5 per cent aqueous solution of the salt yields, with silver nitrate T.S., a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added in small quantity to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. On further addition of the solution, the precipitate is reduced to metallic mercury"—(*U. S. P.*). The hypophosphite in these reactions is oxidized to sodium phosphate or to phosphoric acid. With mercuric chloride, the following reactions take place: $4HgCl_2+HPO_2H_2+2H_2O=4HgCl+4HCl+H_3PO_4$; and $4HgCl+HPO_2H_2+2H_2O=4Hg+4HCl+H_3PO_4$. Likewise, sodium hypophosphite, upon warming with cupric sulphate, produces copper hydride, and subsequently, metallic copper (see *Acidum Hypophosphorosum*). A delicate test for hypophosphites is as follows: Nitric acid solution of ammonium molybdate is mixed with solution of a hypophosphite; if a small quantity of sulphurous acid is now added, a blue precipitate, or in diluted solution, a blue coloration is produced, which becomes more intense upon warming. Phosphoric and phosphorous acid and their salts do not give this reaction, which is interfered with, however, by chlorates, sulphides, and thiosulphates; but their effect can be removed by boiling with diluted hydrochloric acid (E. J. Millard, *Amer. Jour. Pharm.*, 1889, p. 129). The *U. S. P.* tests for possible impurities of sodium hypophosphite, are as follows: "A solution of 0.5 Gm. of the salt in 1 Cc. of water, should yield no precipitate upon the addition of 1 Cc. of sodium bitartrate T.S. (limit of potassium). The aqueous solution (1 in 20) should not be colored red by the addition of a drop of phenolphtalein T.S., nor effervesce on the addition of an acid (absence of caustic alkali or carbonate); nor should it be rendered turbid by ammonium oxalate T.S. (absence of calcium). In the aqueous solution (1 in 20), acidulated with hydrochloric acid, an equal volume of hydrogen sulphide T.S. should not produce any turbidity (absence of arsenic, lead, etc.). After heating 10 Cc. of the aqueous solution (1 in 20) with 1 Cc. of nitric acid, separate portions of the solution should remain clear upon the addition of silver nitrate T.S. (absence of chloride), and of barium chloride T.S. (absence of sulphate). Not more than a slight cloudiness should be produced in the aqueous solution of the salt by magnesia mixture (limit of phosphate). Potassium ferrocyanide T.S. should not produce in the acidulated solution any blue color (absence of iron). If 0.1 Gm. of dry sodium hypophosphite be dissolved in 10 Cc. of water, mixed with 7.5 Cc. of sulphuric acid and 40 Cc. of decinormal potassium permanganate V.S., and the mixture boiled for 15 minutes, it should require not more than 3 Cc. of decinormal oxalic acid V.S. to discharge the red color corresponding to at least 97.96 per cent of the pure salt"—(*U. S. P.*). (In this connection, see an extensive investigation into the quantitative determination of hypophosphites, by Frank X. Moerk, *Amer. Jour. Pharm.*, 1889, pp. 326 and 386.)

Action, Medical Uses, and Dosage.—The hypophosphites are administered in Eclectic practice when it is desired to improve the nutrition of the nerve centers, and thereby increase the general nutrition of the body. Introduced along with other hypophosphites, by Dr. Churchill, as a remedy for *consumption*, it has, like all other agents, proved a failure in that direction, so far as a cure is concerned. It does, however, prove of benefit in this complaint, as well as in *chronic bronchitis*, *anemia*, *syphilis*, *scrofula*, and *bone diseases*, with insufficient osseous material, so far as to correct the serious loss of nerve power or nerve depression, which accompanies them. This, in fact, is its chief value. The dose is from 2 to 25 grains, given, preferably after meals.

Pharmaceutical Preparation.—NUTRITIVE HYPOPHOSPHITES (*Syrup of hypophosphites compound*, with quinine, strychnine, and manganese). This preparation is a specialty of the Wm. S. Merrell Chemical Co., of Cincinnati, O. It is a tonic and reconstructive, representing the combined virtues of the hypophosphites of calcium, sodium, potassium, iron, manganese, quinine, and strychnine.

SODII HYPOSULPHIS (U. S. P.)—SODIUM HYPOSULPHITE.

FORMULA: $Na_2S_2O_3+5H_2O$. MOLECULAR WEIGHT: 247.64.

SYNONYMS: *Sodium thiosulphate*, *Natrium subsulphurosum*, *Natrium hyposulphurosum*, *Hyposulphis sodicus*.

"Sodium hyposulphite should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Take of crystallized carbonate of sodium, 32 parts; distilled water, 64 parts: sublimed sulphur, 10 parts. Dissolve the carbonate in the water, add the sulphur, and pass a stream of sulphurous acid gas through the solution. When the gas is in excess, being no longer dissolved, hyposulphite of sodium is in solution. Boil for a few minutes, filter, evaporate by a gentle heat to a third of its volume, and set aside in a cool place to crystallize. This process practically consists in the formation of sodium sulphite and simultaneous absorption of sulphur to form hyposulphite, as follows: $Na_2CO_3+3O_2=Na_2SO_3+CO_2$; and $Na_2SO_3+S=Na_2S_2O_3$.

Description.—Sodium hyposulphite should, preferably, be named *sodium thiosulphate*, because it is not the salt of hyposulphurous acid (H_2SO_2), a deep-yellow liquid, having strongly reducing properties, discovered by Schützenberger, and named by him *hydrosulphurous acid*. The sodium salt of this acid has the formula $NaHSO_2$, and is obtained when zinc is allowed to act upon a cold solution of sodium bisulphite in water, while contact with air is avoided. The salt, in aqueous solution, is spontaneously converted into *thiosulphate*, as follows: $2NaHSO_2=S_2O_3Na_2+H_2O$; hence the latter may be regarded as the anhydride of the true sodium hyposulphite. Similarly, free hyposulphurous acid decomposes, in aqueous solution, into water and thiosulphuric acid, the latter, being very unstable, is then decomposed into sulphur, water, and sulphur dioxide, as follows: $S_2O_3H_2=S+H_2O+SO_2$ (see *Tests*, below). In commercial usage, the wrong term, sodium hyposulphite for the thiosulphate, is firmly established. The salt, as described by the *U. S. P.*, occurs in "colorless, transparent, monoclinic prisms, odorless, and having a cooling, afterward bitter taste. Permanent in the air below 33° C. (91.4° F.), but efflorescent in dry air above that temperature. Soluble in 0.65 part of water at 15° C. (59° F.), and in about 0.5 part at 20° C. (68° F.); at a boiling heat, the solution is rapidly decomposed. Insoluble in alcohol, slightly soluble in oil of turpentine. When rapidly heated to about 50° C. (122° F.), the salt melts. When slowly heated until it is effloresced, and afterward to 100° C. (212° F.), it loses all its water of crystallization (36.3 per cent), and at a red heat is decomposed, sulphur being evolved, while a residue of sodium sulphide and sulphate remains. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper"—(*U. S. P.*). Its solution, kept in closed vessels, deposits sulphur, and changes into sulphite; in warm air it becomes sulphate of sodium, depositing sulphur. "An aqueous solution of the salt readily dissolves many salts of silver (chloride, bromide, iodide, oxide, etc.), and discharges the color of a solution of iodine or of starch iodide"—(*U. S. P.*). Upon the dissolving power of sodium hyposulphite for silver chloride, etc., depends its well-known use in photography, to fix the image on an exposed plate, a process which consists in dissolving out the silver salt unacted upon by light. With silver chloride a soluble, double salt ($NaAgS_2O_3$) is formed. If iodine acts on sodium hyposulphite, the following reaction takes place: $2Na_2S_2O_3+I_2=2NaI+Na_2S_4O_6$ (sodium tetrathionate). Upon this reaction depends its useful application in iodometry (see *Tests*, below). Similarly, the salt converts chlorine into sodium chloride; hence it is used as an *antichlor*, to remove from paper-pulp and fabrics, the chlorine which may have been retained in the bleaching process (compare *Sodii Bisulphis*).

Tests.—The *U. S. P.* directs for sodium hyposulphite the following tests: "If ferric chloride T.S. be dropped into the aqueous solution (1 in 20), a dark violet color will be produced, which disappears rapidly upon agitation. Addition of sulphuric or hydrochloric acid to the aqueous solution liberates from it sulphur dioxide (known by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S., and held in the escaping gas), and causes a white precipitate of sulphur (distinction from sulphite or bisulphite). If to 5 Cc. of the aqueous solution (1 in 20) an equal volume of hydrogen sulphide T.S. be added, no coloration or turbidity should be perceptible either before or after the addition of 1 Cc. of ammonia water (absence of lead, iron, etc.). The aqueous solution should not be rendered turbid by the addition of ammonium oxalate T.S. (absence of calcium). The aqueous solution of the salt (1 in 20) should not be colored red by a drop of phenolphtalein T.S. (absence of caustic alkali or carbonate); nor should a drop of silver nitrate T.S. produce a brown or a black precipitate in 5 Cc. of this solution (absence of sulphide)"—(*U. S. P.*). It must be remembered, however, that sodium hyposulphite (thiosulphate) produces with silver nitrate a white precipitate of silver hyposulphite ($Ag_2S_2O_3$), which turns black upon warming, silver sulphide (Ag_2S) being formed as follows: $Ag_2S_2O_2+H_2O+Ag_2S+H_2SO_4$. "In a dilute aqueous solution (1 in 80), barium chloride T.S. should produce no turbidity (absence of sulphate). If 0.25 Gm. of sodium hyposulphite be dissolved in 10 Cc. of water and a few drops of starch T.S. added, it should require at least 9.9 Cc. of decinormal iodine V.S. to produce a permanent blue color (corresponding to at least 98.1 per cent of the pure salt"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Hyposulphite of sodium acts as a resolvent, alterative, and sudorific. It has been used as a substitute for the natural sulphurous waters, in *chronic diseases of the skin*, *secondary syphilis*, *gout*, *rheumatism*, *piles*, etc., and in *biliary calculi*, in which it is said to exert a solvent action. Later it was introduced and has been advantageously used as an azymotic, etc. (see *Magnesii Sulphis* for full description of its antizymotic uses). All fungous and low forms of vegetation are destroyed by sodium thiosulphate, and it will arrest fermentative and putrefactive changes within or without the body. It deodorizes putrid discharges from any part of the system. For this deodorizing property, it has been very successfully employed in *carcinomatous affections*, and in *pulmonary gangrene* and *fetid bronchitis*, often curing the last-named complaint. Here it is used internally and by atomization. Internally, it has been found efficient in a species of *water-brash*, in which the fluid ejected is very frothy, and contains a fungous growth, or plant, called *sarcina ventriculi*. Any *acidity of the stomach* must first be removed, after which give a tablespoonful of a mixture composed of infusion of quassia, 3 fluid ounces; hyposulphite of sodium, 1 or 1½ drachms. If given before acidity has developed, it will prevent the fluids of the stomach becoming sour, and check any fermentative changes that may be going on in the stomach or bowels. It has also been employed successfully in *diphtheritic* and *aphthous ulcerations of the mouth*, both internally and as a local application. Externally, it has been employed in *pruritis vulvæ*, *favus*, *sycosis*, *impetigo*, etc. For many of the purposes to which the salt is applied, sodium sulphite will be found preferable. Sodium hyposulphite will remove the stains of iodine from garments, bedding, utensils, etc. Its dose is from 10 to 60 grains in pills or aqueous solution. A syrup is composed of 1 drachm of the hyposulphite, 2 ounces and 7 drachms of sugar, and 1½ fluid ounces of water; dissolve with gentle heat, and filter. The dose is from 1 to 4 tablespoonfuls. A bath (*Balneum Sodæ Hyposulphitis*) is also prepared from it as follows: From 1 to 4 ounces of the sodium salt, as may be required, is added to enough water to form a bath. If a small quantity of diluted sulphuric acid, or of vinegar, be added to the bath while the patient is immersed, sulphurous acid and sulphur are set free.

Specific Indications and Uses.—Fermentative dyspepsia, with yeasty vomiting; pallid mucous membranes, with white, pasty, or dirty-white exudate upon the tongue.

Related Salt.—SODII ET ARGENTI HYPOSULPHIS, *Sodium and silver hyposulphite* ($NaAgS_2O_3+H_2O$). This salt is said to act locally like silver nitrate, though less severely, and, when pure, stains neither the skin nor clothing. It is useful in *urethral discharges*, a solution of 1 or 2 parts in 200 parts of water being about the proper strength. The salt is prepared by dissolving freshly prepared silver oxide in an aqueous solution of sodium hyposulphite and crystallizing by careful evaporation at the ordinary temperature.

SODII IODIDUM (U. S. P.)—SODIUM IODIDE.

FORMULA: NaI. MOLECULAR WEIGHT: 149.53.

"Sodium iodide should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Sodium iodide may be prepared by the action of iodine upon solution of caustic soda in the manner described under *Potassii Iodidum;* or, preferably, obtained by double decomposition between solution of ferrous iodide (previously prepared by the action of iodine upon iron filings in the presence of water) and sodium carbonate, as follows: $FeI_2+Na_2CO_3 = FeCO_3+2NaI$. After filtering from the precipitated ferrous carbonate, the solution of sodium iodide is evaporated to dryness, and the salt is at once put into dry, well-stoppered bottles (compare *Sodii Bromidum*). Like sodium bromide, this salt crystallizes in two forms, dependent on the temperature of the crystallizing solutions. From hot solutions, cubical, anhydrous crystals are produced. If allowed to crystallize spontaneously, at ordinary temperatures, monoclinic prisms or plates are formed, containing 2 molecules of water, and efflorescent in dry air.

Description.—Sodium iodide of the *U. S. P.* forms "colorless, cubical crystals, or a white, crystalline powder, odorless, and having a saline and slightly bitter taste. In moist air, it deliquesces and becomes partially decomposed into sodium carbonate and free iodine, assuming, thereby, a reddish color. Soluble, at 15° C. (59° F.), in 0.6 part of water, and in about 3 parts of alcohol; in 0.33 part of boiling water, and in 1.4 parts of boiling alcohol. When heated, the salt melts, and at a bright-red heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral or but feebly alkaline to litmus paper"—(*U. S. P.*).

Tests.—"If to 5 Cc. of the aqueous solution (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a yellow color. On agitating this mixture with a few drops of chloroform, the latter will acquire a violet color. If the salt be in distinct crystals, only few monoclinic prisms (containing 2 molecules of water) should be found among the regular cubes of the anhydrous salt. On drying 1 Gm. of the salt at 100° C. (212° F.), it should not lose more than 0.05 Gm. in weight (absence of more than 5 per cent of water.). A solution of 1 Gm. of the salt in 1 Cc. of water, should yield no precipitate with 1 Cc. of sodium bitartrate T.S. (limit of potassium). The aqueous solution (1 in 20), slightly acidulated with acetic acid, should remain clear after the addition of ammonium oxalate T.S. (absence of calcium), or of an equal volume of hydrogen sulphide T.S. (absence of arsenic, etc.). The addition of ammonium sulphide T.S., should not produce either a coloration or a turbidity in the aqueous solution (absence of zinc, iron, aluminum, etc.). If 1 Gm. of the salt be dissolved in water, and 0.05 Cc. (1 drop) of decinormal oxalic acid V.S. added, no red color should be produced by the addition of a drop of phenolphtalein T.S. (limit of alkali). The aqueous solution, slightly acidulated with hydrochloric acid, should not be colored blue upon the addition of potassium ferrocyanide T.S. (absence of iron). If 0.5 Gm. of the salt be dissolved in 10 Cc. of freshly boiled, distilled water, and the solution mixed with a few drops of starch T.S., no blue color should appear either at once (absence of free iodine), or after the addition of a drop of diluted hydrochloric acid (absence of iodate)"—(*U. S. P.*). The addition of hydrochloric acid liberates both iodic and hydriodic acids, which react upon each other with liberation of iodine, as follows: $IO_3H+5IH = 6I+3H_2O$. "If 5 Cc. of the aqueous solution (1 in 20) be acidulated with hydrochloric acid, and 0.5 Cc. of barium chloride T.S. added, no immediate turbidity should appear (limit of sulphate). If 5 Cc. of the aqueous solution be gently heated with 1 drop of ferrous sulphate T.S. and 0.5 Cc. of potassium hydrate T.S., no blue color should appear after acidulating the mixture with hydrochloric acid (absence of cyanide)"—(*U. S. P.*). Cyanide may possibly be present, because iodine nearly always contains iodine cyanide (*Digest of Criticisms on the U. S. P.*, Part I, 1897). "If 1 Gm. of the salt be mixed with 0.5 Gm. of iron filings and 0.5 Gm. of powdered zinc, and heated in a test-tube with 5 Cc. of sodium hydrate T.S., no ammoniacal vapors should be evolved (absence of nitrate or nitrite). If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. added, it should not require more than 34.5 Cc. nor less than 33.4 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to at least 98 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Locally, this salt is stimulant, antiseptic, and deodorant, and for these purposes it has been used upon *offensive ulcers*. It has been proposed as a substitute for potassium iodide internally, its admirers claiming that it is less likely to produce gastro-intestinal and broncho-pulmonic irritation, and skin eruptions. On the other hand, it is claimed to be a much feebler therapeutic agent. It is especially recommended in cases of *syphilis* and *eczema*, in which the potassium salt is apparently indicated, but where the system is greatly depressed.

SODII NITRAS (U. S. P.)—SODIUM NITRATE.

FORMULA: $NaNO_3$. MOLECULAR WEIGHT: 84.89.

SYNONYMS: *Chili saltpetre, Cubic nitre, Nitrum cubicum, Sodæ nitras, Nitras sodicus, Azotas sodicus, Nitrate of soda.*

"Sodium nitrate should be kept in well-stoppered bottles"—(*U. S. P.*).

Source and History.—Sodium nitrate was prepared as early as 1683, by Bohn. A commercial grade was later termed *South American saltpetre*, although the term saltpetre properly belongs to the potassium salt. It is found in south Peru and Chili, imbedded in large tracts of soil a few feet below the surface. The nitrate deposits occupy a stretch of about 120 miles in length and 2 miles wide, and are found below a layer of clay and sand. The nitrate occurs mixed with about 20 to 30 per cent of sodium chloride, also with calcium and magnesium sulphates and chlorides, bromides, and iodides. This saline deposit, known to the natives as *caliche* or *terra salitrosa*, is removed by blasting. After undergoing a process of crystallization, the product is put into sacks and exported in the form of moist masses of crystals, containing from 1 to 2 per cent of sodium chloride (see *Amer. Jour. Pharm.*, 1872, p. 319). Commercial grades have been differentiated as *white crystalline, gray crystalline, yellow, white compact* and *gray compact*. Upon reaching this country the salt is purified by recrystallization from water.

Description and Tests.—Sodium nitrate forms rhombohedral crystals, resembling a cube (*cubical nitre*), and isomorphous with calcspar. The shape of the crystals, and the yellow color it communicates to flame, distinguish it from nitrate of potassium. Its therapeutical effects are similar to those of nitrate of potassium, without so readily disturbing digestion. It is chiefly used in the manufacture of nitric and sulphuric acids, and in the making of fireworks, but is an unfit ingredient for gunpowder, on account of its deliquescence. Nitrate of potassium is prepared from it by decomposing it with chloride of potassium (see *Potassii Nitras*). It is also used in preparing sodium arsenate (which see). The *U. S. P.* describes it as in "colorless, transparent, rhombohedral crystals, odorless, and having a cooling, saline, and slightly bitter taste. Deliquescent in moist air. Soluble, at 15° C. (59° F.), in 1.3 parts of water, and in about 100 parts of alcohol; in 0.6 part of boiling water, and in 40 parts of boiling alcohol. When heated to 312° C. (593.6° F.), the salt melts without decomposition. At a higher temperature, it evolves oxygen, and is reduced to nitrite. On red-hot charcoal, it deflagrates. To a non-luminous flame, it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper. If the aqueous solution be mixed in a test-tube with a drop of diphenylamine T.S., and sulphuric acid carefully poured in, so as to form a separate layer, a deep-blue color will appear at the line of contact. A solution of 0.5 Gm. of the salt in 1 Cc. of water, should not be precipitated or rendered turbid by 1 Cc. of sodium bitartrate T.S. (limit of potassium). The aqueous solution (1 in 20) should not be colored or rendered turbid by the addition of hydrogen sulphide T.S., or ammonium sulphide T.S. (absence of arsenic and metallic impurities); nor by the addition of equal parts of ammonia water and sodium phosphate T.S. (absence of calcium, magnesium, etc.). If the aqueous solution be mixed with a few drops, each, of hydrogen sulphide T.S. and starch T.S., and then some chlorine water poured carefully upon the mixture, no blue color should appear at the line of contact (absence of iodate and iodide). No turbidity should be produced within 5 minutes in the aqueous solution, acidulated with nitric acid, on the addition of either barium chloride T.S. (limit of sulphate), or silver nitrate T.S. (limit of chloride)"—(*U. S. P.*). (Also compare *Potassii Nitras.*)

Action, Medical Uses, and Dosage.—The action of large doses of sodium nitrate resembles that of potassium nitrate. The continued use of doses ranging from 20 to 90 grains, does not affect the appetite and bowels, but slows and weakens the heart's action, causes emaciation, pallid countenance, mental weakness, and general debility. On account of its mildly purgative action, it has been successfully used in *dysentery* and *diarrhœa*, from 1 to 2 ounces, largely diluted, being given in 24 hours. It is likewise diuretic, and, on account of its marked property of effecting a solution of false membranes, it has been used locally in *diseases of the throat*, characterized by these fibrinous deposits. Not only is the salt diuretic, but, in doses of 2 or 3 drachms, it greatly increases the excretion of urea, besides acting upon the skin, and influencing the vegetative system of nerves, "controlling irritation and inflammation" (Scudder). Concerning this agent, Prof. Scudder writes: "The indications for its use in acute diseases are a swollen and puffed tongue, covered with a white or yellowish mucus; the mouth may be dry or moist, but the tongue must never show contraction, be elongated, or pointed, or deep-red. In other words, we must observe the general indications for the administration of an alkali. Probably the special cases in which it will be found of most advantage are these: When the pulse is full, the surface flushed, slightly dusky or purplish; eyes injected, though not dry; an increased perspiration, though the skin remains hot" (*Spec. Med.*, p. 91). Dose, 1 drachm to 2 ounces, largely diluted, in 24 hours.

Specific Indications and Uses.—These have been sufficiently indicated above.

SODII NITRIS (U. S. P.)—SODIUM NITRITE.

FORMULA: $NaNO_2$. MOLECULAR WEIGHT: 68.93.

SYNONYM: *Nitrite of soda.*

"Sodium nitrite should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Sodium nitrite is produced by the reduction of sodium nitrate with charcoal or starch, etc., at a red heat. The mass is lixiviated with water and crystallized. By another process, a product, containing not less than 98 per cent of the salt, may be obtained by melting *pure* sheet-lead (2½ parts, by weight) with sodium nitrate (1 part), in a shallow iron vessel, with continuous agitation. Yellow oxide of lead (litharge) is formed. Cool the mass, lixiviate with water, concentrate, and allow to crystallize. (For further details, see *Amer. Jour. Pharm.*, 1889, p. 618.) This salt was made official because of its use in the preparation of spirit of nitrous ether.

Description and Tests.—Sodium nitrite is officially described as forming "white, opaque, fused masses, usually in the form of pencils, or colorless, transparent, hexagonal crystals; odorless, and having a mild, saline taste. When exposed to the air, the salt deliquesces and is gradually oxidized to sodium nitrate. Soluble in about 1.5 parts of water at 15° C. (59° F.), and very soluble in boiling water; slightly soluble in alcohol. When heated, the salt melts, and at a red heat it is decomposed, yielding oxygen, nitrogen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an alkaline reaction with litmus paper. If the aqueous solution of the salt be mixed with some potassium iodide T.S., and a few drops of an acid added, iodine will be liberated, and nitrogen dioxide gas will escape with effervescence"—(*U. S. P.*). Upon this reaction is based the quantitative test for the purity of the salt as given below. The reaction takes place as follows: $HNO_2+HI=H_2O+I+NO$. "The salt should readily dissolve in 20 parts of water, forming a colorless solution, and leaving no insoluble residue (absence of insoluble impurities). If 1 drop of hydrochloric acid and a few drops of starch T.S. be added to 5 Cc. of the aqueous solution, no blue coloration should appear (absence of iodide). If 5 Cc. of the aqueous solution be mixed with an equal volume of hydrogen sulphide T.S., no coloration or precipitate should be produced (absence of lead, arsenic, copper, etc.). If 0.15 Gm. of sodium nitrite be dissolved in 5 Cc.

of water, and introduced into a nitrometer, then followed by a solution of 1 Gm. of potassium iodide in 6 Cc. of water and 15 Cc. of normal sulphuric acid, the liberated nitrogen dioxide gas should measure not less than 50 Cc. at 15° C. (59° F.), or 51.7 Cc. at 25° C. (77° F.), corresponding to not less than 97.6 per cent of the pure salt"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sodium nitrite acts upon the system exactly as amyl nitrite and nitroglycerin do, except that its effects are more uniform, less pronounced, and continue longer. This is accounted for by the lesser solubility of the drug and from the fact that it is less rapidly eliminated from the system (see *Amyl Nitris*). Serious symptoms have been observed from the use of the drug, for when first introduced it was given in doses but little short of toxic. The conditions in which it is of value are those in which the other nitrites have been found so serviceable, viz.: It relieves the pain and spasm of *angina pectoris* in which its action is more prolonged than that of glonoin or amyl nitrite, *nervous asthma*, *dyspnœa* from transient pulmonic obstruction, *hemicrania*, and other *headaches* depending chiefly upon cerebral anemia and in the milder forms of *convulsions* and *epileptoid seizures* where the bromides are contra-indicated. In the latter, its effects have been unsatisfactory. It has been used with marked results in *double aortic disease*, *insomnia*, from cardiac affections, *renal disorders*, with relaxed blood pressure, and in *granular disease of the kidney*, associated with a *dilated heart*. The indications are dyspnœa, frontal headache, or dizziness. As a heart stimulant, it may be used whenever the innervation of that organ is impaired; when the heart muscle is undergoing degeneration or when the valves are diseased or imperfect in action. As the salt does not decompose in water it has been preferred to other nitrites. The dose is from 1 to 2 grains, repeated as necessary, or gradually increased until the desired effect is produced. A single dose should not exceed 2 grains. POTASSIUM NITRITE has been found to possess similar properties.

Specific Indications and Uses.—(See *Amyl Nitris.*)

SODII PHOSPHAS (U. S. P.)—SODIUM PHOSPHATE.

FORMULA: $Na_2HPO_4+12H_2O$. MOLECULAR WEIGHT: 357.32.

SYNONYMS: *Sodium orthophosphate, Phosphate of soda, Sodæ phosphas, Phosphas natricus, Phosphas sodicus, Disodium hydrogen phosphate, Medicinal tribasic phosphate of sodium.*

"Sodium phosphate should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Source and Preparation.—Sodium phosphate is a constituent of the urine of the carnivora, and is prepared from the calcium phosphate of bones by treating the latter material with sulphuric acid and water, which produces soluble acid calcium phosphate and insoluble calcium sulphate, as follows: $Ca_3(PO_4)_2+2H_2SO_4=2CaSO_4+(PO_4H_2)_2Ca$. After filtering, the solution, while hot, is neutralized with solution of sodium carbonate, until it is distinctly alkaline to litmus paper, the desired phosphate being formed according to the equation: $(PO_4H_2)_2Ca+2Na_2CO_3=2PO_4HNa_2+Ca_3CO+CO_2+H_2O$. The liquid is then evaporated to crystallization. For analytical purposes, it is better to add pure crystallized carbonate of sodium to pure phosphoric acid solution, in a porcelain dish, as long as it causes an effervescence, and until the reaction is alkaline. It is placed in the cold to crystallize, the crystals are separated, spread on filtering paper to dry, and kept in a cool place. The mother liquor, on evaporation, yields fresh quantities of crystals.

Description.—Sodium phosphate occurs in "large, colorless, monoclinic prisms, odorless, and having a cooling, saline taste. The crystals effloresce in the air, and gradually lose 5 molecules of their water of crystallization (25.1 per cent). Soluble in 5.8 parts of water at 15° C. (59° F.), and in somewhat less than 1.5 parts of boiling water; insoluble in alcohol. When heated to about 40° C. (104° F.), the salt fuses, yielding a colorless liquid. At 100° C. (212° F.) it loses all its water of crystallization (60.3 per cent), and at a red heat it is converted into sodium pyrophosphate. It imparts to a non luminous flame an intense, yellow color. The aqueous solution is slightly alkaline to litmus paper, but not to phenolphtalein paper"—(*U. S. P.*).

According to more recent experiments, however, pure sodium phosphate does redden phenolphtalein (see C. E. Smith, *Digest of Criticisms on the U. S. P.*; and Brunner, *Amer. Jour. Pharm.*, 1898, p. 548). "A 5 per cent aqueous solution of the salt yields a white precipitate with magnesia mixture"—(*U. S. P.*). The latter is a mixture of magnesium sulphate, ammonium chloride, and ammonia water (see *Test Solutions*), and the crystalline precipitate has the formula $PO_4NH_4Mg+6H_2O$ (compare *Sodii Arsenas*). With the 5 per cent aqueous solution, the *U. S. P.* further directs: "With silver nitrate T.S. it yields a yellow precipitate, soluble in ammonia water and in nitric acid"—(*U. S. P.*). This precipitate is tribasic silver phosphate (Ag_3PO_4); it is formed according to the equation: $Na_2HPO_4+3AgNO_3=Ag_3PO_4+2NaNO_3+HNO_3$. Thus, the solution becomes acid. Silver chloride differs from silver phosphate in being white, and insoluble in nitric acid. "If 0.5 Cc. of the aqueous solution (1 in 20) be mixed with 1 Cc. of ammonium molybdate T.S., the mixture will at once assume a yellow color, and, after a few minutes, yield a yellow precipitate, the appearance of which is hastened by a gentle heat"—(*U. S. P.*). The precipitate is ammonium phospho-molybdate, having the approximate composition $10MoO_3+PO_4(NH_4)_3$. The precipitate is insoluble in diluted acids, but soluble in aqueous ammonia and fixed alkalies. From the colorless ammonia solution, magnesia mixture precipitates the crystalline compound above mentioned. Phosphate of sodium is incompatible with magnesia, soluble calcium salts, and solutions of metallic salts, with all of which it forms insoluble phosphates; it is also incompatible with alkaloids, and with mineral acids. Neither the commercial nor the pharmacopœial salt is favored by Eclectic physicians who prefer a dried powdered form nearly free from water and much stronger than the crystalline compound.

Tests.—Commercial sodium phosphate at one time contained large quantities (20 to 60 per cent) of sodium sulphate (*Amer. Jour. Pharm.*, 1875, p. 371, also 1881, p. 511). To test sodium phosphate for impurities, the *U. S. P.* directs as follows: "No residue should be left on dissolving the salt in water (absence of calcium, etc.). No turbidity or coloration should be produced in the aqueous solution by the addition of a small quantity of ammonium sulphide T.S.; or of an equal volume of hydrogen sulphide T.S. after the addition of a few drops of hydrochloric acid (absence of metallic impurities). If 1 Gm. of the powdered salt be shaken with 3 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), then a small piece of pure tin-foil added, and a gentle heat applied, no brown coloration should appear within 15 minutes (limit of arsenic). If 0.5 Gm. of the salt be dissolved in 4 Cc. of water, and 1 Cc. of sodium bitartrate T.S. then added, the solution should remain perfectly clear (limit of potassium). No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of carbonate). On adding to 5 Cc. of the aqueous solution (1 in 20) 0.5 Cc. of silver nitrate T.S., a pure yellow precipitate will be formed, which should not become dark-colored by heating (absence of hypophosphite, etc.), and which, upon the addition of nitric acid, should yield a perfectly clear, or, at most, only a very slightly opalescent, liquid (limit of chloride). If to 5 Cc. of the aqueous solution, acidulated with hydrochloric acid, 0.5 Cc. of barium chloride T.S. be added, the solution should not be rendered more than very slightly opalescent (limit of sulphate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Phosphate of sodium, formerly known as *subphosphate of soda*, is a mild, saline cathartic, but very apt to gripe, and at a time when cathartics were more in vogue than at present, it was considered well adapted to *febrile* and *inflammatory diseases*, and for children and others whose stomachs are delicate or irritable. As a laxative and cholagogue, however, it is mild and very efficient when administered in small doses. In children's disorders it is a particularly valuable remedy. In *infantile constipation* or *diarrhœa*, with white and green foul-smelling stools, and especially in the *bowel disorders* of bottle-fed children, from 3 to 5-grain doses, 3 times a day, act as a mild laxative and correct the unpleasant symptoms. It is equally valuable in *infantile dyspepsia* with pallid tongue and membranes, and sour eructations, and occasionally colic. Associated often with inactivity of or irritation of the bowels is a general condition of *malnutrition* which is corrected by this drug, which, under the specific conditions named above, acts as a valuable restorative. Here the dose should be from 1 to 3 grains 3 times a day administered with the food, and particularly with milk. It is a good remedy in many *hepatic troubles.* When the pallid tongue and membranes indicate it it may be given with confidence in the *jaundice* of small children associated with impairment of nutrition. It is a good remedy for *jaundice* resulting from *biliary catarrh* in adults, using from 20 to 30 grains of the salt in a day's time, and the smaller dose in a wineglassful of water after each meal persisted in from 2 to 3 months, will radically cure *hepatic colic*, employing, when the paroxysms come on, an inhalation of chloroform (Locke). For habitual and recurring *bilious headache* in weak and nervous individuals, with loaded tongue and sallow skin, give from 10 to 15 grains of the salt, in water or milk, 5 times a day; and for *obstinate* or *habitual constipation*, with or without *colic* and *indigestion*, give a drachm in a couple of ounces of water, night and morning. The dose, for cathartic purposes, is from 6 to 12 drachms, in water, milk, soup, gruel, or broth; as a laxative for adults, 10 to 30 or 60 grains; for children, 3 to 5 grains; as a restorative, 1 to 3 grains. The salt is best given in water or warm milk. The salt employed by Eclectic physicians is the dried, powdered sodium phosphate, known as specific sodium phosphate.

Specific Indications and Uses.—Pale tongue and membranes, general malaise and inanition; tender abdominal muscles and anorexia; restless, yet with strong inclination to sleep, but frequently awakening; dirty tongue and sallow skin; tongue coated golden-yellow and moist, or a dry, furred coating upon a pallid tongue; white and green diarrhœa, with malnutrition; or stools, hard, white, pasty, or spongy, which float upon water; infantile constipation, with impaired nutrition; habitual constipation, with hard, dry fæces; acid eructations; biliary colic; bilious headache; jaundice.

SODII PYROPHOSPHAS (U. S. P.)—SODIUM PYROPHOSPHATE.

FORMULA: $Na_4P_2O_7+10H_2O$. MOLECULAR WEIGHT: 445.24.

SYNONYMS: *Natrium pyrophosphoricum, Pyrophosphas sodicus.*

Preparation and History.—Allow crystallized sodium phosphate (10 ounces) to effloresce in warm air, then expose the salt to a dull-red heat, until a small portion of the ignited mass, dissolved in water, causes a white precipitate, without a yellow tinge, with silver nitrate. Dissolve the mass in 5 pints of water at 100° C. (212° F.), filter, and allow to crystallize. This produces 6 ounces of sodium pyrophosphate. (Compare *Sodii Phosphas;* also see Dr. Squibb's process, *Amer. Jour. Pharm.*, 1860, p. 36.)

Description and Tests.—"Colorless, transparent, monoclinic prisms, or a crystalline powder, odorless, and having a cooling, saline, and feebly alkaline taste. Permanent in cool air, slightly efflorescent in warm air. Soluble in 12 parts of water at 15° C. (59° F.), and in 1.1 parts of boiling water: insoluble in alcohol. When heated to 100° C. (212° F.), the salt loses its water of crystallization (40.34 per cent) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass. To a non-luminous flame, it imparts an intense, yellow color. Its aqueous solution is feebly alkaline to litmus and to phenolphtalein paper. A 5 per cent aqueous solution of the salt yields with magnesia mixture a white precipitate; with silver nitrate T.S., it yields a precipitate of a pure white color (distinction from *orthophosphate*), soluble in ammonia water and nitric acid. With ammonium molybdate T.S., no precipitate is formed within 15 or 20 minutes, even when a gentle heat is applied (distinction from *orthophosphate*)"—(*U. S. P.*). The behavior of sodium pyrophosphate toward salts of various metals can be utilized to effect the analytical separation of some of these metals (G. Vortmann, *Amer. Jour. Pharm.*, 1888, p. 421). "No turbidity or coloration should be produced in the aqueous solution (1 in 20) by the addition of a small quantity of ammonium sulphide T.S.; or of an equal volume of hydrogen sulphide T.S. after the addition of a few drops of hydrochloric acid (absence of metallic impurities). If 1 Gm. of the powdered salt be shaken with 3 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), then a small piece of pure tin-foil added, and a gentle heat applied, no brown coloration should appear within 15 minutes (limit of arsenic). If 0.5 Gm. of the salt be dissolved in 6 Cc. of water, and 1 Cc. of sodium bitartrate T.S. then added, the solution should remain perfectly clear (limit of potassium). No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of carbonate). In the aqueous solution of the salt, rendered acid by nitric acid, not more than a very slight opalescence should be produced by silver nitrate T.S. (limit of chloride), or by barium chloride T.S. (limit of sulphate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt is of value chiefly on account of its use in preparing ferric pyrophosphate. Its action and uses are those of sodium phosphate, being, however, a third stronger, consequently the dose should be correspondingly less.

SODII SALICYLAS (U. S. P.)—SODIUM SALICYLATE.

FORMULA: $NaC_7H_5O_3$. MOLECULAR WEIGHT: 159.67.

"Sodium salicylate should be kept in well-stoppered bottles, protected from heat and light"—(*U. S. P.*).

Preparation.—Mix together, in a glass or porcelain vessel, pure salicylic acid (33 parts) and sodium bicarbonate (20 parts), and gradually add 20 parts of pure distilled water. Carbon dioxide is rapidly disengaged, and solution of sodium salicylate is formed. The proportions given insure a slight excess of acid, whereby a perfectly white salt is obtained. After most of the carbonic acid gas has escaped, expel the remainder by evaporating to dryness on a water-bath at a temperature not exceeding 60° C. (140° F.). Recrystallize the residue from 95 per cent alcohol. Instead of the foregoing, pure salicylic acid (100 parts) and uneffloresced crystallized sodium carbonate (103 parts), with sufficient water to produce a paste, may be employed, and, after straining through clean muslin, if necessary, proceed as directed in the first process. Excess of alkali would produce a brownish product. Contact with iron must be avoided, and the salicylic acid, as well as the carbonate should be pure.

Description and Tests.—This compound is described by the *U. S. P.* as "a white, amorphous powder, odorless, and having a sweetish, saline taste. Permanent in cool air. Soluble in 0.9 part of water, and in 6 parts of alcohol at 15° C. (59° F.); very soluble in boiling water or alcohol; also soluble in glycerin"—(*U. S. P.*). If the salt does not entirely dissolve in water, the residue is liable to consist of salicylic acid. "When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaves a residue of sodium carbonate. To a non-luminous flame, it imparts an intense, yellow color. The aqueous solution slightly reddens blue litmus paper. Ferric chloride T.S. added to an excess of a concentrated solution of the salt, produces a red precipitate, but when added to a very dilute solution (1 in 100), it produces a deep violet-blue color. If copper sulphate T.S. be added to the aqueous solution (1 in 20), a green color will be produced. On adding to about 0.2 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and then, cautiously, about 1 Cc. of methylic alcohol in drops, on heating the mixture to boiling, the odor of methyl salicylate will be evolved. Hydrochloric or sulphuric acid produces in a concentrated aqueous solution of the salt a voluminous, white precipitate, which, after being separated by filtration, and washed, should conform to the reactions and tests given under *Acidum Salicylicum*. The aqueous solution should be colorless, even when concentrated, and should not effervesce on the addition of acids (absence of carbonate). When the solution (1 in 20) is mixed with a small quantity of ammonium sulphide T.S., or with an equal volume of hydrogen sulphide T.S., no coloration or turbidity should appear (absence of metallic impurities). If 1 Gm. of the salt be dissolved in a mixture of 50 Cc. of alcohol and 25 Cc. of water, then acidulated with nitric acid and filtered, a portion of the filtrate should not be rendered turbid by the addition of a few drops of barium chloride T.S. (absence of sulphate). Another portion of the filtrate should remain clear on the addition of a few drops of silver nitrate T.S. (absence of chloride). If 1 part of the salt be agitated with 15 parts of cold, concentrated sulphuric acid, no brown color should be produced within 15 minutes (absence of readily carbonizable, organic impurities)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The action and uses of sodium salicylate are practically those of salicylic acid (which see), whose dangerous qualities it also shares. From the fact that salicylic acid is practically insoluble in water, this salt has largely superseded it, for, as a rule, an alkali is generally employed to render the acid soluble, thus converting it into an alkaline salt of salicylic acid. Sodium salicylate is much less apt to prove irritant to the gastric membranes than the acid, which, in itself, is a sufficient recommendation for its selection. The chief use for salicylate of sodium is in *acute articular* and *muscular rheumatism*. It does not, however, cure all cases, but is adapted to those in which the tongue is full, purplish, or leaden in color, and when the rheumatic parts are reddened, with a slight purplish discoloration, when pressed upon (Scudder). It is said to render relapses more frequent, and not to lessen mortality from rheumatic complaints. It is valuable in some disorders dependent upon a *rheumatic diathesis*, as *rheumatic pharyngitis*, *rheumatic iritis* and *ophthalmia*, and *detachment of the retina of rheumatic origin*. The pains of *dysmenorrhœa*, *pleurisy*, *sciatica*, and *biliary colic* are often relieved by it, and, for its antiseptic properties, it has been used in some of the *summer diarrhœal disorders*. Locally, it is useful in *catarrhal disorders*. Prof. Ellingwood (*Mat. Med. and Therap.*, p. 559) praises it in *acute coryza*, with supraorbital and frontal fullness, sneezing, watery secretions, chilliness, malaise, and general depression; also in *supraorbital pain* of catarrhal, neuralgic, or rheumatic origin; in *whooping-cough* (2 or 3 grains, 2 or 3 times a day), and in *nervous cutaneous pruritus* (15 grains, 3 times a day). About 5 to 20 grains are the ordinary doses for sodium salicylate, repeating, in severe rheumatic disorders, every 4 hours. The heart should be carefully watched (compare *Acidum Salicylicum*).

Specific Indications and Uses.—Antirheumatic, when the tongue is full, purplish, or leaden-hued, showing spots when the fur is lifted, fever is not especially high, and the affected parts are red, with some purplish discoloration, particularly when pressed upon.

Related Salts.—POTASSIUM SALICYLATE ($2KC_7H_5O_3.H_2O$). Take salicylic acid, 100 parts, and potassium bicarbonate, 72 parts, proceeding as in the preparation of sodium salicylate. Forms readily soluble, silky needles, which are stable in a dry atmosphere.

SODIO-THEOBROMINE SALICYLATE ($C_7H_7NaN_4O_2.NaC_7H_5O_3$).—This is the recently introduced *Diuretin*, a body produced by mixing equal molecular weights of sodium salicylate and sodium theobromine, both in aqueous solution, and evaporating to dryness. Theoretically, it should contain of theobromine, 49.7 per cent, and of salicylic acid, 38.1 per cent. It is a white, odorless powder, possessing a saline, bitterish, alkaline taste. It is soluble in warm alcohol, and in half its weight of warm water; upon cooling, the solution remains clear. Ether and chloroform do not dissolve it. Acids, and even the carbon dioxide of the air, readily decompose it, freeing the theobromine in insoluble form; hence, it should be well secured from air, and should not be dispensed in powders (compare *Pharm. Centralhalle*, 1890, p. 311; and *Amer. Jour. Pharm.*, 1890, p. 617). According to Dr. W. Cohnstein (*Berlin. Klin. Woch.*, Jan., 1893), diuretin acts by directly irritating the renal-secreting elements. Diuretin has little or no physiological action upon the heart and nervous system, except in large doses. It occasionally disorders the stomach and bowels, producing vomiting and diarrhœa, headache, fever, ecchymoses, etc. Therefore, it should be used with caution. Great prostration has been observed from 5 to 7 grammes, hence, not more than from 3 to 4 grammes should be given in a day (Askanazy). Diuretin is used chiefly as a remedy for *dropsy*. By its stimulating power upon the renal epithelium, a pronounced and persistent diuresis is the result, but the kidneys must be in a good condition to act. It is of little value in ascites of hepatic origin, but in *renal dropsy* and *cardiac dropsy*, with valvular lesions, it is an efficient agent. Its diuretic action is less when chronic nephritis is present than when dropsy depends upon diseases of the heart and blood vessels. It has proved itself a fairly constant and good remedy in *angina pectoris*, *cardiac asthma*, and *chronic cardiac dyspnœa*, when due to *aortic diseases* or *chronic nephritis* (Askanazy). According to Keyes (*Therap. Gazette*, 1893), it does not uniformly avert *urethral* or *urinary fever*, a condition for which he first thought it efficient. Dose, 10 to 20 grains, every 4 hours, in water or mint-water, or in powder with sugar, and sometimes with 1½ grains of digitalis leaves, as indicated.

SODIUM SULPHOSALICYLATE ($C_6H_3[OH]CO_2HSO_3Na$).—Sulphosalicylic acid ($C_6H_3.SO_3H.OH.CO_2H$) is first prepared by the action of sulphuric acid upon pure salicylic acid; then the sulphosalicylic acid is neutralized with sodium carbonate. Colorless crystals of the above salt are formed. Soluble in about 30 parts of water, the solution being acid in reaction. Employed as a remedy for *articular rheumatism* in place of sodium salicylate.

SODIUM DIIODOSALICYLATE ($2C_6H_2.OH.I_2.COONa$ $5H_2O$).—Iodine and iodic acid are allowed to act upon salicylic acid in alcoholic solution, whereby diiodosalicylic acid is produced. By neutralizing this acid with sodium carbonate, long, flat, acicular crystals, or laminæ, of a white salt of the above composition are formed. It is soluble in about 50 parts of slightly warmed water. It is employed in broken doses (from 20 to 40 grains daily) as an analgesic, antiseptic, and antipyretic. It is said to control the heart's action, producing sedation, and is employed in *skin diseases of a parasitic type*.

Sodium Dithiosalicylate.—If molecular amounts of salicylic acid and sulphur chloride be mixed and heated, for a time, to a temperature between 120° and 150° C. (248° and 302° F.), hydrogen chloride is evolved, and yellowish, resin-like *dithiosalicylic acid* (see below) is formed, which is, in reality, a mixture of isomeric acids. This mixture is dissolved in solution of sodium carbonate, and sodium chloride is now added, which has the effect of precipitating *salt No. 1*, while *salt No. 2* remains in solution. Salt No. 1 is non-crystalline, yellowish, hygroscopic, alkaline, and soluble in water with a brown color. It is employed chiefly in veterinary medicine, a 5 per cent solution being used. Salt No. 2, the one preferred in medical practice, is a non-crystalline, gray-white, extremely hygroscopic powder, very soluble in water and forming an alkaline, brown-black solution. Alcohol dissolves this salt but not salt No. 1. Sulphur bromide or iodide may be substituted for sulphur chloride in the preparation of these compounds. This agent is claimed to be a better antiseptic than sodium salicylate, and has been employed in *rheumatic fever*, *gonorrhœal rheumatism*, and in *acute articular rheumatism*. It is said not to produce unpleasant tinnitus and other head symptoms. Dose, 3 grains, night and morning. Larger doses (30 to 80 grains) have been given, however, but caution should be excercised in the use of such larger doses.

Sodium Formate ($NaCHO_2.H_2O$).—Sodium salicylate occasionally induces renal congestion, and sodium formate has been proposed as a substitute under such circumstances. It has not, however, been used to any extent. It is a colorless, crystalline compound, odorless, saline, and bitter, very deliquescent in moist air, and freely soluble in water. It melts in its water of crystallization. It is produced by neutralizing pure sodium carbonate (or bicarbonate) with formic acid.

Dithiosalicylic Acid ($[C_6H_3[OH]COOH.S]_2$).—A light-yellow powder, dissolving easily in alcohol, glacial acetic acid, and benzene. It is produced, as stated above, by heating equal molecular quantities of salicylic acid and sulphur chloride to a temperature between 120° and 150° C. (248° and 302° F.), dissolving the fused mass in caustic soda solution, and precipitating with hydrochloric acid. It was introduced as a substitute for salicylic acid, and its sodium salt is even preferred by some to the acid or to sodium salicylate, the advantage claimed being the greater energy of the compound, and the comparative freedom from gastric disturbances. Tinnitus aurium, nausea, and diaphoresis result from 10-grain doses. The usual dose for *rheumatism*, and as an antiseptic, is 3 grains, repeated as the exigencies of the case may require.

Antispasmin.—A white, somewhat hygroscopic powder, said to be composed of 1 molecule of narceine-sodium and 3 molecules of sodium salicylate combined. Of narceine about 50 per cent is present. With water it forms a quite permanent solution. According to Demme, in doses of ½ to 1 grain, it is analgesic and hypnotic, and is recommended for *cramps with pain*.

SODII SANTONINAS.—SODIUM SANTONINATE.

Formula: $2NaC_{15}H_{19}O_4.7H_2O$. Molecular Weight: 696.50.

Preparation.—Add to solution of soda (3½ ounces), water (1 ounce). Heat the solution on a water-bath. Then add santonin (1 ounce); digest until dissolved; filter; wash the strainer with a small amount of boiling water; set aside and allow to crystallize by cooling. By evaporating the decanted mother liquor to a smaller bulk more of the salt is yielded. Continue evaporation as long as colorless crystals are produced. Should colored crystals form, acidulate the liquor with hydrochloric acid and recover the santonin which is thus freed. About 1¼ ounces of the sodium salt are obtained by this method. Another process consists in converting santonin into calcium santonate, and decomposing this by sodium carbonate (*Amer. Jour. Pharm.*, 1877, p. 174).

Description.—If this salt be crystallized from alcohol it forms small prisms, or a fine mass of needles. When crystallized from water it corresponds to the description given below. On account of its changing to a yellow color under the action of light, it should be kept in well-stoppered, dark, amber-colored bottles, in a dark place. The *U. S. P.* (1880) describes this salt as "colorless, transparent, tabular, rhombic crystals, slowly colored yellow by exposure to light, slightly efflorescent in dry air, odorless, having a mildly saline and somewhat bitter taste, and a slightly alkaline reaction. Soluble in 3 parts of water and in 12 parts of alcohol at 15° C. (59° F.); in 0.5 part of boiling water, and in 3.4 parts of boiling alcohol. When heated to 100° C. (212° F.), until it ceases to lose weight, the salt loses 18 per cent of its weight (water of crystallization). At a higher heat it chars and finally leaves an alkaline residue, which imparts an intense yellow color to a non-luminous flame. The aqueous solution, on the addition of hydrochloric acid, deposits a crystalline precipitate, which is soluble in chloroform, and

113

which yields, with alcoholic solution of potassa, a scarlet-red liquid, gradually becoming colorless"—(*U. S. P.*, 1880).

Tests.—"A 5 per cent aqueous solution of the salt should not be precipitated nor be rendered turbid by test solution of carbonate of sodium (absence of alkaline earths), nor by picric or tannic acids (absence of alkaloids)"—(*U. S. P.*, 1880). Ferric chloride should not produce a violet coloration with its aqueous solution (absence of salicylates). (Also compare *Santonin.*)

Action, Medical Uses, and Dosage.—This agent is more soluble than santonin, which property also renders it more liable to absorption and consequent poisonous effects, and thereby leaving less of the santonin to produce the effect intended—that of expelling *lumbricoid worms.* This it does, less efficiently, however, than santonin. The dose for a child is from 1 to 5 grains with sugar, twice a day; for adults, 5 to 10 grains. A purgative should follow on the next day. An aqueous enema of this salt has been employed to remove "*thread worms.*"

Related Compound.—SODII SANTONINAS ALBUMINATUS. Take santonin (1 part), sodium bicarbonate (4 parts), and dry, perfectly soluble albumen (2 parts), and digest the mixture with water (50 parts) at about 60° C. (140° F.), until dissolved. Filter, evaporate by gently heating, and dry the product on glass (Pavesi, 1876). This compound forms pearly-lustrous, brilliant white scales, having both an alkaline and bitter taste. Water dissolves it; the solution when treated with hydrochloric acid precipitates albumen and santonin, while carbon dioxide escapes with effervescence. This salt is an anthelmintic, especially used locally for *rectal worms* (*ascarides*) and internally for *lumbricoids.* Mixed with sugar, from 2 to 5 grains may be given twice a day to children; from 5 to 10 grains to adults. Follow on second day with a laxative.

SODII SULPHAS (U. S. P.)—SODIUM SULPHATE.

FORMULA: $Na_2SO_4+10H_2O$. MOLECULAR WEIGHT: 321.42.

SYNONYMS: *Glauber's salt, Sodæ sulphas, Sulfas sodicus, Sulfas natricus, Sulphate of soda, Sal mirabile Glauberi, Vitriolated soda.*

"Sodium sulphate should be kept in well-closed vessels"—(*U. S. P.*).

History and Preparation.—Sulphate of sodium is also known as *Vitriolated soda* and *Glauber's salt*, so named from Glauber who first described it in 1658. It occurs more or less abundantly in the mineral springs of Carlsbad, Cheltenham, Sulphur Springs of Virginia, in the Geyser springs, and the Andes. Extensive deposits are found near Tiflis in the Caucasus, and in the small lakes of New Mexico and other parts of the United States. Sodium sulphate is also found in the ashes of some marine plants and in the blood, urine, and other animal fluids. Sodium sulphate is obtained in large quantities as a by-product in the making of sodium carbonate by the Léblanc process (see *Sodii Carbonas*). It is also formed in many other processes involving double decomposition, *e. g.*, in the preparation of ammonium chloride by the sublimation of a mixture of ammonium sulphate and sodium chloride; in the preparation of nitric acid, or of magnesium carbonate, etc., and on a large scale by exposing a mixture of concentrated solution of sodium chloride and magnesium sulphate as occurring, for example, in the mother liquors obtained in the preparation of sea salt (see *Sodii Chloridum*), at a low temperature, the following reaction taking place: $2NaCl+MgSO_4=MgCl_2+Na_2SO_4$. The salt prepared from the Friedrichshall Mineral Spring, as early as 1767, and known as *Sal Aperitivum Friedericianum*, was sodium sulphate.

Description.—Sulphate of sodium crystallizes in large, monoclinic prisms; when rapidly crystallized, the crystals are small and acicular, still containing the same quantity of water of crystallization. The salt resembles in appearance the sulphates of magnesium and zinc. The *U. S. P.* describes it as occuring in "large, colorless, transparent, monoclinic prisms, or granular crystals, odorless, and having a bitter, saline taste. The salt effloresces rapidly in the air, and finally loses all its water of crystallization"—(*U. S. P.*). According to the formula $Na_2SO_4+10H_2O$, it loses about 56 per cent of its weight upon efflorescence. A salt of the formula $Na_2SO_4+7H_2O$, crystallizing in the rhombic system, has also been obtained. Above 34° C. (93.2° F.), only the anhydrous salt (Na_2SO_4) can exist. Glauber's salt is "soluble at 15° C. (59° F.), in 2.8 parts of water. The solubility increases up to 34° C. (93.2° F.), when its maximum is attained, 1 part of the salt then dissolving in somewhat less than 0.25 part of water; from thence it gradually decreases with rising temperature, until 1 part requires 0.47 part of boiling water for solution. Insoluble in alcohol; soluble in glycerin. When heated to 33° C. (91.4° F.), the salt fuses, and, on being heated to 100° C. (212° F.), loses all its water (55.9 per cent). At a red heat the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper"—(*U. S. P.*). Sulphate of sodium is incompatible with the hydroxides of barium, calcium, and potassium, and soluble salts containing these bases, and with mercurous salts and the salts of silver and lead, sulphates of these metals being precipitated.

Tests.—"A 5 per cent aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in nitric acid. If to 5 Cc. of the aqueous solution (1 in 20) 1 Cc. of sodium phosphate T.S. and 0.5 Cc. of ammonia water be added, no turbidity or precipitate should be produced, even after agitation (absence of magnesium, etc.). The solution should not effervesce on the addition of an acid (absence of carbonate). It should not be colored or rendered turbid by the addition of ammonium sulphide T.S.; or of an equal volume of hydrogen sulphide T.S., after being acidulated with hydrochloric acid (absence of arsenic and metallic impurities). After acidulation with nitric acid, the aqueous solution should remain clear, or at most be rendered only very slightly opalescent, on the addition of silver nitrate T.S. (limit of chloride)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sulphate of sodium is a mild but efficient cooling laxative or purgative, promoting secretion and exhalation from the gastro-intestinal membrane, without causing inflammation or fever. It appears to impede the coagulation of blood, and also causes endosmosis of the serum. On account of its disagreeable taste, it has been gradually displaced by the sulphate of magnesium. Its usual dose is 6 or 8 drachms dissolved in 8 or 10 fluid ounces of water; when its water of crystallization is removed by drying or efflorescence the dose must be decreased to 3 or 4 drachms. As a diuretic, the dose must be smaller, and diluted with considerable water. A few drops of aromatic sulphuric acid may be advantageously added to lessen its bitter taste; or some citric acid, lemonade, or sweetened carbonated water. As a purgative it has been successfully used to relieve *plethoric conditions*, and it has given good results in *gastric ulcers*, *dropsy*, and *dysentery*. In the latter condition it was formerly much used in Eclectic practice in the form of the *white liquid physic*, which contains it. According to M. de Luca, crystallized sulphate of sodium has the property of holding the fibrin of the blood in solution, and acts favorably in causing *opacities* and *spots on the cornea* to wholly or partially disappear; he reduces this salt to a very fine powder, and by means of a camel's-hair pencil deposits it upon the eyeball, repeating the process twice a day; it causes no unpleasant sensation, and after several days of treatment the opacities commence to gradually disappear.

Sodium sulphate has a specific use outside of its cathartic application, and that is to stimulate retrograde metamorphosis and excretion. When the tissues are pale, full, and sodden, the tongue pallid and full and easily pitted by the teeth, the remedy will be specifically indicated. For this purpose an aqueous solution (grs. x to xx to Oj) may be freely taken. In this manner it forms a good remedy for *biliary calculi*. A 3 x trituration is said by Prof. Webster to control green *diarrhœa* accompanying childhood affections, as *teething*, *cholera infantum*, *entero-colitis*, etc. He also values it in *typhlitis*, and in *irritable conditions of the liver* bordering upon inflammation, the organ being swollen and sensitive to pressure. Under the Schüessler doctrine sodium sulphate is a good remedy (3 x trituration) in *cough* with thick, ropy, greenish expectoration, such as may be present in *bronchitis* and *humid asthma*. This class of practitioners also value it in faulty elimination of the fluids of the body, and especially where this gives rise to *bilious headache*, *thin bilious diarrhœa*, *bilious vomiting*, *diabetes*, *gout*, *moist skin eruptions*, *puffy erysipelas*, and *non-inflammatory œdema*. Solution of sodium sulphate is a good antidote to *acute poisoning with carbolic acid* and with *lead*. In *chronic lead poisoning* it will be borne longer by the stomach than iodide of potassium. Dose for purgation, 4 to 8 drachms, largely diluted; for specific purposes, the fraction of a grain to 2 grains.

Specific Indications and Uses.—Tissues pale, full and sodden; tongue full, pallid, and easily pitted by the teeth; watery or greenish diarrhœa; hepatic fullness and tenderness; biliousness. Large doses in dysentery, lead poisoning and poisoning by carbolic acid.

Other Forms of Sodium Sulphate.—SODII SULPHAS EXSICCATUS, *Dried sodium sulphate.* Four parts of the dried form of sodium sulphate are equivalent to 8 of the crystallized salt. According to the *German Pharmacopœia*, it is prepared by allowing the crystallized sulphate to effloresce at a temperature not exceeding 25° C. (77° F.). It is then dried at a temperature between 40° and 50° C. (104° and 122° F.) until it has lost one-half its weight. Hence it retains some of its water of crystallization (see *Sodii Sulphas*). The white powder is then passed through a sieve and placed in well-stoppered vials.

SODII SULPHAS EFFERVESCENS (*Br. Pharm.*), *Effervescent sulphate of sodium.*—Take of sulphate of sodium, in crystals, 50 ounces (Imp.); bicarbonate of sodium, in powder, 50 ounces (Imp.); tartaric acid, in powder, 27 ounces (Imp.); citric acid, in powder, 18 ounces (Imp.)." Dry the sodium sulphate until it has lost 56 per cent of its weight; powder the product and mix it with the other ingredients. Place the whole in a dish or pan of suitable form heated to between 93.3° and 104.4° C. (200° and 220° F.). When the mixture, by aid of careful manipulation of the powder, begins to aggregate, stir it assiduously until it has assumed a granular character; then separate it into granules of uniform size by means of suitable sieves. Dry the granules at a temperature not exceeding 54.4° C. (130° F.). The product should weigh about 100 ounces (*Br. Pharm.*, 1898). This is a laxative to be taken in cold water while it is still effervescing. The dose ranges from ¼ to ½ ounce.

Related Salts.—SODII SULPHOVINAS, *Sodium sulphovinate* ($NaC_2H_5SO_4.H_2O$), *Sodium ethylsulphate.* To prepare this compound, 1 part of sulphuric acid is gradually added to an equal amount of alcohol. The mixture develops heat, and sulphovinic acid ($C_2H_5HSO_4$) is formed. The sodium salt is obtained by removing the excess of sulphuric acid by means of sodium carbonate and the addition of sufficient alcohol to precipitate the sodium sulphate. The sodium sulphovinate is in alcoholic solution, and is obtained by evaporating the solution to dryness. Or, chalk is added to the crude sulphovinic acid, which precipitates the excess of sulphuric acid as calcium sulphate, while in solution is calcium sulphovinate, which is then decomposed with sodium carbonate (see Charles Rice, *Amer. Jour. Pharm.*, 1873, p. 60, and *ibid.*, 1877, p. 443). Sodium sulphovinate forms hexagonal transparent tables, or if obtained by evaporation, a granular powder. Both forms readily effloresce on exposure to a dry atmosphere and deliquesce in moist air. The crystals fuse at about 80° C. (176° F.), losing some of their water of crystallization. If crystallized from alcohol they contain alcohol in the place of water of crystallization. They decompose above 100° C. (212° F.), giving off inflammable alcoholic vapors; the residue consists of sodium bisulphate ($HNaSO_4$). To test-paper the salt is neutral. It is soluble in water, glycerin, and alcohol, and sparingly in absolute alcohol. Ether does not dissolve it. It has a feebly bitter, and subsequently sweetish taste. This salt is proposed as a tasteless laxative not likely to produce colic. It is, however, an unstable preparation. Dose, about ½ ounce.

SODIUM SULPHOMETHYLATE ($NaCH_3SO_4.H_2O$).—Prepared like the preceding salt, using methyl alcohol instead of ethyl alcohol (see M. Rabuteau, *Amer. Jour. Pharm.*, 1880, p. 220). Its properties are those of sulphovinate of sodium. It is unstable, not unpleasant in taste. Declared a cathartic without producing colicky pains or cramps. Dose, about ½ ounce.

SODII SULPHIS (U. S. P.)—SODIUM SULPHITE.

FORMULA: $Na_2SO_3+7H_2O$. MOLECULAR WEIGHT: 251.58.

SYNONYMS: *Natrum sulphurosum, Sulfis sodicus, Sulfis natricus.*

"Sodium sulphite should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Preparation.—First produce *sodium bisulphite* (see *Sodii Bisulphis*) by saturating a solution of a definite quantity of sodium carbonate with sulphur dioxide, and then add an equal quantity of sodium carbonate. The following reaction takes place: $2NaHSO_3+Na_2CO_3=2Na_2SO_3+H_2O+CO_2$. Evaporate to crystallization, being careful to exclude the air. (On the preparation of several sulphites, see *Amer. Jour. Pharm.*, 1889, p. 584, and 1890, p. 150.)

Description.—The *U. S. P.* describes the salt as in "colorless, transparent, monoclinic prisms, odorless, and having a cooling, saline, sulphurous taste. In air the salt effloresces, and is slowly oxidized to sulphate. Soluble in 4 parts of water at 15° C. (59° F.), and in 0.9 part of boiling water; sparingly soluble in alcohol. When gently heated, the salt softens somewhat, but does not fuse. Above 100° C. (212° F.), the crystals lose all their water (50 per cent), without fusing or changing their shape. At a red heat, the salt fuses to a reddish-yellow mass of sodium sulphate and sodium sulphide. To a non-luminous flame, the salt imparts an intense, yellow color. The aqueous solution is neutral or feebly alkaline to litmus paper"—(*U. S. P.*). The form generally employed by Eclectic physicians is the finely-powdered anhydrous salt (Na_2SO_3). It is less liable to changes than the hydrated compound ($Na_2SO_3+7H_2O$).

Tests.—"Upon the addition of hydrochloric acid to the salt or its solution, sulphur dioxide gas is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. and held in the escaping gas; the solution remains clear, no sulphur being separated (distinction from *hyposulphite*). The aqueous solution (1 in 20) should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide T.S., either before or after the addition of ammonia water in slight excess (absence of metallic impurities). If a solution of 2.5 Gm. of the salt in 11 Cc. of diluted hydrochloric acid be heated sufficiently to expel the sulphur dioxide, then 0.15 Cc. of barium chloride T.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate). If 1.2 Gm. of sodium sulphite be dissolved in 10 Cc. of diluted nitric acid, the solution heated to expel the gases, then 0.4 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unchanged by the further addition of silver nitrate V.S. (limit of chloride). If 0.63 Gm. of the salt be dissolved in 25 Cc. of water recently boiled to expel air, and a little starch T.S. be added, at least 48 Cc. of decinormal iodine V.S. should be required to produce a permanent blue tint (each cubic centimeter corresponding to 2 per cent of the pure salt)"—(*U. S. P.*). The latter determination is based upon the oxidation of the sulphite to sulphate, as follows: $Na_2SO_3+H_2O+I_2=2IH+Na_2SO_4$. Analysis of four commercial specimens, according to Wm. A. Puckner (*Western Druggist*, 1897, p. 254), showed only 54, 66.5, 74, and 92.5 per cent of the pure salt, instead of 96 per cent. Large amounts of sulphate were present.

Action, Medical Uses, and Dosage.—Sulphite of sodium, as well as the bisulphite, were introduced to the profession, along with other sulphites, by M. Polli, as azymotics, as described under *Magnesii Sulphis* (which see). These several sulphites are employed in the same diseases, and for the same purposes, both internally and externally, and their efficacy in the diseases in which they have been recommended is now generally acknowledged by the medical profession. Whether used internally or externally, it evolves sulphurous acid, upon which the remedial virtues of all the sulphites appear chiefly to depend. Besides this, the alkaline element is present, thus overcoming conditions of excessive acidity. It agrees well with the stomach, has no local irritating properties, and acts as a diuretic. Dr. Astrié highly recommends the sulphite of sodium as a remedy to the *effects of mercury* upon the system; the thick precipitate formed by the union of white of egg and a solution of corrosive sublimate, is at once restored to a transparent fluid by a few drops of a solution of the sulphite of sodium.

The special use of sulphite of sodium in the Eclectic school, is in that very common condition met with in many diseases—the broad, pallid tongue, with white or dirty-white coating, and extremely fetid breath, although the latter is not always present. With these conditions present, the name of the disease is immaterial, and the prompt response to the action of the remedy will do more to convert one to a belief in the specific action of medicines than all of the arguments which may be presented. There are special disorders in which it is especially recommended, following the indications as laid down above, and these are *fermentative and putrefactive conditions*, *typhoid and other fevers*, *erysipelas*, *smallpox*, *tonsillitis* and other forms of *sore throat*, *herpes*, *scabies*, *ringworm*, etc. The dose of the sulphite of sodium is from 10 to 60 grains, 3 times a day.

Specific Indications and Uses.—Pallid, broad tongue, with white or dirty-white, pasty exudate, and pallid mucous membranes; fetor; fermentative and putrefactive processes; parasitic skin affections.

SODII SULPHOCARBOLAS (U. S. P.)—SODIUM SULPHOCARBOLATE.

FORMULA: $NaSO_3C_6H_4(OH)+2H_2O$. MOLECULAR WEIGHT: 231.56.

SYNONYMS: *Sodium paraphenolsulphonate*, *Sulphocarbolate of sodium*.

Preparation.—Dissolve 2 parts of sulphocarbolate of calcium (see *Related Compounds*) in 4 parts of distilled water, and stir into it solution of sulphate of sodium until in slight excess; rather more than 1½ parts of crystallized sulphate of sodium will be required. Permit the mixture to stand a few hours, then filter, and wash the precipitate with distilled water until the runnings are nearly tasteless. Evaporate the filtrate to dryness, on a steam or water-bath, and dissolve the residue in boiling alcohol (about 10 parts), then filter, and place it in a cold situation to crystallize. In case a trace of sulphate of sodium is not objectionable, the crystallization from alcohol may be dispensed with. The aqueous solution should then be evaporated until a skin forms upon the surface, and then be allowed to crystallize.

Description and Tests.—As thus prepared, sulphocarbolate of sodium is in the form of small, needle-like crystals, white, very soluble in water, less so in alcohol, and insoluble in ether. The *U. S. P.* describes the salt as occurring in "colorless, transparent, rhombic prisms, odorless, and having a cooling, saline, slightly bitter taste. Somewhat efflorescent in dry air. Soluble, at 15° C. (59° F.), in 4.8 parts of water, and in 132 parts of alcohol; in 0.7 part of boiling water, and in 10 parts of boiling alcohol. When heated a little above 100° C. (212° F.), the salt loses all its water (15.5 per cent) and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue of sodium sulphate amounting to 30.6 per cent of the original weight. To a non-luminous flame, it imparts an intense, yellow color. The aqueous solution is neutral to litmus paper"—(*U. S. P.*). It does not precipitate with barium chloride. If a small crystal be boiled with nitric acid, and the liquid be then neutralized with solution of caustic potash, a yellow color will result (carbazotate or picrate of potassium). This test is not distinctive, as it applies to carbolic acid and carbolates as well as sulphocarbolates. "A dilute solution (1 in 100) of the salt is rendered pale-violet by ferric chloride T.S., but remains clear; barium chloride T.S. leaves the solution clear, but if a portion of the salt be ignited, and the residue dissolved in water, the same reagent will produce in the solution a copious, white precipitate. In the aqueous solution (1 in 20) neither hydrogen sulphide T.S. nor ammonium sulphide T.S. should produce any turbidity or coloration (absence of metallic impurities); nor should more than a faint opalescence be produced by barium chloride T.S. (limit of sulphate), or by silver nitrate T.S. (limit of chloride)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sulphocarbolate of sodium is simply a disinfectant. At one time it was highly extolled as an efficient internal remedy in *scarlatina*, *diphtheria*, *typhoid fever*, in *septicæmic diseases* generally, and even in *phthisis pulmonalis*, but well-conducted trials of it in these affections have not sustained such marvellous assertions. It undoubtedly exerts a good influence in the fermentative forms of *dyspepsia* and *diarrhœa*, and destroys *thrush*. The *vomiting of pregnancy* is sometimes relieved by it. It has been found more useful as a local application, employed in aqueous solution in the form of spray; used in this manner, it has been sometimes beneficial in *gangrenous conditions*, and in the removal of the *pseudo-membranous exudations* encountered in *aphthæ*, *scarlatina*, and *diphtheria;* and, in these cases, it owes its properties to the phenic acid present. Its dose, internally, is from 5 to 25 grains, in solution.

Related Compounds.—SULPHOCARBOLATES, *Sulphophenates*. Sulphocarbolates are salts prepared respectively from *ortho* and *para* phenol-sulphonic acids ($C_6H_4.SO_3H.OH$). When concentrated sulphuric acid and carbolic acid are mixed together in equal proportions, and the mixture digested at from 40° to 50° C. (104° to 122° F.), the *ortho* acid is mainly formed. When the temperature is increased to 149° C. (300° F.), this acid changes to the *para* phenol-sulphonic acid. Neither acid is known in an absolute state. In commerce, distinctions are not made in the salts derived from the two, and, perhaps, their therapeutical actions are identical. The *para* sulphocarbolates are very easily prepared, and consequently are found almost exclusively in the markets. The salts of both acids are all soluble in water, generally soluble in hot alcohol and glycerin, but insoluble in ether. Most of the ortho salts are more soluble than the corresponding para salts. Commercial sulphocarbolates are made very easily by mixing equal parts of sulphuric and carbolic acids, and heating the mixture to 149° C. (300° F.). The mixture, upon cooling, is diluted with water, neutralized with the necessary quantity of carbonate, and evaporated to crystallization. Adhering sulphates are removed by dissolving the salt in warm water, and recrystallizing. This forms the *para* sulphocarbolates, which are usually obtained in nice large crystals. (See an extensive study of the sulphocarbolates, by F. B. Power and E. J. Ræuber, in *Pharm. Rundschau*, 1889, pp. 103–110.

CALCII SULPHOCARBOLAS, *Sulphocarbolate of calcium*. Formula: $Ca2C_6H_5SO_4$. Molecular Weight: 385.18.—Melt 16 troy ounces of carbolic acid, in a porcelain dish, and, with constant stirring, pour into it 16 troy ounces of concentrated sulphuric acid, and then apply the heat of an expanded steam or water-bath for 24 hours. Dilute the mixture with 8 pints of cold distilled water, and gradually stir into it powdered carbonate of calcium, until effervescence ceases; then permit the mixture to stand for a few hours, filter, wash the precipitate with water, and evaporate the mixed filtrates to dryness over a water-bath. The product (about 20 troy ounces) will be impure sulphocarbolate of calcium, usually of a pink color. To purify it, redissolve it in water, filter, and again evaporate to dryness. When the sulphuric and carbolic acids are mixed, the result is a deep pink-colored liquid, or often brownish-red, from impurities in the latter acid. This coloring matter adheres most persistently to the salt. The yield is never so large as theory would indicate. To purify the salt, uncombined sulphuric acid is thrown out as sulphate of calcium, upon addition of the carbonate of calcium, and the subsequent heat evaporates the free carbolic acid. Sulphocarbolate of calcium may be used to prepare the other sulphocarbolates. The more expensive barium carbonate may be substituted for calcium carbonate in the foregoing operation, and sulphocarbolate of barium be formed in like manner as the sulphocarbolate of calcium. Neither sulphocarbolate of calcium nor sulphocarbolate of barium are used as medicines.

Sodii Carbolas, *Sodium carbolate, Sodium phenate* (NaC_6H_5O).—The alkaline carbolates have been highly extolled for uses similar to the acid. The carbolate of sodium (*Phénol Sodique*), is the one more commonly used. It is an easily decomposed preparation, soluble in water and carbolic acid, and may be made by neutralizing pure crystallized carbolic acid in solution with caustic soda; press the resulting crystals between bibulous paper, and then dry them under a bell-glass over a dish of sulphuric acid. As a local application, this will be found very useful in *burns, scalds, stings of bees, wasps, bites of spiders*, etc.; in *chilblain, erysipelas*, many *cutaneous affections, hemorrhoids*, and *soft, spongy, swollen*, or *ulcerated gums;* when applied by means of compresses, it arrests *hemorrhage from leech bites, cuts, spongy gums*, etc.; when sprinkled around places infested by insects, parasites, or animalculæ, it destroys them, or drives them away. The fumes of this preparation are said to relieve *whooping-cough*, and it has been used internally in *scarlet fever*. Dose, 5 to 30 grains. It is a good deodorizer and checks putrefaction (see also *Liquor Sodii Carbolatis*).

Magnesii Sulphocarbolas, *Magnesium sulphocarbolate* ($Mg[SO_3C_6H_4.OH]_2.7H_2O$).—Forms in rhombic prisms or acicular crystals.

Potassii Sulphocarbolas, *Potassium sulphocarbolate* ($KSO_3C_6H_4[OH]$), also forms shining acicular crystals.

SODII VALERIANAS.—SODIUM VALERIANATE.

Formula: $NaC_5H_9O_2$. Molecular Weight: 123.77.

Synonyms: *Sodæ valerianas, Natrium valerianicum, Valerianus natricus, Valerianas sodicus.*

Preparation.—This salt is prepared by very careful oxidation of *amylic alcohol* or *fusel oil* ($C_5H_{11}OH$), with diluted sulphuric acid and potassium bichromate in a distilling apparatus, neutralizing the distilled valerianic acid ($C_5H_{10}O_2$) accurately with sodium hydroxide, and evaporating to dryness. (For details regarding this process, see *Br. Pharm.*, 1885, and this *Dispensatory*, preceding edition.)

Description and Tests.—Valerianate of sodium crystallizes with difficulty, but may be obtained in the form of a cauliflower-like mass. It fuses at 140° C. (284° F.), and on cooling forms a white solid mass, which has a greasy or soapy feel. Its odor is like valerianic acid; its taste sweet but nauseous. It is very deliquescent, soluble in alcohol or water, and should not be alkaline in reaction. When treated with sulphuric acid a powerful odor of valerian is evolved. Neither hydrogen sulphide nor ammonium sulphide should produce colorations with its aqueous solution (absence of metals), nor should a precipitate be occasioned in acid solution by barium chloride (absence of sulphates).

Action, Medical Uses, and Dosage.—Valerianate of sodium is not used to any extent as a medicine, but for the preparation of the valerianates of iron, quinine, etc., by double decomposition of the sodium salt with salts of the respective bases. It might be used with advantage in *nervous* and *irritable habits*, attended with *acidity of the stomach*, but probably has no advantages over the corresponding ammonium compound. Dose, 1 to 5 grains.

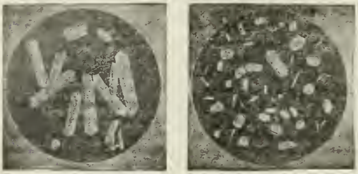
SOLANUM CAROLINENSE.—HORSE-NETTLE.

The root and fruit of *Solanum Carolinense*, Linné.

Nat. Ord.—Solanaceæ.

Common Names: *Horse-nettle, Bull-nettle, Sand-brier, Treadsoft, Treadsaf.*

Fig. 231.



Solnine, from Solanum Carolinense.

Botanical Source.—Horse-nettle is an herbaceous perennial plant, from 8 to 18 inches high. The stem is simple and erect, though sometimes prostrate and branching from the root. The more or less contorted root is from $\frac{1}{8}$ to $\frac{1}{4}$ inch in diameter, having a thick bark surrounding a slender woody center; it descends deeply and vertically into the soil. The leaves are alternate, oblong, ovate; obtusely lobed, wavy, with yellowish prickles on midrib and larger veins of both surfaces, and extending along the petiole and main stem, where they become quite stout. The surfaces of stems and leaves are stellate (4, 6, or 8-rayed) pubescent. The flowers are borne in simple cymes or racemes, becoming lateral in fruit. Flowers regular, calyx 5-parted, sepals pointed, corolla rotate, with 5 ovate lobes and pale-blue, violet, or more rarely white. Stamens 5, yellow, inserted on the corolla; anthers 4-celled, 4 times as long as the filaments, and opening by pores at the tip. They are counivent and form a cone around the pistil. The style and stigma are single. The fruit, when ripe, is an orange- or lemon-colored berry from $\frac{1}{2}$ to $\frac{3}{5}$ inch in diameter; 2-celled, the seeds being attached to the central placenta. The seeds are pale-yellow, smooth, shining, oval, and flattened. The dried fruit has a shrunken or reticulated appearance. (Also see microscopy and illustration of Solanum Carolinense, by C. J. Johnson, in *Amer. Jour. Pharm.*, 1897, pp. 76–84, and by M. C. Thrush, *ibid.*, pp. 84–89.)

History.—Horse-nettle is a common and abundant wild plant flourishing in waste places and around cultivated fields, frequently in patches in almost all parts of our country. It grows from Connecticut to Iowa, and southward to the Gulf of Mexico. It frequently grows so abundantly as to be a nuisance, preferring sandy or gravelly slopes, railroad grades, etc., with a south sunny exposure. The root and berries are employed medicinally. Specific solanum carolinense is prepared from the root. Attention was called to this plant by Porcher (*Report on Indigenous Medical Plants of South Carolina*) in the middle of the present century, who quotes from a French work (Mérat and De Lens *Dictionnaire Univ. de Matière Médicale*, Paris, Vol. VI, 1837) that M. Louis Valentin used the berries in idiopathic or non-traumatic tetanus (see also A. Clapp, M. D., *Report on Medical Botany*, 1850–51; and Robert Hogg, *Natural History of the Vegetable Kingdom*, 1858). Porcher also refers to an article (*Journal Gén. de Méd.*, Vol. XL, p. 13), which gives "*A notice of the different methods of treating Tetanus in America, with observations on the good effects of the S. Carolinense.*" According to Porcher, it possessed "some reputation among the negroes of this state (South Carolina) as an aphrodisiac." Its revival as a medicine was due to reports by Dr. J. L. Napier, of Blenheim, S. C. (*Medical World*, 1889; and *Amer. Therapist*, 1892).

Chemical Composition.—Complete chemical analyses of the root-bark, leaves and berries of Solanum Carolinense were made by G. A. Krauss (*Amer. Jour. Pharm.*, 1890, p. 601, and 1891, pp. 65 and 216); of the berries, also by Harry Kahn (*ibid.*, 1891, p. 126). From the root-bark Krauss obtained by consecutive extraction with petroleum-ether and ether, an alkaloid crystallizing in hard, shining prisms, soluble in ether, benzol, and chloroform, and being non-glucosidal. Alcohol then abstracted a glucosidal alkaloid which showed the reactions for *solanine*. The ether-soluble alkaloid, the author believes to be probably *solanidine* (compare *Dulcamara*). The leaves and the berries contained the same substances. Prof. J. U. Lloyd (*Amer. Jour. Pharm.*, 1894, p. 161) independently obtained from the root of this plant an ether-soluble, well-crystallizable alkaloid (see illustration, above), which he provisionally named *solnine*. It is practically insoluble in water and diluted ammonia water, soluble in diluted acids and in cold chloroform; from boiling alcohol it crystallizes in needles resembling hydrastine. Its melting point is 131° C. (267.8° F.), thus differing markedly from solanine, which melts at 235° C. 455° F.), also differing from solanidine, the melting point of which, according to Watt's *Dictionary*, is 191° C. (375.8° F.). The root-bark contains about 0.4 per cent, the berries about 1.3 per cent, of total alkaloids, the presence of which explains the toxic action of the drug. (For further constituents of volatile oil, starch, *solanic acid*, etc., see the papers quoted.)

Action, Medical Uses, and Dosage.—This agent is reputed antispasmodic, and has been recommended chiefly for convulsive disorders. It was early used by Valentin in *non-traumatic tetanus* (see *Medical History*). While success with has been recorded in *chorea*, *puerperal eclampsia*, *infantile*, and *hysterical convulsion* its chief use has been in *epilepsy*, and particularly that form in which the paroxysms are severest at or brought on at the menstrual periods. The drug needs further investigation. The dose of the fluid extract is from 10 to 60 drops; of specific solanum carolinense, 10 to 30 drops.

SOLIDAGO.—SWEET-SCENTED GOLDENROD.

The tops and leaves of *Solidago odora*, Aiton.

Nat. Ord.—Compositæ.

COMMON NAMES: *Sweet goldenrod*, *Sweet-scented goldenrod*, *Fragrant-leaved goldenrod*, *Blue mountain tea*.

Botanical Source.—This plant has a perennial, woody, much branched, and creeping root, and a slender, round, yellowish-green stem, smooth or slightly pubescent below, pubescent at top, often reclined, and 2 or 3 feet in height. The leaves are closely sessile, linear-lanceolate, broad at base, entire, acute, rough at the margin, but otherwise smooth, with a prominent midrib, and covered with small pellucid dots. The flowers are of a deep golden-yellow color, in a terminal compound, and usually secund-paniculate raceme, the branches of which are very slender, rigid, and spread almost horizontally, are each accompanied by a small leaf, and support the flowers on downy pedicels, which put forth from the upper side of the peduncle, and have small, linear, subulate bracts at their base. Scales of the involucre oblong, acute, smooth, or slightly pubescent, the lower ones are shorter, and closely imbricating the rest. Florets of the ray few, with oblong, obtuse, yellow ligules, those of the disk funnel-shaped, with acute segments. The pappus is shorter than the florets of the disk. The leaves of this plant are from 1½ to 3 inches long by from 3 to 5 lines broad, with a strong, yellowish midvein, but no veinlets (L.—G.—W.).

History, and Chemical Composition.—This plant is common to the United States, growing in dry, fertile woodlands and sunny hills, and flowering from July to October. There are many species of this genus growing throughout the country, and which differ from each other in their degree of astringency and fragrance. The leaves and tops are the parts used; they have an odor, when bruised, resembling anise and sassafras, and a slightly astringent, spicy, rather pleasant taste; they contain a volatile oil, which may be procured by distilling them with water; it is of a pale-yellowish color. The oil obtained from the flowers is said to differ from that yielded by the leaves. When properly dried, the leaves form an excellent substitute for tea, and are collected and used for this purpose, under the name of "Blue mountain tea," among the German population in central Pennsylvania. The leaves impart their virtues to alcohol or boiling water; but boiling injures their properties. From the whole plant of *Solidago rugosa*, Wm. P. Oberhauser (*Amer. Jour. Pharm.*, 1893, p. 122) obtained 0.996 per cent of volatile oil; the odor of the oil from the flowers and the leaves resembles that of origanum. The flowers of *S. bicolor*, also growing in Pennsylvania, contain volatile oil and 2.5 per cent of a bitter resin (Adam Conrath, *ibid.*, 1873, p. 253). The flowering and fresh herb of *S. canadensis* yields 0.63 per cent of volatile oil, chiefly consisting of *pinene*, with *borneol*, *bornyl-acetate*, and *cadinene* (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899).

Action, Medical Uses, and Dosage.—Sweet-scented goldenrod is gently stimulant and carminative, and, in warm infusion, diaphoretic. It may be given in infusion in *flatulent colic*, *amenorrhœa*, *sickness at the stomach*, and as a pleasant drink in convalescence from severe *dysentery*, *diarrhœa*, *cholera morbus*, etc.; and may also be added to nauseating medicines to render them more agreeable to the taste. The oil is carminative and diuretic; and its tincture or essence has been used as a diuretic in *suppression of urine among infants*, and as a local application in some forms of *headache*. Its essence is useful to remove *flatulency*, check *vomiting*, relieve *cramp of the stomach*, and to mask the unpleasant flavor of nauseous medicines. The flowers are said to be aperient, tonic, astringent, and diuretic and have been found beneficial in *gravel*, *urinary obstructions*, *ulceration of the bladder* and in the early stage of *dropsy;* taken in infusion (herb ℥i to water Oj) in doses of 1 or 2 fluid ounces; the oil, from 1 to 3 drops.

Related Species.—*Solidago rigida*, Linné, *Hard-leaf goldenrod*. This plant is also termed *Rigid goldenrod*. It has a simple stem, corymbose above, terete, striate, rough, minutely hairy, very leafy, 3 to 5 feet in height. Leaves 1 to 4 inches long, ovate-oblong, rough. with minute rigid hairs; upper ones entire, veiny, thick, rigid; lower closely sessile by a broad base, slightly serrate; radical ones lanceolate, acuminate, nerved, petiolate, sometimes nearly 1 foot long, 2 or 2½ inches broad. Flowers yellow, in a terminal, compound, close, compact, paniculate raceme. Heads very large, about 34-flowered; rays twice the length of the obtuse involucre, deep-yellow, from 7 to 10, and about 3 lines by 1. Scales of the involucre round-obtuse, nerved, membranaceous at the edges (W.—G.). This is a tall species, growing in dry fields and rocky woods throughout the United States, and is abundant in the western prairies, flowering in August and September. It is the styptic plant of old Dr. Bone, of New Jersey, who is said to have suppressed *hemorrhages* from large blood-vessels by applying it locally, in the powdered state; a property likewise attributed to the variable *Solidago virga aurea*, Linné, or *European goldenrod*, found in this country and Europe. The leaves and blossoms of *S. rigida* are the parts employed. They have an astringent taste, and yield their virtues to water or alcohol. Hard-leaf goldenrod is tonic, astringent, and styptic. In powder or infusion, it is beneficial in all *external hemorrhages*, *epistaxis*, *hemoptysis*, *hematemesis*, and *hemorrhage from the bowels*. Applied with excellent effect, in form of poultice, to *old ulcers*. The oil is diuretic. This plant deserves further investigation.

Solidago virga aurea, Linné, *European goldenrod*, has been revived as a diuretic and remedy for *urinary disorders*.

Solidago gigantea, Aiton, *Smooth three-ribbed goldenrod*, will likewise be found to possess similar virtues.

Chrysopsis argentea, *Silver aster*, also named *C. graminifolia*, belonging to this family of plants, forms a very powerful styptic application to *wounds*, and said to be the sheet-anchor in field-surgery among the Cherokees. Internally, it is beneficial in *diarrhœa*, *dysentery*, *aphthous ulceration of the mouth*, etc.

SOPHORA.—SOPHORA.

The seeds of *Sophora speciosa*, Bentham.

Nat. Ord.—Leguminoseæ.

ILLUSTRATION: *Amer. Jour. Pharm.*, 1886, p. 466.

Botanical Source, History, and Chemical Composition.—An evergreen shrub, or tree, with odd-pinnate, smooth leaves, the leaflets of which are in pairs of 3 to 5. The leaflets are ovate in outline, about an inch long, either obtuse or pointed, pale-green below, and glossy and deep-green on the upper surface. The flowers are blue, sometimes tinted with white, have 10 stamens, small campanulate calices, are very fragrant, and borne in close racemes. The fruit is a nearly round, indehiscent pod, 2 or 3 inches long, tough, slightly constricted, at intervals separated by the seeds, and coated with a pubescence of a light brown-gray color. The subglobular seeds are of a red color, are depressed at the hilum, and less than ½ inch in length. *Sophora speciosa* grows in Texas, and yields a bean which, it is said, is sometimes employed as a medicine by the Indians of southwestern Texas, producing delirious exhilaration and subsequent sleep of 2 or 3 days. Not more than ½ bean is taken, it being asserted that an entire bean will kill a man. Dr. H. C. Wood (*Amer. Jour. Pharm.*, 1877, p. 617, and 1878, p. 283) prepared, from specimens of the bean, an alkaloid, soluble in ether and diluted acids, and named it *sophorine*. Prof. Plugge (*Archiv der Pharm.*, 1891, p. 563) believes it to be identical with the alkaloid *cytisine* (see *Laburnum*). (A complete quantitative analysis of the seeds, with description and illustration of the plant, is given by M. Kalteyer and W. E. Neil, in *Amer. Jour. Pharm.*, 1886, p. 465.)

Action, Medical Uses, and Dosage.—Of the alkaloid, *sophorine*, a mere speck paralyzed a frog, and $\frac{1}{20}$ grain caused a cat to sleep many hours. From an overdose, death followed in a few hours. Its action is similar to that of the calabar bean. It appears to be a spinal sedative, and occasions death through the respiration. This remedy deserves investigation. According to Dr. Scudder, "it may be employed as a stimulant to the cerebro-spinal centers, when there is a defect of reflex action, imperfect respiration, and *threatened paralysis*. It also relieves the excited innervation from atony, and thus gives rest and sleep" (*Spec. Med.*, p. 247). A tincture of the seeds, with 98 per cent alcohol, is suggested, 5 drops of which may be added to 4 fluid ounces of water, the dose of the dilution being a tablespoonful.

Related Species.—*Sophora japonica*, Linné. This is a fine tree, a native of China or Japan. The flowers, under the name *Wai-fa* or *Wai-hwa*, are used in those countries for dyeing silk a yellow color, and to produce a beautiful green, when mixed with a proper proportion of blue. All parts of the tree are purgative, and persons who prune it, as well as workmen who are engaged in turning the dry wood, are affected by it. Foerster 1882 obtained from it the yellow glucosid, *sophorine*, which splits into *sophoretin* and *isodulcite* when treated with diluted sulphuric acid also see R. Wachs, *Amer. Jour. Pharm.*, 1894, p. 35).

Sophora sericea, Nuttall.—Nebraska to California. The seeds and root of this small herb yielded F. A. Wentz *United States Agricultural Report*, 1879) an impure liquid alkaloid, thought to be identical with *sophorine*.

Sophora tomentosa yielded Greshoff (*Pharm. Jour. Trans.*, Vol. XII) a fluid alkaloid, which Prof. Plugge (1891; see *Sophora speciosa*) regarded identical with *cytisine*.

SORBUS.—MOUNTAIN ASH.

The fruit of *Pyrus aucuparia*, Gærtner (*Sorbus aucuparia*, Linné; *Mespilus aucuparia*, Scopoli).

Nat. Ord.—Rosaceæ.

Botanical Source.—This tree, which is of medium size, bears odd-pinnate leaves composed of obtuse leaflets, which are pubescent or downy upon their under surface. The fruit, or part employed, is bright-red, globular, berry-like, and of small size. The remains of the calyx-limb cap the fruit, which is acid to the taste, and contains 3 or 4 two-seeded cells.

History and Chemical Composition.—The tree yielding mountain ash berries is indigenous to Europe and the western portions of Asia. It is known as the *Rowan tree*, and is sometimes cultivated in America for its landscape effects. The ripe fruits contain much malic acid, with citric acid. The unripe fruits contain tartaric acid (Liebig). In addition, the following principles were found: (1) The sugar *sorbin* (*sorbinose*, $C_6H_{12}O_6$), discovered by Pelouze (1852) in fermented juice of the berries; it is isomeric with dextrose, as sweet as cane-sugar, non-fermentable, crystallizing in rhombic prisms, lævo-rotatory, and capable of reducing Fehling's solution; remains unaffected by boiling with diluted acids; (2) *sorbite* ($C_6H_{14}O_6$) isomeric with mannite and dulcite, insoluble in water, soluble in boiling alcohol, optically inactive, not reducing Fehling's solution; discovered by Boussingault (1872); (3) *sorbic acid* ($C_6H_8O_2$) is an unsaturated crystallizable acid, volatile with the vapors of water; discovered by A. W. Hofmann (1859) in the juice of the unripe berries. A peculiar tannin (*sorbitannic acid* of Vincent and Delachanal) is also present in the fruits. Wicke (1852) found bitter amygdalin in the bark and the buds.

Action, Medical Uses, and Dosage.—The ripe fruit of sorbus, when infused with water, furnishes an acidulous and astringent gargle for acute *diseases of the pharyngeal vault and tonsils*, with excessive secretion. The bark and the unripe fruit are employed in infusion, or decoction in *scurvy* and *diarrhœa*, and topically to *relaxations of the anal or vaginal walls and throat*, all with profuse secretion. The very astringent qualities of sorbus render it a good agent for poultices when one of such a character is desired.

Related Species.—*Pyrus Americana*, De Candolle (*Sorbus Americana*, Marshall), and the *Pyrus sambucifolia*, Chamisso et Schlechtendal (*Sorbus sambucifolia*, Rœmer), are two indigenous species resembling the European tree but bearing smaller fruits. Both are known as *American mountain ash*.

Cratægus.—The bark, fruit, and leaves of this genus of plants are sometimes employed as astringents and tonics. (See also *Cratægus Oxyacantha.*)

Pyrus coronaria, Linné, *Crab apple*, *Pyrus arbutifolia*, Linné filius, *Chokeberry*. Both of these species have the properties of sorbus.

SPARTEINÆ SULPHAS (U. S. P.)—SPARTEINE SULPHATE.

FORMULA: $C_{15}H_{26}N_2H_2SO_4+4H_2O$. MOLECULAR WEIGHT: 403.23.

"The neutral sulphate of an alkaloid obtained from scoparius"—(*U. S. P.*).

Preparation.—*Sparteine* ($C_{15}H_{26}N_2$), the volatile alkaloid contained in broom (see *Scoparius*), was discovered in 1853 by Stenhouse, and is prepared by extracting the plant with water acidulated with sulphuric acid, concentrating the fluid and distilling with caustic soda. The distillate is neutralized with hydrochloric acid, evaporated to dryness, and the residue distilled with solid caustic potash. Ammonia gas escapes first, then the base distills. Sparteine, when freshly prepared, is a colorless, thick oil of bitter taste; its odor resembles that of aniline. It is heavier than water and boils at 288° C. (550.4° F.). It is soluble in alcohol, chloroform, and ether, almost insoluble in water, and not at all soluble in benzol or benzin. Upon dry distillation it yields pyridine (C_5H_5N) and derivatives of the latter. It forms salts with acids. To prepare the sulphate, neutralize the base with sulphuric acid and allow to crystallize.

Description and Tests.—Sparteine sulphate occurs in "colorless, white, prismatic crystals, or a granular powder, odorless, and having a slightly saline and somewhat bitter taste. Liable to attract moisture when exposed to damp air. Very soluble in water and alcohol. When heated to about 83° C. (181.4° F.), the salt begins to lose its water of crystallization, all of which escapes at 100° C. (212° F.). At about 136° C. (276.8° F.) it melts, and, upon ignition, it is consumed, leaving no residue. The salt is neutral to litmus paper. If 25 Cc. of ether be added to about 0.1 Gm. of sparteine sulphate in a test-tube, then a few drops of dilute ammonia water, so that the latter shall not be in excess, and an ethereal solution of iodine (1 in 50) be afterward added until the liquid, when shaken, turns from an orange to a dark reddish-brown color, the bottom and sides of the test-tube will, after a short time, be found coated with minute, dark greenish-brown crystals, distinctly seen with a lens after the liquid has been poured out"—(*U. S. P.*). In consequence of a similar reaction taking place, sparteine sulphate is incompatible with potassium iodide (see *Amer. Jour. Pharm.*, 1891, p. 595). "On shaking 0.05 Gm. of the salt, in a test-tube, with 5 Cc. of potassium or sodium hydrate T.S., the liquid will at first be turbid, and small drops of sparteine will gradually collect on the surface. If a strip of moistened red litmus paper be suspended in the mouth of the test-tube, and a gentle heat then applied, the test-paper will gradually acquire a blue color, but no ammoniacal odor should be perceptible (absence of ammonium salts)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sparteine, and scoparius, from which it is derived, are employed to regulate the heart's action, and to produce diuresis, both of which effects they sometimes fail to accomplish. The diuretic virtues of the latter are believed to reside more largely in scoparine than in sparteine, though the former has not been well investigated. As a rule sparteine does not produce diuretic effects in the healthy individual (Masius). Dr. J. V. Laborde was the first to point out the action of sparteine upon the heart, and his views were subsequently confirmed in the main by Masius, Germain Sée, and others. The toxic symptoms in the lower animals from the administration of sparteine are muscular trembling, incoordinate movements, impeded respiration, convulsions, both tonic and clonic, quickened pulse, with feeble heart-action, while finally all of the functions are feebly performed and death occurs from asphyxiation. Both the centers of motion in the spinal axis and of respiration are paralyzed by it. A tendency to somnolence and dilated pupils has also been observed in animals. In man the chief effects that have been observed from over-doses are nausea, dizziness, heaviness of the limbs, and irregular heart-action.

Therapeutically, sparteine is employed chiefly in *cardiac diseases* to augment in force the action of the heart and arteries, and to regulate arhythmical movements of the former. It appears that when the cardiac action is abnormally slow as from functional exhaustion (Sée), and when the pulsations are abnormally rapid (Clarke), the heart is spurred to action by it in the first instance and gradually slowed to normal in the second. By some it is regarded as superior to digitalis as a heart tonic and is free from cumulative effects; others regard it as only secondary to that drug as a heart remedy. It has the advantage of acting quickly, in from $\frac{1}{2}$ to $\frac{3}{4}$ of an hour, reaching its maximum power in 5 or 6 hours, and its effects sometimes last nearly a week. The affections in which it has received praise as a remedy are: *irregular heart-action from valvular lesions*, or *debility of the cardiac muscle; slow heart-action due to functional exhaustion; obstructive heart disease with palpitation, and tumultuous heart-action; functional palpitation* (prompt results); *mitral regurgitation*, and *aortic regurgitation with irritable and enlarged heart.* In *mitral stenosis* its effects are less beneficial, but in *exophthalmic goitre* its action is said to be pronounced. In *asthma* with cardiac complications it has proved a good but slow remedy. In the obstructive heart diseases the smaller or fractional doses ($\frac{1}{20}$ to $\frac{1}{10}$ grain) produce the best effects, whereas large doses (1 to 2 grains) are apt to induce pain, præcordial tightness, and other distressing symptoms. Sparteine has favorably influenced the course of *dropsy* only when dependent upon cardiac diseases, other forms of dropsy being totally unaffected by it. The salt of sparteine usually administered is the sulphate. In the matter of dosage there is a wide variance among authorities on heart affections, the most universally employed doses ranging from $\frac{1}{20}$ to $\frac{1}{2}$ grain 4 times a day. The daily amount recommended by Sée was 2 grains; by Houde, $1\frac{2}{3}$ to $7\frac{1}{2}$ grains; by Clarke, $\frac{1}{2}$ grain, which may be gradually increased without toxic effects to 12 grains. The dose, according to Voight, is from $\frac{1}{64}$ to $\frac{1}{16}$ grain. The beginning dose of sparteine sulphate should not be greater than $\frac{1}{6}$ grain, to be increased as circumstances warrant.

Specific Indications and Uses.—Functional heart diseases, with enfeebled heart-action; cardiac palpitation, with tumultuous heart-action; weak, irregular heart; dropsy of cardiac origin.

SPERGULARIA.—SAND-SPURREY.

The roots and plant of *Spergularia rubra*, Presl. (*Arenaria rubra*, Linné; *Lepigonum rubrum*, Fries; *Spergularia rubra*, var. *campestris*, Gray's *Manual; Buda rubra*, Dumortier).

Nat. Ord.—Caryophylleæ.

Common Names: *Sand-spurrey, Red-sandwort, Spurrey-sandwort.*

Botanical Source.—The Spergularia rubra is an inconspicuous annual weed, found both in the United States and Europe, in dry, sandy situations, more commonly near the coast, but not in brackish places. The stems are many, and from the same root, matted, much branched, from 6 to 12 inches in length, and lying prostrate on the sand. The leaves are linear, fleshy, and about 1 inch long; they are opposite, and have, generally, smaller leaves clustered in their axils; they are surrounded, at the base, by 2 dry, triangular, scale-like stipules. The flowers are small, numerous, axillary, and appear throughout the summer; they are borne on slender peduncles, about $\frac{1}{2}$ inch long, which are reflexed in fruit. The calyx has 5 scarious-edged sepals. The corolla has 5 rose-colored, entire petals, about the length of the sepals. The fruit is a dry, many-seeded pod, opening by 3 valves.

Spergularia salina (Presl.) and *Spergularia media* (Presl.), the only other native species of Spergularia, are found in brackish, sandy places. They closely resemble the *S. rubra*, and have, probably, the same properties. *Spergularia arvensis*, Linné, a naturalized weed, has a similar appearance to *Spergularia rubra*, but can be distinguished by having whorled leaves.

History and Chemical Composition.—Spergularia rubra has been recommended as a remedy, and, it is said, has long been employed in Malta and Sicily. It was analyzed by M. Legout, of Algiers, where the plant is very abundant; by Dr. Jacquème, of Marseilles; and by Vigier, of Paris. The latter finds (*Jour. Pharm. Chim.*, 1879, Vol. XXX, p. 375) that the medicinal action of the plant is due to the large proportion of alkalies and aromatic resins which it contains. One hundred parts of the dry plant yielded, upon incineration, 8.72 grammes of a deliquescent ash, 87 per cent of which was soluble in water. The ash contained no lithium.

Action, Medical Uses, and Dosage.—This plant was employed in Sicily and neighboring countries as a secret remedy, for many years, in the form of a tisane, and sold at exorbitant prices. A specimen of the plant having been obtained by an individual, who had been benefited by the use of the tisane, was analyzed by M. Legout, a pharmacist, and its therapeutic action tested in some of the Paris hospitals by M. Bertherand and others. It has been found very efficient in the treatment of *gravel*, having been largely experimented with in Europe. The best preparation for administration is a decoction, which exerts a stimulating action upon the circulation and the secretions, especially those of the urinary organs. The discharge of gravel through the ureters is facilitated under its use, and *nephritic colic*, when present, is promptly relieved. Five drachms of the plant to a pint of water is the medium dose, to be taken daily; it may be sweetened, if desired. Pills or syrup may be substituted for the decoction, in doses of 15 grains, every 1, 2, or 3 hours. M. Vigier advises the following powder as preferable to the other preparations: Take of aqueous extract of Spergularia rubra, 154 grains; powdered white sugar (free from glucose), 461 grains; mix thoroughly together, and divide into 5 equal papers or packets; 1 of these to be added to a quart of water, and to be drank during the day. A similar quantity of extract in 1½ fluid drachms of pure glycerin and 3 fluid ounces of distilled water, gives a solution that keeps well, and of which the dose is a teaspoonful, to be repeated 5 times a day—equivalent to a quart of the decoction. With regard to this plant, as a therapeutic agent, a writer observes: "We can understand that a plant so rich in constituent elements, in chloride of potassium and sodium, in alkalies, and in aromatic principles, must have a powerful action upon the animal economy. Combined with the albuminous juices of the vegetable, the chlorides must act otherwise than in the free state."

SPIGELIA (U. S. P.)—SPIGELIA.

The rhizome and roots of *Spigelia marilandica*, Linné.
Nat. Ord.—Loganiaceæ.
COMMON NAMES: *Pinkroot*, *Carolina pink*, *Maryland pink*, *Worm-grass.*
ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 180.

Botanical Source.—Carolina pink is an herbaceous, indigenous plant, with a perennial, very fibrous, yellow root, which sends up several erect, simple, nearly smooth, 4-angled stems, of a purplish color, 6 to 20 inches high. The leaves are opposite, sessile, ovate-lanceolate, acute or acuminate, entire and smooth, with the margin and veins roughish-hairy; they are 3 or 4 inches long by 1½ or 2½ inches broad; the stipules are scarcely perceptible. The flowers are few in number, in a terminal secund spike, supported on short pedicels; they are somewhat club-shaped, scarlet externally, yellow internally, from 1½ to 2 inches in length. The calyx is persistent, with 5 long, linear, subulate, finely-serrulate divisions, which are reflexed in the ripe fruit. The corolla is funnel-shaped, 4 times as long as the calyx, the tube inflated in the middle and angular at top, divided into 5 acute, spreading segments, the edges of which are slightly tinged with green. Stamens short, inserted into the mouth of the corolla between the segments; anthers oblong, heart-shaped, and exserted. Ovary small, superior, and ovate; style about the length of the corolla, jointed near its base, and terminating in a linear, fusiform, fringed stigma, projecting considerably beyond the corolla. The capsule is double, consisting of 2 cohering, 1-celled, globular carpels attached to a common receptacle, and containing numerous, small, angular seeds (L.—W.—G.—B.).

Fig. 232.

Spigelia marilandica.

History.—Botanists have varied in their classification of this plant. Besides the above-given order, *Loganiaceæ*, we find it classed in the natural order *Gentianaceæ*, also *Spigeliaceæ* and *Rubiaceæ;* suborder, *Spigeliæ*. It is usually known as the *Carolina pink* or *Worm-grass*. This plant is a native of the United States, growing in dry, rich soils, and on the borders of woods in the southern states, and flowering in May and June. The plant, of which several varieties exist, was used by the natives as an anthelmintic long before the discovery of America, and through them a knowledge of it was imparted to the early settlers, who used it for some years before it was introduced to the profession. Drs. Lining, Chalmers, and Garden, of South Carolina, acquainted the medical public with its uses, since which time it has become an official remedy. It is generally received in bales or casks from the western states, in which section it has been found growing in great abundance. The part used is the rhizome and its roots.

Description.—Pinkroot is composed of a number of delicate, crooked, corrugated fibers, of a dark-brown color externally, issuing from a short, dark-brown rhizome. Age impairs the virtues of pinkroot. Often the roots of other plants, particularly those of *Phlox Carolina*, Linne, also known as *Carolina pink* and *Georgia pink*, will be found mixed with those of spigelia; they, together with the stalks and leaves of the latter, should be carefully removed before preparing the medicine for administration.

The *U. S. P.* describes pinkroot as "of horizontal growth, about 5 Cm. (2 inches) or more long, 2 or 3 Mm. ($\frac{1}{12}$ or $\frac{1}{8}$ inch) thick, dark purplish-brown, bent, somewhat branched, on the upper side with cup-shaped scars; on the lower side with numerous, thin, brittle, lighter-colored roots, about 10 Cm. (4 inches) long; the rhizome internally with a whitish wood and a pith which is usually dark-colored or decayed; odor somewhat aromatic, taste sweetish, bitter and pungent. It should not be confounded with the underground portion of *Phlox Carolina*, Linné (*Nat. Ord.*—Polemoniaceæ), the roots of which are brownish-yellow, rather coarse, straight, and contain a straw-colored wood underneath a readily removable bark"—(*U. S. P.*). Prof. Maisch suggests (*Amer. Jour. Pharm.*, 1883, p. 631) that the virtues ascribed to spigelia might, in reality, be those of phlox, since this root has long been used in the southern states. Prof. Trimble (*ibid.*, 1886, p. 479) found in the root of phlox a peculiar camphor (*phloxol*), which is soluble in petroleum-ether with red fluorescent color. Spigelia does not yield such a substance, hence petroleum-ether may be used to distinguish phlox from spigelia chemically. (For the microscopic characteristics of phlox, also see H. G. Greenish, *Pharm. Jour. Trans.*, Vol. XXI, 1891, p. 839.) *Phlox glaberrima*, Linné, has like properties, and is said to resemble spigelia more than Georgia pinkroot does.

Chemical Composition.—Wackenroder found in the root, fixed oil (a trace), acrid resin, tannic acid, a bitter, acrid principle, etc. Dr. R. H. Stabler, in a later analysis of pinkroot, found it to contain a volatile oil, tannic acid, wax, inert resin, salts, etc. He believes the activity to reside in a bitter, acrid principle, which is soluble in water or alcohol, insoluble in ether, non-volatile, neutral, and deliquescent. The alkaline carbonates do not diminish its activity. Water and alcohol are equally good solvents for its medicinal virtues (*Amer. Jour. Pharm.*, 1857, p. 511). In 1879, Mr. W. L. Dudley (*Amer. Chem. Jour.*, Vol. I, p. 104) found the active constituent to be a volatile alkaloid, *spigeline*, yielding precipitates with alkaloidal reagents, and resembling coniine and nicotine. It was obtained by distilling ground pinkroot with calcium hydroxide.

Action, Medical Uses, and Dosage.—Pinkroot is an active and certain vermifuge, especially among children. In large doses, it is very apt to purge, and produce various unpleasant symptoms, as increased action of the heart and arteries, dizziness, dilatation of the pupils, imperfect vision, and muscular spasms, often terminating in convulsions, together with various other indications of narcosis. One of its more frequent effects is spasmodic twitchings of the eyelids. These symptoms seldom happen when catharsis is produced, either by the drug alone, or exhibited in combination with a purgative. The toxic effects are counteracted by the diffusible stimulants, alcohol, ammonia, and ammonium carbonate. The powdered root may be given to a child from 2 to 4 years of age, in doses of 5 to 20 grains; or 1 or 2 fluid ounces of a strong infusion, administering it twice a day for a few days, and then giving an active purgative. A jelly has been recommended as an agreeable form of administration, as follows: To 16 fluid ounces of water add 8 ounces of pulverized pinkroot, and 4 drachms of Corsican moss, and boil down to 10 fluid ounces. The decoction should then be decanted into a saucepan containing 2½ ounces of white sugar, and again boil down, carefully stirring with a silver spoon, until 4 ounces of jelly are obtained. Then strain through a sieve into a jar containing 2 drops of the essence of citron or caraway. It will keep for some time in a cool place, and its flavor may be improved by substituting syrup of raspberries, strawberries, gooseberries, or mulberries, etc., for the sugar. It is also useful in those conditions of the system, caused by *worms*, which resemble *infantile remittent* and other *febrile diseases*, and *hydrocephalus*. A well-known worm tea is composed of pinkroot, ½ ounce; senna, 2 drachms; savine, ½ drachm; manna, 2 drachms. Mix, and infuse in a pint of water. Dose, 1 to 2 fluid ounces. Anthelmintic dose of powdered pinkroot, for an adult, 1 to 2 drachms. Spigelia is a remedy for *endocardial troubles*, but is regarded as inferior to the *Spigelia Anthelmia*, Linné, both being used for the same purposes in *cardiac affections* (see *Related Species*).

Related Species.—*Spigelia Anthelmia*, Linné (*Anthelmia quadriphylla*), *Demerara pinkroot*. An annual of the West Indies and South America. The root has been used by the natives of those countries for centuries as an anthelmintic. It is the form of spigelia official in the *Homœopathic Pharmacopœia* (1890), and possesses decided narcotic qualities. It was introduced into Europe by Dr. Browne, in 1751. The French gave it the name *Brinvilliers*, after the Marchioness de Brinvillière, the celebrated poisoner, executed in 1676, and who is said to have used this drug upon her victims. The fresh plant is very poisonous, and contains the volatile alkaloid, *spigeliin* (Boorsma, in Dragendorff's *Heilpflanzen*, 1899). This drug is said to act specifically upon the heart, and particularly the endocardium. It is valued by some practitioners in *cardiac palpitation* and *endocarditis*, especially the rheumatic form, and to guard against relapses of *cardiac rheumatism*. *Painful conditions of the heart*, the pain extending along the arm, *angina pectoris*, and *cardiac neuralgia*, with palpitation, are conditions in which it is employed with asserted success. Large doses debilitate the heart. Browne (1751 compared its narcotic power to that of opium. The usual method of administering this drug is to add from 10 to 15 drops of the Homœopathic mother tincture to 4 fluid ounces of water, the dose of which is a teaspoonful every 2 hours.

Other Anthelmintics.—*Vernonia anthelmintica*. East Indies. The bitter, nauseous, black seeds of this plant, in doses of 50 to 60 grains, are valued in Ceylon as an anthelmintic.

Sethia acuminata.—Ceylon. The juice of this plant and the dried, powdered leaves are reputed vermifuge. Dose, 15 grains.

SPILANTHES.—PARA CRESS.

The herb and flower-heads of *Spilanthes oleracea*, Jacquin.

Nat. Ord.—Compositæ.

Common Name: *Para cress.*

Botanical Source and Description.—The genus Spilanthes is a tropical family of (mostly) annual weeds, with opposite leaves, and terminal, stalked, flower-heads. It is closely allied to Bidens, differing, chiefly, in the achenia, which are plano-convex, with a membranous winged margin. The pappus consists of 2 short awns. The receptacle is conical and paleaceous. *Spilanthes oleracea* is a native of South America, and is often cultivated in tropical countries, where it is used as a salad. It is known under the name *Para cress.* It is a small, erect herb, of rapid growth, and has cordate stalked leaves. The flowers are small, yellow, and solitary, on terminal peduncles. The Chinese derive a blue coloring matter from *Spilanthes tinctoria*, Loureiro, similar to indigo. *Spilanthes Acmella*, Linné, an East Indian species, has properties akin to those of *Spilanthes oleracea*. Spilanthes oleracea has an acrid, aromatic taste, resembling, but more powerful than, peppermint. Analysis has shown it to contain volatile oil, an acrid resin, tannin, etc., and an alkaloid (Buchheim). When chewed spilanthes occasions a copious flow of saliva.

Action, Medical Uses, and Dosage.—Spilanthes is an acrid, aromatic sialagogue, and which, like the galanga root, has been recommended in *flatulence*, to improve the appetite and digestive functions, and to overcome *nausea* and *vomiting*. It may also be used in *non-mercurial ptyalism*, and in *inflammations of the mouth and throat*, using fractional doses of a strong tincture (recent herb, ℥viij to alcohol, 98 per cent, Oj). The natives of the countries to which it is indigenous, are stated to have employed it advantageously in *gouty and rheumatic affections*, in *uric acid gravel*, in *dropsical effusions*, and even to remove *intestinal worms*. A tincture of it placed on cotton, and introduced into the cavity of a decayed tooth, will, it has been remarked, promptly relieve *toothache*. It is not employed in this country.

SPIRÆA.—HARDHACK.

The herb of *Spiræa tomentosa*, Linné.

Nat. Ord.—Rosaceæ.

Common Names: *Hardhack*, *Meadow-sweet*, *White-leaf*, *Silver-leaf*, *Steeple-bush*, *Whitecap*.

Fig. 233.

Spiræa tomentosa.

Botanical Source.—This plant is a small shrub, about 3 or 4 feet in height, with several simple, straight, round, ferruginous-tomentose, hard, brittle stems. The leaves are alternate, simple, ovate-lanceolate, smoothish and dark-green above, rusty white with a dense tomentum beneath, unequally serrate, crowded, on short petioles—they are 1½ to 2 inches in length, and about one-half as wide. The flowers are small, very numerous, light-purple or rose-colored, in a short, dense, slender, terminal spike, or pyramidal cluster of some beauty. Stamens numerous, exserted, and conspicuous; styles 5; carpels 5, distinct, and woolly; seeds awl-shaped at each end (W.—G.).

History.—This is a beautiful shrub, common in low grounds and moist meadows, throughout the United States, flowering from May to August. The herbaceous part is used, especially the leaves and bark. It has an odor somewhat resembling that of black tea, and a very astringent, bitter taste, which properties it imparts to boiling water in infusion. It appears to contain tannic and gallic acids, volatile oil, and bitter extractive. The fruit is persistent, remaining through the winter, and furnishing food for the snowbird.

Action, Medical Uses, and Dosage.—Hardhack has been found an excellent astringent in *summer complaint of children*, *diarrhœa*, and other diseases requiring this class of remedies, and is less offensive to the stomach than most agents of this kind. It has likewise proved efficient as a tonic in cases of *debility*, *convalescence from diarrhœa*, *dysentery*, etc., and to improve the digestive functions. *Passive hemorrhages*, and *menorrhagia* have been treated with it, while as an injection good results have been obtained from its use in *gleet* and *leucorrhœa*. It is generally given in infusion, the dose being 1 or 2 fluid ounces. A very elegant extract, not inferior to catechu, may be made by carefully evaporating an infusion made by percolation, and which may be given in doses of from 2 to 20 grains. A tincture, well representing the virtues of spiræa, may be prepared from 8 ounces of the fresh leaves and bark to 1 pint of 76 per cent alcohol.

Related Species.—*Spiræa Ulmaria*, Linné. This plant bears small white flowers in corymbs supported on long peduncles. It is indigenous to Europe, where it is known as *Meadow-sweet* and *Queen of the meadow*. It has been introduced into this country and is frequently found in cultivation, in which case the flowers are usually double. The chief constituent of this plant is *oil of meadow-sweet*, first observed in 1835 by Pagenstecher. It is heavier than water, strongly aromatic, solidifies at —20° C. (—4° F.), and produces a deep-violet color with solution of ferric chloride. It consists chiefly of *salicylic aldehyde* ($C_6H_4OH.CHO$) (Dumas, Ettling, 1839), formerly called *salicylous acid;* some free *salicylic acid*, a small quantity of *methyl salicylate* (Schneegans and Gerock, 1892), and traces of *piperonal* (see *Piperinum*) and *vanillin;* also very little of a camphor-like body and a terpene (Ettling). According to Schneegans and Gerock, salicylic aldehyde does not preexist in the flowers, but is formed during distillation by the action of a ferment upon a substance as yet unknown; it is not salicin. See details regarding the chemistry of the oils obtainable from the different parts and species of Spiræa, in Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 550. This plant is diuretic, astringent, and tonic. It has been employed in *fevers*, like Virginia snakeroot, in *dropsy*, and in *retention of urine* due to *prostatic enlargement*. It relieves urino-genital irritation, influences the prostate gland checking *prostatorrhœa*, and is useful in *gleet*, *chronic cervicitis*, and *chronic vaginitis with leucorrhœal discharges*.

Spiræa filipendula, Linné.—Europe. The pyriform or moniliform tubers found upon the long radicles of this plant are reputed useful in restraining excessive mucous discharges. *Hydrophobia* has also been treated with it. The root contains sugar, starch, and tannin, and when recent an essential oil, probably that common to other species of Spiræa, and salicylic aldehyde, for the latter is known to be present in the branches and leaves of this plant.

Spiræa Aruncus, Linné.—Europe and United States. A perennial herb, with slender racemes of many, small white blossoms. The herb has an aromatic bitterish, astringent taste, and the odor is pleasant. The flowers, upon distillation with water, yield salicylic aldehyde, while the herb yields none, but produces hydrocyanic acid. For further details, see Gildemeister and Hoffmann, *loc. cit.;* also see *Amer. Jour. Pharm.*, 1892, p. 306.

SPIRITUS.—SPIRITS.

Spirits, as now prepared, are simply alcoholic solutions of essential oils or other volatile bodies. Formerly they were made by the distillation of mixtures of water and aromatic substances, hence their name. As many of the oils usually entering into spirits do not vaporize at the boiling point of alcohol, it is customary, in distilling them, to dilute the alcohol with a sufficient amount of distilled water to insure the volatile substances being carried over into the condenser with the aqueous vapors. When aromatic plants are used, they should be first macerated in the alcohol for a few days, and then distilled by means of steam or a salt-water bath. In the *German Pharmacopœia*, *Spiritus* is the official term for *alcohol*.

SPIRITUS ACIDI FORMICI (N. F.)—SPIRIT OF FORMIC ACID.

SYNONYMS: *Spiritus formicarum* (*Ger. Pharm.*), *Spirit of ants*.

Preparation.—"Formic acid, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; distilled water, two hundred and twenty-five cubic centimeters (225 Cc.) [7 fl℥, 292 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the formic acid with the distilled water, and add enough alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—Formic acid is required by the *German Pharmacopœia* to have a specific gravity of 1.060 to 1.063"—(*Nat. Form.*). Formerly, *Spiritus Formicarum* was made by macerating recently collected ants (10 parts) with alcohol (15 parts) and water (15 parts), and distilling off 20 parts.

Uses.—(See *Acidum Formicum.*) Dose, 10 to 60 minims.

SPIRITUS ÆTHERIS (U. S. P.)—SPIRIT OF ETHER.

SYNONYM: *Liquor anodynus mineralis Hoffmanni.*

Preparation.—"Ether, three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl℥, 475 ♏]; alcohol, six hundred and seventy-five cubic centimeters (675 Cc.) [22 fl℥, 396 ♏]. To make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*)

Action, Medical Uses, and Dosage.—Spirit of ether is employed like *Hoffmann's Anodyne*, its pain-relieving property being due to the ether it contains. The dose is from 1 to 3 fluid drachms, in sweetened water.

SPIRITUS ÆTHERIS COMPOSITUS (U. S. P.)—COMPOUND SPIRIT OF ETHER.

SYNONYM: *Hoffmann's anodyne.*

Preparation.—"Ether, three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl℥, 475 ♏]; alcohol, six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏]; ethereal oil, twenty-five cubic centimeters (25 Cc.) [406 ♏]. To make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

History.—Commercial Hoffmann's anodyne is not always prepared by the official process, but may be a hydro-alcoholic solution of the last fraction of distillate obtained in the rectification of ether, which contains both light and heavy oils of wine. Only that produced by the official directions (see *Oleum Æthereum*), and which alone contains the heavy oil of wine, should be employed in medicine.

Description and Test.—Compound spirit of ether is a colorless liquid, having an aromatic and ether-like odor, and a feebly sweetish, pungent taste. It is neutral or but slightly acid to litmus paper. The almost imperceptible residue left upon igniting the fluid, in a porcelain or glass dish, is acid to both taste and test-paper. Water is rendered slightly opalescent by a very small quantity of the spirit (40 drops to 1 pint), and larger amounts produce a turbidity from the separation of the ethereal wine. If oily globules appear upon the surface, they are to be tested for fixed oil by allowing them to be absorbed by filtering paper; should the latter, when exposed to heat, remain greasy, fixed oil is present.

Action, Medical Uses, and Dosage.—This agent is used very much as ether is used internally, but is more permanent in its effects. It is stimulant, antispasmodic, and anodyne. In the absence of active fever, it may be used to give rest in various forms of *nervousness*, as *hysteria*, *restlessness*, *insomnia*, etc. It relieves pain, and is useful in *flatulent*, *biliary*, and *menstrual colic*. It is an excellent remedy for *depression of spirits* and *melancholia*, and is useful when asphyxia is threatened, and as a nerve stimulant in the depression of low forms of *fever*. It lowers temperature, and, locally applied, proves serviceable to check vascular excitation, and sometimes gives relief in *strangulated hernia*. Dose, ½ to 2 fluid drachms, in sweetened water.

SPIRITUS ÆTHERIS NITROSI (U. S. P.)—SPIRIT OF NITROUS ETHER.

"An alcoholic solution of ethyl nitrite ($C_2H_5N_2O$=74.87), yielding, when freshly prepared, and tested in a nitrometer, not less than 11 times its own volume of nitrogen dioxide (NO=29.97)"—(*U. S. P.*).

SYNONYMS: *Spiritus nitri dulcis*, *Sweet spirit of nitre* (*niter*), *Spiritus nitrico-æthereus*, *Spiritus ætheris nitrici*.

Preparation.—"Sodium nitrite, six hundred and thirty-five grammes (635 Gm.) [1 lb. av., 6 ozs., 175 grs.] (see Dr. Charles Rice, *Digest of Criticisms on the U. S. P.*, Part I, 1897); sulphuric acid, five hundred and twenty grammes (520 Gm.) [1 lb. av., 2 ozs., 150 grs.]; sodium carbonate, ten grammes (10 Gm.) [154 grs.]; potassium carbonate, completely deprived of water by drying, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; deodorized alcohol, water, each, a sufficient quantity. Dissolve the sodium nitrite in one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water, and put the solution into a suitable flask, connected with a condenser kept cold by ice-cold water; then add five hundred and fifty cubic centimeters (550 Cc.) [18 fl℥, 287 ♏] of deodorized alcohol, and mix well. Through a cork, fitted into the mouth of the flask, insert a funnel-tube, dipping below the surface of the liquid. With the condenser connect a receiver, and keep this surrounded by a mixture of common salt and crushed ice. Then gradually introduce into the flask, through the funnel-tube, the sulphuric acid, previously diluted with one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water. Distillation will usually commence before the whole of the acid has been added. When all the acid has been introduced, regulate the distillation by the application or withdrawal of a gentle heat until no more nitrous ether distills over. Wash the distillate, first, with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of ice-cold water, to remove any alcohol which may have passed over, and then remove any traces of acid by washing the ether with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of ice-cold water, in which the sodium carbonate had previously been dissolved. Carefully separate the ether from the aqueous liquid, and agitate it, in a well-stoppered vial, with the potassium carbonate, to remove traces of water. Then filter it through a pellet of cotton, in a covered funnel, into a tared bottle, containing two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏] of deodorized alcohol. Ascertain the weight of the nitrous ether filtered into the alcohol by noting the increase of weight of the tared bottle and contents, and then add enough deodorized alcohol to make the mixture weigh twenty-two (22) times the weight of the nitrous ether added. Lastly, transfer the product to small, dark, amber-colored, well-stoppered vials, and keep them in a cool place, remote from lights or fire"—(*U. S. P.*).

In this process, sulphuric acid liberates nitrous acid from sodium nitrite, which at once reacts with the alcohol present to form ethyl nitrite, as follows $HNO_2+C_2H_5OH = C_2H_5.NO_2+H_2O$. Instead of preparing the pure ether as an intermediary product, as directed by the *U. S. P.*, Prof. Feil (*Amer. Jour. Pharm.*, 1899, p. 500) recommends the preparation of the finished product direct, by allowing sulphuric acid (20 grammes) to flow into a mixture of sodium nitrite (30 grammes) and alcohol (300 grammes) contained in a liter flask, and connected with a reflux condenser. After the reaction is completed by the aid of heat, the product is filtered, and alcohol added to make 450 grammes, the yield being about 75 per cent of the theoretical.

The spirit of nitrous ether of the *U. S. P.*, 1880, was prepared by distillation of alcohol, nitric acid, and sulphuric acid. The reaction depended on the reduction of nitric to nitrous acid by the alcohol; in consequence, the latter was partly oxidized, and a number of by-products, *e. g.*, ethylic aldehyde, were formed. The *British Pharmacopœia* prepares the spirit by distillation of alcohol and nitric acid in the presence of copper.

Description and Tests.—The *U. S. P.* describes sweet spirit of nitre as "a clear, mobile, volatile, and inflammable liquid of a pale-yellowish, or faintly greenish-yellow tint, having a fragrant, ethereal, and pungent odor, free from acridity, and a sharp, burning taste. Specific gravity about 0.836 to 0.842 at 15° C. (59° F.). When freshly prepared, or even after being kept for some time with but little exposure to light and air, it is neutral to litmus paper. When long kept, or after having been freely exposed to air and light, it acquires an acid reaction, but it should not effervesce when a crystal of potassium bicarbonate is dropped into it. If a test-tube be half filled with the spirit, and put into a water-bath heated to 65° C. (149° F.), until it has acquired this temperature, the spirit should boil distinctly upon the addition of a few small pieces of broken glass. If 10 Cc. of the spirit be mixed with 5 Cc. of potassium hydrate T.S., previously diluted with 5 Cc. of water, the mixture will assume a yellow color, which should not turn decidedly brown within 12 hours (limit of aldehyde). If 5 Cc. of recently prepared spirit of nitrous ether be introduced into a nitrometer, and followed, first, by 10 Cc. of potassium iodide T.S., and then by 10 Cc. of normal sulphuric acid, the volume of nitrogen dioxide generated at the ordinary indoor temperature (assumed to be at or near 25° C. or 77° F.), should not be less than 55 Cc. (corresponding to about 4 per cent of pure ethyl nitrite)"—(*U. S. P.*). This method was suggested by A. H. Allen, in 1885 (see *Amer. Jour. Pharm.*, 1885, p. 187), and is based upon the following reaction: $2C_2H_5NO_2+2IK+H_2SO_4=2C_2H_5OH+K_2SO_4+N_2O_2+I_2$. Accordingly, the volume of nitrogen dioxide gas evolved is in proportion to the quantity of pure ether present. Other methods, based on the determination of the quantity of iodine liberated in this reaction, have not proved successful, owing to secondary reactions (see R. Fischer and J. A. Anderson, *Pharm. Archives*, 1898, p. 169). A more reliable method seems to be that which depends on the reaction between ethyl nitrite and potassium chlorate in nitric acid solution, whereby hydrochloric acid is formed, the quantity of which may be determined by silver nitrate V.S. The reaction is principally as follows: $3C_2H_5NO_2+HClO_3+3H_2O=3C_2H_5OH+3HNO_3+HCl$. (For further details regarding this method, see Carl E. Smith, *Amer. Jour. Pharm.*, 1898, p. 273.) Spirit of nitrous ether, when kept for a long time, even in well-closed bottles, undergoes various changes—among these, decrease of ethyl nitrite, increase of acidity, formation of aldehyde, acetic acid, and acetic ether. (For details as to the keeping qualities of spirit of nitrous ether, see, among other papers, P. MacEwan, in *Amer. Jour. Pharm.*, 1884, pp. 378–385, from *Pharm. Jour. Trans.;* and John C. Hunter, *ibid.*, 1888, p. 349; also see an extensive bibliography of spirit of nitrous ether, by W. O. Richtmann and J. A. Anderson, in *Pharm. Archives*, July, 1899.)

Action, Medical Uses, and Dosage.—Spirit of nitrous ether, when inhaled, is a narcotic poison; its accidental inhalation during sleep is said to have caused death. The symptoms produced by its inhalation are quickening of the pulse, arterial throbbing, giddiness, headache, nausea, leaden-hued lividity of the lips and finger tips, followed by flushed countenance, and, in excessive quantities, muscular debility, mental confusion, rapid, irregular, thready pulse, dyspnœa, cyanosis, and convulsions. If sufficiently prolonged, death takes place. Internally, excessive doses cause gastro-intestinal irritation, with colic and vomiting. When the preparation becomes old, free nitrous acid is formed, and its internal administration will be followed by pain in the stomach and gripings. Pareira gives the following mode of treatment for persons who have inhaled spirit of nitrous ether, as well as carbonic acid gas: "Remove the patient immediately into the open air, and place him on his back, with his head somewhat elevated. Produce artificial respiration by pressing down the ribs, forcing up the diaphragm, and then suddenly removing the pressure. Dash cold water over the body, apply bottles of hot water to the feet, with frictions, inhalations of ammonia, and other stimulants.

When not adulterated with water or alcohol, spirit of nitrous ether is a stimulant and antispasmodic, in its actions closely resembling those of sulphuric ether, but less energetic. As a diuretic, it is considered useful in *dropsy*, associated with diseased heart, more so than when connected with diseased kidney; being a stimulant diuretic, it is best adapted to asthenic conditions. In dropsy, it may be advantageously combined with syrup of squill, acetate, bicarbonate, or nitrate of potassium, or tincture of digitalis. It is useful in *strangury*, especially that produced by cantharis, *ardor urinæ*, and is a good addition to copaiba as a diuretic for diminishing the acrimony of the urine, and in the latter stages of *gonorrhœa*. However, it will be found an uncertain diuretic, not always exerting this influence in cases where it is administered. If the patient be kept warm, it is more likely to act upon the skin than kidneys, producing diaphoresis. It is useful in *inflammatory disorders of the urinary tract*. If the inflammatory condition is mild, it acts better than when very active. It is of service in *painful and difficult urination of children*, and overcomes *urethral spasm* and some cases of *spasmodic stricture*. For these troubles it should be given in infusion of watermelon-seed or spearmint. For *suppression of urine* in children it is a positive remedy. It is not, however, the remedy for *retention* of the urine, for, being diuretic, it increases the flow into an already over-filled bladder, only to increase the discomfort and pain. Here the catheter is demanded. In *Bright's disease*, with congestion and scanty urine, it may be used temporarily only.

Sweet spirit of nitre is often used in *fevers* as a sedative and mild diaphoretic, and may be given alone, or in conjunction with other agents, to cause diuresis and perspiration. As a rule, the dose administered is too large. The small doses, as a teaspoonful of 1 fluid drachm, in 4 fluid ounces of water, are far preferable. It thus slows the pulse, reduces temperature, and promotes secretion. It is especially adapted to the *fevers of childhood*, where the skin, though hot, is moist. Its effects in *ephemeral fevers* are pronounced. If fever and inflammation are very active, other agents will do better work, but in asthenic conditions, as *low grades of fever*, with marked irritation of the nerve centers, with tendency to spasm, it may be used with confidence. When there is unrest, gastric irritability, nausea, and vomiting, it allays the general irritability and often induces sleep. As a carminative, it is frequently useful in relieving *flatulence*, and allaying *nausea*. It is also useful in *gastrodynia* and *intestinal spasms*. On account of its volatility, it may be applied externally to produce cold by its evaporation.

Locally, this agent may give relief in *local pains*, as in *neuralgic headache*. In *inflammatory swellings*, in *threatened boils*, *carbuncles*, and *abscesses*, in *mumps*, in *glandular enlargements*, and in *rhus poisoning* it is said to be very efficient, and for *bites* and *stings*, is reputed unequalled. In all these cases it should be freely applied and allowed to evaporate, lest blistering occurs. Only recently prepared sweet spirit of nitre should be employed locally, as the free acid of old preparations frequently produces cutaneous irritation. The dose of spirit of nitrous ether is from a fraction of a drop to 1 fluid drachm, according to the indications to be fulfilled. It should be given well diluted.

Specific Indications and Uses.—Increased temperature, frequent pulse, dry skin, renal inactivity, and nervous irritability; nausea, flatulence, and intestinal spasms. Best adapted to asthenic conditions.

SPIRITUS AMMONIÆ (U. S. P.)—SPIRIT OF AMMONIA.

"An alcoholic solution of ammonia (NH_3 = 17.01) containing 10 per cent, by weight, of the gas"—(*U. S. P.*).

SYNONYMS: *Ammoniated alcohol, Spiritus ammoniaci caustici dzondii, Liquor ammonii caustici spirituosus.*

Preparation.—"Stronger ammonia water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; alcohol, recently distilled, and, after distillation, kept in glass vessels, a sufficient quantity. Pour the stronger ammonia water into a flask provided with a safety funnel, and connected, by means of a glass condenser, with a well-cooled receiver containing five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol, the delivery tube of the condenser reaching to near the bottom of the receiver. Heat the flask carefully, and very gradually, to a temperature not exceeding 60° C. (140° F.), and maintain it at that temperature for about 10 minutes. Then disconnect the receiver, and, having ascertained the ammoniacal strength of the contents by means of normal sulphuric acid (rosolic acid test-solution being used as indicator), add enough alcohol to make the product contain ten (10) per cent, by weight, of ammonia. Keep the spirit in glass-stoppered bottles, in a cool place"—(*U. S. P.*).

The process of 1870 (*U. S. P.*) directed the generation of ammonia gas from lime and ammonium chloride, a process which we prefer. Care should be taken to use redistilled alcohol and to keep it in glass vessels if it is not to be used at once. Alcohol from barrels contains organic matters which are colored deep yellow by the action of ammonia. The solution contains 10 per cent (by weight) of ammonia gas.

Description.—"A colorless liquid, having a strong odor of ammonia, and a specific gravity of about 0.810 at 15° C. (59° F.). When diluted with water, it should respond to the tests for identity and purity mentioned under ammonia water (aqua ammoniæ). If 3.4 Gm. (or 4.2 Cc.) of spirit of ammonia be diluted with water, it should require, for complete neutralization, 20 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 0.5 per cent of ammonia). rosolic acid being used as indicator"—(*U. S. P.*).

It should not effervesce with diluted hydrochloric acid; should it do so it has become carbonated. (As to its keeping qualities, see J. U. Lloyd, *Amer. Jour. Pharm.*, 1896, p. 301.)

Action, Medical Uses, and Dosage.—This spirit is seldom used internally, the aromatic spirit being preferred. Its action is that given under *Aqua Ammoniæ*. It dissolves resinous and other bodies precipitated by water, hence it is frequently added to liniments of which it should constitute not more than ⅐ part. Dose, 10 to 30 drops, largely diluted with water.

SPIRITUS AMMONIÆ AROMATICUS (U. S. P.)—AROMATIC SPIRIT OF AMMONIA.

SYNONYMS: *Spiritus ammoniæ compositus, Sal volatile.*

Preparation.—"Ammonium carbonate, in translucent pieces, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; ammonia water, ninety cubic centimeters (90 Cc.) [3 fl℥, 21 ♏]; oil of lemon, ten cubic centimeters (10 Cc.) [162 ♏]; oil of lavender flowers, one cubic centimeter (1 Cc.) [16 ♏]; oil of nutmeg, one cubic centimeter (1 Cc.) [16 ♏]; alcohol, seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. To the ammonia water, contained in a flask, add one hundred and forty cubic centimeters (140 Cc.) [4 fl℥, 352 ♏] of distilled water, and afterward the ammonium carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the carbonate is dissolved. Introduce the alcohol into a graduated bottle of suitable capacity, add the oils, then gradually add the solution of ammonium carbonate, and afterward enough distilled water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Set the liquid aside during 24 hours in a cool place, occasionally agitating, then filter it through paper, in a well-covered funnel. Keep the product in glass-stoppered bottles, in a cool place"—(*U. S. P.*).

It was formerly made as follows: Take of chloride of ammonium, 5 ounces; carbonate of potassium, 8 ounces; cinnamon, cloves, each, bruised, 2 drachms; lemon peel, 4 ounces; alcohol, water, each, 5 pints. Mix them, and distill off 7½ pints (*Lond.*).

Description.—"A nearly colorless liquid when freshly prepared, but gradually acquiring a somewhat darker tint. It has a pungent, ammoniacal odor and taste. Specific gravity about 0.905 at 15° C. (59° F.)"—(*U. S. P.*). Oil of pimenta was substituted for oil of nutmeg in the *U. S. P.*, 1880, but caused the formation of an undesirable deep-red or brown color (see Andrew Blair, *Amer. Jour. Pharm.*, 1885, p. 79).

Action, Medical Uses, and Dosage.—The aromatic spirit of ammonia is antacid, stimulant, and aromatic; it is a good diffusible stimulant, and is used in *sick headache, hysteria, flatulent colic, fainting*, etc., in doses of from 30 to 60 drops, or more, in sweetened water.

SPIRITUS AMMONIÆ FETIDUS.—FETID SPIRIT OF AMMONIA.

Preparation.—Take of asafœtida, 1½ ounce (Imp.); strong solution of ammonia, 2 fluid ounces (Imp.); alcohol (90 per cent), a sufficient quantity. "Break the asafœtida into small pieces, and macerate it in a closed vessel in 15 fluid ounces of the alcohol for 24 hours; distill until alcoholic vapors cease to be condensed; mix the distillate with the strong solution of ammonia, and add sufficient alcohol to make 1 pint"—(*Br. Pharm.*, 1898).

Some oil of asafœtida passes over in distillation so that the product is an alcoholic solution of asafœtida oil mixed with strong ammonia water.

Test.—"Twenty-five cubic centimeters should require for neutralization at least 42.5 Cc. of the volumetric solution of sulphuric acid, corresponding to at least 2.88 Gm. of ammonia (NH_3) in 100 Cc."—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—A general stimulant and nerve stimulant combined. Useful in *hysterical complaints*, and in *flatulent colic* with *gastric acidity* and *indigestion*. Dose, ½ to 1 fluid drachm, well diluted with water.

SPIRITUS AMYGDALÆ AMARÆ (U. S. P.)—SPIRIT OF BITTER ALMOND.

SYNONYM: *Essence of bitter almond.*

Preparation.—"Oil of bitter almond, ten cubic centimeters (10 Cc.) [162 ♏]; alcohol, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oil in the alcohol, and add enough distilled water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Action and Medical Uses.—This agent should be very carefully employed, each fluid ounce containing about 5 minims of oil of bitter almonds. It is employed very largely as a flavoring substance, but a few drops being necessary to produce the desired flavor. It is an unsafe preparation.

SPIRITUS ANISI (U. S. P.)—SPIRIT OF ANISE.

SYNONYMS: *Tinctura olei anisi, Tincture of oil of anise, Essence of anise.*

Preparation.—"Oil of anise, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; deodorized alcohol, nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This preparation is aromatic, antispasmodic, and carminative, and may be employed in *flatulency, cough, cramp of the stomach*, and to flavor other preparations. The dose is from 20 to 60 drops for an adult, in sweetened water. The following forms a very pleasant preparation for cough: Take of aqua ammoniæ, tincture of opium, each, 1 fluid ounce; essence of anise, ½ fluid ounce. Mix. Dose, from 20 to 60 drops.

SPIRITUS AROMATICUS (N. F.)—AROMATIC SPIRIT.

Preparation.—"Compound spirit of orange (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; deodorized alcohol, nine hundred and thirty-five cubic centimeters (935 Cc.) [31 fl℥, 272 ♏]. Mix them. Preserve the product, if it is to be kept in stock, in completely filled and well-stoppered vials or bottles, and stored in a cool and dark place. Aromatic spirit may also be prepared in the following manner: Sweet orange peel, fresh, and deprived of the inner, white portion, six hundred and seventy-five grammes (675 Gm.) [1 lb. av., 7 ozs., 354 grs.]; lemon peel, fresh, eighty-five grammes (85 Gm.) [3 ozs. av.]; coriander, bruised, eighty-five grammes (85 Gm.) [3 ozs. av.]; oil of star-anise, one and one-half cubic centimeters (1.5 Cc.) [24 ♏]; deodorized alcohol, a sufficient quantity to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. Macerate the solids during 4 days with forty-five hundred cubic centimeters (4500 Cc.) [152 fl℥, 78 ♏] of deodorized alcohol; then add the oil of star-anise, filter, and pass enough deodorized alcohol through the filter to make the product measure five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. *Note.*—When good, fresh essential oils can not be readily obtained for preparing the compound spirit of orange, the second formula may be used. But the product obtained by it should not be employed in mixtures containing *iron*, as the latter would cause a darkening of the mixture"—(*Nat. Form.*).

Uses.—This agent enters into the formation of many of the *elixirs*, being the chief constituent of *Aromatic Elixir* (*Elixir Aromaticum*).

SPIRITUS AURANTII (U. S. P.)—SPIRIT OF ORANGE.

Preparation.—"Oil of orange peel, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; deodorized alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Uses.—Employed in flavoring mixtures.

SPIRITUS AURANTII COMPOSITUS (U. S. P.)—COMPOUND SPIRIT OF ORANGE.

Preparation.—"Oil of orange peel, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; oil of lemon, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; oil of coriander, twenty cubic centimeters (20 Cc.) [325 ♏]; oil of anise, five cubic centimeters (5 Cc.) [81 ♏]; deodorized alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place"—(*U. S. P.*).

This process is essentially that of the *National Formulary* (1st ed.), which comments as follows: "The essential oils used in this preparation, particularly those of orange and lemon, must be as fresh as possible, and *absolutely free* from any terebinthinate odor or taste. They should be diluted as soon as received, with a definite quantity of deodorized alcohol, which will retard deterioration. They should not be kept in stock, undiluted, for any length of time, or should at least be kept in bottles completely filled, and in a dark place. The alcoholic solution should be kept in the same manner. If oil of Curaçao orange of good quality can be obtained, it is advisable to use this, in place of ordinary oil of orange, as it imparts to the spirit a finer flavor"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This is a pleasant carminative and flavoring agent, used chiefly, for the latter purpose, in the preparation of the official *Aromatic Elixir* (*Elixir Aromaticum*). Dose, 1 fluid drachm, well diluted with water.

Related Preparation.—SPIRITUS CURASSAO (N. F.), *Spirit of Curaçao.* "Oil of Curaçao orange, one hundred and sixty-five cubic centimeters (165 Cc.) [5 fl℥, 278 ♏]; oil of fennel, three cubic centimeters (3 Cc.) [49 ♏]; oil of bitter almond, three-fourths of a cubic centimeter (0.75 Cc.) [12 ♏]; deodorized alcohol, eight hundred and thirty-two cubic centimeters (832 Cc.) [28 fl℥, 64 ♏]. Mix the oils with the deodorized alcohol, and keep the spirit in completely filled and well-corked bottles, and stored in a cool and dark place. *Note.*—The essential oils used in this case must be as fresh as possible, and *absolutely free* from any terebinthinate odor or taste. Oil of Curaçao orange may be obtained without difficulty in the market, but it should be carefully examined as to its quality, immediately upon receipt, and should not be kept in stock, for any length of time, without special precautions. A still finer quality of oil of orange is that derived from Citrus nobilis, which is known in the market as oil of mandarin"—(*Nat. Form.*).

SPIRITUS CAMPHORÆ (U. S. P.)—SPIRIT OF CAMPHOR.

SYNONYMS: *Tinctura camphoræ, Tincture of camphor.*

Preparation.—"Camphor, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the camphor in eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, filter through paper, and pass enough alcohol through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). The assay of spirit of camphor may be readily accomplished by means of the polariscope (see *Amer. Jour. Pharm.*, 1893, p. 382).

Action, Medical Uses, and Dosage.—This tincture is stimulant and antispasmodic. It is used externally as a stimulant and anodyne in *sprains, bruises, chilblains, paralysis*, and *chronic rheumatism*. Internally, it is used for various purposes, in commencing *diarrhœa*, in *flatulency, nausea, griping pains*, and wherever a stimulating or antispasmodic action is required. The dose is from 10 to 60 drops, in mucilage or syrup, or merely added to water or gruel. (For other uses, see *Camphora*.)

SPIRITUS CARDAMOMI COMPOSITUS (N. F.)—COMPOUND SPIRIT OF CARDAMOM.

Preparation.—"Oil of cardamom, two cubic centimeters (2 Cc.) [33 ♏]; oil of caraway, three-fourths cubic centimeter (0.75 Cc.) [12 ♏); oil of cinnamon, cassia, one-half cubic centimeter (0.50 Cc.) [8 ♏]; alcohol, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oils in the alcohol, add the glycerin, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation is intended as a flavoring ingredient, being equivalent to the official *Tinctura Cardamomi Composita*, without the coloring matter"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This spirit is carminative and is chiefly employed in flavoring mixtures. Dose, 1 fluid drachm, diluted.

SPIRITUS CARUI.—SPIRIT OF CARAWAY.

SYNONYMS: *Tinctura olei carui, Tincture of oil of caraway, Essence of caraway.*

Preparation.—Take of oil of caraway, 1 fluid ounce; stronger alcohol, 11 fluid ounces. Mix with agitation.

Action, Medical Uses, and Dosage.—This is aromatic, carminative, and antispasmodic. It may be used in *flatulency, nausea*, etc., and to flavor mixtures. The dose is from 20 to 60 drops, in sweetened water.

SPIRITUS CHLOROFORMI (U. S. P.)—SPIRIT OF CHLOROFORM.

SYNONYMS: *Chloric ether, Spirit of chloric ether.*

Preparation.—"Chloroform, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; alcohol, nine hundred and forty cubic centimeters (940 Cc.) [31 fl℥, 377 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—At one time this spirit was used under the name *chloric ether*, as an anæsthetic, but as such it is not now employed. It is a good form for the internal exhibition of chloroform, and is particularly valuable in the various forms of *colic—flatulent*, *biliary*, *hepatic*, and *menstrual*—and in *visceral neuralgia* and other forms of *abdominal pain*. Dose, 10 to 40 minims, well diluted.

SPIRITUS CINNAMOMI (U. S. P.)—SPIRIT OF CINNAMON.

Synonyms: *Tinctura olei cinnamomi*, *Tincture of oil of cinnamon*, *Essence of cinnamon*.

Preparation.—"Oil of cinnamon, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*)

Action, Medical Uses, and Dosage.—This tincture possesses the stimulant and aromatic properties of cinnamon, and may be beneficially employed in *menorrhagia* and *uterine hemorrhage*, for which a teaspoonful may be taken in a wineglass of sweetened water, every 5, 10, or 30 minutes, according to the urgency of the symptoms.

SPIRITUS FRUMENTI (U. S. P.)—WHISKEY.

"An alcoholic liquid obtained by the distillation of the mash of fermented grain (usually of mixtures of corn, wheat, and rye), and at least 2 years old"—(*U. S. P.*).

Synonym: *Whisky*.

Source and History.—According to the *Standard Dictionary* the name "*whiskey*" is derived from the Gælic *uisgebeatha*, meaning "water of life" (*uisge*, water, + *beatha*, life). Whiskey, in this country, is generally distilled from the fermented mash made from mixtures of corn, wheat, and rye. In Great Britain barley, rye, and oats are most commonly used, while in Germany potatoes are the raw materials chiefly employed. Whiskey is generally named from its source as *Rye whiskey*, *Corn whiskey*, *Potato whiskey*, and when prepared from cider, as it sometimes is, *Apple whiskey* or *Brandy*. Scotch whiskey is distilled from barley. In all cases, a certain quantity of malted barley, must be mixed with the cereals, etc., in order that their starch be converted into sugar (*maltose*) which subsequently undergoes fermentation (see *Alcohol*). Sometimes conversion of the starchy material into sugar (*dextrose*) is effected by means of diluted acids (see *Saccharum*). To obtain the whiskey from the fermented mash, distillation followed by rectification is resorted to. The result of the first distillation is called *low wines*. These are rectified by a second distillation which first yields a milky spirit containing oily matters and is called *foreshot;* the clear spirit which follows is called *high wines*. The freshly distilled product, known as *raw spirit* or *raw whiskey*, is harsh and unfit for use. It is put into casks or tanks where it is allowed to remain for at least 2 years (ageing process), when it becomes mellowed and pleasanter in flavor, certain compound-ethers being developed.

Individual cereals have distinctive volatile constituents which impart to the whiskey a peculiar flavor and odor, and an expert may readily detect these distinctive differences. A most objectionable contamination of whiskey is the *grain oil* or *fusel oil* (*amylic alcohol*), which is generated during fermentation of the mash. Its boiling point being much above that of water and of ethyl alcohol, the greater part of it remains behind if the distillation be carefully conducted. Still, traces of fusel oil are generally present in whiskey. Amylic alcohol is the substance which imparts to raw spirit its disagreeable odor. In the ageing of the spirit, fusel oil is believed to be gradually oxidized and forms valerianic ether but some contend that it is partially converted into free valerianic acid. Among other constituents present in small quantities is *œnanthylic acid;* in old whiskey both acetic and valerianic acids are present, giving to the liquid a feeble acid reaction. (For an interesting account of the manufacture of whiskey, see C. K. Gallagher, *Proc. Amer. Pharm. Assoc.*, 1883, pp. 375 and 477.)

Description and Tests.—Whiskey varies in color from pale-amber to deep-brown. When first prepared it is colorless, but upon standing in casks or tanks, it gradually assumes a brown color, which is also sometimes imparted to it by the addition of caramel. Both the odor and taste of aged whiskey is agreeable to most persons. It is officially demanded to be at least 2 years old, and to conform to the following requirements: "An amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Its specific gravity should not be more than 0.930, nor less than 0.917, corresponding, approximately, to an alcoholic strength of 44 to 50 per cent by weight, or 50 to 58 per cent by volume. If 100 Cc. of whiskey be very slowly evaporated in a tared capsule on a water-bath, the last portions volatilized should not have a harsh or disagreeable odor (absence of more than traces of fusel oil from grain); and the residue, when dried at 100° C. (212° F.), should not weigh more than 0.25 Gm. This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or aromatic substances). It should almost completely dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light green by a few drops of dilute ferric chloride T.S. made by mixing the latter with 10 volumes of water (absence of more than traces of oak tannin from casks). To render 100 Cc. of whiskey distinctly alkaline to litmus should not require more than 1.2 Cc. of potassium hydrate V.S. (limit of free acid)"—(*U. S. P.*). Mr. Joseph W. England (*Amer. Jour. Pharm.*, 1897, p. 584) finds that the acid standard for a good whiskey should be at least 1.4 or 1.5 Cc. of *decinormal* caustic potash solution, neutralizing 10 Cc. of whiskey, phenolphtalein being used as indicator.

Action and Medical Uses.—Locally, whiskey is applied to *wounds*, etc., for its antiseptic and stimulant effects. Internally it is employed for the purposes named under alcohol (see *Alcohol*). While less agreeable and less efficient than brandy, and differing considerably in action, even as one grade of whiskey or brandy may differ from another, it has come into almost universal employment instead of brandy on account of its inexpensiveness and comparative freedom from adulterants. It is less constipating than brandy but is more liable to offend the stomach, and to produce gastric, renal, and hepatic affections.

SPIRITUS GAULTHERIÆ (U. S. P.)—SPIRIT OF GAULTHERIA.

SYNONYM: *Essence of wintergreen.*

Preparation.—"Oil of gaultheria, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Uses.—Chiefly used as a flavoring essence.

SPIRITUS GLONOINI (U. S. P.)—SPIRIT OF GLONOIN.

"An alcoholic solution of glonoin (glyceryl [or propenyl] trinitrate, or nitroglycerin; $C_3H_5[NO_3]_3=226.58$), containing 1 per cent, by weight, of the substance. Spirit of glonoin should be kept and transported in well-stoppered tin cans, and should be stored in a cool place, remote from lights or fire. Great care should be exercised in handling, packing, transporting, or storing the spirit, since a dangerous explosion may result if any considerable quantity of it be spilled and the alcohol be partly or wholly lost by evaporation" (*U. S. P.*).

SYNONYMS: *Spirit of nitroglycerin*, *Liquor trinitrini* (*Br.*), *Liquor glonoini*, *Liquor nitroglycerini*, *Solution of glonoin*, *Solution of trinitrin*, *Solution of nitroglycerin.*

Description.—"A clear, colorless liquid, possessing the odor and taste of alcohol. Caution should be exercised in tasting it, since even a small quantity of it is liable to produce a violent headache. The same effect is produced when it is freely applied to the skin. It is neutral to litmus paper. Specific gravity 0.826 to 0.832 at 15° C (59° F.). On diluting 10 Cc. of the spirit with 15 Cc. of water—both liquids, as well as the mixture, when measured, being brought to 15° C. (59° F.)—the liquid will exhibit at most a faint cloudiness, but the addition of a further portion of 5 Cc. of water should produce a white turbidity. If the specific gravity of the spirit be higher than 0.840, or if 10 Cc. of it be rendered turbid by less than 10 Cc. of water, the spirit should be rejected"—(*U.S.P.*). J. B. Nagelvoort tests a 10 per cent spirit of nitroglycerin by pouring a measured volume into excess of water, and collecting and measuring the volume of the oil after it has completely settled (*Amer. Jour. Pharm.*, 1894, p. 527). (See below.)

Nitroglycerin.—This body is variously known as *glonoin*, *glonoine*, *pyroglycerin*, *nitroglycerine*, *trinitrin*, *trinitrine*, and *propenyl* (or *glyceryl*) *trinitrate*. It was first prepared by Sobrero, of Turin, in 1847. It is a very dangerous article to prepare, and we shall not give the process. Nitroglycerin is an oily, colorless, or light-yellow fluid, having a specific gravity from 1.595 to 1.600. At —20° C. (—4° F.), it solidifies and forms long needles. Heated carefully to 160° C. (320° F.), it is decomposed, evolving red vapors, without any detonation. At about 250° C. (518° F.), it detonates violently. By placing a drop on an anvil and striking it with a hammer, it instantly detonates. When properly prepared and free from acid, it may be kept for any length of time. Sulphuric acid added to its ethereal solution, decomposes it, precipitating a large amount of sulphur. When exposed to light or a warm temperature, glonoin undergoes decomposition. It is an exceedingly dangerous substance, and may even explode spontaneously, and always by percussion, or when dropped on a moderately hot iron, although touching it with a flame does not cause its explosion. Infusioral earth, impregnated with nitroglycerin, gives it a compact form, which constitutes the well-known substance, *dynamite*. It likewise forms the basis of *glyoxylin*, *giant powder*, *dualin*, and similar blasting explosives. It was introduced as a blasting material by Alfred Nobel, a Swede, in 1862. According to this engineer, 1 volume of nitroglycerin, exploded, liberates nearly 10,400 volumes of gas, whereas but 800 volumes are liberated by a like amount of gunpowder.

Glonoin (or nitroglycerin), for medicinal purposes, is usually procured by wholesale dealers in drugs directly from the factory where it is made, in form of a 10 per cent solution in alcohol. Such a solution is non-explosive, and may be diluted, as occasion requires, to the strength of 1 per cent. It should be noted, however, that exposure to a cold atmosphere will cause some nitroglycerin to separate (see J. B. Nagelvoort, *loc. cit.*, who gives an assay method for this solution). The specific gravity of the 10 per cent solution is 0.863 at 15° C. (59° F.). Solutions of glonoin, particularly the stronger (10 per cent), should always be transported or kept in tin cans, and *never in glass* or other fragile vessels. Should the container of a solution of glonoin be broken, and the contents be soaked up by wood, or packing material, the latter may become dangerously explosive when the alcohol has evaporated. Dr. V. Coblentz recommends (*Handbook of Pharmacy*, 1895, p. 255) that, in case nitroglycerin is spilled, a solution of caustic potash or soda be poured over the spot, which causes the decomposition of nitroglycerin into its harmless constituents. Should the proportion of glonoin to porous material be not more than 70 parts of the former, and not less than 30 parts of the latter, the compound will be non-explosive (except by a detonator); and if the proportions are not more than 52 parts of the former, and not less than 48 parts of the latter, the compound can not even be detonated. But, in the presence of substances readily yielding oxygen, such as nitrates, chlorates, etc., so small a proportion as 5 per cent of glonoin will produce a dangerously explosive combination. When handling an alcoholic solution of glonoin, care should be taken that it be not brought in prolonged or extended contact with the skin, as it is readily absorbed, and will then cause its characteristic physiological effects (distressing headache, nausea, etc.). (Adapted from *Nat. Form.*, 1st ed.)

Action, Medical Uses, and Dosage.—The effects of nitroglycerin are precisely similar to those of *Amyl Nitris* (which see). Its effects, however, are less transient, but more slowly produced. In some individuals, a fraction of a drop is sufficient to cause distressing symptoms. Violent headache, with arterial throbbing, is frequently produced by a 1-drop dose of a 1 per cent solution. Ten drops have produced giddiness, weariness, violent-throbbing headache, as if the head would burst, and semi-unconsciousness. In its administration the smallest amounts must be first administered, the dose being gradually increased as indicated. Toleration sometimes becomes established, so that 8 or 10 drops may be taken at a dose. The treatment for overdoses of spiritus glonoini, or nitroglycerin, and amyl nitrite should consist in the use of such remedies as produce contraction of the blood vessels, thus raising arterial tension and diminishing the blood supply to the brain and nerve centers. Belladonna (or atropine), ergot (or sclerotinic acid), and strychnine are physiologically antagonistic. Inhalations of ammonia, ammonia internally, atropine or ether subcutaneously, recumbent posture, warmth to the body and cold to the head, sinapisms to epigastrium or to feet, may be resorted to in case of serious results from these agents. Fortunately, the effects of nitroglycerin and amyl nitrite are quite transient, and death is not likely to occur from ordinary doses, even though such doses may occasion, in susceptible individuals, alarming symptoms.

Spirit of glonoin (or nitroglycerin in pill has come to be an important remedy in troubles due to *cerebral anemia*. Thus it often proves a prompt remedy for *anemic headache*, and for cases of *sunstroke*, where there is a pale face and other evidence of anemia of the brain. In minute doses (second or third dilution of spirit of glonoin, gtts. x to xv, to water, 4 fluid ounces; teaspoonful every 2 or 3 hours it has been advised in *sunheat*, *headache*, aggravated by solar heat, *menstrual headache*, and other non-febrile, full, throbbing headaches, *flushing of the face* at the climacteric, and in *neuralgic dysmenorrhœa*. Foltz obtained good results from nitroglycerin in *tinnitus aurium*, dependent upon faulty heart-action due to organic changes in the heart. Its great reputation has been acquired in the treatment of *cardiac pain*, particularly *angina pectoris*, and for *dyspnœa* and *pseudo-angina*. In these cases, it acts similarly to amyl nitrite, and may well follow the more prompt effects of that drug to insure greater permanency of action. It is less apt than amyl nitrite to produce flushing of the face, which, as a rule, is but slight. *Cardiac neuralgia* is well treated with it. It has an important place in the treatment of *asthma*, *asphyxiation by drowning*, *carbon dioxide or other gases*, *opium poisoning*, with uræmic symptoms, *poisoning by chloroform*, *sea-sickness*, *hydrophobia*, and *tetanus*. According to A. W. Mayo Robson, it is a good remedy for *acute* and *chronic nephritis*, with great arterial tension, and a remedy to relieve *vascular tension in the aged*. It has also been advised to ward off the chill in *intermittents*, and as a remedy for *pernicious malarial disease*. Mikhalkine, of Russia, declares it one of the best of remedies for *sciatic neuralgia*. He advises the following solution: Spirit of glonoin, 5 grammes; tincture of capsicum, 7.5 grammes; peppermint-water, 15 grammes. Dose, 5 to 10 drops, 3 times a day. Nitroglycerin may be employed for the other conditions mentioned under *Amyl Nitris*. The dose of nitroglycerin ranges from $\frac{1}{200}$ to $\frac{1}{25}$ grain, in pill; of spiritus glonoini, from a fraction of a drop to 8 drops, the larger doses being employed only where toleration has become established. For angina pectoris, Murrell (*Man. of Mat. Med. and Therap.*) proposes the following formula: Nitroglycerin, $\frac{1}{100}$ grain; amyl nitrite, $\frac{1}{4}$ grain; menthol. $\frac{1}{50}$ grain; capsicum, $\frac{1}{100}$ grain, these being the proportions and amounts for a single pill, which should be coated.

Specific Indications and Uses.—Tensive spasmodic disorders of the heart, as in angina pectoris; cardiac pain; neuralgic pain, with anemia; fluttering, irregular pulse; depression; cerebral anemia; nervous spasms, with cerebral anemia; nervous headache, with pallor; dyspnœa, from cardiac hypertrophy; asthmatic breathing.

SPIRITUS JUNIPERI (U. S. P.)—SPIRIT OF JUNIPER.

Preparation.—"Oil of juniper, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*). A more agreeable spirit may be prepared if oil of juniper berries, as directed, instead of common oil of juniper, be employed. It is improved by keeping.

Action, Medical Uses, and Dosage.—Diuretic and carminative, and frequently added to diuretic medicines, to enhance their value in *ascites*. Dose, $\frac{1}{2}$ to 1 fluid drachm.

SPIRITUS JUNIPERI COMPOSITUS (U. S. P.)—COMPOUND SPIRIT OF JUNIPER.

Preparation.—"Oil of juniper, eight cubic centimeters (8 Cc.) [130 ♏]; oil of caraway, one cubic centimeter (1 Cc.) [16 ♏]; oil of fennel, one cubic centimeter

(1 Cc.) [16 ♏]; alcohol, fourteen hundred cubic centimeters (1400 Cc.) [47 fl℥, 163 ♏]; water, a sufficient quantity to make two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏]. Dissolve the oils in the alcohol, and gradually add enough water to make the product measure two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏]"—(*U. S. P.*). This preparation is closely related to *Holland gin*, and is designed as a substitute therefor. Age improves it, its flavor is pleasant, provided good essential oils are used, and it is more uniform in composition than ordinary gin.

Action, Medical Uses, and Dosage.—Compound spirit of juniper is carminative and diuretic, and is frequently added to diuretic mixtures to increase their efficiency in *ascites*. The dose is from 1 to 4 fluid drachms.

SPIRITUS LAVANDULÆ (U. S. P.)—SPIRIT OF LAVENDER.

Preparation.—"Oil of lavender flowers, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; deodorized alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Spirit of lavender is a pleasant carminative and stimulant. Externally it is used as a cooling lotion in *headache* and *febrile complaints*, and as an agreeable perfume. The dose is from ½ to 1 fluid drachm, in sweetened water.

Related Preparation.—SPIRITUS OPHTHALMICUS (N. F.), *Ophthalmic spirit, Alcoholic eyewash.* "Oil of lavender, two cubic centimeters (2 Cc.) [33 ♏]; oil of rosemary, six cubic centimeters (6 Cc.) [97 ♏]; alcohol, ninety-two cubic centimeters (92 Cc.) [3 fl℥, 53 ♏]. Mix them by agitation, and, if necessary, filter the liquid through paper"—*Nat. Form.*).

SPIRITUS LIMONIS (U. S. P.)—SPIRIT OF LEMON.

SYNONYM: *Essence of lemon.*

Preparation.—"Oil of lemon, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; lemon peel, freshly grated, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; deodorized alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oil of lemon in nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of deodorized alcohol, add the lemon peel, and macerate for 24 hours. Then filter through paper, and add, through the filter, enough deodorized alcohol to make the spirit measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Uses.—Spirit of lemon is used simply as a flavoring substance for medicinal mixtures.

SPIRITUS MENTHÆ PIPERITÆ (U. S. P.)—SPIRIT OF PEPPERMINT.

SYNONYMS: *Essence of peppermint, Tinctura olei menthæ piperitæ, Tincture of oil of peppermint.*

Preparation.—"Oil of peppermint, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; peppermint, bruised, ten grammes (10 Gm.) [154 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oil of peppermint in nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of alcohol, add the peppermint, and macerate for 24 hours. Then filter through paper, and add, through the filter, enough alcohol to make the spirit measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). The purpose of adding peppermint is to give the preparation a green color.

Action, Medical Uses, and Dosage.—Tincture of oil of peppermint, more commonly known as *essence of peppermint*, is carminative and antispasmodic. It may be used in *nausea, colic, flatulency, cramp*, or *griping of the bowels*, etc. The dose is from 10 to 30 drops, on sugar or in sweetened water.

SPIRITUS MENTHÆ VIRIDIS (U. S. P.)—SPIRIT OF SPEARMINT.

SYNONYMS: *Essence of spearmint, Tinctura olei menthæ viridis, Tincture of oil of spearmint.*

Preparation.—"Oil of spearmint, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; spearmint, bruised, ten grammes (10 Gm.) [154 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oil of spearmint in nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of alcohol, add the spearmint, and macerate for 24 hours. Then filter through paper, and add, through the filter, enough alcohol to make the spirit measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This preparation is antispasmodic, carminative, and diuretic, and may be employed similarly to the essence of peppermint. Added to solution of potassium acetate it adds to the diuretic efficiency of the latter, by increasing the watery constituents of the urine, whereas the solid constituents are removed by the potassium salt. The dose is from 20 to 40 drops, on sugar or mixed with sweetened water.

SPIRITUS MYRCIÆ (U. S. P.)—SPIRIT OF MYRCIA.

SYNONYM: *Bay rum.*

Preparation.—"Oil of myrcia, sixteen cubic centimeters (16 Cc.) [260 ♏]; oil of orange-peel, one cubic centimeter (1 Cc.) [16 ♏]; oil of pimenta, one cubic centimeter (1 Cc.) [16 ♏]; alcohol, twelve hundred and twenty cubic centimeters (1220 Cc.) [41 fl℥, 121 ♏]; water, a sufficient quantity to make two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏]. Mix the oils with the alcohol, and gradually add water until the solution measures two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏]. Set the mixture aside, in a well-stoppered bottle, for 8 days, then filter it through paper, in a well-covered funnel"—(*U. S. P.*).

History and Description.—Bay rum as prepared in the West Indies is distilled from the fresh leaves of the *Myrcia acris*, Swartz. The best quality is produced when the leaves and the ripe berries are distilled together with a good grade of St. Croix rum by means of steam. (For an interesting article by A. H. Riise, regarding the history and manufacture of bay rum, see *Amer. Jour. Pharm.*, 1882, p. 278; also see *Oleum Myrciæ.*) But little bay rum is prepared in this country directly from the leaves, much of the spirit now employed being the substitute, the alcoholic solution of oils as directed by the *Pharmacopœia*. In the official process the water is directed to be gradually added; this is to insure against a milkiness that is apt to ensue when solutions of essential oils in alcohol are rapidly diluted with water. Treatment with paper-pulp removes such cloudiness as may remain in the liquid after unsuccessful filtration. Bay rum, as prepared by the official process, is an almost colorless or pale-yellowish liquid having a refreshing spice-like and characteristic fragrance.

Action and Medical Uses.—Bay rum is used almost exclusively as an agreeable perfume and a cooling and refreshing application to the head, in *nervous headache*, *syncope*, and various mild *nervous affections*. It also soothes *irritated* or *chafed parts*, and is extensively used by barbers to subdue any irritation which may have been produced by shaving.

SPIRITUS MYRISTICÆ (U. S. P.)—SPIRIT OF NUTMEG.

SYNONYM: *Essence of nutmeg.*

Preparation.—"Oil of nutmeg, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage. This spirit is employed occasionally for flavoring purposes. Dose, from ½ to 1 fluid drachm.

SPIRITUS ODORATUS.—PERFUMED SPIRIT.

Synonyms: *Spiritus coloniensis*, *Aqua coloniensis*, *Alcoolatum fragrans*, *Cologne water*.

Preparation.—The formula of the *National Formulary*, which differs slightly in the proportions given by the *U. S. P.*, 1880, is as follows: "Oil of bergamot, fifteen cubic centimeters (15 Cc.) [243 ♏]; oil of lemon, eight cubic centimeters (8 Cc.) [130 ♏]; oil of rosemary, seven cubic centimeters (7 Cc.) [114 ♏]; oil of lavender flowers, four cubic centimeters (4 Cc.) [65 ♏]; oil of orange flowers, four cubic centimeters (4 Cc.) [65 ♏]; acetic ether, two cubic centimeters (2 Cc.) [33 ♏]; water, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]; alcohol, eight hundred and forty cubic centimeters (840 Cc.) [28 fl℥, 194 ♏). Dissolve the oils and the acetic ether in the alcohol, and add the water. Set the mixture aside, in a well-closed bottle, for 8 days, then filter through paper in a well-covered funnel"—(*Nat. Form.*). (For other formulæ, see *Amer. Jour. Pharm.*, 1887, p. 187, and 1888, p. 102, etc.)

Uses.—This spirit is used only as a perfume.

SPIRITUS OLEI VOLATILIS (N. F.)—SPIRIT OF VOLATILE OIL.

Preparation.—"Any spirit or alcoholic solution of a volatile oil, for which no formula is given by the *U. S. P.*, or by this *Formulary*, should be prepared in accordance with the following general formula: Any volatile oil, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; deodorized alcohol, nine hundred and thirty-five cubic centimeters (935 Cc.) [31 fl℥, 272 ♏]. Dissolve the volatile oil in the deodorized alcohol. *Note.*—The strength of the spirit thus prepared is approximately 5 per cent, by weight, provided the specific gravity of the oil is in the neighborhood of 0.900"—(*Nat. Form.*).

SPIRITUS PHOSPHORI (U. S. P.)—SPIRIT OF PHOSPHORUS.

Synonym: *Tincture of phosphorus.*

Preparation.—"Phosphorus, one and two-tenths grammes (1.2 Gm.) [19.5 grs.]; absolute alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Weigh the phosphorus in a tared capsule containing water, then dry it carefully and quickly with blotting paper, and introduce it into a flask containing one thousand cubic centimeters (1000 Cc.) 33 fl℥, 391 ♏] of absolute alcohol. Connect the flask with an upright condenser supplied with cold water, and apply the heat of a water-bath, so that the alcohol may be kept gently boiling, until the phosphorus is dissolved. Then allow the liquid to become cold, and, if necessary, add to it enough absolute alcohol to make it measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Lastly, transfer the spirit to small, dark, amber-colored vials, which should be securely stoppered, and kept in a cool and dark place"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Phosphorus.*) This spirit furnishes a convenient method for the administration of phosphorus, about $\frac{1}{15}$ grain being contained in 1 fluid drachm. "This preparation is intended for preparing the elixir of phosphorus. It is unsuited for internal administration without corrigents. Care should be taken that it be not confounded with Thompson's solution of phosphorus (see *Liquor Phosphori*, N. F.)"—(*Nat. Form.*, 1st ed.). The dose is from 10 to 60 minims.

SPIRITUS RECTIFICATUS (BR.)—ALCOHOL (90 PER CENT).

"A liquid containing 90 parts, by volume, of ethyl hydroxide (C_2H_5OH) and 10 parts, by volume, of water, obtained by the distillation of fermented saccharine liquids"—(*Br. Pharm.*, 1898). (See *Alcohol.*)

Synonym: *Rectified spirit.*

"Alcohol (90 per cent) is only slightly stronger than the rectified spirit of the *British Pharmacopœia*, 1885, containing, by volume, 1.35 per cent, or, by weight, 1.65 per cent, more ethyl hydroxide"—(*Br. Pharm.*, 1898).

Diluted alcohol is official in the present *British Pharmacopœia*, in four grades, containing, respectively, 70, 60, 45, and 20 per cent of ethyl hydroxide, by volume. The *Spiritus Tenuior* (*Proof Spirit*) of the *British Pharmacopœia*, 1885, containing about 57 per cent of absolute alcohol, by volume, is no longer official.

SPIRITUS ROSMARINI.—SPIRIT OF ROSEMARY.

SYNONYM: *Spiritus anthos.*

Preparation.—"Take of oil of rosemary, 1 fluid ounce; rectified spirit, 49 fluid ounces. Dissolve"—(*Br. Pharm.*, 1885). The spirit of rosemary of the *British Pharmacopœia*, 1898, contains 5 times the proportion of oil of rosemary present in the spirit of rosemary of the *British Pharmacopœia*, 1885.

Action, Medical Uses, and Dosage.—This agent is an efficient nerve stimulant, and may be employed in *hysteroidal affections.* Externally, it is applied to assuage *local pains.* Dose, 1 fluid drachm.

SPIRITUS SAPONATUS (N. F.)—SPIRIT OF SOAP.

Preparation.—"Castile soap, in shavings, one hundred and seventy-five grammes (175 Gm.) [6 ozs. av., 76 grs.]; alcohol, six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Introduce the soap into a bottle, add the alcohol and two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, cork the bottle, and immerse it in hot water, frequently shaking. When the soap is dissolved, allow the bottle and contents to become cold, then add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter. *Note.*—The *Spiritus Saponatus* of the *German Pharmacopœia*, is prepared by saponifying olive oil with potassa, and then adding alcohol and water. If time permits, the spirit ought to be set aside, in a moderately cold place, for about 12 hours, before it is filtered"—(*Nat. Form.*).

Action and Medical Uses.—This agent is employed like *Liniment of Soft Soap* (*Linimentum Saponis Mollis, U. S. P.*) in the treatment of numerous *skin affections.*

SPIRITUS SASSAFRAS.—SPIRIT OF SASSAFRAS.

SYNONYMS: *Tinctura olei sassafras, Tincture of oil of sassafras, Essence of sassafras.*

Preparation.—Take of oil of sassafras, 1 fluid ounce; stronger alcohol, 11 fluid ounces. Mix with agitation.

Action, Medical Uses, and Dosage.—This tincture is stimulant, carminative, diuretic, and alterative. Its principal use is to flavor syrups and other fluid preparations. The dose is from 10 to 30 drops on sugar, or mixed with sweetened water.

SPIRITUS SINAPIS (N. F.)—SPIRIT OF MUSTARD.

Preparation.—"Volatile oil of mustard, two grammes (2 Gm.) [31 grs.]; alcohol, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix them. *Note.*—This preparation is official in the *German Pharmacopœia*"—(*Nat. Form.*).

Action and Medical Uses.—This agent should never be used internally. Externally, it is a powerful rubefacient, and may be cautiously employed where a counter-irritant effect is desired.

SPIRITUS VINI GALLICI (U. S. P.)—BRANDY.

"An alcoholic liquid obtained by the distillation of the fermented, unmodified juice of fresh grapes, and at least 4 years old"—(*U. S. P.*).

SYNONYM: *Spirit of French wine.*

Source and History.—Brandy is the product obtained by distilling wine. The *U. S. P.* formerly required that French wines be used, but now admits the product of any grape wine that meets the official requirements. The greatest brandy-producing country is France, and the French brands most esteemed are known as Cognac and Armagnac, both of which are mild and agreeable in flavor. Next in order are the brandies of Bordeaux and Rochelle. Spain, Portugal, and Germany also produce considerable brandy. California and the vine-growing sections of the states now furnish large amounts of this spirit. As distilled from the wine in France it is first colorless and is known as *white brandy;* this is then put into casks made of new oak, which wood after a time imparts to the spirit a pale amber hue, when it is known as *pale brandy.* A preparation used as an addition to brandies or for making the imitation of brandy by mixing it with alcohol, is prepared in that country from the wine-lees and grape-marc, and has the name *eau de vie de marc.* It contains a large amount of odorous constituents, and when wholly or partially deprived of its alcohol constitutes commercial *oil of grapes.* California now furnishes large amounts of good brandy. The chief Ohio and Mississippi valley brandy is the *Catawba*, which, when prepared from the lees, has the Catawba wine flavor, but when prepared from the marc contains fusel oil and at first is unpleasant to the taste, but becomes mellow as it ages. All brandies are improved by age. There is marked variation in the flavor of different brandies depending upon the kind and condition of the grapes employed in making the wine, the care exercised in the preparation of it, and the age of the wine employed. The most fragrant brandy is that distilled from old wines. Compounded brandies are frequently on the market.

Description and Tests.—The *U. S. P.* demands that brandy conforms to the following description: "A pale amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Its specific gravity should not be more than 0.941, nor less than 0.925, corresponding, approximately, to an alcoholic strength of 39 to 47 per cent by weight or 46 to 55 per cent by volume"—(*U. S. P.*). The odor of brandy is due to certain ethers which occur in minute amounts; the chief of these are œnanthic and acetic ethers, and possibly propylic and related ethers (see enumeration of volatile constituents in *Amer. Jour. Pharm.*, 1886, p. 427). Tannin from the oak casks and altered sugar from the caramel often employed to color it are present. The odor of good brandy remains for several hours distinct in the glass from which it has been poured.

"If 100 Cc. of brandy be very slowly evaporated in a tared capsule on a water-bath, the last portions volatilized should have an agreeable odor free from harshness (absence of fusel oil from grain or potato spirit); and the residue, when dried at 100° C. (212° F.), should not weigh more than 1.5 Gm. This residue should have no sweet or distinctly spicy taste (absence of added sugar, glycerin, or aromatic substances). It should almost completely dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light-green by a few drops of dilute ferric chloride T.S. made by mixing the latter with 10 volumes of water (absence of more than traces of oak tannin from casks). To render 100 Cc. of brandy distinctly alkaline to litmus should require not more than 1 Cc. of potassium hydrate V.S. (limit of free acid)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The general effects of brandy are those mentioned under alcohol (see *Alcohol*). It is, however, when pure, more palatable and grateful to the stomach than other alcoholics, and is less likely to occasion renal and hepatic diseases. Mixed with milk and sweetened with sugar it is extensively used in *low forms of fever*, and in *threatened collapse* it may be injected hypodermatically. The dose of brandy is determined largely by the condition of the patient demanding it.

SPONGIA.—SPONGE.

The skeleton of *Spongia officinalis*, Linné.

Class: Poriphera. *Order:* Ceratospongia.

ILLUSTRATION: *Amer. Jour. Pharm.*, 1881, p. 182.

Source, Description, and History.—The familiar article, known as *sponge*, is the skeleton of a marine growth that was once classed as a *zoophyte*, or plant animal. It grows attached to submarine rocks, and consists of three parts the horny skeleton, the gelatinous, dark-colored, fleshy matter, called *sarcode*, and the curious and beautiful spicules, anchor-like spines of calcareous or silicious substance, which hold the fleshy mass together. The latter is transversed by a system of channels, which end in numerous surface pores, the larger ones being called *oscula*. Through these openings the sea water, from which the sponge draws its nourishment, is continually propelled by special organs of the animal. The shape of the sponge, the distribution of the oscules on the surface, the fineness of the texture, and the elasticity of the sponge, determine its quality. *Turkey* or *Mediterranean sponge*, from Smyrna, collected in the Grecian Archipelago, Syria, and the Red Sea, is the finest grade, usually cup-shaped, and the oscules are crowded near the center of the cup. The less valuable grades occur in shallow waters, while the finest kinds grow at a depth of 20 to 30 fathoms (120 to 180 feet), and are secured by divers. (For an interesting account, see *Amer. Jour. Pharm.*, 1875, p. 272, from *Scientific American*, and *ibid.*, p. 322; also 1872, p. 369.) *West India* or *Bahama sponge*, collected along the Bahama Islands, is much coarser, oblong or convex, and, according to Hyatt (1876), is distinguished as *reef* or *glove sponge*, *sheep's-wool sponge*, *abaco-velvet*, *cay-velvet*, *grass*, *hard-head*, and *yellow sponge* (see description of each, by E. M. Holmes, in *Amer. Jour. Pharm.*, 1887, pp. 258–262). Considerable sponge-fishing is also carried on along the west and south coast of Florida, where, by means of hooks attached to a long pole, the sponges are torn from the rocks on which they grow. They grow there at a depth of from 3 to 6 fathoms (18 to 36 feet), and can be plainly seen from the surface of the water when viewed through a glass plate, which forms the bottom of a wooden bucket. (For much interesting details, see W. B. Burk, *Amer. Jour. Pharm.*, 1895, pp. 21–26.)

When first taken from the sea, sponge has a fishy odor, and has to be squeezed and washed to free it from gelatinous matter, otherwise it would speedily putrefy. Sometimes it is first buried in sand for a few days to remove the gelatinous matter, and, afterward, soaked, squeezed, and washed. The sponge of commerce is soft, light, flexible, and compressible, absorbs water, and thereby swells up, burns with an animal odor, is dissolved by liquor potassæ, and is colored yellow by nitric acid. To prepare it for use, it should first be beaten and well shaken, then placed in water for 1 or 2 days, beaten again, dried, and shaken to remove sand and other foreign substances, after which it may be placed in very dilute hydrochloric or sulphuric acid, to dissolve the earthy concretions, and finally washed in several waters to free it from acid. Solution of sulphurous acid, or chlorine gas, is usually employed to *bleach* sponge. A good method is to soak the sponge for not longer than 10 minutes in a solution of potassium permanganate (2 per cent), and subsequently dipping it in a solution of oxalic acid (2 per cent), previously slightly acidulated with sulphuric acid. Several other methods are suggested (see below).

Chemical Composition.—Edward C. C. Stanford gives the following analysis of true Turkish sponge: Water, 19.4 per cent; organic matter, 69.39 per cent; ash, soluble in water, 2.21 per cent (containing iodine, 0.2 per cent); ash, insoluble in water (sand, etc.), 9 per cent (*Amer. Jour. Pharm.*, 1884, p. 584; also see Preuss, following page). The organic matter of sponge is called *spongin*. It is a nitrogenous body allied to, but different from, *sericin* (*fibroin*), which composes silk-cocoon and spider-webs. Boiling with diluted sulphuric acid produces *glycocoll* and *leucin*, while sericin yields *tyrosin* and *serin*.

Action and Uses.—Sponge, when properly prepared, is of much utility to the surgeon, on account of the facility with which it absorbs fluids, and is much used for removing blood during operations, which would otherwise interfere with their safe and rapid termination; to imbibe acrid discharges from *wounds* and *ulcers*, and to check *external hemorrhages* from small blood vessels, by pressing it upon the bleeding part. Sponges that have been used in surgical operations, or for any of the above purposes, must be thoroughly washed with boiling water before being used again, and, even then, should be subjected to antiseptic treatment. Gauze, cotton, or compressed lint are far safer than sponges for the above-named purposes. Sponge has likewise been used for dilating *sinuses*, *wounds*, etc., and producing premature delivery, by introducing a piece of sponge tent, of a conical form, into the mouth of the uterus, and allowing it to remain there for a time, and then changing it until, by its swelling and the irritation it produces, uterine contractions are caused. The same procedure is sometimes instituted for the relief of *dysmenorrhœa* (see also *Spongia Usta*). However, for the latter purpose specially constructed dilators are preferred to the sponge tent.

Related Products and Derivatives.—Spongia Usta, *Burnt sponge, Spongia tosta.* Cut the sponge in pieces, and bruise it, so as to free it from foreign matters adhering to it; burn it in a covered iron vessel, until it becomes black and friable; afterward reduce it to a very fine powder (Dunc.—*Lond.*). The burning or roasting should not be carried further than carbonization, and until a sample taken out is easily pulverizable. The yield of burnt sponge is about 50 per cent. According to Pereira, its efficacy is due to the presence of iodine and bromine compounds. Preuss obtained from sponge, by calcination, iodide of sodium, 2.14 per cent; bromide of magnesium, 0.76 per cent; carbon and silicious matter, 32.7 per cent; sodium chloride, 11.2 per cent; calcium sulphate, 16.4 per cent; calcium carbonate, 10.3 per cent; calcium phosphate, 3.5 per cent; oxide of iron, 2.87 per cent; magnesia, 0.47 per cent. Burnt sponge, if good, should evolve violet fumes (*vapor of iodine*), when treated with concentrated sulphuric acid in a flask. Said to be alterative and antiscrofulous, and has been efficient in *scrofula, bronchocele, diseases of the skin,* and *tuberculous affections* generally. Its dose is from ½ to 2 or even 3 drachms. There is no doubt of the efficacy of spongia usta in *goitre*, but since it was learned that its virtues probably depended upon the iodine it contains, the agent has been largely superseded by iodine itself. There are some, however, who contend that it will cure cases that resist the action of iodine. Homœopaths employ burnt sponge, under the name of *Spongia* or *Spongia tosta*, in *affections of the larynx*, particularly *croup, croupous cough, coughs of laryngeal phthisis, in goitre,* and many other conditions. In homœopathic pharmacy, Turkey sponge is employed and roasted brown (not burnt), and, finally, tinctured in alcohol (see *Homœopathic Pharmacopœia*, 1890). This is usually administered in the second and third attenuations. A pill, which has acquired some considerable reputation in the cure of *scrofula* and *tuberculous maladies* generally, called the *iodine pill*, and which I made known to the profession several years since, is made as follows: Take of iodine, 50 grains; sulphate of morphine, 10 grains; burnt sponge, 100 grains. Triturate these well together, and into a fine powder, and then form the mixture into a pill mass, by the addition of molasses or other compatible medium, and divide into 100 pills. To be kept in a dry place. Dose, 2 or 3 pills, daily (J. King).

Spongia Decolorata (N. F.), *Decolorized sponge, Bleached sponge.*—"Sponge, potassium permanganate, sodium hyposulphite, hydrochloric acid, water, each, a sufficient quantity. Free the sponge from sand and any other obvious impurities or damaged portions by beating, washing, and trimming; then soak it for about 15 minutes in a sufficient quantity of solution of potassium permanganate, containing fifteen grammes (15 Gm.) [231 grs.] to the liter (33 fl℥, 391 ♏), wringing the sponge out occasionally, and replacing it in the liquid. Then remove it and wash it with water, until the latter runs off colorless. Wring out the water, and then place the sponge into a solution of sodium hyposulphite, containing sixty grammes (60 Gm.) [2 ozs. av., 51 grs.] to the liter. Next add for every liter of the last-named solution used, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of hydrochloric acid, diluted with two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water. Macerate the sponge in the liquid for about 15 minutes, expressing it frequently and replacing it in the liquid. Then remove it, wash it thoroughly with water, and dry it. In the case of large and dark-colored sponges, this treatment may be repeated until the color has been removed as far as possible. *Note.*—If it is desired to keep the sponge soft, and to prevent it from shrinking when dry, it may be dipped, after having been finally washed, into a mixture of 1 volume of glycerin and 5 volumes of water, after which it is to be wrung out and allowed to dry"—(*Nat. Form.*).

Spongia Cerata, or Sponge Tent.—The sponge tent, made by impregnating sponge with melted wax, pressing it between two iron plates, and then forming it into size and shape required, is not resorted to as frequently as formerly, in enlarging *sinus orifices* and *canals*, particularly the os uteri.

Spongia Compressa, *Compressed sponge, Sponge tent.*—Compressed sponge may be prepared by cutting perfectly clean sponge, of best quality, while still moist, into elongated strips of desired size, and securely winding them with twine, so that, when dried, a cylindrical form is obtained. Compressed sponges, tampons, etc., may also readily be made by first moistening the sponge with water, then cut or mold it into any shape, or press it into a tube of the required diameter, and immerse it in alcohol of 95 per cent. The sponge permanently retains the shape given to it. To remove this firmness, it is only required to moisten the sponge with water. The *National Formulary* directs as follows: "Sponge, a sufficient quantity; mucilage of acacia (*U. S. P.*), 1 volume; water, 9 volumes. Mix a sufficient quantity of mucilage of acacia and of water, in the proportion of 1 volume of the former to 9 volumes of the latter, and immerse in the liquid the sponge, previously freed from sand and other obvious impurities, and cut into suitable pieces. When the sponge has been thoroughly impregnated, firmly wrap twine around it so as to bring it to the desired shape, and then dry it. *Note.*—Sponge thus prepared is best preserved with the twine wrapped around it. If the twine is removed, special care should be taken to protect the sponge against damp air"—(*Nat. Form.*).

Vegetable Sponge, Gourd Towel.—The fibrillated network of a cucurbitaceous plant, the *Luffa ægyptiaca*, Miller (*Momordica Luffa*, Linné). Used like sponge. Also *Luffa fœtida*, Cavanilles, and *Luffa Petola*, Seringe.

Antiseptic Sponge.—For information concerning antiseptic sponges, see for example, *Amer. Jour. Pharm.*, 1889, pp. 21 and 473.

STANNUM.—TIN.

SYMBOL: Sn. ATOMIC WEIGHT: 118.8.

Source and Preparation.—This metal is found in nature in the form of a dioxide (SnO_2) termed *tinstone* or *cassiterite*, and *wood tin*, or more rarely as a sulphide, mixed with iron, and called *tin pyrites*. It occurs in East India, in Saxony, and in England (Cornwall and Devonshire), Austria, Australia, and the United States. The bulk of the tin produced comes from England, but the purest is the Asiatic (*Banca tin*). When the oxide is found in loose grains, it is called *stream tin*, from which *grain tin* is obtained by smelting the oxide with charcoal in a reverberatory furnace. Another variety of the oxide, *mine tin*, when crushed, washed, roasted, and smelted with coal and limestone, yields *block tin*. *Malacca tin* occurs commercially in quadrangular pyramids with flattened bases, and *Banca tin* in wedge-shaped pieces.

Description, Tests, and Uses.—Pure tin is of a nearly silver-white color, but a freshly cut surface, when exposed to the air, soon loses its brilliant luster and becomes grayish. Tin is very malleable and may be beaten into leaves $\frac{1}{2000}$ of an inch thick (*tin-foil*). Tin is flexible, producing, when pure, a crackling noise upon being bent (*tin-cry*), due to the internal friction of its crystals. At a low temperature, tin disintegrates into small crystals. It melts at 235° C. (455° F.) and volatilizes at a white heat. When heated to whiteness with access of air, it burns with a brilliant light, tin dioxide (SnO_2) being formed. It is sparingly ductile, and has a specific gravity of 7.3. Tin is soluble in hot hydrochloric acid, forming a colorless solution of stannous chloride ($SnCl_2$); when solution of chloride of gold is added, a dark purplish precipitate, *purple of Cassius*, is formed. Tin dissolves in aqua regia with formation of stannic chloride ($SnCl_4$). Nitric acid oxidizes tin to insoluble metastannic acid ($SnO_2.H_2O$). Tin forms two lines of salts: *stannous*, derived from the stannous oxide (SnO), and *stannic salts*, derived from stannic or dioxide (SnO_2). Stannous salts form a brown precipitate with hydrogen sulphide (SnS), stannic salts a light-yellow precipitate (SnS_2); both are soluble in ammonium polysulphide with formation of ammonium sulpho-stannate ($SnS_2.S[NH_4]_2$). Impurities liable to be present in even the best grade of tin, are traces of copper, lead, or iron. The inferior grades contain arsenic, antimony, lead, zinc, bismuth, copper, iron, etc. Arsenic or antimony may be detected in Marsh's apparatus (see *Acidum Arsenosum*). These elements will mostly be given off during the solution of the metal in hydrochloric acid, as hydrides (hydrogen compounds) of arsenum and antimony; any portion which is not thus volatilized will form a blackish deposit in the liquid, and when washed, dried, and heated on charcoal before the blowpipe, arsenic will be detected by the garlic odor, and antimony by the white volatile film and metallic globules on the charcoal. Sulphur, another frequent impurity in tin, is also evolved in combination with hydrogen, as hydrogen sulphide, recognizable by its blackening a strip of paper saturated with solution of lead acetate. Copper is detected by adding to the solution of tin in hydrochloric acid, excess of ammonia water; this precipitates the stannous hydroxide while copper goes into solution and imparts to the supernatant liquor a blue color. Iron is discovered by the deep-red color with sulphocyanide of potassium, if the tin solution has been treated with aqua regia to convert the iron into chloride. If lead is present in a small quantity, it is detected by solution of sulphate of sodium, which causes an almost insoluble precipitate of sulphate of lead. If present in large quantities, chloride of lead will crystallize from solution of the impure tin in hydrochloric acid. Tin is much used in the arts, for tinning copper and iron vessels, and as a constituent of some important alloys with copper and other metals in varying proportions, *e. g.*, *bronze*, *gun-metal*, *bell-metal*, *mirror-metal*, etc. With lead it forms *solder*. In medicine tin has been used as a vermifuge, in two or three forms. Pure tin is not considered poisonous, though fats, acids, etc., which have remained for some time in tin vessels, are said to have caused colic and vomiting. The following preparations have been used.

Tin Preparations and Salts.—STANNI PULVIS, *Powder of tin*, *Granulated tin*. Prepared by triturating melted tin while it cools. The powder thus produced has been administered for the expulsion of *tape-worm* and the *lumbricoides* and has also proved beneficial in *epilepsy* produced by worms. The dose is ½ ounce, in syrup or molasses, repeated every morning before breakfast, and, after it has thus been taken for several days in succession, an active purgative should be given. *Tin filings* (*stanni limatura*) have also been used. Powder of tin should not be administered when it becomes oxidized nor when it contains other metals, notably lead. Undoubtedly tin acts both mechanically and by some inherent quality of its own. The practice, however, is a barbarous one and has justly been abandoned.

STANNI BISULPHIDUM (SnS_2), *Bisulphide of tin.*—Also known by the names of *Aurum musivum* or *Mosaic gold.* It is obtained by placing a mixture of 12 parts of tin, 7 parts of sulphur, 3 parts of mercury, and 3 parts of sal ammoniac in a black-lead crucible, which is adjusted so as to form part of a retort, and exposing the whole to a strong heat for 8 hours. A complicated reaction takes place, as the result of which the mosaic gold (SnS_2) remains. According to Pelletier it may also be prepared by heating together in a retort, a mixture of equal parts of sulphur and oxide of tin. It is in the form of light, golden-yellow scales, which are insoluble in water or alcohol, soluble in hot liquor potassæ forming a green solution of potassium stannate (K_2SnO_3) and thiostannate (K_2SnS_3). It is soluble and decomposed when boiled in nitro-hydrochloric acid, stannic chloride ($SnCl_4$) being formed, but is not acted upon by either nitric or hydrochloric acids. Its specific gravity is from 4.4 to 4.6. It forms a *bronze powder* much used in the arts, especially by the manufacturers of paper hangings. In medicine, 10 to 20 grains of the bisulphide, as a dose, mixed with honey, and repeated 2 or 3 times a day, have been used to remove *tapeworm* (P.).

STANNI BICHLORIDUM, *Chloride of tin, Stannous chloride* ($SnCl_2.2H_2O$).—Also known as *Protochloride of tin, Dichloride of tin, Salt of tin*, etc. It may be prepared by dissolving granulated tin, 1 part, in boiling hydrochloric acid (specific gravity 1.130), 4 parts, until no more action is perceptible on the metal, then evaporating the solution so that it may crystallize. The crystals have the composition $SnCl_2+2H_2O$. Their aqueous solution decomposes upon standing with formation of a white insoluble oxychloride $Sn(OH)Cl$. An excess of hydrochloric acid prevents this decomposition. Stannous chloride is a strongly reducing agent. It reduces metallic mercury from solution of mercuric chloride, as follows: $2HgCl_2+SnCl_2=2HgCl+SnCl_4$; $2HgCl+SnCl_2=2Hg+SnCl_4$. Chloride of tin has been used as a vermifuge against *tapeworm;* as an antispasmodic in *epilepsy, chorea*, and other *spasmodic diseases;* as a stimulant to paralyzed muscles in *paraplegia;* as an antidote in *poisoning by corrosive sublimate;* and as an external application in *chronic cutaneous diseases.* Internally, the dose is from $\frac{1}{16}$ grain to ½ grain, 2 or 3 times a day, in the form of pills, or taken in the spirit of hydrochloric ether. Externally, it possesses astringent, irritant, and caustic properties, and, after being absorbed, like the antimonials acts powerfully on the skin. It has been used in solution, ⅛ grain to 1 grain in a fluid ounce of distilled water. As a poison, it causes spasmodic movements of the muscles of the extremities and of the face, and sometimes paralysis; its antidotes are milk, and other albuminous substances (P.). More recently this salt has been recommended as a disinfectant in surgery.

STANNI TETRACHLORIDUM, *Tetrachloride of tin, Stannic chloride, Spiritus fumans Libavii.*—Obtained by dissolving tin in aqua regia, or by conducting chlorine gas over melted tin. A fuming liquid decomposing upon boiling. With ammonium chloride it forms a double salt, *pink salt* ($SnCl_4.2NH_4Cl$), used as a mordant in dyeing.

STAPHISAGRIA (U. S. P.)—STAPHISAGRIA.

The seed of *Delphinium Staphisagria*, Linné (*Staphisagria macrocarpa*, Spach *Nat. Ord.*—Ranunculaceæ.

COMMON NAME AND SYNONYMS: *Stavesacre; Semen staphisagriæ, Staphisagriæ semina, Staphidisagriæ, Semina pedicularis.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 4.

Botanical Source.—*Delphinium Staphisagria* is an elegant, stout, upright herb, and about the same height as the *Delphinium Consolida* (1½ to 2 feet). The stems and petioles are hispid, with long, soft hairs. The leaves are broad, palmated, petioled, and 5 to 9-cleft. The flowers are bluish-gray, in terminal, lax racemes, with hairy pedicels at least an inch long, and bracts inserted at their base. Petals 5, dirty-white, the 2 lower spatulate. Spur hardly 2 lines long. Capsules 3, large, villous, containing many globose, 3-cornered, thick, black seeds (L.).

History and Description.—The *Delphinium Staphisagria* is a native of the south of Europe, growing in waste places. The seeds are the official part. They are about the size of rye-grains, somewhat triangular, sometimes quadrangular, slightly arched, blackish-brown, and wrinkled externally, and containing a white, oily nucleus; their odor is faint, but unpleasant, and their taste acrid, bitter, pungent, and disagreeable. They yield their properties to water or alcohol (P.—T.). They are officially described as about 5 Mm. (⅕ inch) long, 3 or 4 Mm. (⅕ to ⅙ inch) broad, flattish-tetrahedral, one side convex, brown or brownish-gray, with reticulate ridges, containing a whitish, oily albumen, and a straight embryo; nearly inodorous; taste bitter and acrid"—(*U. S. P.*). The roots and flowers have also been used in medicine.

Chemical Composition.—The seeds of staphisagria contain some volatile and fatty oil, gum, etc., and several alkaloids (a total of about 1 per cent), which were discovered as early as 1819 by Brandes, and by Lassaigne and Feneulle, and given the collective name, *delphinine.* Marquis and Dragendorff (1877) isolated crystallizable *delphinine* and *delphisine*, and amorphous *delphinoidine*, all soluble in ether, and amorphous *staphisagrine*, very little soluble in ether (1 in 855). The latter base, according to Stojanow (*Amer. Jour. Pharm.*, 1890, p. 394), is a mixture of at least four alkaloids. F. B. Ahrens (*ibid.*, 1899, p. 413) obtained from the seeds a new alkaloid, *staphisagroine* ($C_{20}H_{24}NO_4$). Marquis isolated his alkaloids by extracting the bruised seeds with alcohol acidulated with tartaric acid; the alcohol is then distilled off, the residual acid-liquid shaken out with petroleum-ether, which takes up a green, fatty oil; the acid-liquid is then neutralized with sodium bicarbonate, and the solution shaken out with ether. This, upon evaporation, yields crystals of *delphinine*, mixed with *delphisine* and *delphinoidine*. From the aqueous solution which yielded these alkaloids to ether, *staphisagrin* is abstracted by means of chloroform. *Delphinine* and *delphisine* (both of the formula $C_{31}H_{49}NO_7$, Stojanow) give no color reactions with sulphuric acid, nor with Fröhde's reagent; both readily dissolve in chloroform and alcohol. *Delphinine* has an acrid and benumbing taste, and is closely related to aconitine physiologically. It is but faintly alkaline, and melts at 191° C. (375.8° F.) (Stojanow). *Delphisine* is bitter in alcoholic solution, with burning after-taste. It melts at 189° C. (390.2° F.). *Delphinoidine* is bitter, scarcely acrid, and has a narcotic action. With sulphuric acid, it produces red-brown, with Fröhde's reagent (molybdic and sulphuric acids), blood-red, turning cherry-red. It melts at 152° C. (306.6° F.). *Staphisagroine*, of Ahrens, does not give any of the above color reactions.

Fig. 234.

Delphinium Staphisagria.

Action, Medical Uses, and Dosage.—Staphisagria possesses the same properties as the *Delphinium Consolida* (see *Related Species*), but in a higher degree. In large doses, they are irritant poisons; in medicinal doses, the former is emetic, cathartic, and narcotic, but its action is too violent and uncertain for these indications. An infusion of the seeds of stavesacre may, however, be advantageously used both by the mouth and in injection, as a vermifuge. The powdered seeds, mixed with lard, have been found useful in some forms of *cutaneous disease*, and to destroy *lice* in the hair; a tincture or infusion of the bruised seeds, in vinegar, may be employed for the same object. The seeds have likewise been used in some countries to intoxicate fish.

Delphinine possesses the peculiar properties of the seed in an eminent degree. It is very poisonous, expending its force more especially upon the brain and nerves; 6 grains of it dissolved in vinegar killed a dog in 40 minutes. The symptoms are vomiting, giddiness, and convulsions. Dr. Turnbull states that pure delphinine may be given in doses of ½ grain, to the extent of 3 or 4 grains a day, without any unpleasant results. It sometimes purges, mostly promotes diuresis, and occasions feelings of heat and tingling in various parts of the body. If used at all, it should be with excessive caution. Externally, it has been successfully used in *neuralgia*, *earache*, *rheumatism*, and *paralysis*. It is applied by friction over the part in the form of ointment or alcoholic solution, in proportions varying from 10 to 30 grains of delphinine to 1 ounce of the vehicle, and the friction should be continued until some redness and burning are produced. Its local action much resembles that of veratrine. Later investigators do not seem to agree as to the action of delphinine, some contending that it acts but little on the periphereal nerves, but chiefly upon the circulation and respiration, and that in poisoning by it, artificial respiration may avert fatal effects; on the other hand, it has been contended that it acts chiefly as an analgesic, though its asphyxiating properties are admitted. Staphisagrine is less energetic than delphinine, does not induce convulsions, depress the pulse, nor affect the cerebrum, but, like the latter, it kills by asphyxiation. Undoubtedly, the action of the combined alkaloids of staphisagria closely resembles that of aconitine (Kobert).

Staphisagria is chiefly employed for its effects upon the genito-urinal apparatus of both the male and female, though its action upon the nervous system is peculiar and pronounced. The latter is best exhibited in *hysteria* and *hypochondriasis*, with depression of spirits, despondence, moroseness, and "violent outbursts of passion" (Scudder). It is a remedy for *chronic inflammation and atony of the renal and reproductive organs*, though its use is contraindicated in active inflammatory conditions. Prof. J. M. Scudder, M. D., considered staphisagria almost, if not quite, a specific in controlling *irritation of the urino-genital apparatus*, as in *prostatorrhœa*, resulting from masturbation; in *chronic irritation of the neck of the bladder*, especially when the result of *gonorrhœa* or *cold*, and associated with temporary *enlargement or irritation of the prostate;* in *chordee;* and in *gonorrhœal prostatitis*. He has also found it useful in *uterine affections*, attended with deep-seated soreness, dragging, bearing-down pain, painful or scalding micturition, and *leucorrhœa;* in *gonorrhœa*, in *amenorrhœa*, in *mental irritability and restlessness* attending painful or exhausting diseases, in *hysteria* and *hypochondria*, and in *prolapsus uteri*, where there are evidences of feeble circulation in the reproductive organs. He gave a teaspoonful, 3 or 4 times a day, of a mixture of 1 fluid drachm of specific staphisagria in 4 fluid ounces of water. Staphisagria, in therapeutical doses, appears to be a permanent stimulant, somewhat resembling nux vomica, increasing innervation, stimulating free circulation, improving the appetite and digestion, giving tone to the sexual organs, and removing morbid mental depression. I have found it decidedly useful in *chronic irritable states of the bladder* (J. King). It gives marked relief in that form of *urinal incontinence* in old men, with vesical and prostatic irritation and frequent teasing or urgent desire to micturate. *Irritability of the vesiculæ seminales and the prostatic ducts* is relieved by it. *Catarrh of the bladder* is often cured with it. In *menstrual disorders*, it is indicated when the intermenstrual periods are prolonged, and the flow continues too long when established. It lessens *sea-sickness* and the *vomiting of pregnancy*. As a rule, it is not a curative agent in *spermatorrhœa*, but does good work when the parts are irritable and the patient is nervous and anemic. Here it is contraindicated by plethora. *Facial and cervical neuralgia* are often relieved by staphisagria, and it is of some service in *ophthalmic affections*, evidenced particularly by itching and irritation. For this purpose, it has been used successfully in *ophthalmia*, *amaurosis*, and in *scrofulous affections of the eyes*, with glutinous secretions. Staphisagria may be administered when, in reading, black spots appear before the eyes (Locke). The dose of specific staphisagria (the preparation is most employed) is from 1 to 5 drops, the fractional doses being generally preferred. Delphinine may be given in doses of from $\frac{1}{60}$ to $\frac{1}{10}$ grain; tincture of staphisagria, 1 to 20 drops.

Specific Indications and Uses.—Irritation and chronic inflammatory conditions of the genito-urinal tract; painful, scalding micturition; prostatorrhœa; urinal incontinence of aged men; urethral irritation, with a sensation of incomplete urethral evacuation—a sensation as if a drop of urine were rolling along in the canal; menstrual derangements, with long intermenstrual intervals, and prolonged flow; spermatorrhœa in anemic subjects; depression of spirits; hypochondriasis; hysteria, with uterine or ovarian irritation, despondence, moroseness, and violent outbursts of passion; black specks before the eyes in reading; mental irritability and restlessness in painful and exhaustive diseases; uterine disorders, with feeble pelvic circulation, deep-seated soreness, dragging, and bearing-down pains; leucorrhœa; and painful urination. Contraindicated by active inflammation.

Related Species.—*Delphinium Consolida*, Linné, variously known as *Larkspur*, *Knight's spur*, and *Lark's claw*. Delphinium Consolida is an annual herb, with a simple, slender root, and a suberect, leafy stem, from 1½ to 2 feet high, with alternate spreading branches. Leaves sessile, in many deep divisions, which are 3-cleft, subdivided into narrow, linear, acute segments. Flowers bright-blue or purple, in terminal, lax, few-flowered racemes; bracts single or divided, longer than the pedicels. Corolla monopetalous; two spurs combined in one. Carpels solitary, smooth, follicular; seeds numerous, dark-brown or black, angular, very rough (L.). Delphinium Consolida is a native of Europe, and has become naturalized in the United States, growing in woods and fields, and flowering in June and July. The flowers of the wild plant are blue; of the cultivated, blue, red, or white. The whole plant contains an acrid principle, more abundant in the seeds. The seeds furnish considerable oil, and a blue pigment is obtained from the flowers, which is rendered permanent by alum. Diluted alcohol is its best solvent. The root, as well as the leaves (*herba*), flowers (*flores*), and seeds (*semen consolidæ*, *consolidæ regalis*, and *consolidæ calcatrippæ*), have at various times been used in medicine. As "*Delphinium*," the seeds were official in the *U. S. P.* of 1870. The seeds of the D. Consolida contain volatile oil, fixed oil, gum, resin, gallic acid, etc. (T. C. Hopkins, *Amer. Jour. Pharm.*, 1839, pp. 1–8), and an alkaloid, *calcatripine*. This resinous body, soluble in alcohol, chloroform, and ether, was isolated from the dried herb by E. Masing, in 1883. It exists in small amount (0.02 per cent), and, under the influence of chemical agents, readily decomposes. W. Wicke (*Amer. Jour. Pharm.*, 1855, p. 152), obtained *aconitic acid* ($C_6H_6O_6$) from D. Consolida. The flowers of D. Consolida are considered diuretic, emmenagogue, and vermifuge. They were formerly used as a local application to *wounds*, and the decoction was recommended as efficient in some *ophthalmic affections*. The seeds possess similar properties with those of the D. Staphisagria, but less energetic. A tincture of them has been recommended in *calculus*, as a vermifuge, and to destroy *lice* in the hair. It has also been found useful in *spasmodic asthma* and *dropsy*. It is made by adding 2 ounces of the seed to a quart of diluted alcohol, of which 10 drops may be given 3 times a day, gradually increasing the quantity until the system is influenced by it. The root possesses similar virtues, but is seldom employed. A drachm or 2 of the flowers of D. Consolida, placed in 1 pint of hot water, and slowly simmered down to ½ pint, then strained and sweetened, is said to be an excellent remedy for *cholera morbus*, to be administered in teacupful doses, at short intervals, until relief is obtained. As an antiemetic in the *vomiting of autumnal fevers* and other diseases, this plant is highly extolled, calming the stomach speedily, and giving a delightful relief; it is used in infusion, made similar to the above, by adding ½ ounce of the leaves and flowers to ½ pint of boiling water. The dose is a wineglassful, to be repeated every ½ hour or oftener, if necessary. This plant undoubtedly deserves further investigation. The seeds of the D. Consolida, in tincture, have been found to possess similar properties to the D. Staphisagria, but in a lesser degree. An infusion of the flowers has been found useful in *dysentery*.

Delphinium Ajacis, Linné, of south Europe, and the indigenous species, *Delphinium azureum*, Michaux, of central United States, and *Delphinium exaltatum*, Aiton, of the middle states, seem to possess properties similar to those of *Delphinium Consolida*.

Aquilegia vulgaris, Columbine.—A well-known perennial, native of Europe, all parts of which are medicinal. It has antiscorbutic, diuretic, and diaphoretic properties, and was formerly employed in *scurvy* and *jaundice*. It undoubtedly possesses active properties. Linnæus states that children have been killed by overdoses of the plant. According to Jorissen (*Jahresb. der Pharm.*, 1885, p. 16), the plant, upon distillation with water, yields hydrocyanic acid.

STATICE.—MARSH ROSEMARY.

The root of *Statice caroliniana*, Walter (*Statice Limonium*, Linné, var. *caroliniana*, Gray).

Nat. Ord.—Plumbaginaceæ.

COMMON NAMES: *Marsh rosemary*, *Inkroot*, *Sea-lavender.*

Botanical Source.—*Statice caroliniana* is a perennial maritime plant, indigenous, having a large, fleshy, fusiform, or branched, brownish-red root, from which arises, annually, a scape and leaves. The leaves are radical, petiolate, cuneiform, or narrow obovate, smooth, veinless, obtuse, mucronated, level and flat on the margin. The scapes are round, smooth, slightly scaly, flexuose, terminated by a panicle of numerous branches, which bear the flowers on the upper side only. Flowers pale bluish-purple, alternate, erect, mostly in pairs, but appearing singly in consequence of one expanding before the other. The peduncles are short, forked, and concealed by several sheathing scales. Calyx funnel-shaped, scarious and pink at the edge, 5-angled, the angles ciliate, ending in long acute teeth, with sometimes, not always, minute intermediate teeth. Petals 5, spatulate, obtuse, and longer than the calyx. Stamens 5, inserted in the claws of the petals; anthers heart-shaped. The ovary is superior, small, obovate, with 5 ascending styles, shorter than the stamens. Fruit an oblong, utricle, 1-seeded, and inclosed in the calyx (L.).

History and Description.—The resemblance which this plant bears to the foreign *Statice Limonium* is such as to have induced many botanists to rank it as a variety. They will be found to differ, however, in the American species having smaller flowers, and flat, somewhat wedge-shaped leaves, while the leaves of the

S. Limonium are oblong and wavy at the margins. Probably these slight differences are sufficient to require a distinct position, and the position given it by Gray (var. *caroliniana*) is sufficiently warranted to give it the name *Statice Limonium*, var. *caroliniana*. Marsh rosemary is common in the salt-marshes on the Atlantic shore of the United States, bearing flowers from August to October. The part used is the root, which is rather large and heavy, inodorous, but having a saltish, amarous, and strongly astringent taste. Alcohol or water takes up its properties, especially when hot or boiling.

Chemical Composition.—Mr. E. Parrish, who analyzed it, found it to consist of about 12 per cent of tannic acid, volatile oil, resin, gum, albumen, caoutchouc, extractive, coloring matter, woody fiber, and several salts (*Amer. Jour. Pharm.*, 1842, p. 116).

Action, Medical Uses, and Dosage.—Marsh rosemary is a strong astringent, and has long been used, in the form of infusion or decoction, as a domestic remedy in *diarrhœa, chronic dysentery*, etc. It is not indicated in the acute stages of these affections, but will be found very efficient as an astringent and tonic, after the active symptoms have subsided. It also relieves irritation of the mucous membranes. It is an efficient remedy in *atonic dyspepsia, pulmonary hemorrhage, chronic laryngitis, bronchorrhœa*, and other *catarrhal disorders*, with profuse secretion. The decoction is very useful as a gargle or wash in *ulcerations of the mouth and throat, scarlatina anginosa*, etc. Externally, the powdered root may be applied to *old ulcers*, or made into an ointment, as a soothing application for *piles*. The decoction is likewise very useful as an injection in *chronic gonorrhœa, gleet, leucorrhœa, prolapsus ani and uteri*, and in some *ophthalmic affections*. It may be used in all cases where astringents are indicated. A tincture of the fresh root (℥viii to alcohol, 98 per cent, Oj) may be given in doses of from 1 to 20 drops. The decoction (℥i to aqua Oj), in doses of from ½ to 1 fluid ounce.

Related Species.—*Statice Limonium*, Linné (see above), of Europe, is possessed of the same powers, but in a less degree. The infusion may be given in doses of from ½ to 2 fluid ounces, every 2, 3, or 4 hours.

Statice mucronata, Linné.—Morocco. Natives employ the root, called *safrifa*, as a nervine.

Statice latifolia, Smith.—Russia and Spain. Root employed in tanning leather. Has properties similar to Marsh rosemary.

Statice speciosa, Linné.—Siberia. Used like Marsh rosemary.

Statice braziliensis, Buaycura, Baycuru, Biacura, or *Guaycura*.—Brazil. Contains tannin (12.15 per cent), volatile oil (trace), acrid, sharp resin, and an alkaloid, *baycurine*, crystallizing in white, feathery needles, isolated by F. A. Dalpe, in 1884 (*Amer. Jour. Pharm.*, 1884, p. 361). Baycura is used in Brazil as an astringent and discutient for *glandular and other enlargements*.

Plumbago europæa, Leadwort, Dentellaria.—A European, herbaceous perennial, the root of which yielded Dulong an acrid, yellow, crystallizable body, *plumbagin*. The plant, and especially the root, when chewed, is extremely acrid, and acts as a decided sialagogue. *Toothache* is said to be relieved by masticating the root, and a decoction of the latter, in olive oil, has been lauded as a remedy for *scabies* and *old ulcers*. Some claim that this plant is almost inert; others that it is destructive topically, and, internally, a dangerous emetic, producing severe gastro-intestinal complications. These differences are probably due to the condition in which the plant is used. According to Sauvage-Delacroix, a young woman rubbed with the root, stated that she felt as if she had been flayed alive (Hogg).

Armeria vulgaris (*Nat. Ord.*—Plumbaginacæ), *Maiden pink*.—Europe. This is reputed a good diuretic.

STELLARIA.—CHICKWEED.

The plant *Stellaria media*, Smith (*Alsine media*, Linné).

Nat. Ord.—Caryophyllaceæ.

Common Names: *Chickweed, Star chickweed.*

Botanical Source.—This plant is the *Alsine media* of Linnæus. It is an annual or biennial weed, 6 to 15 inches in length, with prostrate, branched, brittle, round, jointed, and leafy stems, distinguished by the alternate, lateral, hairy lines, extending from joint to joint. The leaves are ovate, ovate-cordate, and glabrous; the lower on hairy petioles. Flowers small, white, in forked cymes; petals 2-parted, shorter than the calyx. Stamens varying, 3, 5, or 10 (W.—G.).

History.—This is a common plant throughout the United States, growing in fields and around dwellings, in moist, shady places, probably introduced from

Europe. It flowers from the beginning of spring to the end of autumn. The seeds are eaten by poultry and birds. The whole herb is used, when recent.

Action, Medical Uses, and Dosage.—Chickweed appears to be a cooling demulcent. I have seen the fresh leaves bruised and applied as a poultice to indolent, intractable *ulcers* on the leg, of many years' standing, with the most decided and immediately beneficial results; to be changed 2 or 3 times a day. In *acute ophthalmia*, the bruised leaves will likewise be found a valuable application. An ointment, made by bruising the recent leaves in fresh lard, may be used as a cooling application to *erysipelatous and other forms of ulceration*, as well as in many forms of *cutaneous disease* (J. King). A tincture of Stellaria media has been extolled in some quarters as a remedy for *rheumatic pains* of a fugitive and shifting character.

STICTA.—STICTA.

The lichen, *Sticta Pulmonaria*, Linné (*Lobaria Pulmonaria*, *Pulmonaria reticulata*, *Lichen pulmonarius*).

Nat. Ord.—Lichenes.

COMMON NAMES: *Lungwort lichen*, *Lungmoss*, *Tree lungwort*, *Oak lungwort*.

Botanical Source and History.—This lichen grows upon tree trunks, and is leafy, laciniated, smooth, and obtuse; green on the upper surface, pitted, and somewhat reticulated. On the under surface it is downy. The shields are mostly marginal. The whole lichen is somewhat coriaceous and cartilaginous. This lichen is found upon the trunks of large trees and upon rocks in England and in this country, especially in New England, New York, Pennsylvania, and the Carolinas, being found mostly in mountainous districts. The *Homœopathic Pharmacopœia* directs a tincture of that growing upon *Acer saccharinum*, or Sugar maple. The drug used is imported from Europe, none of consequence being collected in this country. Sticta makes a dark-brown colored tincture. According to Knop and Schnedermann (1847), the bitter principle contained in this lichen is *stictic acid*, allied to cetraric acid from Iceland moss.

Action, Medical Uses, and Dosage.—Sticta is a remedy for *pain* and *cough*. It acts upon the base of the brain and the vagus, and parts supplied by that nerve, relieving irritation. When its specific indications are followed it proves a very important remedy, and it is one that is frequently neglected. "Pain in shoulders, back of the neck, and extending to the occiput," were the indications long ago pointed out by Prof. Scudder with whom the remedy was a favorite. Atonic troubles are those in which it does the best work. With the above-named guides to its selection it will be found useful to reduce elevated temperature, due to irritation, and when pain and cough are due to irritation of the vagus they are controlled by it. "Cough, associated with pain in the shoulders or in the extrinsic respiratory muscles," is also relieved by sticta. The sticta pulse is soft but has a peculiar wiry thrill. With such a pulse it will have a good effect in disturbed heart-action. Sticta is a remedy for *rheumatism*, when in the shoulders or chest walls, or in the smaller joints, being in all cases associated with cervical and occipital pain. It is a good remedy for *muscular pain* in the regions mentioned when accompanying *catarrhal fever* and *epidemic influenza*. By far the most general employment of sticta is in *irritative coughs* whether acute or chronic. With the cough there are, besides the cervical and occipital pain, dull pains in the chest, increased upon taking a deep breath, and a sense of soreness like that from a bruise or muscular over-exertion. When such irritation and cough is present it will sometimes check *chills*, *hectic fever*, and *night-sweats* in confirmed *phthisis* (Scudder). Prof. Webster confines its action in cough to the upper tracheal region. The sticta cough is wheezing, rasping, dry, and persistent, and comes on mostly, according to Webster, during the dusty months of July and August. He finds it particularly valuable in *hay fever* and *summer influenza* with the point of irritation in the upper part of the trachea. Others have found it of special value in the irritating, persistent, and exhaustive cough of *phthisis*, *bronchitis*, *laryngitis*, and in *whooping-cough*, *croupal cough*, and *catarrhal asthma*. Ellingwood speaks of its value in sharp hacking cough, especially that occurring in the early part of the year and in wheezing, tight cough, with sharp quick pain in the respiratory tract. Sticta is also useful in chronic *nasal catarrh* with reflex irritation, and stands conspicuous as a remedy for *la grippe*, with free nasal discharge of hot, watery mucus, subsequently becoming thick, yellow, greenish, or bloody. Sticta has cured *sick headache* when the characteristic indications were present, and Dr. Scudder used it with success in *scarlet fever*, with occipital pain. The dose of specific sticta is from a fraction of a drop to 10 drops; of the powder (seldom employed), 1 to 10 grains.

Specific Indications and Uses.—"Pain in the shoulders, back of neck, and extending to the occiput." Soreness and dull pain in chest or extrinsic respiratory muscles, increasing by a deep breath; irritation of base of brain and parts supplied by the pneumogastric nerve; irritative cough; cough persistent, dry, rasping, wheezing, or short, hacking, with quick darting pains in chest-walls; rheumatism involving the muscles and smaller joints; hay-fever with headache; catarrhal disorders with frontal tension, sneezing, coryza, and conjunctivitis.

STILLINGIA (U. S. P.)—STILLINGIA.

The root of *Stillingia sylvatica*, Linné (*Sapium sylvaticum*, Torrey).

Nat. Ord.—Euphorbiaceæ.

Common Names: *Queen's delight, Queen's root, Silver leaf, Yaw root.*

Illustration: Bentley and Trimen, *Med. Plants*, 241.

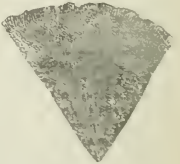
Botanical Source.—This plant was named in honor of Dr. Benjamin Stillingfleet. It is a perennial herb, with a glabrous somewhat angled stem, which, upon being broken, gives out a milky sap, and which attains the height of 2 to 4 feet. The leaves are sessile, lance-oblong, tapering at the base, serrulate, and somewhat leathery. The flowers are yellow, on a terminal spike; the male flowers with a hemispherical involucre, many-flowered or wanting, perianth tubular, erose, florets scarcely longer than the bracteal scales; stamens 2 or 3, and exserted. Female flowers with an inferior, 1-flowered calyx; style 3-cleft; capsule 3-grained (Eaton—Wi.).

Fig. 235.

Stillingia sylvatica.

History and Description.—This plant is found growing in sandy soils from Maryland to the Gulf of Mexico, and in Mississippi and Louisiana, flowering from April to July. A whitish acrid juice exudes from the plant when cut or broken. It is much more active in its recent state, than when dried, and loses much of its medicinal virtue by age. The root is the part used. As officially described, it is "about 30 Cm. (12 inches) long and nearly 5 Cm. (2 inches) thick, subcylindrical, slightly branched, compact, wrinkled, tough, grayish-brown, breaking with a fibrous fracture, showing a thick bark and porous wood, the inner bark and medullary rays having numerous yellowish-brown resin-cells; odor peculiar and unpleasant; taste bitter, acrid, and pungent"—(*U. S. P.*). Alcohol or water extracts its virtues, but its best solvent is diluted alcohol.

Fig. 236.



Section of Stillingia.

Chemical Composition.—The root of Stillingia sylvatica contains tannin (11.6 per cent), gum, starch, volatile oil (3.25 per cent) of a strong, disagreeable odor, an acrid oil soluble in ether, an acid resin, and leaves (5 per cent) of ash (see Wm. Bichy, *Amer. Jour. Pharm.*, 1885, p. 528, and J. H. Harmanson, *ibid.*, 1882, p. 386). According to Bichy, an alkaloid, *stillingine*, is present, but this is doubted by E. G. Eberhardt (Lilly's *Bulletin*, No. 17, Nov., 1891). For so-called oil of stillingia, see *Related Species and Derivatives.*)

Action, Medical Uses, and Dosage.—In large doses, stillingia vomits and purges, producing in many instances a peculiar, disagreeable burning sensation in the stomach, or some portion of the alimentary canal, accompanied with more or less prostration of the system. In less doses it is an alterative, exerting an influence over the secretory and lymphatic functions, which is unsurpassed by few, if any other of the known alteratives. It must, however, be fresh or recent material to be of any therapeutic value, and undoubtedly many of the failures to obtain good results in the use of stillingia are due to the fact that preparations from old and worthless material have been employed. It is an American remedy of much importance and value, and is extensively used in all the various forms of *primary* and *secondary syphilitic affections*, in which it appears to have a most decided action; also in *scrofulous*, *hepatic* and *cutaneous affections*, in which its administration is followed by the most successful results (J. King). In regard to its effects upon *syphilis* there appears to be much discordance of opinion among physicians, and this is probably due to the fact that in earlier years it was undoubtedly much overrated, that poor preparations have been employed and that the special conditions favoring its action have not been properly observed. When the specific indications for the drug have been followed the results have been fully as good as have been obtained from any of the antisyphilitics. The cases for its exhibition in syphilitic and other affections are these in which the tissues are feeble and are tardily removed and renewed; the mucous membranes are predominantly affected and the skin secondarily; and the mucous surfaces are tumid, red, and glistening, and secretion is scanty. With these indications it has been very successfully used in *syphilitic* and *strumous diseases*, and *chronic inflammations with low deposits*. It has been found very beneficial in *chronic laryngeal* and *bronchial affections*, and in *leucorrhœa*. Small pieces of the recent root, chewed occasionally through the day, have effectually and permanently cured *laryngitis* and *bronchitis*. In fact stillingia is one of the most important of laryngeal remedies, not only relieving irritation of that important organ, but proving beneficial in irritative disorders of the fauces, trachea, and bronchiæ. It is, therefore, an important *cough* remedy, and we have observed the irritative *winter-cough* of years' standing promptly cured with small doses of specific stillingia. A strumous diathesis adds to its adaptability to *chronic coughs*. This remedy exerts some influence upon the periosteal structures and is applicable to the periosteal pains in old cases of syphilis with tendency to periosteal destruction and the formation of nodes and exostoses, as of the tibia, head, and face. It is likewise said to favorably influence the persistent pains of *chronic periosteal rheumatism*. Stillingia is a very important remedy, and by improving the lymphatic functions aids in good blood-making and nutrition, and may be taken without harm for a continued period. It is very important, however, that the proper preparations be used. As before stated the root, when long kept, has its active properties impaired; as a rule, syrups and decoctions are of less value than the alcoholic preparations of the fresh drug, as the properties are but imperfectly extracted by water. The stronger alcoholic preparations (as a strong tincture), the fluid extract (which may be given with aromatics, as oil of anise or caraway), and especially specific stillingia, are far preferable to other forms of administration (see *Stillingia Liniment*). The oil is entirely too acrid for internal use, unless it be well incorporated with some mucilaginous or saccharine substance. But as an external stimulating application, the oil will be found very valuable in many instances. One drop of it placed upon the tongue, and repeated 3 or 4 times a day, is reputed to have proved successful in cases of severe *croup*. Stillingia liniment, both externally and internally, is an excellent remedy in various forms of croup. Dose of the tincture from ½ fluid drachm to 1 fluid drachm; of the decoction, 1 or 2 fluid ounces; of specific stillingia, 1 to 20 drops.

Specific Indications and Uses.—Feeble tissues, with tardy removal of broken-down material, and slow renewal of the parts; mucous membranes, tumid, red, and glistening, with scanty secretion; skin affections, with irritation and ichorous discharge; laryngeal irritation, with paroxysmal, hoarse, croupous cough; irritation of the superior pharynx just behind the fauces, with cough; winter-cough of irritation; periosteal pain and tendency to form nodes; an important remedy in struma and syphilitic affections.

Related Species and Derivatives.—*Stillingia sebifera*, Michaux (*Sapium sebifera*, Roxburgh; *Croton sebifera*, Linné; *Excæcaria sebifera*, Müller). A Chinese tree, also cultivated in the tropics. The seeds are imbedded in a vegetable fat known as *Chinese tallow*, which is obtained by expressing the bruised fruits previously freed from the kernels. It is solid, without odor, fuses at 44.5° C. (112° F.) and contains a small portion of stearin, but is made up mostly of palmitin. An oil is also yielded by the seeds (see *Pharm. Jour. Trans.*, Vol. XXI, 1891, p. 943).

Oil of Stillingia is a concentrated alcoholic preparation made by percolating the powdered root with full strength alcohol and evaporating the percolate to a creamy consistence. It has a dark-red color, a slight odor, the taste of the drug, and leaves an acrid sensation in the throat and fauces which is persistent in effect. This preparation is prone to gelatinize and precipitate. Often it changes to a brown mush and should then be thrown away as useless. Stillingia yields a colorless fixed oil to proper solvents, which, however, does not carry the medicinal value of the drug. (For remarks by Prof. King and Wm. Saunders concerning this and other similar preparations, see previous editions of this *Dispensatory*.)

STRAMONIUM.—STRAMONIUM.

The seeds and leaves of *Datura Stramonium*, Linné.

Nat. Ord.—Solanaceæ.

Common Names: *Thorn-apple*, *Jamestown-weed*, *Jimpson* or *Jimson-weed*, *Stinkweed*, *Apple of Peru*, etc.

Illustration: Bentley and Trimen, *Med. Plants*, 192.

Fig. 237.

Datura Stramonium.

Botanical Source.—This plant is a bushy, smooth, fetid, annual plant, 2 or 3 feet in height, and in rich soil even more. The root is rather large, of a whitish color, giving off many fibers. The stem is much branched, forked, spreading, leafy, and of a yellowish-green color. The leaves are from the forks of the stem, large, ovate, smooth, unequal at the base, variously and acutely sinuated and toothed, veiny, dark-green above, and paler beneath. The flowers are large, axillary, erect, white, and about 3 inches long. Corolla funnel-shaped, regular, angular, plaited, with 5 mucronate lobes. Calyx oblong, 5-angled, 5-toothed, dropping off from its base by a circular, horizontal incision, which remains permanently at the base of the ovary. Stamens 5; anthers erect and oblong; style filiform; stigma thick, obtuse, and bilobed. Ovary free, oval, hairy, and 4-celled. The fruit is a large, dry, prickly capsule, ovate, half 4-celled, with 4 valves, and numerous black, reniform seeds, attached to a longitudinal receptacle, which occupies the center of each cell (L.).

Datura Tatula, or *Purple stramonium*, differs from the above, in having its stem purplish, or dark-red, and with minute green punctations, and its flowers of a dull deep-purple at the angles, and purple stripes inside.

Fig. 238.

Capsule and seed of Datura Stramonium.

History and Description.—Stramonium is a well-known poisonous weed, growing in all parts of the United States, along roadsides, waste grounds, etc., and flowering from July to September. Its native country is unknown. It is found growing in Asia, Europe, Canada, Mexico, and Peru. The whole plant has an unpleasant, fetid, narcotic odor, which diminishes upon drying. Almost every part of the plant is possessed of medicinal properties, but the officinal parts are the leaves and seeds. The leaves should be gathered when the flowers are full blown, and carefully dried in the shade. They have a rank odor when fresh, especially when bruised, which is lost on drying, and a mawkish, amarous, nauseous taste. They impart their properties to water, alcohol, and the fixed oils. Water distilled from them slightly possesses their odor, but does not contain their active properties. The seeds, when bruised, emit the peculiar heavy odor of the herb. They should be gathered when ripe. Spirit, water, and fixed oils take up their active properties Stramonium leaves and seeds are thus officially described:

I. STRAMONII FOLIA (*U. S. P.*), *Stramonium leaves.*—"About 15 Cm. (6 inches) long, petiolate, dark-green, smooth, ovate, pointed, unequal, especially at the base, coarsely and sinuately toothed; thin, brittle, and nearly inodorous; taste unpleasant, bitter, and nauseous"—(*U. S. P.*). (See comparison of microscopical structure of stramonium, belladonna, and henbane leaves, by J. O. Schlotterbeck and A. Van Zwaluwenburg, in *Proc. Amer. Pharm. Assoc.*, 1897, p. 202.)

II. STRAMONII SEMEN (*U. S. P.*), *Stramonium seed.*—"About 4 Mm. ($\frac{1}{6}$ inch) long, reniform, flattened, pitted, and wrinkled; testa dull brownish-black, hard, inclosing a cylindrical, curved embryo, imbedded in a whitish, oily perisperm; of an unpleasant odor when bruised, and of an oily and bitter taste"—(*U. S. P.*).

Chemical Composition.—The seeds of Datura Stramonium contain the alkaloid *daturine*, said to be combined with malic acid (Brandes, 1821). It was first obtained pure and crystallized by Geiger and Hesse, in 1833, who also found it to occur in the leaves and the herb. It is now known to be a mixture of several alkaloids. Von Planta (1850) pronounced daturine to be identical with *atropine*, the principal belladonna alkaloid. Ladenburg (*Amer. Jour. Pharm.*, 1880, p. 368) differentiated daturine into atropine and *hyoscyamine*, the latter alkaloid predominating. E. Schmidt, however, contended that atropine predominates (*ibid.*, 1884, p. 440). It is accepted that *hyoscyamine* is the principal datura alkaloid; other alkaloidal constituents being *atropine* and *hyoscine*. (For the chemistry of these alkaloids, see *Atropina*, *Hyoscyamus*, and *Belladonna*.) The seeds of Datura Stramonium contain fatty oil (25 per cent), from which a new fatty acid, *daturic acid* ($C_{17}H_{34}O_2$), was isolated by Gérard (*Amer. Jour. Pharm.*, 1890, p. 493). It stands intermediate between palmitic and stearic acids. *Stramonin* is an indifferent, crystallizable, tasteless body, obtained from the seeds by Trommsdorff. As to the quantity of total alkaloids in various parts of the plant, Dr. A. R. L. Dohme (*ibid.*, 1893, p. 482) concludes that the stems contain more alkaloid (0.3 to 0.4 per cent, volumetrically) than even the seeds (0.25 to 0.29 per cent), and the latter more alkaloid than the leaves (0.21 to 0.23 per cent, and 0.27 per cent for green leaves), etc. Herb gathered in July and August contained more alkaloid than that collected in June (*ibid.*, 1894, p. 503, from *Proc. Amer. Pharm. Assoc.*). J. B. Nagelvoort (1897) finds the flowers of *Datura alba*, Linné, to contain a notable quantity of total alkaloids.

Action, Medical Uses, and Dosage.—In large doses, stramonium is an energetic, narcotic poison, producing dryness of the throat, thirst, nausea, giddiness, nervous agitation, dilatation of the pupil, obscurity of vision, headache, disturbance of the cerebral functions, perspiration, occasional relaxation of the bowels, and, in some cases diuresis (P.). When about to prove fatal, maniacal delirium, loss of voice, dryness of throat, etc., are usually present. In fact, the physiological action of stramonium is practically the same as that of belladonna, though it is thought to influence the sympathetic more strongly, to occasion irregular heart-action, and induce greater delirium. Full doses of it are said to increase the sexual appetite and power. Daturine, though chemically similar to atropine, produces a more profound effect, both as a mydriatic and in other ways, and is more liable to produce depression, heart failure, and unconsciousness. (For further consideration of the effects of stramonium and daturine, see *Belladonna* and *Atropinæ Sulphas*.)

Daturine is seldom employed in medicine. It is a very energetic poison, $\frac{1}{8}$ grain having killed a sparrow in 3 hours, and nearly proved fatal to a cat, when applied to the eye. Very minute quantities applied to the eye occasion protracted and excessive dilatation of the pupil. In cases of poisoning by stramonium and its alkaloid, the best mode of obtaining relief is to evacuate the stomach by emetics or the stomach-pump, after which vinegar and water may be used, with mucilaginous drinks, at a later period, and strong coffee, tea, and other stimulating drinks, if there is much prostration. The physiological antidote is opium (or morphine) its employment being guided by the degree of pupillary contraction produced. Electricity and pilocarpine may also be useful. According to Garrod, caustic alkalies, but not their carbonates, destroy the active principle of stramonium

Datura fatuosa is employed in India by a brotherhood of thieves and murderers—the *Daturiahs*, successors of the *Thugs*, or *Phansigars*, who formerly waylaid and strangled their victims. The powdered seeds are mixed with flour and given with food.

In medicinal doses, stramonium acts as an anodyne antispasmodic, without causing constipation, and will prove serviceable in cases where opium can not be given. It does not readily produce sleep, but if sleep follows, it is generally due to the alleviation of pain or nervous irritability produced by the drug. Belladonna has proved serviceable in *gastritis* and *enteritis*, and may likewise be used to allay *neuralgic pains*. It is very remarkable that a plant so closely allied to belladonna in physiological action, should be so different in some of its therapeutical effects, and particularly in regard to pain. For deep-seated pain, as of *neuralgia*, etc., it is far less effective than belladonna, but for *superficial neuralgia*, when locally applied, it is more effective than that drug. It well illustrates the fallacy of prescribing remedies for certain effects, because of known physiological action of a drug—the therapeutical effects often being widely at variance. Again, it is more effective in *mental disorders* than is belladonna. Besides, while daturine, in some respects, exceeds atropine in power, in many respects it does not in the least accomplish the therapeutical results of the latter. Stramonium, in combination with quinine, forms an invaluable preparation which has been found beneficial in *intermittent fever*, *periodic pains*, *headache*, *dysmenorrhœa*, *delirium tremens*, etc. It is said that the seeds exert an influence to prevent abortion.

While less effective than belladonna for the relief of pain, it may be employed in *neuralgic dysmenorrhœa*, with nervous irritation, *tic-douloureux*, *spasmodic intestinal pain*, *sciatica*, *rheumatism*, and *syphilitic pain*. It is a minor remedy for some forms of *epilepsy*. It has been lauded for *vertigo* and *headache*, from disordered conditions of the stomach produced by hyperacidity, and is also endorsed for *muscular tremblings* of the hands of functional or reflex origin, and associated with great restlessness. When *gastric headache* is accompanied with marked nervous erethism and unsteadiness, its action is specific.

Stramonium is a remedy of value in troubles resulting from *cerebral irritation*, in abdominal derangements, when due to irritation of the sympathetic. It has long borne a reputation as a remedy for *acute delirium*, and in *acute mania*, the patient being violent, boisterous, angry, and possessed of a destructive tendency. Such delirium may occur as a grave symptom in inflammatory and febrile diseases, particularly in *zymotic diseases*. The dose here ranges from a fraction of a drop to 4 drops of specific stramonium. In regard to its action in maniacal excitement and other nervous disorders, Dr. Scudder (*Spec. Med.*, p. 251) says: "It may be given in acute diseases when the patient is *furiously delirious;* in *delirium tremens*, when the patient is enraged and inclined to injure those present, destroy furniture, or harm himself; in *violent mania;* in *epilepsy*, associated with or followed by maniacal excitement. In chronic disease, it is enough that the patient feels inclined to violent outbursts of passion, and has difficulty in restraining himself." It is often a remedy of value in *hysterical mania*, with convulsions, and alternate laughing and weeping, and for *globus hystericus*. With these conditions, there is usually headache, flushed face, and sexual irritation (Locke). Prof. Locke speaks of it as a good remedy in some forms of *paralysis* following convulsions, strong injections, or shock, or due to suppressed eruptions. Bloating and redness of the face indicate it. For *retrocession of the eruptions* in the *exanthemata*, it is of considerable value, though less efficient than belladonna. As an antidote to the *opium habit*, stramonium may be given as follows: ℞ Specific stramonium, ℥ss; tincture of cardamom, ℥iijss. Mix. Sig. Begin with 10-drop doses and increase as may be necessary (Locke). Stramonium is indicated in *cough*, with constriction and difficult deglutition and impaired innervation. It gives temporary relief in purely *spasmodic asthma*, but usually fails when dyspnœa or asthmatic breathing are due to pulmonary or cardiac diseases. As a remedy for asthma, it was introduced into England, in 1802, by General Gent, who brought the custom from India, where the smoking of datura, under the name *gharbhah* ("forgetfulness of home"), was common. It soon became very fashionable for individuals having difficult breathing to smoke gharbhah. For spasmodic asthma, the remedy may be given internally, and the following may be smoked or burned so as to be inhaled:

R Powdered stramonium leaves, ℥i; powdered anise seeds, powdered potassium nitrate, āā ℥ss. Mix without trituration. Sig. Burn a thimbleful of this powder under a conical vessel, as a funnel, and inhale the fumes. Or equal amounts of sage and stramonium leaves may be smoked in a pipe until slight nausea is induced (Locke). It is useful in severe paroxysms of *whooping-cough*, with hemorrhage from the mouth and nose, and in *hæmoptysis*, brought on by fits of coughing, or by spasm. It is a better cough remedy than opium, as it does not arrest the secretions. Stramonium has been extolled for its effects in *milk-sickness*. In plethoric habits, and in patients with determination to the head, the larger doses of stramonium must be administered with caution, keeping the excretory organs, as the skin, kidneys, and bowels, in an active condition during its employment.

Externally, a poultice of the fresh leaves, bruised, or the dried leaves in hot water, will be found an excellent application over the bowels, in severe forms of *gastritis*, *enteritis*, *peritonitis*, *acute rheumatism*, *painful bladder affections*, *pleurisy*, etc. "I have in many instances applied the leaves to the perineum, in cases of *retention of urine* from enlarged prostate, where it was impossible to introduce a catheter, and, after having allowed them to remain for about $\frac{1}{2}$ hour, have been enabled to pass the catheter with ease and facility, and thus afford relief to the patient. I have met with similar good results in *spasmodic urethral stricture*" (J. King). It will also be found beneficial as a local medication to all species of *painful ulcers*, *acute ophthalmia*, taking care not to produce too great mydriasis, *swelled breasts*, *orchitis*, *parotitis*, and other *glandular inflammations*, *vulvar inflammation*, *inflammatory rheumatism*, and *irritable hemorrhoidal tumors*. An ointment of it is very valuable in many of the above diseases, but it should be prepared carefully without too great heat, from fresh leaves and stems, if possible. In cases where the leaves can not be obtained, a plaster of the alcoholic extract or inspissated juice may be applied over the affected parts, or the extract may be rendered thin by heating it in diluted alcohol, and then forming into a poultice with meal or moistened bread and applied. The ointment is exceedingly efficient in *cutaneous hypertrophy around the anus*, attended with great itching, and sometimes with sero-purulent secretion. Dose of the powdered leaves or seeds, from $\frac{1}{10}$ to 5 grains; of the extract, which is the best form of administration, from $\frac{1}{20}$ to 2 grains; of the tincture, for which the seeds, bruised, are preferable, from a fraction of a drop to 30 drops; specific stramonium, $\frac{1}{30}$ to 10 minims.

Specific Indications and Uses.—Delirium, furious, enraged, and destructive; continuous talking; restless, can not rest in any position, seems to be fearful; pain, especially when superficial and localized; spasm, with pain; cerebral irritation; bloating and redness of face; purely spasmodic asthma; convulsive cough.

STRONTII BROMIDUM (U. S. P.)—STRONTIUM BROMIDE.

FORMULA: $SrBr_2+6H_2O$. MOLECULAR WEIGHT: 354.58.

"Strontium bromide should be kept in glass-stoppered vials"—(*U. S. P.*).

Preparation.—Neutralize pure strontium carbonate (freed from calcium or barium) with hydrobromic acid, having always an excess of the strontium salt. Filter and evaporate the transparent solution until the salt begins to crystallize. Allow to cool, separate the crystals and dry them carefully, avoiding a high temperature lest efflorescence should occur.

Description and Tests.—This compound is official in the *U. S. P.* (1890) for the first time. As demanded by that authority it is in "colorless, transparent, hexagonal crystals, odorless, and having a bitter, saline taste. Very deliquescent"—(*U. S. P.*). Mr. Carl E. Smith (*Pharm. Review*, 1896, p. 268) points out that the salt when free from calcium, does not deliquesce, even in a humid atmosphere, although it absorbs some moisture. Hence, deliquescence is an indication of calcium being present. "Soluble in 1.05 parts of water at 15° C. (59° F.), and in 0.5 part of boiling water. It is readily soluble in alcohol, and is precipitated from this solution upon the addition of an equal volume of ether, in which it is insoluble. When heated, the crystals at first melt, and then lose all their water (30.4 per cent). The anhydrous salt fuses at 630° C. (1166° F.). To a non-luminous flame the salt communicates an intense, red color. The aqueous solution is neutral to litmus paper. With calcium sulphate T.S. the aqueous solution (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate T.S., and other soluble sulphates. With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If a few drops of chloroform be added to 5 Cc. of the solution, then 1 Cc. of chlorine water, and the mixture shaken, the liberated bromine will dissolve in the chloroform, communicating to it a yellow or brownish-yellow color. The aqueous solution (1 in 20) should not be affected by hydrogen sulphide T.S. either before or after acidulation with a drop of hydrochloric acid (absence of arsenic, lead, copper, etc.); nor by ammonium sulphide T.S. (absence of iron, aluminum, etc.). It should form no precipitate with potassium dichromate T.S. (absence of barium)"—(*U. S. P.*). Mr. Carl E. Smith (*loc. cit.*) ascertained that about 0.25 per cent of barium salt escapes notice by this test. "If a few drops of starch T.S. be mixed with 5 Cc. of the aqueous solution, and then 1 or 2 drops of chlorine water added, no blue color should appear (absence of iodine). If 0.3 Gm. of strontium bromide, rendered anhydrous by thorough drying before being weighed, be dissolved in 10 Cc. of water, and 3 drops of potassium dichromate T.S. be added, it should require not more than 24.6 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to at least 98 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The action of this agent is undoubtedly largely due to the bromine it contains, and closely resembles that of the corresponding potassium salt for which it is proposed as a substitute. It is, however, less irritating to the stomach and bowels, much less liable to produce pronounced somnolence, and not so likely to provoke a rash and other effects of bromism. It has been successfully employed in *epilepsy*, in which it is better borne than the potassium salt, in gastric dilatation with gaseous accumulations, *gastric catarrh*, and the *nervous disorders of the stomach* to which the potassium compound is adapted but not well tolerated. According to Sée, it has a marked control over the amount of sugar excreted in *diabetes mellitus*, is a remedy against *lactic* and *acetic fermentations* and the gases arising from decomposition. The dose, as proposed by Sée, is from 120 to 180 grains per day. (See also *Strontii Lactas.*)

Strontium and Its Salts.—Strontium (Symbol: Sr. Atomic Weight: 87.2) is one of the rarer elements, and was first obtained by Davy, in 1808, by means of electrolysis. It received its name from having been produced from a mineral (*strontianite*) found in the neighborhood of Strontian, in Argyllshire, England. Strontium occurs in nature chiefly as strontium sulphate ($Sr.SO_4$) (*celestine*), and strontium carbonate ($SrCO_3$) (*strontianite*). Large deposits of the latter mineral are found in Westphalia, Germany, and both minerals occur in Pennsylvania and New York; celestine on Put-in-Bay Island, Lake Erie, etc. The ashes of bladder-wrack (*Fucus vesiculosus*) and the waters of some mineral springs contain it in the form of sulphate and chloride. Occasionally it is found as an accessory constituent of minerals and some soils, from which it finds its way into the sap of plants (see Prof. Trimble, on the occurrence of strontium in species of Castanopsis from Singapore, *Amer. Jour. Pharm.*, 1897, p. 296; also see L. F. Kebler and C. H. LaWall, on the presence of strontium in opium, *ibid.*, p. 244).

Strontium is a yellow metal harder than lead, malleable, and has a specific gravity of 2.5. It melts at a red heat, readily oxidizes in the air, and if heated burns with a brilliant light. The flame of strontium and that of its compounds is of a beautiful crimson hue. The nitrate is much employed in the making of *red fire* for pyrotechnic display and signal lights. Strontium readily decomposes water, and like sodium or potassium, must be kept under petroleum. Strontium has become of great technical importance also in the recovery of sugar from the molasses (see *Saccharum*). The introduction of the salts of strontium into medicine, in 1890, is due to Dr. J. V. Laborde (*Amer. Jour. Pharm.*, 1891, pp. 129 and 352), who also demonstrated the innocuousness of strontium salts, though Vulpian is said to have previously (1885) advocated their use. (For the preparation of pure strontium salts, see *Western Druggist*, 1892, p. 383).

Strontium Hydroxide ($Sr[OH]_2$).—This compound may be prepared pure, according to H. B. Dunham (1893), by the following method: Convert strontium nitrate into an oxide by heating the former for 20 minutes in a capsule by direct fire. Slake the product with an excess of water, allow the solid portion to settle, and decant the clear solution. Repeat the last part of the operation, and by this means the more easily soluble (1 in 20) barium hydroxide will be removed. To free it from calcium compounds dissolve the base in 2.4 parts of boiling water and set aside to crystallize. Transparent prismatic crystals of the composition $Sr(OH)_2 + 8H_2O$ result, soluble in 60 parts of cold water. This substance has been recommended by Dunham as a substitute for the carbonate in the preparation of the iodide, bromide, and lactate of strontium, because it is much more easily prepared pure than the carbonate.

STRONTII IODIDUM (U. S. P.)—STRONTIUM IODIDE.

FORMULA: SrI_2+6H_2O. MOLECULAR WEIGHT: 448.12.

"Strontium iodide should be kept in dark amber-colored, glass-stoppered vials"—(*U. S. P.*).

Preparation.—Strontium iodide is prepared by neutralization of freshly-made hydriodic acid with pure strontium carbonate. Filter out the excess of strontium salt, evaporate the clear solution, and allow it to crystallize by cooling. Hydroxide of strontium may be substituted for the carbonate, and it may also be used in preparing the bromide, for, according to Dunham (1893), it may be more easily obtained in a pure state than the carbonate.

Description and Tests.—This compound is also one of the new official salts, and should conform to the following requirements: "Colorless, transparent, hexagonal plates, odorless, and having a bitterish, saline taste. Deliquescent, and colored yellow by exposure to air and light. Soluble in 0.6 part of water at 15° C. (59° F.), and in 0.27 part of boiling water. Also soluble in alcohol, and slightly in ether. When cautiously heated, the crystals melt and gradually lose their water (24.05 per cent), becoming anhydrous. At a red heat, it is decomposed, losing iodine, and leaving a residue of strontium oxide. To a non-luminous flame it communicates an intense red color. The aqueous solution is neutral, or very slightly acid, to litmus paper. With calcium sulphate T.S. it slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate T.S., or other soluble sulphates. With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S. or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If a few drops of starch T.S. be added to 5 Cc. of the solution, and then 1 Cc. of chlorine water, a bluish-black color will appear. The aqueous solution (1 in 20) should not be affected by hydrogen sulphide T.S., either before or after acidulation with a drop of hydrochloric acid (absence of arsenic, lead, copper, etc.); nor by ammonium sulphide T.S. (absence of iron, aluminum, etc.). No turbidity should be produced in the aqueous solution by potassium dichromate T.S. (absence of barium). If 0.3 Gm. of strontium iodide, rendered anhydrous by thorough drying before being weighed, be dissolved in 10 Cc. of water and 3 drops of potassium dichromate T.S. be added, it should require not more than 18 Cc. of decinormal silver nitrate V.S., to produce a permanent red color (corresponding to at least 98 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt, which contains nearly 57 per cent of iodine, has been proposed as a substitute for potassium iodide. It lacks depressing properties and does not irritate the gastro intestinal tract. The dose is from 2 to 20 grains, well diluted with water. (See also *Strontii Lactas.*)

STRONTII LACTAS (U. S. P.)—STRONTIUM LACTATE.

FORMULA: $Sr(C_3H_5O_3)_2+3H_2O$. MOLECULAR WEIGHT: 318.76.

Preparation.—Strontium lactate is prepared by dissolving carbonate of strontium in an aqueous solution of lactic acid, using heat, if necessary, to accomplish solution. Filter, and evaporate to dryness, employing a moderately low temperature. It may likewise be prepared by neutralizing lactic acid with strontium hydroxide, and evaporating the solution to dryness.

Description and Tests.—Officially described, strontium lactate is in the form of "a white, granular powder, or crystalline nodules, odorless, and having a slightly bitter, saline taste. Permanent in the air. Soluble in about 4 parts of water at 15° C. (59° F.), and in less than 0.5 part of boiling water. The solution saturated at a boiling heat remains liquid for many hours, even after being cooled to 0° C. (32° F.). Soluble in alcohol. When heated to 110° C. (230° F.), the salt loses its water (16.9 per cent). At a higher temperature, it first fuses, then is decomposed, giving off inflammable vapors, and leaves a residue of strontium carbonate and carbon, which, on the addition of hydrochloric acid, effervesces and communicates an intense, red color to a non-luminous flame. The aqueous solution (1 in 20) is slightly acid to litmus paper. With calcium sulphate T.S., the solution slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids. The same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate T.S., or other soluble sulphates. With potassium chromate T.S., it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to 5 Cc. of the solution (1 in 20) 1 Cc. of sulphuric acid be added, then 1 Cc. of decinormal permanganate V.S., the red color will rapidly disappear, while the mixture will effervesce and give off the odor of aldehyde. If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should form a perfectly clear, colorless solution, leaving no insoluble residue (absence of carbonate, oxalate, etc.). The aqueous solution should not be affected by hydrogen sulphide T.S., either before or after acidulation with a drop of hydrochloric acid (absence of arsenic, lead, etc.); nor by ammonium sulphide T.S. (absence of iron, aluminum, etc.). No turbidity should be produced in the solution by potassium dichromate T.S. (absence of barium)"—(*U. S. P.*). (Regarding the sensitiveness of this test, see under *Strontii Bromidum*.) "If 0.5 Cc. of silver nitrate T.S. be added to 5 Cc. of the aqueous solution (1 in 20), not more than a slight opalescence should be perceptible (limit of chloride, etc.). If 0.5 Gm. of the salt be placed upon a watch-glass, and 1 Cc. of sulphuric acid be carefully poured upon it, no effervescence should occur (absence of carbonate, oxalate, etc.); nor should any penetrating odor be perceptible, even after gentle heating (absence of butyrate, propionate, etc.); nor should the acid assume, within 10 minutes, a deeper color than a pale straw-yellow (limit of readily carbonizable, organic impurities). If 1.33 Gm. of the salt, rendered anhydrous, before being weighed, by careful drying at 110° C. (230° F.), be ignited, until most of the carbon has diappeared, and then dissolved in 10 Cc. of water, it should require, for complete neutralization, not less than 9.9 Cc. of normal sulphuric acid (corresponding to at least 98.6 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*). Prof. Charles O. Curtman (*Pharm. Rundschau*, 1893, p. 32) found commercial specimens to be mostly or almost nearly anhydrous.

Action, Medical Uses, and Dosage.—Dr. J. V. Laborde (Chief of the Physiological Laboratory of the Faculty of Medicine of Paris), in 1890, was the first to demonstrate the harmlessness of the salts of strontium. Besides this, he observed that assimilation and nutrition were promoted by them, and that obstinate and painful *dyspepsia* was relieved by their use. Germain Sée confirmed the claims of Laborde, and regarded the pure salts as preferable to the alkaline carbonates in gastric disorders. The lactate of strontium, particularly, bids fair to become a valuable remedy in disorders of the assimilative and nutritive functions. Already good results have been obtained from its exhibition in *gastric debility*, *indigestion*, and *general depravity of the nutritive processes*. In *chronic kidney affections*, it seems to have produced remarkable results. Laborde regarded it, as well as the other salts of strontium, as diuretic, but in the case of the lactate such a property is denied by Constantin Paul. However, most clinicians agree that it favorably influences various forms of *nephritis* and *albuminuria*, diminishing the amount of albumin excreted, though diuresis be not necessarily increased. This is thought to be due to the conjoint action upon the digestive tract, and to a special action upon the renal tissues. The parenchymatous and epithelial varieties of nephritis are best treated with it, according to Paul, who states that even intense fever does not prevent its beneficial action. It is thought to be particularly indicated in the *parenchymatous nephritis of rheumatic and gouty individuals*, and the *albuminuria* preceding and following child-birth. Not only is the amount of albumen lessened or checked, but the general health of the patient becomes markedly improved. In some cases, the albumen reappears in the urine if the salt be withdrawn, and will disappear again upon resumption of the treatment. It has been suggested in the *post-scarlatinal* or *glomerular form of nephritis*. The interstitial variety of *nephritis* receives the least benefit from its use. As the elimination of nitrogenous material and diminution of the urates take place when this salt is administered, it is asserted to have proved useful in *gout* and *rheumatism*. It is also said to be a cardiac sedative and to have a good influence in *disease of the heart-muscle* and *valves*. In regard to dosage, there is some discordance, See maintaining that the dose should be from 120 to 160 grains a day, while Malbec puts the daily quantity at 30 to 150 grains. Probably the best method is to administer from 10 to 20 grains of the salt every 3 or 4 hours.

STROPHANTHUS (U. S. P.)—STROPHANTHUS.

"The seed of *Strophanthus hispidus*, De Candolle, deprived of its long awn"—(*U. S. P.*).

Nat. Ord.—Apocynaceæ.

ILLUSTRATION: Köhler's *Medizinal Pflanzen*.

Botanical Source and History.—The genus Strophanthus which produces this drug, is chiefly of African origin, and consists, at present, of more than 25 species. (Regarding the geographical distribution of the various species in Africa, see E. M. Holmes, *Pharm. Jour. Trans.*, Vol. XXIII, 1892–93, pp. 868 and 927.) Plants of this genus have usually woody stems, emitting a milky juice when wounded, and are generally twining vines, which climb the highest trees. The seed of commerce is probably collected from various species indiscriminately, which have been classified and differentiated by Pax, Planchon, Hartwich, Holmes, Blondel, and others. The medicinally valuable strophanthus seeds are yielded chiefly by two species—*S. hispidus* and *S. Kombé*. Both are official in the *German Pharmacopœia*, only the former in the *U. S. P.*, and the latter in the *Br. Pharm.*

Strophanthus hispidus, De Candolle, was one of four species described by De Candolle as early as 1802, and is the species to which this drug was first ascribed. Its habitat is Senegambia and Guinea, and other parts of western Africa. The stem is a twining, milky shrub, with opposite hirsute leaves (hence the name *hispidus*, Latin for bristly, hairy). The flowers are borne in terminal, many-flowered, dense cymes. The calyx consists of 5 hairy, green sepals about the length of the corolla tube. The corolla is white, with a short, funnel-shaped tube, yellowish within, and furnished with 10 small, nectariferous glands. The segments of the corolla are very long, tapering, slender, hairy without, having a length sometimes of 8 inches, and are the conspicuous part of the flower, giving the plant its generic name (from *strophos*, Greek for twisted cord). The stamens are 5, with sagittate anthers and slender filaments. The pistil consists of 2 distinct carpels, each of which, if fertilized, ripens into a long pod, filled with numerous seed. The seed, each bearing a slender style, terminating in a plumose pappus, consisting of long, fine hairs, is the part used in medicine, after being deprived of their awns.

Strophanthus Kombé, Oliver, is a similar plant, native, however, of eastern Africa, and was differentiated from *S. hispidus* by Oliver, in 1885. It has the same hirsute leaves, but they are more coriaceous. The sepals are shorter than the corolla tube, and cymes are fewer flowered than the *S. hispidus*. Some botanists contend that *S. Kombé* is merely a variety of *S. hispidus*.

Although, as before stated, the genus Strophanthus was established as far back as the year 1802, it was not until the early 60's that the drug came to the general notice of Europeans as being one of the several arrow-poisons (*e. g.*, *inée* or *onaye*, in Senegambia, from *S. hispidus*, and *S. Kombé*, on the east coast, from *S. Kombé*) used among the African native tribes. (Regarding details on arrow-poisons, see article on Strophanthus, by J. U. Lloyd, in *Western Druggist*, 1897, p. 403, from which most of the subject herein presented is derived.) In this connection, the following observation, regarding arrow-poisons among the American Indians, may be of interest: "In some of my western work I have found among the Indians that the poisoning of their arrows, while mixed up a great deal with useless ceremonials, and often, no doubt, nearly useless plant extracts, has a basis in some sort of poison, probably ptomaine, or something of that character, derived from rotten meat. This was the case among the Klamath and Modoc Indians" (Frederick V. Coville, botanist to United States Government, in a private letter to Prof. Lloyd).

The powerful cardiac properties of the drug were recognized by Sharpey (1862), Pelikan (1865), Fraser (1871), but not until about 1885 did strophanthus gain a foothold in medical practice. As the demand for strophanthus began to increase, substitution by allied, though often inert, species became frequent. It was, therefore, recommended that the seeds be purchased in the follicles, and that chemical tests for the active principle, *strophanthin*, be applied to the seeds (see *Chemical Composition*). (Regarding substitution of the seeds by *Kickxia Africana*, Bentham, see E. M. Holmes, *Pharm, Jour. Trans.*, Vol. XVII, 1886–87, p. 903; and P. Siedler, *Ber. d. Deutsch. Pharm. Ges.*, 1898, pp. 222–228.)

Description.—The *U. S. P.* describes strophanthus thus: "About 15 Mm. ($\frac{3}{5}$ inch) long and 4 or 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ inch) broad, oblong-lanceolate, flattened and obtusely edged, grayish-green, covered with appressed, silky hairs, one side with a ridge extending into the attenuated, pointed end; kernel white and oily, consisting of a straight embryo, having 2 thin cotyledons, and surrounded by a thin layer of perisperm, nearly inodorous; taste very bitter. A decoction, prepared with 1 part of the seed and 10 parts of water, has a brownish color, and is not changed in appearance on the addition of iodine T.S., ferric chloride T.S., or potassium mercuric iodide T.S."—(*U. S. P.*).

Chemical Composition.—In 1877, the name *strophanthin* was given by Hardy and Gallois (*Jour. Pharm. Chim.*, Vol. XXV, p. 177) to a crystalline but non-glucosidal substance obtained from the seed of *Strophanthus hispidus* by extracting the latter with alcohol acidulated with hydrochloric acid. Thus it might have been strophanthidin (see below), but it is described as being soluble in cold, more soluble in warm water. Prof. T. R. Fraser, of Edinburgh, isolated from the same source amorphous, glucosidal *strophanthin* capable of being hydrolyzed with diluted acids (slowly in the cold, more rapidly by heat) into sugar and *strophanthidin*, a crystallizable body (*Pharm. Jour. Trans.*, Vol. XX, 1889–90, pp. 328–335). In addition to strophanthin, Prof. H. Thoms (*Berichte der Deutsch. Chem. Ges.*, 1898, p. 271) found the seeds of this species to contain the bases *choline* and *trigonelline*, the latter being the characteristic alkaloid of fenugreek. An alkaloid (*ineïne*) was previously indicated by Hardy and Gallois (*loc. cit.*) in the awns of the seeds; the observation could not be subsequently verified. As to the seeds of *Strophanthus Kombé*, Catillon (1880) affirmed the existence of two glucosids, one being *strophanthin*, the other nitrogen-bearing and splitting with acids into sugar and a distinct alkaloid. Arnaud in 1888 gave strophanthin from Kombé seeds the formula $C_{31}H_{48}O_{12}$, and concludes that it is *methyl-ouabain* (see *Related Principles*, p. 1849).

Strophanthin of Fraser, is a very bitter, amorphous, nitrogen-free glucosid, freely soluble in water and alcohol, insoluble in pure ether or chloroform (A.W. Gerrard, 1887). It is also insoluble in a concentrated solution of ammonium sulphate (H. Thoms, 1898). Strophanthin produces with concentrated sulphuric acid a bright-green color which is permanent for some time. The seeds containing strophanthin (occurring in the endosperm and sometimes also in the cotyledons) give the same reaction, hence may be readily distinguished from seeds devoid of this active principle (see *e. g.*, Hartwich, *Archiv der Pharm.*, 1892, p. 411). *Strophanthidin* is crystallizable, insoluble in ether, "very slightly soluble in cold water" (Fraser), soluble in alcohol, moderately soluble in chloroform and amyl alcohol. According to F. Feist (*Berichte der Deutsch. Chem. Ges.*, 1898, p. 534), it yields by oxidation, among other products, benzoic acid. It is stated that strophanthin from *S. hispidus* is amorphous, that from *S. Kombé* crystallizable.

Kombic acid is a peculiar acid obtained by Fraser from Kombe seeds. Its aqueous solution is precipitated by lead acetate. To assay tincture of strophanthus for strophanthin, Mr. Barclay proposes to convert this active principle by hydrolysis into the more positive *strophanthidin*. (See two interesting papers on this subject in *Pharm. Jour. Trans.*, Vol. III, 1896, p. 463, and Vol. VII, 1898, p. 655.)

Action, Medical Uses, and Dosage.—Externally applied, strophanthus preparations appear to exert no special effects unless applied with hydrous wool fat, when the effects of the drug are said to be apparent. The seeds, however, applied to the cornea produce prolonged anæsthesia (Steinbach). Three or 4 drops of a solution of strophanthin (1 in 1000) applied to the cornea also produce total anæsthesia, including sensibility to heat and cold (difference from cocaine), these sensations being the last to yield and the first to revive after its application. A disagreeable irritation of the conjunctiva has been produced by this use of strophanthin; it has no effect on intraocular pressure or upon vision-accommodation. Strophanthus is a muscle poison. When taken internally its action is primarily upon the voluntary muscles, increasing their contractility, and if the dose be poisonous it causes tetanic paralysis, the muscles being unable to regain their former normal flexibility. Under its toxic influence the muscles first become enfeebled, then somewhat rigid, fibrillary twitchings, which are spontaneous, non-rhythmical and increasing contractions, somewhat similar to those of chorea, are observed, and finally the muscles become pallid, non-contractile and hard. It is these effects that render strophanthus an efficient arrow-poison, the muscular paralysis produced rendering the animal an easy prey to its pursuer. When the muscles are in extreme paralysis lactic acid has been observed to replace the normal alkaline condition. Strophanthus muscular paralysis consists chiefly in diminishing the ability of the muscles to relax, and then in destroying this capability, producing a condition difficult to distinguish from *rigor mortis*.

Strophanthus does not appear to affect either the spinal cord or to act upon its nerve trunks. Its specific action upon the heart is due to direct contact (through the blood) with the muscular fibres of that organ and not to any effect upon the cardiac nerves. A large dose so increases contractility that a more perfect, energetic, and prolonged systole is the result, and the capability of the muscle to relax is lost, or so diminished that diastole can not take place; after death the ventricle is so completely contracted as to almost efface the cavity, the heart passing from life directly into *rigor mortis*. According to some it may cease either in systole or diastole. The caliber of the blood vessels is but little influenced by strophanthus; it is strongly diuretic in so far as lack of secretion depends upon low blood pressure, *i. e.*, it increases diuresis in so far as increased blood pressure produces an increased urinary product. It is also thought by some to act specially upon the renal secreting structures. When one is in good physiological condition it is said to have little or no diuretic action; but in diseased conditions, with low blood pressure, it is asserted to excel digitalis in diuretic power.

If strophanthus be given in large doses it produces gastro-intestinal irritation with vomiting and diarrhœa. Small doses, however, act as a bitter tonic, improve the appetite, augment gastric action, and promote digestion. In proper doses it strengthens the heart-muscle, slows cardiac action, increases the interval between beats, reduces the pulse-rate, and powerfully increases arterial tension, not by any effect (to any extent at least) upon the vessels, but by strengthening the heart-muscle, giving increased power. Whether or not the drug is cumulative is still an unsettled question, though it probably is not cumulative unless given too freely in over-lapping doses. The action of strophanthus upon the heart is probably greater than that of any other drug, and its active principle is of far greater potency than the digitalis derivatives.

Strophanthus is a remedy for *weak heart* from debility of the cardiac muscle, with lack of proper contractile power, as shown by a rapid, weak pulse, and very low blood pressure. The disordered action of the heart is due to lack of tonicity and not from weak walls due to depositions of fat, in which case the drug must be used with extreme circumspection, though in small doses it has been recommended by some as a remedy for *cardiac fatty degeneration*, as it has also in *atheroma of the arteries* in the aged. It is a remedy for *præcordial pain* and for *cardiac dyspnœa*. It has been strongly endorsed in heart affections with *disorders of compensation*. Strophanthus is a remedy for valvular heart disease only so far as there is *muscular insufficiency*, where the compensatory increase of muscular action is not sufficient to offset the valvular insufficiency. "It has been reported useful in cases of *mitral regurgitation with dilatation; mitral stenosis with regurgitation; regurgitation with œdema*, *anasarca*, *dyspnœa*, etc.; *mitral insufficiency with palpitation*, *præcordial pain*, *cyanosis*, *dyspnœa*, etc." (*Annual of Eclectic Med. and Surg.*, Vol. I, 1890, p. 25). Dr. S. Schiller (*ibid.*, p. 40), a keen observer, says: "When the balance in the circulation has become impaired, as a result of insufficiency of the valves of the heart from organic disease with a general dropsical condition, strophanthus, although affording temporary relief in some cases, has failed in every case in my hands to reestablish the compensation. The result was the same whether the mitral, the tricuspid, or the semilunar valves were most involved. These are the cases of heart disease in which digitalis is *the* remedy. However, evidence is strong to show that when the muscular insufficiency can be corrected in these cases then the remedy will do good service. Dr. Schiller looks upon the drug as a remedy for what is ordinarily termed *functional heart disease*, when not sympathetic. The heart-action is rapid or abnormally slow, or the rhythm is bad, a condition common in school children at puberty when forced to overstudy. Strophanthus is well endorsed as a remedy for the *irritable heart* of tobacco smokers, masturbators, and those addicted to the use of alcoholics and narcotics.

Acute endocarditis and the *reflex palpitation* of neurasthenic, hysterical, and chlorotic subjects have been signally benefited by strophanthus, while it appears to give better cardiac power during or after *typhoid* and other *adynamic fevers*, when heart failure threatens. It should be remembered as a remedy for *threatened cardiac failure* in any disease. Full doses should be given for the relief of *angina pectoris*, and the remedy should be continued for a period after the attack. It is less efficient, because slower in action, than amyl nitrite or nitroglycerin, but may be given for more permanent effects after the evanescent action of these agents has passed off. In *pulmonary congestion* and in *acute bronchitis* or *acute pneumonia* it may be employed when there is deficient heart-action.

Strophanthus has been praised for prompt results in *cardiac asthma* and *bronchial asthma*, with œdema; in *whooping-cough* it has many advocates; it assists the action of iron salts in *pernicious anemia* and is credited with the cure of *traumatic tetanus*. *Goitre* is asserted to have been cured with it, and large doses (8 to 25 drops several times a day) have been said to cure a large proportion of cases of *exophthalmic goitre*, with irregular cardiac action. Dr. S. Schiller reports great relief to the heart symptoms in two cases of exophthalmic goitre, with disappearance of the bronchocele in one case (*Annual of Eclectic Med. and Surg.*, Vol. I, p. 40). Strophanthus has also been lauded as a remedy for *chronic nephritis*, with *albuminuria*, in *anasarca*, and in *ascites* from hepatic cirrhosis. It is of little value in œdema and other forms of dropsy or kidney affections unless dependent upon cardiac disorders. Dr. W. E. Bloyer (*Ec. Med. Jour.*, 1897, p. 51) reports a case of anasarca in which 5-drop doses, every 2 hours, produced an enormous flow of urine and thin alvine discharges, completely draining the tissues in less than 12 hours. Finally, strophanthus is given credit for the cure of a large number of cases of *Asiatic cholera*, and it has been asserted useful in *urticaria* and *psoriasis*.

This agent does not take the place of digitalis, each having its own field of action. It may, however, follow the use of other heart tonics, and particularly those evanescent in action, as amyl nitrite and nitroglycerin. As it does not affect the caliber of the vessels it may be used in preference to digitalis when it is not desirable to add extra work to the heart. It is well borne by the aged and by children. Wilcox (see *Ec. Med. Jour.*, 1897, p. 394) sums up the advantages of strophanthus over digitalis as follows: "Greater rapidity, modifying pulse-rate within an hour; absence of vaso-constrictor effects; greater diuretic power; no disturbance of digestion; absence of cumulation; greater value in children; great safety in the aged." He further summarizes its uses as follows: "All cases in which we wish to establish compensation; all cases of arterial degeneration in which a remedy which causes more energetic cardiac contraction is required; all cases of cardiac disease where diuresis is necessary; all cases of weak or irritable hearts; all cases of cardiac disease in childhood or old age." These we would qualify by adding *when the heart-muscle is at fault*.

Strophanthus should be avoided or very cautiously used in advanced muscular degeneration, in pronounced mechanical defects of the heart, and in fully and over-compensated hearts. There is great variation in strength in various batches of tincture of strophanthus owing to lack of uniformity in the crude drug employed. The dose of tincture of strophanthus is from 1 to 10 drops; of specific strophanthus, $\frac{1}{2}$ to 10 minims; of strophanthin, $\frac{1}{500}$ to $\frac{1}{60}$ grain. All of which should be cautiously administered.

Specific Indications and Uses.—Weak heart, due to muscular debility; muscular insufficiency; rapid pulse, with low blood pressure; cardiac pain, with dyspnœa.

Related Principles and Preparations.—UKAMBIN. If not identical with Kombe arrow poison, this substance is at least closely related. The active crystalline principle belongs to the digitalis group, and produces death by arresting cardiac action.

Exuja or Echugin.—Said to be derived from *Adenium Boehmianum* (*Nat. Ord.* Leguminosæ), and employed as an arrow-poison by southwest African Ovambos. Its active principles were found to be a glucosid whose physiological effects were much like those produced by strophanthin, and a resinous substance (*echugon*). The glucosid *echugin* ($C_5H_8O_2$) forms small, satiny, colorless plates insoluble in ether but easily dissolved by water and alcohol. It constitutes about 10 per cent of exuja, which is an odorless, very bitter, blackish-brown crumbly mass.

Hippo and Vakamba.—The Sakayes and Somangs of Africa employ these two arrow-poisons. They induce emesis and tetanic convulsions and paralyze both heart and lungs simultaneously. The action of vakamba, however, is less tetanic, though the effects upon the muscle are observed sooner than with hippo (Laborde).

Ouabaio.—A poison said to be derived from *Carissa Schimperi*, A. De Candolle (*Acokanthera Schimperi* [DeC.], Bentham and Hooker; *A. Ouabaio*, Cathelineau). Arnaud (1888) obtained therefrom an active principle *ouabain* ($C_{30}H_{46}O_{12}$) a very poisonous, amorphous glucosid which he also obtained from *Strophanthus glaber* to the extent of nearly 5 per cent (*Pharm. Jour. Trans.*, Vol. XIX, 1888–89, pp. 162 and 606). It resembles strophanthin chemically, and is intensely deadly, $\frac{1}{65}$ grain reputed to have been fatal. Locally it is reputed tenfold more powerful than cocaine as a local anæsthetic. It kills by its action upon the lungs and heart. It has been proposed as a remedy for *whooping-cough* ($\frac{1}{500}$ grain), but is evidently too dangerous a poison to be employed in such a malady.

Onobaio.—This arrow-poison is used by the inhabitants of Obok, situated on the Gulf of Aden. It occurs in small, brown resinous balls. Small doses of it arrest pulmonary action; but large doses promptly arrest the action of both heart and lungs.

Dajaksh.—The Borneo arrow-poison paralyzes the heart (Braidwood).

Incassa Poison.—An ordeal bark of Africa said to be a violent heart-poison (Liebreich). (For other arrow and ordeal poisons, see under *Nux Vomica.*)

STRYCHNINA (U. S. P.)—STRYCHNINE.

Formula: $C_{21}H_{22}N_2O_2$. **Molecular Weight**: 333.31.

"An alkaloid obtained from Nux vomica, and also obtainable from other plants of the natural order *Loganiaceæ*"—(*U. S. P.*).

Synonym: *Strychnia.*

History and Preparation.—Strychnine was discovered by Pelletier and Caventou (1818) in St. Ignatius beans (see *Ignatia*), and, subsequently, also in nux vomica and other species of Strychnos, always accompanied by the alkaloid *brucine.* The latter is more soluble in boiling water and diluted alcohol than strychnine, and brucine nitrate is more soluble in water than strychnine nitrate. These differences permit separation of both alkaloids. Strychnine is obtained almost exclusively from the seeds of nux vomica. A practical difficulty consists in the toughness of the seeds. These are previously exposed to heat, then powdered; or the seeds are softened by prolonged boiling with diluted sulphuric acid (Merck). The process of the *British Pharmacopœia* (1885) consists in extracting the powdered seeds by prolonged digestion with diluted alcohol, distilling off the alcohol, precipitating *igasuric acid* with lead acetate, evaporating the filtrate, and adding aqua ammoniæ to slight excess, drying the precipitate, and extracting it with alcohol. Upon evaporation of the solvent, the bulk of strychnine crystallizes first; it is obtained pure by recrystallization. (For a summary of other methods, see Husemann and Hilger, *Pflanzenstoffe*, 1884. p. 1284.)

Description.—The *U. S. P.* thus describes strychnine: "Colorless, transparent, octohedral, or prismatic crystals, or a white, crystalline powder, odorless, and having an intensely bitter taste, perceptible even in highly dilute (1 in 700,000) solution. Permanent in the air. Soluble, at 15° C. (59° F.), in 6700 parts of water, and in 110 parts of alcohol; in 2500 parts of boiling water, and in 12 parts of boiling alcohol. Also soluble in 7 parts of chloroform, but almost insoluble in ether"—(*U. S. P.*). It is also insoluble in caustic alkalies, moderately soluble in fixed and volatile oils and creosote, in amyl alcohol (181 parts), benzol (164 parts), and glycerin (300 parts) (compare the solubilities of *brucine*, under *Nux Vomica*). "When heated to 268° C. (514.4° F.), strychnine melts. Upon ignition, it is consumed, leaving no residue. Strychnine has an alkaline reaction upon litmus paper"—(*U. S. P.*). With acids, it forms crystallizable salts of an intensely bitter taste. Chemically, strychnine is a derivative of the base quinoline ($C_6H_4{:}C_3H_3N$), and is still under investigation. (For the quantitative separation of strychnine and brucine, see *Nux Vomica.*) Another method recommended by Gordin and Prescott (*Amer. Jour. Pharm.*, 1899, p. 18), is that of Dunstan and Short (*ibid.*, 1883, p. 579), which consists in precipitating strychnine with potassium ferrocyanide from solution slightly acidulated with sulphuric acid. Brucine is precipitated only in concentrated solution.

The solutions of strychnine in diluted acids are precipitated by all alkaloidal reagents. Mercuric chloride occasions a white precipitate, composed of plumose tufts and acicular, radiating crystals. Platinum chloride and gold chloride produce pale-yellow crystals. Picric acid will occasion a pale-yellow precipitate of very delicate needles, arranged in tufts or in radii. Potassium iodide produces a rich amber-yellow or reddish-brown precipitate, composed of minute prisms. Chloride of iron, perchloric acid, iodine, tannic acid, potassium chromate and bichromate, ammonia water, potassa, soda, and potassium and sodium carbonates, each, produce a precipitate; hence, all of these reagents are incompatible with salts of strychnine. This alkaloid enters into a crystallizable compound with iodoform (*Amer. Jour. Pharm.*, 1882, p. 119). It also combines with chloroform, but not unless the solution is heated, in a sealed tube, to 120° C. (248° F.), and higher (P. F. Trowbridge, *Archiv der Pharm.*, 1899, p. 624) Strychnine resists putrefactive influences exceedingly well. Dr. Riekher (*Neues Jahrbuch der Pharm.*, Vol. XXIX, 1868, p. 1) was able to determine its presence in the heart, lung, and liver of a steer, after the specimens had been kept for 11 years in loosely-covered jars, under the roof of a house. (Also see G. Welborn, *Proc. Amer. Pharm. Assoc.*, 1893, p. 865.)

Tests.—The most characteristic test for strychnine is the violet-blue color, produced with strong sulphuric acid and oxidizing agents. With cold sulphuric acid alone, pure strychnine produces a colorless solution. The *U. S. P.* gives the following directions for the color test, and for the limit of brucine: "If a minute quantity of strychnine be dissolved in about 0.5 Cc. of concentrated sulphuric acid on a white porcelain surface, and a small crystal of potassium dichromate slowly drawn across the liquid with a glass rod, there will be produced at first, momentarily, a blue color, which quickly changes to purplish-blue, then gradually to violet, purplish-red, and cherry-red, and finally to orange or yellow. On dissolving 0.02 Gm. of strychnine in 2 Cc. of nitric acid (specific gravity 1.300), in a small test-tube, the acid should not turn more than faintly yellow (limit of *brucine*)"—(*U. S. P.*). (Regarding the latter test, see brucine, under *Nux Vomica.*) The blue coloration in the strychnine test is also obtained by other oxidizers, *e.g.*, dioxide of manganese (MnO_2), of lead (PbO_2), potassium permanganate, etc., and the reaction is exceedingly delicate, being obtainable with $\frac{1}{100}$ milligramme of alkaloid, provided brucine is absent. The presence of large quantities of brucine interferes with the reaction (see Flückiger-Nagelvoort, *Reactions*, Detroit, 1893; and H. Beckurts, *Archiv der Pharm.*, 1892, p. 551; also see Dr. T. G. Wormley's work on the *Micro-Chemistry of Poisons*, 1885, pp. 542–612).

Action, Medical Uses, and Dosage.—(See *Strychninæ Sulphas* and *Nux Vomica.*)

Salts of Strychnine.—STRYCHNINÆ CITRAS, *Citrate of strychnine*, may be made by dissolving, with a gentle heat, in a sufficient quantity of distilled water, 192 parts of dried citric acid, and then adding 346 parts of pure strychnine. By gentle evaporation the citrate may be obtained in crystals. The above proportions correspond to an acid salt ($C_6H_8O_7.C_{21}H_{22}N_2O_2$). The dose is from $\frac{1}{16}$ to $\frac{1}{20}$ grain, to be given cautiously till the desired effect is produced.

STRYCHNINÆ TARTRAS, *Tartrate of strychnine*, may be obtained by dissolving in a sufficient quantity of distilled water, 156 parts of tartaric acid, and then adding 346 parts of strychnine, and evaporating as above. It is also an acid salt, and has the formula $C_4H_6O_6.C_{21}H_{22}N_2O_2+3H_2O$ (Arppe). The dose is the same as for the citrate.

STRYCHNINÆ ACETAS, *Strychnine acetate.*—This solution forms crystals, which, when evaporated in solution, lose a portion of their acid. It does not easily crystallize. Soluble in chloroform (about 15 parts) and in water (96 parts).

STRYCHNINÆ HYDRIODAS, *Strychnine hydriodate* ($C_{21}H_{22}N_2O_2.HI$).—To solution of a salt of strychnine add solution of potassium iodide. Collect the precipitate, dissolve it in alcohol, and allow to crystallize. It forms very bitter, 4-angled needles, or white scales; dissolves but sparingly in water at ordinary temperatures, but dissolves quite readily in alcohol. The salt holds 72.2 per cent of the alkaloid.

STRYCHNINÆ HYDROCHLORAS, *Strychnine hydrochlorate* ($2[C_{21}H_{22}N_2O_2.HCl]3H_2O$).—Dissolve strychnine in warm diluted hydrochloric acid, and allow to cool. Silky, acicular crystals, containing 84 per cent of the alkaloid. Soluble in cold water (50 parts); loses its water of crystallization quite readily.

Strychninæ Nitras, *Strychnine nitrate* ($C_{21}H_{22}N_2O_2.HNO_3$).—Dissolve strychnine in warm diluted nitric acid, and allow to cool. Extremely bitter, colorless needles are formed, which contain 84 per cent of strychnine. It dissolves in cold water (90 parts), boiling water (3 parts), cold alcohol (70 parts), boiling alcohol (5 parts), and glycerin (26 parts); somewhat soluble in fixed oils and absolute alcohol, not soluble in ether and carbon disulphide. This agent is official in the *Ger. Pharm.* It has been largely used in the treatment of the *alcohol habit.*

Strychninæ Hydrobromas, *Strychnine hydrobromate* ($C_{21}H_{21}N_2O_2.HBr$).—This salt contains 80.4 per cent of the base. It crystallizes in prismatic needles, easily soluble in diluted alcohol, but sparingly in strong alcohol. Water (32 parts) effects its solution. According to Bullock, it is prepared by the interaction of strychnine sulphate and potassium bromide in diluted alcoholic solution whereby potassium sulphate forms an insoluble precipitate. The reaction is as follows: $(C_{21}H_{22}N_2O_2)_2.H_2SO_4+2KBr \quad K_2SO_4+2C_{21}H_{22}N_2O_2.HBr$.

Strychninæ Phosphas, *Strychnine phosphate* ($\frac{1}{100}$ to $\frac{1}{16}$ grain), has been advised in *pregnancy,* when the patient is exhausted or anemic (see Ellingwood's *Mat. Med. and Therap.*, pp. 169 and 170). Prepared by dissolving strychnine in phosphoric acid.

Strychninæ Arsenias, *Strychnine arseniate,* may be given, in doses of $\frac{1}{200}$ to $\frac{1}{80}$ grain, in *debility* and prostration of the aged, or those suffering from the effects of severe disease. It possesses, in an increased proportion, the antimalarial effects of strychnine. Prepared by dissolving strychnine in aqueous arsenic acid (AsO_4H_3).

STRYCHNINÆ SULPHAS (U. S. P.)—STRYCHNINE SULPHATE.

Formula: $(C_{21}H_{22}N_2O_2)_2H_2SO_4+5H_2O$. Molecular Weight: 854.24.

Synonym: *Strychniæ sulphas* (*U. S. P.*, 1870).

"Strychnine sulphate should be kept in well-stoppered vials"—(*U. S. P.*).

Preparation.—To diluted, warm sulphuric acid, add a slight excess of pure powdered strychnine. Filter, and allow to crystallize. Rhombic, neutral, prismatic crystals, containing 5 molecules of water, are deposited upon cooling the saturated, hot solution. By dissolving the neutral sulphate in diluted sulphuric acid, long, thin needles of the acid salt ($C_{21}H_{22}N_2O_2.H_2SO_4$) are formed upon evaporation. Reversedly, the neutral salt may be obtained from the acid salt, by dividing a solution of the latter into two equal parts, precipitating one-half by aqua ammoniæ, and adding this precipitate to the other half (Rammelsberg, *Amer. Jour. Pharm.*, 1881, p. 627; also see M. W. Coleman, *ibid.*, 1883, p. 113).

Description.—The *U. S. P.* describes the neutral salt as occurring in "colorless or white prismatic crystals, odorless, and having an intensely bitter taste, perceptible even in highly dilute (1 in 700,000) solution. Efflorescent in dry air. Soluble, at 15° C. (59° F.), in 50 parts of water, and in 109 parts of alcohol; in 2 parts of boiling water, and in 8.5 parts of boiling alcohol. Almost insoluble in ether. When heated at 100° C. (212° F.), the salt slowly loses its water of crystallization (10.51 per cent); more rapidly when heated to 110° C. (230° F.). When quickly heated to 200° C. (392° F.), the salt fuses. Upon ignition, it is consumed, leaving no residue"—(*U. S. P.*).

Tests.—"On adding potassium or sodium hydrate T.S. to an aqueous solution of the salt, a white precipitate is thrown down, which is insoluble in an excess of the alkali, and which should conform to the reactions and tests of strychnine (see *Strychnina*). Barium chloride T.S., added to the aqueous solution, throws down a white precipitate, insoluble in hydrochloric acid. On dissolving 0.05 Gm. of strychnine sulphate in 2 Cc. of nitric acid (specific gravity 1.300), in a small test-tube, the acid should not turn more than faintly yellow (limit of brucine)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Nux vomica and strychnine (see also *Nux Vomica*) act chiefly, if not solely, by stimulating the spinal cord and medulla oblongata, and without affecting the functions of the brain. The terminal nerves and nerve trunks are little, if at all, affected by strychnine, except in very large doses. Even then, its influence is not thought to be marked. The slightest observable effects from small doses are twitches of the muscles of the arms and legs, occurring especially during sleep, accompanied with restlessness, some anxiety, acceleration of the pulse, and generally slight perspiration. Sometimes the action of the bowels is increased, and the discharge of urine is either augmented or discharged more frequently; it likewise promotes the venereal appetite. Large doses occasion very violent starting of the muscles; even a tendency to lockjaw, succeeded by stiffness, weariness, pain or rending in the limbs. In their highest degree, these effects amount to violent tetanic spasms, occurring in frequent fits.

with brief intervals of repose, acute sensibility, and dreadful alarm. If the spasms continue, opisthotonos ensues. The risus sardonicus is observed in strychnine poisoning. The convulsions may be so violent as to throw the victim off a bed. Through whatever form or structure strychnine is introduced into the body, it exerts this action more or less, operating with an energy proportioned to the activity of absorption where it is applied. It is supposed to be a cumulative poison like mercury or digitalis, nor does its activity diminish under the influence of habit, as with opium. M. Duclos states that, under the influence of positive electricity, the symptom of poisoning by strychnine increase, while they lessen or cease altogether when negative electricity is applied. The long-continued use of strychnine, in excessive amounts, tends to impair the digestive organs, and while small amounts favor diuresis, large quantities impair that function by producing spasm of the bladder muscles. Strychnine is eliminated in part by the kidneys, and may also impair the contractile power of the sphincter vesicæ. When strychnine kills, it usually does so by causing spasm of the respiratory muscles, producing asphyxia. As some patients are powerfully affected by the smallest doses of this agent, too much caution can not be employed in its administration. Thirty grains of powdered nux vomica (equal to about 1 seed, or $\frac{1}{3}$ grain of strychnine), in 2 doses, proved fatal, while death followed the administration of 3 grains of the alcoholic extract; $\frac{1}{16}$ grain of strychnine proved fatal to a small child in 4 hours, while $\frac{1}{2}$ grain has killed an adult. Toxic symptoms are often produced by so small a dose as $\frac{1}{12}$ grain. Poisoning by nux vomica is slower than by strychnine. The usual length of time in which the latter proves fatal is 2 hours, though death has resulted in 15 minutes, and has been delayed 6 hours. If the patient survives longer than 6 hours, he is likely to recover. There are no characteristic internal post-mortem appearances, though, as a rule, there is congestion of the meninges, and the blood throughout the body is black and liquid. The body stiffens after death, and may be arched, with incurvated toes. Rigidity of the body has been known to persist for months.

In poisoning by strychnine or nux vomica, the patient must be kept absolutely quiet, no noises should be permitted, nor should even a draught of air be permitted to strike the body. Apomorphine, hypodermatically, or other emetics, by mouth, should be given to induce vomiting, while lard, sweet oil, milk, charcoal, or tannin, may be given with a view of enveloping the poison or retarding its absorption. The spasms should be controlled with chloroform. Chloral and potassium bromide have also been asserted to be effectual, as have also atropine, tobacco, and nicotine. Physostigma is also useful, but must be carefully employed, lest exhaustion follow its use. This may, however, be guarded against by the use of stimulants. Artificial respiration may be performed, the forcible action required being less likely to produce spasms than light and superficial contact with the skin.

"I would observe here that, 13 years ago, a favorite Newfoundland bitch, with 3 pups about 2 months old, were poisoned by some evil-minded person, by strychnine placed on meat. One of the pups died in the convulsed condition common to the influence of strychnine; the others were attacked with spasmodic twitchings, which continued to increase. From some cause the bitch vomited up her meat, a portion of which was eaten by 2 chickens, about 6 or 8 weeks old. To the bitch and the remaining 2 pups, I gave about a gill of sweet oil to each, followed by about 4 grains of camphor to the mother, and 2 grains to the pups, in some bread. They recovered and were doing well. Of the chickens, one was apparently dying, lying on the ground, wings outspread, mouth open, and with frequent spasmodic jerks; the other trembled and spasmodically staggered around like an intoxicated person. To each of these I gave about a grain of camphor in butter, and fastened them up, and in an hour they had fully recovered. I mention these facts that further inquiries may be made as regards the antidotal power of camphor in poisoning by strychnine. To determine whether strychnine was the poison administered, the meat vomited by the dogs was carefully examined, and strychnine found present. Both dogs and chickens were actively purged. Since the above occurrence, tannin oil, freely given, and camphor, have been found excellent antidotes to strychnine, also the tinctures of iodine, and bromine, and chlorine" (J. King).

Dr. John Bartlett strongly recommends a solution of common salt as an antidote to strychnine poisoning, from the invariable success attending its use with poisoned dogs (*Amer. Drug. Cir.*, Vol. XI, 1868). Folker, in the *Lancet*, July, 1867, relates an instance where a healthy man had taken over 2 grains of strychnine, who was saved by the use of chloroform, internally and externally, aided by repeated small doses of tincture of aconite. In *Amer. Med. Record*, 1867, is a case related where a young man, residing at Chardon, Ohio, who had poisoned himself with 3 grains of crystallized strychnine, was saved by the internal use of camphor, and inhalations of chloroform, continued for several hours. *The Medical Times and Gazette*, May, 1868, also relates a case where a little girl, 4 years of age, had taken strychnine by mistake, and was saved by being kept under the anæsthetic influence of chloroform for a couple of hours. The *Med. and Surg. Reporter of Philadelphia*, 1867, relates a case where 3½ grains of strychnine had been swallowed, and, in 24 hours, the person was saved by the administration, every 5, 10, and 15 minutes, of ½-teaspoonful doses of tincture of Cannabis indica. J. Rosenthal, from the results of experiments upon animals, and having observed that artificial respiration caused the convulsions, arising from the influence of strychnine, to cease, and even saved the animals from dying, is strongly inclined to believe that, if any method can be devised by which artificial respiration can be maintained for a long time, all persons poisoned by strychnine can be saved, if too long a time has not been allowed to elapse from its ingestion. This method, if practicable, is reasonable, as strychnine kills by spasmodically arresting respiration.

Strychnine increases the quantity of the blood in the spinal cord, and, hence, is not useful when there is congestion of the cord; it localizes its action entirely upon the sensitive nerves; it is injurious in epilepsy and paralysis, arising from lesions of the encephalon, or congestion of the spinal cord; it is useless in paralysis agitans; but, in small doses, is useful in slight *paralysis*, due to white softening of the spinal cord, and in all cases of functional derangement from want of nervous power. It should be employed in *paraplegia*, without irritation or without increase of the vital properties of the spinal cord, as in cases of *reflex paraplegia*, and white or non-inflammatory softening of the cord. It should be avoided in paralysis with symptoms of congestion, myelitis, or spinal meningitis. It is more useful in *paraplegia* than *hemiplegia*.

Nux vomica is preferred in many gastro-intestinal affections, while strychnine is more generally employed in troubles affecting the nervous system, bladder, heart, and reproductive organs; and the action of the former is chiefly owing to the strychnine it contains. Yet their action differs but slightly, and most largely in degree. The uses of strychnine are those enumerated under *Nux Vomica* (which see). There are some conditions, however, in which strychnine is to be preferred, chiefly on account of its prompt action. Some that are mentioned under *Nux Vomica* are here repeated, and other conditions added.

Strychnine may be administered subcutaneously, and is therefore, of great value in threatened *heart failure*, to prevent *surgical shock*, and in *dyspnœa*, to sustain the breathing function when it seems to be dependent most largely upon the influence of the will, as in *low fevers* and *pneumonia*. This action is particularly marked in *typhoid* and *asthenic types of disease*, with impaired spinal innervation, and imperfect or feeble respiration. Strychnine, hypodermatically, may be used with great advantage in *atonic diarrhœa*, *cholera morbus*, and *Asiatic cholera*. One-fifth grain, in divided doses, is of marked utility in the cold stage of *congestive intermittents*, and in *ague*, with atony of the stomach and impaired innervation. Strychnine is preferred over nux vomica in *impotence*, from exhaustion or weakness, in *urinal incontinence* of the young and the aged, and in *urinal retention* from atony. Strychnine enters largely into the treatment of *dipsomania*, the sulphate or nitrate being preferred. The latter is said to be effectual in preventing *surgical shock*. It is antidotal to *chloral*, *morphine*, or *opium* (early stage of poisoning), and in *asphyxia* from gas or water, or in *chloroform narcosis*. The semi-paralytic state, produced by excess of bromides or lead, is somewhat relieved by it. Strychnine is of marked value in many nervous affections. Occasionally, it gives good results in *tetanus* and *epilepsy*, and, in *chorea*, it first aggravates, and then frequently cures. *Œsophageal spasm* and *hay-fever* are sometimes controlled by it. It has relieved *writer's cramp*. The forms of *paralysis* benefited by strychnine are those functional in character, and often reflex from excesses and rheumatism, neuralgia, concussion of the cord, hysteria, etc. In *post-diphtheritic paralysis*, it is one of our best agents. It relieves *obstinate facial neuralgia*, when atony is a marked feature.

Strychnine is also useful in *hemiplegia*, *paraplegia*, *partial paralysis of particular joints or muscles*, and of the *bladder*. The paralyzed muscles are always first affected if they are thrown into spasms at all. If the remedy is to succeed, improvement begins speedily. It must not be used in recent cases of paralysis, or while general reaction prevails; neither when signs exist either of local irritation in the brain or spinal cord, or of determination of blood to the head. It has been likewise used in various forms of *neuralgia*, *amenorrhœa*, *dysentery*, *rheumatism*, *syphilitic osteocopa*, and *obstinate constipation*. "In the treatment of *gleet*, *urethral stricture*, and *recent enlargement of the prostate*, I have found it a superior remedy, used internally and locally. In *dyspepsia*, when there is a want of appetite, constipation, and a sensation of epigastric weight after eating, I have found the combination of 1 grain of the alcoholic extract of nux vomica, well triturated with 40 grains of the oleoresin of ptelea, and divided into 20 pills, an excellent remedy. Likewise in dyspepsia connected with *impotence*, caused by masturbation or venereal disease; the dose is 1 pill, repeated 3 times a day" (John King). Strychnine will also be found advantageous in many *uterine diseases*, *prolapsus uteri*, etc. Prof. A. J. Howe found the following powder to produce an anodyne influence in cases of *cancer of the uterus*, and other severe diseases, attended with extreme pain: Take of sulphate of morphine, 5 grains; sulphate of quinine, 10 grains; strychnine, 1 grain; liquorice powder, 20 grains; mix thoroughly together, and divide into 20 powders, 1 of which may be taken every 4 or 6 hours, according to the urgency of the symptoms. Dr. Alexander Fleming recommended the following solution of strychnine, for internal use, as being much safer and more efficient than the galenical preparations of nux vomica: "Take of strychnine, 4 grains; distilled water, 10 fluid drachms; dissolve the strychnine thoroughly with the aid of a few drops of diluted hydrochloric acid, and then add alcohol, a sufficient quantity to make the whole measure 20 fluid drachms. This is of uniform strength, passes readily into the circulation, and the dose can be apportioned with accuracy. The commencing dose is 10 minims, and contains $\frac{1}{30}$ grain of strychnine. It should be given on an empty stomach, and diluted with water, to insure its prompt and easy absorption. As a tonic, the dose is 5 minims, 2 or 3 times a day." He also stated that "strychnine should never be given in pill form, because it is hard of solution in the weak acids of the stomach, and several pills may remain unchanged and accumulate there or in the bowels. A change in the secretions may then dissolve and transport them simultaneously into the blood, and give rise to alarming tetanic symptoms. This is commonly the correct explanation of the so-called cumulative action of strychnine—the sudden solution and absorption of hard pills accumulated in the stomach or bowels." The dose of strychnine is from $\frac{1}{30}$ to $\frac{1}{10}$ grain, 2 or 3 times a day. It may be rendered more soluble in alcohol or water, by the addition of a few drops of an acid, as acetic, hydrochloric, nitric, or sulphuric.

Specific Indications and Uses.—(See *Nux Vomica.*) Functional forms of paralysis, due to excesses; atony.

Related Alkaloid.—BRUCINE exerts an influence upon the system very similar to that occasioned by strychnine, but is less energetic. Its dose is from $\frac{1}{8}$ to $\frac{1}{2}$ grain, 3 or 4 times a day. In the administration of brucine and strychnine, or any of their salts, great caution must be observed, and the patient carefully watched during their use. According to Prof. Brown-Sequard, strychnine and brucine have similar effects. Local anæsthesia is reported from the use of a 5 per cent solution of brucine upon mucous membranes, but not upon the skin.

STYRAX (U. S. P.)—STORAX.

"A balsam prepared from the inner bark of *Liquidambar orientalis*, Miller"—(*U. S. P.*) (*Liquidambar imberbe*, Aiton).

Nat. Ord.—Hamamelaceæ.

COMMON NAMES AND SYNONYMS: *Liquid storax*, *Balsamum storacis*, *Prepared storax*, *Styrax præparatus* (*Br.*).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 107.

Botanical Source.—This tree is a native of Asia Minor, in the extreme southwest of which country it is gregarious, forming forests of trees of from 20 to 60 feet high. The leaves are bright-green, perfectly smooth even at the axils of the veins on the under side, shining above, pale beneath, palmate, with serrated, obscurely trilobed divisions. The aments or catkins are of distinct sexes, monœcious, having a common 4-leaved deciduous involucre; males conical; anthers numerous and subsessile; females globose, composed of small scales which surround the ovary, grow together, and gradually enlarge; calyx urceolate, 1-leafed, 2-flowered; styles 2, subulate; capsules 2, oblong, 1-celled, many-seeded (L.—Jus.).

History and Preparation.—Mr. Daniel Hanbury, in 1857, ascertained that the original storax, derived from *Styrax officinale*, had disappeared from commerce, and that the liquid storax then in the market was collected in the southwestern part of Asia Minor, from *Liquidambar orientalis*, or *Oriental sweet-gum tree* (see *Amer. Jour. Pharm.*, 1857, p. 249, and 1863, p. 436). The district opposite the islands of Samos and Rhodus is now known to be the only place on the globe where liquid storax is collected on a commercial scale. This is done, according to Mr. H. Massopust (1896), by removing strips of the whole bark lengthwise, by means of a sharp instrument, laying bare the wood. One-fourth of the total bark is removed in one season, which lasts from July to September, during which time the tree is in its sap. The bark is made into bundles and softened by throwing them into kettles with boiling water, and is then pressed out in bags made of goat's hair or in baskets. The balsam is then put into barrels, together with about one-fourth its weight of water. This is intended to keep the balsam soft and prevent loss of its aroma. Before the storax is put on the market, the water is poured off, and the balsam is kneaded with a stick so as to remove "the last drop of water." On storax so treated, the seller allows 16 per cent of tare. It is also made up in tin cans which are put into boxes (Prof. J. Mœller, *Zeitschr. des Allg. Oesterr. Apotheker-Vereins*, 1896, p. 19). It is shipped to Constantinople, Smyrna, and Bombay, and reaches the western commerce by way of Trieste.

The residual bark from which storax is removed by pressure, is also an object of commerce under the name of *Cortex thymiamati*. It has a strong odor of storax, and is used at Trieste in the preparation of *Storax calamitus*, which is a mixture of ground cortex thymiamati (3 parts) with liquid storax (1 part) and some olibanum (J. Mœller, *loc. cit.*), the purpose being to bring storax into a more easily manageable form. Exposed to the air for some time, it becomes covered with a whitish efflorescence consisting of *styracin* (see page 1856). Much of the commercial storax calamitus however, is merely "an odoriferous sawdust." (See an interesting article on storax, in *Pharm. Era*, Vol. VIII, 1892, p. 135.)

Description and Tests.—The official storax must conform to the following requirements: "A semiliquid, gray, sticky, opaque mass, depositing, on standing, a heavier, dark-brown stratum; transparent in thin layers, and having an agreeable odor and a balsamic taste. Insoluble in water, but completely soluble (with the exception of accidental impurities) in an equal weight of warm alcohol. If the alcoholic solution, which has an acid reaction, be cooled, filtered, and evaporated, it should leave not less than 70 per cent of the original weight of the balsam, in the form of a brown, semiliquid residue, almost completely soluble in ether and in carbon disulphide, but insoluble in benzin"—(*U. S. P.*). This evidently refers to cold benzin, as some constituents of storax are soluble in boiling benzin (see *Chemical Composition*). "When heated on a water-bath, storax becomes more fluid, and if it be then agitated with warm benzin, the supernatant liquid, on being decanted and allowed to cool, will be colorless, and will deposit white crystals of cinnamic acid and cinnamic ethers"—(*U. S. P.*).

Storax is heavier than water. It is sometimes adulterated with mineral matters, resin, turpentine, etc. If large quantities of resins are present, the balsam hardens in cold weather; genuine storax has at all seasons more or less the consistency of honey (J. Mœller, *loc. cit.*). An important aid in detecting the presence of turpentine and other resins in storax consists in determining the acid number, the saponification and iodine numbers, and other data (see for example, F. Evers, *Jahresb. der Pharm.*, 1896, p. 116; and K. Dieterich, *ibid.*, 1897, p. 11). The *British Pharmacopœia* and the *German Pharmacopœia* direct that storax be purified by alcohol previous to its being used medicinally.

Chemical Composition.—The chief constituents of storax are certain esters of cinnamic acid, together with free *cinnamic acid*. These esters are crystallizable *styracin* (*cinnamyl-cinnamate*, $C_6H_5CH:CH.COOC_9H_9$, derived from *cinnamyl-alcohol* C_9H_9OH, or $C_6H_5CH:CHCH_2OH$); oily *phenyl-propylcinnamate* ($C_6H_5CH:CH.COOCH_2CH_2CH_2C_6H_5$), *ethyl cinnamate* ($C_6H_5CH:CH.COOC_2H_5$), and the *cinnamate of* the trivalent alcohol *storesin* ($C_{36}H_{55}[OH]_3$), a substance existing in storax also uncombined and in the form of a sodium compound. It constitutes altogether about one-half of the weight of storax (W. von Miller, *Liebig's Annalen*, 1877, and *Amer. Jour. Pharm.*, 1878, p. 455; also compare *Liquidambar*). Other constituents of storax are water (from about 20 to 25 per cent), the hydrocarbon *styrol*, resin, caoutchouc, *ethyl-vanillin*, traces of benzoic acid, etc.

W. von Miller, in separating these constituents, proceeded as follows: Storax was wrapped in a linen bag and heated in the vapors of distilling water. The distillate contained volatile *styrol* (*styrolene*, *cinnamene*, *phenyl-ethylene*, C_8H_8, or $C_6H_5.CH:CH_2$). The residual storax passed through the cloth, leaving caoutchouc and resin. The storax was next extracted with 3 times its quantity of diluted caustic soda solution (of about 5 per cent NaOH). This dissolved part of the *storesin* and all of the free cinnamic acid. The former was precipitated from the solution by carbonic acid gas, then the latter by hydrochloric acid. The residual storax was extracted with cold alcohol, the solvent distilled off, and the residue treated with hot petroleum-ether, which dissolved *styracin* and the other esters, leaving the remainder of *storesin* undissolved.

Cinnamic acid ($C_6H_5CH:CH.COOH$) is the common constituent of several balsams, *e. g.*, balsam of Peru, tolu, storax, etc., and is formed in old oil of cinnamon by oxidation of cinnamic aldehyde (Dumas and Péligot, 1834). It has also been obtained synthetically from benzaldehyde (bitter almond oil) by Perkin. Storax usually yields between 6 and 12 per cent of the acid, but Loewe obtained as much as 23 per cent. It forms shining, odorless crystals of an aromatic, somewhat acrid taste, soluble in hot water, alcohol, and ether. Oxidizers convert it into benzaldehyde and benzoic acid. Its cinnamyl-ester is *styracin;* its benzyl-ester is *cinnameïn* (see *Balsam of Peru*).

Action, Medical Uses, and Dosage.—Storax is a stimulant, acting more especially upon mucous tissues, as do nearly all balsams. It has been found beneficial as an expectorant in *cough*, *chronic catarrh*, *asthma*, *bronchitis*, and other *pulmonary affections;* also in *gonorrhœa*, *leucorrhœa*, and *gleet*, in which it is as efficient, and more pleasant than copaiba. In fact the uses of storax are very similar to those of the latter balsam. Combined with tallow or lard, it forms a valuable application in many forms of *cutaneous disease*, especially those common to children, as *ringworm*, *tinea*, *ringworm of the scalp*, *scabies*, etc. It forms a good application for *ulcerations*, the result of freezing the fingers or toes. It is much used, on account of its fragrance, for compounding ointments and pills, and is an excellent addition to opium in the form of pill, when it is necessary to conceal the taste and smell of this narcotic; 3 or 4 grains of storax may be combined with 1 grain of opium for this purpose. The dose of storax is from 10 to 20 grains, gradually increased.

Related Species and Preparations.—*Styrax officinale*, Linné, is a small tree growing from 12 to 20 feet or more in height, with the branches alternate and round, having its bark smooth, and the young shoots downy. This plant inhabits the Levant, Palestine, Syria, and is common all over Greece; it is cultivated in several parts of Europe, but at the present day produces no balsam. It formerly yielded true storax, an article no longer in commerce (see *Pharmacographia*).

Liquidambar Formosana, Hance.—Formosa and southern China. Yields "a dry, terebinthinous resin of agreeable fragrance when heated" (*Pharmacographia*). The Chinese use it

Altingia Excelsa, Noronha (*Liquidambar Altingiana*, Blume).—The *rasamala* of Java and Malaysia. Yields a fragrant resin (see *Pharmacographia*).

Symplocos racemosa, Roxburgh (*Nat. Ord.* Stryraceæ), *Lotur bark*.—India. Contains 3 alkaloids, *loturine*, *colloturine*, *loturidine* (Hesse). In dilute acid solutions all show deep violet-blue fluorescence. In India this bark enters into numerous preparations for *bowel disorders*, and a decoction is used to give "firmness to spongy and bleeding gums." It is also used in *menorrhagia*, and as a mordant in dyeing red (Dymock, *Mat. Med. of Western India*).

Mackenzie's Syrup.—A preparation known as Mackenzie's syrup, and which has obtained considerable celebrity in some sections of the country, as a remedy in *consumption*, *coughs*, *laryngitis*, etc., is made as follows: Take of colombo root and horehound, each, 2 ounces; boneset, 1 ounce; pleurisy root, 4 ounces; water, 2 gallons. Boil until one-half of the water has evaporated; subject the articles to another boiling in fresh water, add the two decoctions together, strain and evaporate to 6 quarts. To this add sugar, 5 pounds; Canada balsam, 1 pound; liquid storax, ½ pound; wheat bran, 2 pints; subject to a gentle heat for 2 hours; add beeswax, 1 pound, and let it stand for 24 hours to cool; strain, add 1 pint of yeast, let the mixture stand for 6 days, and put it into well-corked bottles. The dose is 1 or 2 tablespoonfuls, 3 times a day. The sugar aud the balsams are undoubtedly the active agents of this heterogeneous compound.

SUCCI.—JUICES.

Preparation and History.—This class of preparations is official in the *British Pharmacopœia*. Prepared juices were introduced by Squire, in 1830. In 1870, they were made official in the *U. S. P.*, from which they have been dismissed, and, in their stead, the tinctures of recent herbs (TINCTURÆ HERBARUM RECENTIUM) substituted. Succi are prepared by expressing the juice from crushed, fresh plants, and adding thereto 25 per cent of alcohol. Owing to differences in strength, due to methods of cultivation, climate, soil, etc., they must necessarily be of doubtful value so far as uniformity of quality is concerned (compare Farr and Wright, *Chem. and Drug.*, 1896, Vol. XLIX, p. 219).

SUCCUS BELLADONNÆ.—JUICE OF BELLADONNA.

Preparation.—"Bruise the fresh leaves and young branches of Atropa Belladonna, Linne; press out the juice; to every 3 volumes of juice add 1 of alcohol (90 per cent); set aside for 7 days; filter"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Belladonna.*) Dose, 1 to 15 minims.

SUCCUS CONII.—JUICE OF HEMLOCK.

Preparation.—"Bruise the fresh leaves and young branches of Conium maculatum, Linne; press out the juice; to every 3 volumes of juice add 1 of alcohol (90 per cent); set aside for 7 days; filter"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Conium.*) Dose, ½ to 2 fluid drachms.

SUCCUS HYOSCYAMI.—JUICE OF HENBANE.

Preparation.—"Bruise the fresh leaves, flowering tops, and young branches of Hyoscyamus niger, Linné; press out the juice; to every 3 volumes of juice add 1 of alcohol (90 per cent); set aside for 7 days; filter"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Hyoscyamus.*) Dose, ½ to 1 fluid drachm.

SUCCUS LIMONIS.—LEMON JUICE.

"The freshly expressed juice of the ripe fruit of Citrus medica, Linné, var. B. Limonum, Hooker filius"—(*Br. Pharm.*, 1898).

Description and Tests.—"A slightly turbid, yellowish liquid, with a sharply acid taste. Specific gravity 1.030 to 1.040. One fluid ounce contains 30 to 40 grains (or 100 cubic centimeters contain 7 to 9 grammes) of citric acid. When lemon juice is evaporated to dryness, and the residue is incinerated, it should yield not more than 3 per cent of ash; 110 minims (or 100 cubic centimeters) of lemon juice are neutralized by about 11½ grains (or 11.4 grammes) of potassium bicarbonate, by about 9½ grains (or 9.5 grammes) of sodium bicarbonate, and by about 16½ grains (or 16.5 grammes) of sodium carbonate"—(*Br. Pharm.*).

SUCCUS LIMONIS CUM PEPSINO (N. F.)—LIME JUICE AND PEPSIN.

Preparation.—"Pepsin (*U. S. P.*), thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; water, one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl℥, 440 ♏]; glycerin, one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl℥, 440 ♏]; alcohol, ninety cubic centimeters (90 Cc.) [3 fl℥, 21 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [232 grs.]; lime juice, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the pepsin in the water, mixed with about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of lime juice. Then add the glycerin and alcohol, and, lastly enough lime juice to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Incorporate the purified talcum with the liquid, let it stand a few days in a cold place, if convenient, occasionally agitating, then filter through a wetted filter, and finally pass enough lime juice through the filter to restore the original volume. Each fluid drachm represents 2 grains of pepsin (*U. S. P.*)"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Uses, those of *Pepsin*. Dose, 1 to 2 fluid drachms.

SUCCUS SCOPARII.—JUICE OF BROOM.

Preparation.—"Bruise fresh broom tops; press out the juice; to every 3 volumes of juice add 1 of alcohol (90 per cent); set aside for 7 days; filter"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Scoparius.*) Dose, 1 to 2 fluid drachms.

SUCCUS TARAXACI.—JUICE OF TARAXACUM.

SYNONYM: *Juice of dandelion.*

Preparation.—"Bruise fresh taraxacum root; press out the juice; to every 3 volumes of juice add 1 of alcohol (90 per cent); set aside for 7 days; filter"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Taraxacum.*) Dose, 1 to 2 fluid drachms.

SULPHONAL.—SULPHONAL.

FORMULA: $(CH_3)_2C(SO_2C_2H_5)_2$, or $C_7H_{16}S_2O_4$. MOLECULAR WEIGHT: 227.59.

SYNONYM: *Diethylsulphon-dimethylmethane.*

History and Preparation.—Sulphonal is a copyrighted name of a preparation now official in the *German Pharmacopœia* and the *British Pharmacopœia*, 1898. It was first prepared by E. Baumann, in 1886, and is obtained by the action of *mercaptane* ($C_2H_5.SH$) upon acetone ($CH_3.CO.CH_3$), and oxidizing the resulting *mercaptol* with potassium permanganate. The following equations will illustrate the reactions: $CH_3COCH_3+2C_2H_5SH=(CH_3)_2:C:(SC_2H_5)_2$ (mercaptol), and $(CH_3)_2:C:(SC_2H_5)_2+O_4=(CH_3)_2:C:(SO_2C_2H_5)_2$. (For another method, which avoids the employment of the ill-smelling mercaptane, see *Amer. Jour. Pharm.*, 1889, p. 178.)

Description and Tests.—Sulphonal occurs in almost tasteless, odorless, and colorless prismatic crystals, neutral to test-paper. At 125.5° C. (258° F.) it fuses. It is easily soluble in boiling alcohol (2 parts), and dissolves in ether (135 parts), cold water (450 parts, *Br.*; 500 parts, *P. G.*), in boiling water (15 parts), and in cold alcohol (50 parts, *Br.*; 65 parts, *P. G.*). "When ignited with free access of air, it burns away without leaving a residue, and with evolution of sulphur dioxide gas. It is very permanent toward bromine, chlorine, strong alkalies, and acids. The unpleasant, characteristic odor of mercaptane (C_2H_5SH) is evolved when 0.1 gramme of sulphonal is heated, in a test-tube, with powdered charcoal"—(*Ger. Pharm.*). "If a mixture of sulphonal with an equal weight of potassium cyanide be heated, the odor of mercaptane is evolved, and when to the solution of the product, in water, excess of hydrochloric acid and a few drops of a solution of perchloride of iron are added, a reddish color is developed"—(*Br. Pharm.*). The red coloration is that of ferric rhodanide, and indicates the sulphur of sulphonal. The *British Pharmacopœia* further states that "it evolves hydrogen sulphide when gradually warmed with dried sodium acetate. It should yield no characteristic reaction with the tests for chlorides or sulphates"—(*Br. Pharm.*). The *German Pharmacopœia* prescribes that no odor should be developed when dissolving 1 part of sulphonal in 50 parts of boiling water. It also directs that 10 Cc. of a 2 per cent hot, aqueous solution of sulphonal should not at once decolorize 1 drop of solution of potassium permanganate. The presence of unoxidized mercaptol would be indicated by the reduction.

Action, Medical Uses, and Dosage.—Sulphonal is hypnotic, but is said not to be analgesic. Single doses, unless large, do not, as a rule, produce serious effects, but the continued use of the drug may produce any or several of the following results: Nausea, vomiting, mental excitation, languor, headache, gastric pain, vertigo, nervous depression, exhaustion, diarrhœa, and incoordination of muscular movements, particularly staggering gait. Even small doses will, occasionally, produce ill-effects. An ounce has produced death from respiratory paralysis, preceded by stupor, elevated temperature, slow heart-action and respiration, anuria, and complete general anæsthesia (Knagg's *Br. Med. Jour.*, 1890). Death has also resulted after taking 30 grains, but the victim was a nervous wreck. Ptosis, sphincter paralysis, erythematous, rubeolous, and scarlatinous eruptions, and arrest of renal action have also been observed (see case of chronic poisoning from sulphonal in *Amer. Homœopathist*, 1897, p. 419). During its administration the kidneys should be carefully watched, and the bowels should not be allowed to become constipated. It produces, in overdoses, deep wine-colored urine, staining garments with which it may come in contact. When the urine begins to darken in color or become smoky, the agent should be at once discontinued. The duration of sleep produced by sulphonal varies, and can not be prejudged with certainty. As a rule, sleep is slowly produced and quite prolonged. After awakening, mental and physical dullness and sluggishness are often marked. Pain especially retards its action greatly. Those who have used it in *heart affections*, for which it has been advised, declare it a dangerous agent under such circumstances. It has been used with a measure of success in *chorea*, *diabetes*, and *night-sweats*. Its chief use is as a hypnotic, being adapted to *insomnia*, due to mental worry or excitement. It gives sleep to those worrying over spermatorrhœa, gonorrhœa, and similar nervous conditions. It has been most largely used to secure sleep in *insanity* and *delirium tremens*. In *mania*, with general nervous irritation and great excitement, it has produced calm and refreshing sleep. It is better adapted, however, to mild forms of mania. Dr. Locke advises it as a safe remedy (1 or 2-grain doses) in the *restlessness of dentition*, to ward off spasms and to produce sleep. Manley (*Ann. of Ec. Med. and Surg.*, Vol. I, p. 45) speaks highly of sulphonal, having employed it chiefly for the *insomnia of the aged*, and in nervous excitement of drunkards but short of delirium tremens. He had observed no bad effects from the drug. Prof. Locke speaks of it as a good hypnotic in the *insomnia of typhoid fever*, giving 10-grain doses; here it does not seem to impair the nervous system. While it does not stop *cough*, it often gives sleep when cough produces wakefulness. In *rheumatism* and *erysipelas*, if the pain be not too great, it may be employed to give sleep; if pain is great, it will do no good. The patient in whom sleep is produced by sulphonal, should not be awakened lest headache or giddiness be produced, but should be allowed to awaken naturally (Locke). The dose of sulphonal for a child is from 1 to 3 grains; for an adult, 5 to 20 grains. It acts slowly, and, therefore, should be given 1 or 2 hours before bedtime. It should be given in powder, in milk, hot water, beef tea, or soup. It should not be given in tablet form.

Related Compounds.—TETRONAL, *Diethylsulphon-diethylmethane* ($[C_2H_5]_2C[SO_2C_2H_5]_2$). This compound is prepared exactly like sulphonal, except that *diethylketone* ($C_2H_5COC_2H_5$) is employed in the place of dimethylketone (acetone). Tetronal, sulphonal, and trional are analogous, all belonging to the group known as disulphones. Tetronal occurs in shining laminæ or plates, easily soluble in ether and alcohol, and in cold (450 parts) and hot water, forming a solution which is tasteless, and neutral to litmus paper. The melting point is 85° C. (187° F.), which is its distinctive feature, since it gives the same reactions as sulphonal and trional. Tetronal is employed in *insomnia*, due to functional or structural nervous diseases, and particularly for the *sleeplessness of insanity*. Dose, 8 to 30 grains.

TRIONAL, *Diethylsulphon-methylethylmethane* ($CH_3.C_2H_5.C[SO_2C_2H_5]_2$).—This body is prepared like sulphonal, except that, instead of acetone, methylethylketone is employed. It forms plate-like crystals, which are colorless and odorless. At 70° C. (158° F.) they fuse, (see *Tetronal*). Easily soluble in alcohol and ether; less soluble in cold water (1 in 300), and quite readily soluble in water. Action and medical uses identical with those of tetronal. Dose, 8 to 30 grains.

SULPHUR LOTUM (U. S. P.)—WASHED SULPHUR.

Symbol: S. Atomic Weight: 31.98.

Preparation.—Take of "sublimed sulphur, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; ammonia water, ten cubic centimeters (10 Cc.) [163 ♏]; water, a sufficient quantity. Pass the sublimed sulphur through a No. 30 sieve, mix it thoroughly with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water, add ten cubic centimeters (10 Cc.) [163 ♏] of ammonia water, and digest for 3 days, agitating occasionally. Then add one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water, transfer the mixture to a muslin strainer, and wash the sulphur with water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat, and pass it through a No. 30 sieve"—(*U. S. P.*).

Owing to the method of obtaining sulphur by sublimation, the product is apt to be contaminated with sulphuric acid, and volatile foreign bodies, especially small quantities of arsenic, consequently a little ammonia is added to the wash-water to neutralize and remove the acidity as well as dissolve the arsenic.

Description and Tests.—The *U. S. P.* describes washed sulphur as "a fine yellow powder, without odor or taste. Insoluble in water; slightly soluble in absolute alcohol; more readily soluble in benzin, benzol, oil of turpentine, and many other oils; also in ether, in chloroform, and in boiling aqueous solutions of alkaline hydrates. Carbon disulphide promptly dissolves a portion of it, but leaves a residue of insoluble sulphur, which may be dissolved by a boiling solution of an alkaline hydrate. When heated to 115° C. (239° F.), washed sulphur melts, and at a higher temperature volatilizes, or, if air be admitted, burns to sulphur dioxide, which is identified by its characteristic odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas"—(*U. S. P.*). In this reaction, the sulphurous acid reduces the mercurous salt to metallic mercury. "The amount of residue left after volatilizing or igniting a weighed portion of it should not exceed 0.1 per cent. If 0.5 Gm. of washed sulphur be boiled with 10 Cc. of sodium hydrate T.S., it should be completely dissolved, leaving no residue (absence of earthy or metallic impurities). If 0.5 Gm. of washed sulphur be digested for several hours with 10 Cc. of ammonia water, the clear filtrate should not be colored yellow, nor be rendered turbid, by acidulation with hydrochloric acid, even after the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic). If 5 Cc. of water be agitated with 2 Gm. of washed sulphur, the liquid should not change the color of blue or red litmus paper (absence of acid, and of ammonia). If 0.5 Gm. of washed sulphur be boiled with a solution of 0.5 Gm. of potassium cyanide in 5 Cc. of water, and, after filtration, the clear liquid be acidulated with hydrochloric acid, it should not assume a reddish color, even after standing for an hour (absence of *selenium*)"—(*U. S. P.*). The reddish color is that of selenium, produced by the decomposition of potassium selenocyanide (KCNSe) by the acid.

Action, Medical Uses, and Dosage.—(See *Sulphur Sublimatum.*) Dose, a fraction of a grain to 4 drachms, according to whether an alterative or laxative effect is desired.

SULPHUR PRÆCIPITATUM (U. S. P.)—PRECIPITATED SULPHUR.

Symbol: S. Atomic Weight: 31.98.

Synonyms: *Lac sulphuris, Milk of sulphur, Magisterium sulphuris.*

Preparation.—"Sublimed sulphur, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs]; lime, fifty grammes (50 Gm.) [1 oz. av., 332 grs.]; hydrochloric acid, water, each, a sufficient quantity. Slake the lime, and mix it uniformly with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water. Add the sublimed sulphur, previously sifted, and, after thorough mixing, add one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water, and boil the mixture during 1 hour, stirring constantly, and replacing the water lost by evaporation. Then cover the vessel, and permit the contents to cool and to become clear by subsidence. Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually, and with constant stirring, hydrochloric acid, previously diluted with an equal volume of water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it, until the washings are tasteless and cease to give an acid reaction with litmus paper. Then dry the product rapidly, at a moderate heat, and keep it in well-stoppered bottles"—(*U. S. P.*). In this process, a solution of calcium thiosulphate and calcium pentasulphide is formed, as follows: $3CaO+S_{12}=CaS_2O_3+2CaS_5$. The pentasulphide causes the deep-yellow color of the solution. Upon adding hydrochloric acid, the pentasulphide is decomposed as follows: $2CaS_5+2HCl=CaCl_2+Ca(SH)_2+S_8$, or $2CaS_5+4HCl=2CaCl_2+2H_2S+S_8$. An excess of hydrochloric acid must be avoided, and the precipitate of sulphur must be quickly separated from the supernatant liquid, in order to prevent its contamination with coarser sulphur which forms upon standing by secondary reactions, viz., decomposition of calcium thiosulphate by the acid, producing sulphur and sulphur dioxide: $CaS_2O_3+2HCl=CaCl_2+S+SO_2$. Again, the sulphur dioxide may react with some dissolved hydrogen sulphide, as follows: $SO_2+2H_2S=S_3+{}_2H_2O$. If the addition of hydrochloric acid is carried to acidity of the liquid, the precipitated sulphur is liable to be contaminated with ill-smelling, oily hydrogen polysulphides (*e. g.*, H_2S_2 and H_2S_3), and with arsenic sulphide which is formed by the following reaction: $(AsS_4)_2Ca_3$ (soluble calcium sulpharseniate) $+6HCl=As_2S_5+3CaCl_2+3H_2S$. The foregoing is in part the explanation of the reaction as given by B. Hirsch and A. Schneider in their *Commentar zum Arzneibuch für das Deutsche Reich*, Göttingen, 1895.

Description and Tests.—"A fine, amorphous powder, of a pale-yellow color, without odor or taste. Insoluble in water; very slightly soluble in absolute alcohol; readily soluble in carbon disulphide; also in benzin, benzol, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling, aqueous solutions of alkaline hydrates. At 115° C. (239° F.) precipitated sulphur melts, and at a higher temperature its volatilizes, or, if air be admitted, burns to sulphur dioxide, leaving no residue. If 0.5 Gm. of precipitated sulphur be boiled with 10 Cc. of sodium hydrate T.S., it should be completely dissolved leaving no residue (absence of earthy or metallic impurities). If 1 Gm. of precipitated sulphur be digested for several hours with 10 Cc. of ammonia water, a portion of the clear filtrate should not leave any residue on evaporation; nor should another portion be colored yellow, or rendered turbid, by acidulation with hydrochloric acid, even after the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic). If 5 Cc. of water be agitated with 2 Gm. of precipitated sulphur, the liquid should not change the color of blue or red litmus paper (absence of acid or alkali); nor should it leave any residue on evaporation (absence of soluble impurities). If 0.5 Gm. of precipitated sulphur be boiled with a solution of 0.5 Gm. of potassium cyanide in 5 Cc. of water, and, after filtration, the clear liquid be acidulated with hydrochloric acid, it should not assume a reddish color, even after standing for an hour (absence of selenium)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Sulphur Sublimatum.*) Dose, a fraction of a grain to 3 drachms, according to whether an alterative or laxative effect is desired. Sometimes preferred for ointments on account of the smoothness of the product produced.

SULPHUR SUBLIMATUM (U. S. P.)—SUBLIMED SULPHUR.

SYMBOL: S. ATOMIC WEIGHT: 31.98.

SYNONYMS: *Sulphur*, *Sublimed sulphur*, *Flowers of sulphur*, *Flores sulphuris*, *Brimstone*.

Source and Preparation.—Sulphur, as such, is abundant in volcanic districts, especially in Sicily, where it is often found crystallized (*virgin sulphur*). It mostly occurs intermixed with gypsum, limestone, and clay. Combined sulphur widely occurs in the organic world, being an essential constituent of albumen, of wool, horn, hair, etc., and of certain volatile oils, viz.: those of mustard, garlic, onion, asafetida, etc. Among the minerals, sulphur is much distributed in the form of *sulphates*, as gypsum, heavy-spar, epsom salts, etc., or of *sulphides*, as iron pyrites (FeS_2), copper and iron pyrites ($CuFeS_2$), galena (PbS), cinnabar (HgS), black antimony (Sb_2S_3), and zinc blende (ZnS), etc. In the form of hydrogen sulphide, it gives the sulphur mineral waters their peculiar character. In the United States, sulphur deposits occur in Utah, Nevada, California, and other states. In Sicily, *crude sulphur* is obtained by fusion, *i. e.*, heating the ore, with limited access of air, in kilns (*calcaroni*) having a slanting bottom. The melted sulphur collects in a pit in front of the kiln. It is then purified by distillation from iron retorts, the vapors of sulphur being collected in large brick chambers, where they condense on the walls to a fine, impalpable powder called *flowers of sulphur*, or *sublimed sulphur*. When the temperature is allowed to rise, the powder melts again, and collects at the bottom of the chamber. It is drawn off and poured into cylindrical wooden molds, wherein it is allowed to harden, assuming the well-known form termed *roll* or *stick sulphur*. Roll sulphur, obtained in this manner, is called *refined sulphur* or *brimstone*. *Horse brimstone* (*sulphur vivum*, *black sulphur*) was, at one time, used in veterinary practice, and was an impure and variable preparation (see L. F. Kebler, *Amer. Jour. Pharm.*, 1894, pp. 242 and 559). Some sulphur of commerce is derived from the distillation of pyrites minerals.

Description and Tests.—The refined sulphur of commerce is a hard, brittle substance, of greenish-yellow color, and having a faint, peculiar taste and odor. It is unchanged in the atmosphere, is a non-conductor of electricity, and becomes negatively electric when rubbed. Its specific gravity is about 2.00. When heated, sulphur melts at about 115° C. (239° F.), forming a thin liquid of light-red color. At a temperature between 200° and 250° C. (392° and 482° F.), it becomes dark-red and viscid, and at 330° C. (626° F.), it becomes thin again. At 440° C. (824° F.), sulphur volatilizes. Sulphur is known in several *allotropic modifications*, viz.: as (1) rhombic or octohedral sulphur, (2) monoclinic or prismatic sulphur, (3) amorphous or plastic sulphur. The first is the form in which sulphur crystallizes from carbon disulphide and other solvents; the second is obtained when melted sulphur crystallizes slowly; it is gradually converted into the rhombic form. The third modification is formed when melted sulphur, heated above 330° C. (626° F.), is poured in a thin stream into cold water. In this state it is plastic and capable of receiving and retaining delicate impressions of seals, coins, etc. It has a brown color, but is gradually converted into the yellow rhombic modification. The two crystallizable modifications are soluble in carbon disulphide; the amorphous is but partially soluble.

Sulphur forms principally two oxides, viz.: (1) gaseous sulphur dioxide (SO_2), the anhydride of sulphurous acid (see *Acidum Sulphurosum*), and (2) solid sulphur trioxide (SO_3), the anhydride of sulphuric acid (see *Acidum Sulphuricum*).

Sublimed sulphur should conform to the following pharmacopœial requirements: "A fine, yellow powder, having a slight, characteristic odor, and a faintly acid taste"—(*U. S. P.*). The taste is due to the presence of some sulphuric acid that is formed during sublimation. To remove this acid is one of the objects of purifying this sulphur by washing it with diluted ammonia water (see *Sulphur Lotum*). "Insoluble in water; slightly soluble in absolute alcohol; more readily soluble in benzin, benzol, oil of turpentine, and many other oils; also in ether, in chloroform, and in boiling, aqueous solutions of alkaline hydrates"—(*U. S. P.*). The solution contains alkali sulphide and thiosulphate, *e. g.*, $6KOH+8S=2K_2S_3+S_2O_3K_2+3H_2O$. "Carbon disulphide promptly dissolves a portion of it, but leaves a residue of crystalline sulphur, which may be dissolved by a boiling solution of an alkaline hydrate. At 115° C. (239° F.) it melts, and at a higher temperature it volatilizes, or, if air be admitted, burns to sulphur dioxide, characterized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas. When agitated with water, the latter gives an acid reaction with litmus paper. The amount of residue left after volatilizing or burning a weighed portion of it should not exceed 0.5 per cent"—(*U. S. P.*).

The presence of sulphur in any compound may be readily shown by mixing the powdered substance with pure, calcined sodium carbonate, and heating the mixture on charcoal before the blowpipe until it is fused, transferring the bead on a silver coin, and moistening with water. If sulphur is present, a black spot of silver sulphide is formed at once. In organic substances, the presence of sulphur may be ascertained either by oxidizing the sulphur to sulphuric acid, by means of nitric acid or aqua regia, and testing with barium chloride, or by fusing the mass with a small quantity of metallic sodium, which forms sodium sulphide, cautiously dissolving the fused mass in water, and observing the characteristic violet-blue coloration of the sulphide by adding solution of nitroprusside of sodium.

Action, Medical Uses, and Dosage.—Sulphur, in its various forms, is an ancient and very important medicine. In small doses, it is a very efficient alterative, and influences the skin to some extent; no sensible phenomena are produced by doses of 1 to 6 grains of sulphur, but given in doses of a drachm, it excites intestinal action and occasions small, soft, pasty evacuations, which, however, are never watery. One serious objection to its use is that it renders the stools, and even the insensible perspiration, insupportably fetid; which arises from its being converted within the body into sulphuretted hydrogen. If the sulphur contains acid, its operation will be attended with more or less griping. It is probable that sulphur is rendered soluble, and, therefore, absorbable by the sodium compounds of the bile. In doses of from 10 to 20 grains, repeated every hour, it stimulates the circulation, increases temperature, and finally induces sweating. If long administered, the skin and breath exhale the disagreeable odor of sulphur dioxide, the perspiration stains yellow, and silver articles, coming in contact with the exhalations, are tarnished, a coating of silver sulphide being formed. Sulphur, when administered, may be detected in the urine, and if in sufficient quantity may act as a laxative upon the nursing infant of a woman who has taken it. Poisonous effects have been observed from sulphur when given in large amounts. Two ounces taken in a day, in 2 doses, occasioned headache, fever, pupillary contraction, semiconsciousness, cold, clammy perspiration, hematuria, vomiting, and purging of bloody stools, with much griping pain. Two-drachm doses, several times a day, have occasioned some of these symptoms and left an irritable condition of the stomach, persisting for many years. Even a 10 per cent ointment of sulphur, applied to the scalp, has caused serious trouble. As a rule, however, quite large doses of sulphur have been given for some length of time without any unpleasant results. Undoubtedly, many of the above-named effects were produced by the ordinary impurities of the sulphur, and, as a rule, it is these impurities which make sulphur so valuable as an external remedy, but for internal purposes, with few exceptions, washed sulphur should be used. Sulphur should not be given when there is active inflammation or severe febrile manifestations.

One of the old and important uses of sulphur was as a laxative. It is also used in *diseases of the bladder*, and in *pregnancy* as a mild cathartic, either alone, combined with cream of tartar, or with some other saline purgative. It is given alone in from ½ to 2-drachm doses, in milk or molasses; or 30 grains of sulphur combined with 2 drachms of bitartrate of potassium. For *hemorrhoids*, it is an exceedingly efficient agent. When there is severe lumbar pain, constipation, and the evacuations are hard, tenesmic, and more or less bloody, and the rectum protrudes, give ½ drachm of sulphur in milk, and repeat the dose every 2 or 3 days. Sulphur, however, is chiefly employed in Eclectic practice as an alterative and reconstructive agent. In the majority of instances the 1 x trituration is to be preferred. Thus it frequently does excellent service in the *anemic conditions* of scrofulous individuals suffering from female disorders, and may be given with iron when the latter alone is generally ineffectual. It not unfrequently happens that the natural supply of sulphur is insufficient for the perfect elaboration of the protein tissues, and, without doubt, the beneficial action of onions, eggs, mustard, and like substances is largely due to their furnishing sulphur when the system is greatly in need of it. The cases requiring sulphur have a blanched appearance of the skin, the iris and the hair fade in color, and in the middle-aged there is an early tendency to gray hairs; the feces and urine are pale, and the latter contains cystine. If the mucous surfaces are bathed in a mucous flow, and there are itching and burning, the indications are stronger. If the secretions are fetid or cadaverous, and there is evident tendency to decomposition of the fluids and tissues, sulphur is indicated, and, in small doses, will greatly change the condition of disease of which these symptoms are a part. If the bile be imperfectly elaborated so that it fails to exert its antiseptic effects upon the contents of the stomach, sulphur will greatly assist in rectifying the trouble. As a rule, most scrofulous conditions are benefited by sulphur. Use it in *leucorrhœa*, *conjunctivitis*, with red, swollen lids, *mucous diarrhœa*, and *ulcerations*, all depending upon a *scrofulous diathesis*. Take of the 1 x trituration about 10 or 15 grains, night and morning. The same course should be pursued in chronic diseases where the usual alterative acts but slowly or imperfectly; here substitute a month's treatment with sulphur. In *skin affections*, it is an aid to local treatment in affections simulating *itch*, in *herpetic eruptions*, *scald head*, *psoriasis*, and alone in *morph*, and *successive crops of boils*. For that form of irritation behind the ears, and at the angles of the mouth and wings of the nose in scrofulous children, sulphur should form the internal treatment, and salicylic acid and borax the local (Locke). Sulphur is of value in *neuralgia*, *muscular cramps*, and *headaches* due to fullness of blood in the cerebrum, accompanied with vertigo and ringing in the ears.

Sulphur is an efficient remedy in *chronic rheumatism*, giving internally 5-grain doses, and wrapping the affected part in a flannel bandage freely sprinkled with powdered sulphur. In these cases the pain is darting and tearing, and of a scrofulous or syphilitic origin. The scrofulous conditions of females present a good field for the application of alterative doses of sulphur. Thus it is useful in *sore nipples*, *sexual frigidity*, and in that form of *amenorrhœa* where the patient is anemic and a semileucorrhœal flow takes the place of normal menstruation. It is valuable in the *dyspepsia* of strumous origin, with gastric heaviness after meals, bad taste, heartburn, constipation, or tenesmic diarrhœa with offensive stools. It is a remedy for *incontinence of urine*, associated with piles, or cystic irritation, and in *catarrhal conditions of the bladder*. Sulphur is occasionally of value in *paralytic states*, and, as a remedy for *cough*, it fills a very important place. The cough is obstinate and accompanied by loud rattling of mucus within the chest, and expectoration is abundant, yellowish or greenish, and occasionally very offensive. Thus it mitigates the *cough of phthisis*, and is sometimes sufficient to effect a cure in *humid asthma*, *chronic nasal catarrh*, *chronic bronchitis*, and *chronic pertussis*, all with profuse secretion. Dr. Guibourt, of Paris, used sulphur with considerable success in the treatment of *lead colic*, and Dr. Laugantiers, by administering teaspoonful doses every hour of a mixture of 1 teaspoonful of sulphur in 4 fluid ounces of water, found it beneficial in the treatment of *croup*. An insufflation of sulphur is thought to be of service in *diphtheria*, to hasten the removal of the membranes, and it is frequently employed in other *ulcerative forms of sore throat*.

Externally, sulphur is used in various cutaneous diseases of the vesicular, scaly, or papular kind. Sulphur-baths are likewise found beneficial in *scrofula*, *chronic paralysis*, *chronic rheumatism*, *scabies*, and all kinds of *scaly cutaneous disorders;* the sulphurous acid gas, developed by sprinkling sulphur upon a hot iron or other vessel, is applied to the body, the head being protected. The effects occasioned are warmth, redness, and prickling of the integuments, followed by considerable sweating and excitement of the circulation. If the gas should be inhaled, it will prove powerfully irritating to the glottis, and altogether irrespirable, even when diluted with atmospheric air. As this procedure is sometimes apt to irritate the skin considerably, it is not so frequently employed as formerly. Sulphur, locally, is often beneficial in *ecthyma*, *comedones*, *sycosis*, *impetigo*, and *psoriasis*. The effects of sulphur, and of sulphurous acid in cutaneous diseases and rheumatism may be obtained by using the sulphide of potassium in the form of bath, say 2 or 3 ounces to 100 pounds of water.

Sulphur is a specific for *scabies*, and it is for this purpose that it has been most used externally. There are many methods employed, and all of them have for their purpose the destruction of the insect, which is accomplished by sulphur, or, as some contend, by the sulphurous acid formed in the usual sulphur applications. The following ointment is as efficient as any, having first thoroughly and freely washed the parts with soap and water: ℞ Sulphur. ℥i; potassium carbonate, ʒii; lard, ℥iv. Mix. Anoint the parts from 2 to 4 times a day (Locke). Prof. Webster recommends the following: ℞ Lanolin, ℔j; oil of tar, fl℥j; specific veratrum, fl℥i; sublimed sulphur, q.s. Mix. Ft. Unguent. Apply 3 successive nights, omit 3 nights, then apply again in the same order, preceded by a thorough bath each time. This is also recommended as a good application for *psoriasis* and *eczema;* eczematous affections are also well treated locally with sulphur (1 part) and starch (2 or 3 parts) (Locke). Prof. Locke recommends the following hair tonic, provided the hair bulbs are not dead: ℞ Washed sulphur, ʒi; oil of bergamot, gtt. x. Triturate; add glycerin, flʒij, and rose-water, fl℥xij. Apply with a soft sponge once a day.

Prof. Ellingwood (*Mat. Med. and Therap.*, p. 628) speaks favorably of sulphur used alternately with potassium nitrate in stubborn *acne*. His method is to apply (after thorough washing with sulphur or tar soap, rinsing with hot water, and carefully drying with a soft cloth) a lotion of 1 drachm of precipitated sulphur in the morning, and a lotion of 1 drachm of potassium nitrate in the evening, in either case not drying the parts, but allowing them to dry by evaporation. From this procedure he has obtained remarkable results in cases which have resisted other treatment for years. He advises against sulphur *ointments* in this affection on account of the mechanical obstruction produced. The dose of sulphur, as a laxative, is about 1 drachm; as an alterative, ½ grain, or the 1 x trituration, in 5-grain doses.

Specific Indications and Uses.—Hemorrhoids, with severe lumbar pain, constipation, and hard, tenesmic stools, which are sometimes bloody, and the rectum protrudes; scrofula; anemia of scrofula where iron is ineffectual; skin blanched, iris and hair fade, feces and urine pale; cystine in urine; mucorrhœa, with itching and burning; tendency to decomposition of fluids and solids, with fetid secretions; scrofulous ophthalmia, with red, swollen eyes; headache, with cerebral fullness; rheumatic darting or tearing pain; localized pain like the sticking of a pin; cough obstinate, with profuse expectoration; dyspepsia, with gastric weight, heartburn; constipation or offensive, tenesmic diarrhœa; skin affections, simulating itch. Externally, scabies; scaly, vesicular, and papular eruptions; sores at the angles of the mouth, and around the ears and nose.

Related Preparation.—Balsam of Sulphur, *Oleum lini sulphuratum*, *Oleum sulphuratum*, *Sulphurated oil*. Sulphur is partially soluble in hot olive oil, and will be deposited crystalline from a saturated oily solution upon cooling. The oil, however, is partially decomposed, the result being a viscid, acid, reddish-brown liquid of a very offensive odor. The Edinburgh College directed sublimed sulphur (1 part) and olive oil (8 parts), to be boiled together over a slow fire with constant stirring, the process to be conducted in an iron pot large enough to hold three times the amount above directed. The pot should be provided with a cover, to use in case the rising vapors should inflame. This preparation was once used, in doses of 5 to 30 drops, in such respiratory affections as *consumption* and *catarrh*. Owing to its acrid properties, it was abandoned as an internal agent. Locally, it is a stimulant to *foul ulcerations*.

SULPHURIS IODIDUM (U. S. P.)—SULPHUR IODIDE.

Synonym: *Sulfur iodatum*.

Preparation.—"Washed sulphur, twenty grammes (20 Gm.) [309 grs.]; iodine, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]. Mix the sulphur and iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and, by means of a water-bath, gradually, and with occasional agitation, apply a heat not exceeding 60° C. (140° F.), until the ingredients combine and become of a uniformly dark color throughout. Then increase the heat to the boiling point of the water, so as to fuse the mass. Should any iodine have sublimed and condensed on the glass, incline the flask so as to combine the iodine with the fused mass, and then pour the latter out upon a porcelain plate or other suitable cold surface. After cooling, break the product into pieces of suitable size, and keep them in a glass-stoppered bottle, in a cool place"—(*U. S. P.*).

Description.—When united, as directed above, in atomic proportion, iodine and sulphur form what is commonly regarded as *sulphur subiodide* (S_2I_2), or, as sometimes called, *iodine disulphide* (I_2S_2). The *U. S. P.* thus describes it: "Brittle masses of a crystalline fracture, and a grayish-black, metallic lustre, having the odor of iodine, and a somewhat acrid taste. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol and ether dissolve out the iodine, leaving the sulphur"—(*U. S. P.*). The iodine is also removed by cold solutions of potassium iodide, by caustic potash, and volatile oils. "Continued boiling with water vaporizes all the iodine, leaving about 20 per cent of sulphur as residue. On exposing sulphur iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature, a sublimate is formed, containing both iodine and sulphur. At a still higher temperature, the whole is volatilized, leaving only a trace of residue"—(*U. S. P.*). (Also see investigation on the iodides of sulphur, by Prof. H. McLeod, in *Amer. Jour. Pharm.*, 1892, p. 573.)

Action, Medical Uses, and Dosage.—Internally, in doses of from 1 to 6 grains per day, sulphur iodide has been found useful in *scrofulous* and various *cutaneous affections*. It may be given in pill form. Externally, in form of ointment, *Unguentum Sulphuris Iodidi*, 1 part to 8, 12, or 16 parts of lard or cocoanut fat, it has been very efficient in certain chronic cutaneous diseases, as *lupus*, *acne*, *herpes*, *eczema*, *tinea capitis*, etc. If the ointment be strong with the salt, caustic effects may be produced.

SUMBUL (U. S. P.)—SUMBUL.

"The root of *Ferula Sumbul* (Kauffmann) Hooker filius"—(*U. S. P.*) (*Euryangium Sumbul*, Kauffmann; *Sumbulus moschatus*, Reinsch).

Nat. Ord.—Umbelliferæ.

Common Names: *Sumbul*, *Musk-root*, *Jatamansi*.

Illustrations: *Botanical Mag.*, Pl. 6196; Bentley and Trimen, *Med. Plants*, 131.

Botanical Source.—The plant that produces the sumbul-root of commerce, is an herbaceous perennial, with an erect, milk-bearing stem, and is a native of central Asia. The leaves are mostly radical, large, and ternately decompound, with the ultimate segments narrow and toothed. The upper stem leaves are reduced merely to the sheathing bases of the petioles. The flowers are small, yellow, and disposed in compound umbels. The terminal umbels are perfect, the lateral, only staminate. They have 5 stamens, 5 petals, and a 2-carpeled pistil. The fruit consists of 2 dry, seed-like carpels, compressed laterally, and each carpel having 3 dorsal ribs, and 2 narrow lateral wings.

History.—For thirty years after sumbul (musk-root) had become an article of commerce, nothing was known concerning its botanical source. In 1869, Kauffmann, from plants collected in Russian Turkestan, and grown in the Moscow Botanic Garden, established it in a new genus, *Euryangium*, closely related to Ferula, and differing chiefly in the broader vittæ (*Treasury of Botany*). The plant has since, however, been ascribed to *Ferula* by Petournikoff, and by Hooker filius, after an examination of the ripe fruit sent from Russia.

Description.—*Ferula Sumbul*, or *Musk-root* of commerce, reaches our market through Russia. Some specimens are under cultivation in England (see E. M. Holmes, *Amer. Jour. Pharm.*, 1897, p. 314, from *Pharm. Jour.*). Sumbul-root of commerce occurs in pieces or sections, often branched, and from ½ inch to 4 inches in thickness, the diameter of the root ranging from ½ inch to 3 inches. It is brown externally, the bark, in some instances, scaling off in tough, paper-like pieces, resembling birch bark, and again adhering closely to the root. The lower part of the stem is frequently attached to the root, and usually, in such cases, it is broken into a fibrous mass. The cut parts of the roots are covered with a dirty resinous layer, which exuded while fresh. A fresh section of the root shows a very porous, spongy texture; in many cases the fibrous substances being saturated with resinous matter, especially near the bark. There is much difference in the color, some pieces being almost white internally; these we find to contain a comparatively small proportion of resin, and to be of light weight, when compared with the specimens of a brown color. This latter quality of the root is to be preferred, although it is customary, we believe, to select the former. Choice sumbul has a strong odor of musk, is resinous internally, and is aromatic and bitter to the taste. Its medicinal principles seem to be mostly extracted by strong alcohol, the addition of even a small amount of water being objectionable. An inferior sumbul, having only a faint musky odor, is derived from *Ferula suaveolens*, Aitchison (see E. M. Holmes, *loc. cit.*). As demanded by the *U. S. P.*, sumbul is "in transverse segments, varying in diameter from about 2 to 7 Cm. (⅘ to 2⅘ inches), and in length from 15 to 30 Mm. (⅗ to 1⅕ inches); light, spongy, annulate or longitudinally wrinkled; bark thin, brown, more or less bristly fibrous; the interior whitish, with numerous brownish-yellow resin dots and irregular, easily separated fibres; odor strong, musk-like; taste bitter and balsamic"—(*U. S. P.*).

Chemical Composition.—An examination of sumbul was made about 1843, by Reinsch, who found it to contain wax and a balsam; both are extracted from the root by ether. The balsam has a faint, musky odor, strengthened by soaking in water; it dissolves in sulphuric acid, with the production of a blue color. When the root has been previously extracted by ether, alcohol dissolves from it an aromatic resin and a bitter substance, the latter being soluble in water. P. H. Utech (*Amer. Jour. Pharm.*, 1893, p. 465) obtained 6.1 per cent of an aromatic resin, bitter, insoluble in water, soluble in chloroform, ether, carbon disulphide, benzol, etc., almost insoluble in aqueous ammonia. The root also contains about 0.3 per cent of a volatile oil of a musk-like odor. Reinsch and Ricker (1848) obtained about 0.3 per cent of pure *angelic* acid from the root, but according to E. Schmidt (*Archiv der Pharm.*, 1886, p. 529) it does not preexist in the root, but is a decomposition product of the balsam obtainable by means of petroleum-ether. This solvent yielded to J. H. Hahn 17.25 per cent of fixed oil (*Amer. Jour. Pharm.*, 1896, p. 395).

Action, Medical Uses, and Dosage.—Sumbul is a stimulant and tonic to the nervous system; it has been recommended in *low typhus fevers* (to allay intestinal irritation), in *gastric spasm*, *hysteria*, *delirium tremens*, *diarrhœa*, *dysentery*, *leucorrhœa*, *gleet*, *chlorosis*, *asthma*, *chronic bronchitis*, and other maladies accompanied with an asthenic condition. In *nervous diseases* of a low, depressing character, it has been found very useful. Dr. Murawieff, a Russian physician, considers the balsamic resin as the active part, and has proposed its use, in the form of pills or tincture, in *pulmonary diseases*. The drug is seldom used in this country, but it certainly deserves further investigation. It was introduced (1835) as a remedy for *cholera*, but proved useless in that scourge. It is prepared in the form of fluid extract, the dose of which is from 10 to 60 minims, every 2, 3, or 4 hours; a tincture (dried root, ℥viii to alcohol, 98 per cent, Oj) may be administered in doses of 1 to 30 drops.

Pharmaceutical Preparation.—TONO-SUMBUL CORDIAL. This preparation is a specialty of Wm. R. Warner & Co., of Philadelphia. It is composed of sumbul, phosphate of iron, cinchona, acid phosphates, aromatics, and sherry wine. Tonic and cordial.

SUPPOSITORIA.—SUPPOSITORIES.

History.—Suppositories are globular, conical, cylindrical, or club-shaped solid bodies designed for introduction into the urethra, rectum, or vagina, in order to effect a therapeutical influence upon the adjacent parts or upon the general system. In a few instances they are prepared of articles not readily liquefying at the animal temperature, but, generally, they should be slowly fusible. The quantity of the active medicinal agent in each suppository, should, as a general rule, be about 3 times its dose for internal administration; however, with certain articles, or for certain results, more or less of this quantity will occasionally be required, according to the circumstances. Heretofore, when suppositories have been ordered by the physician, they were prepared by pouring the partially cooled mass, of which they were composed, into paper cones, the paper not being removed until the suppository became thoroughly hardened. The only advantage this method possesses is the readiness with which the cones may be made, and of any size required. The objections to it are the length of time required to finish the suppository, and the uncertainty of having the external surface clear, regular, and polished. In the preparation of suppositories, two things are especially required: (1) A composition which will permit the active ingredients to be so regularly diffused that each suppository will contain an equal quantity of the medicinal agent; the composition when cold must be firm, smooth, not liable to crack or split, must not adhere to the mold, and must be readily fusible at the temperature of the body. (2) A mold which, with as little extra manipulation as possible, will give smooth suppositories, of uniform size, shape, and weight, which will permit of their being made with as little loss of time as possible, and from which the suppository can be promptly removed.

For the first purpose, cacao butter (*Oleum Theobromatis*) is generally preferred by pharmacists, being used alone, especially when employed in cold seasons; or, in warm seasons, with the addition of $\frac{1}{5}$ or $\frac{1}{8}$ of wax or spermaceti. Spermaceti is usually preferred to wax, on account of its congealing with greater rapidity. Bullock and Crenshaw preferred, during warm weather, the addition of from $\frac{1}{16}$ to the $\frac{1}{20}$ of paraffin. Dr. W. B. Chapman, of Cincinnati, who at one time made a specialty of suppositories, preferred $\frac{1}{8}$ of Japan wax. The amount of these articles to be added, will depend entirely upon the season and the temperature, as well as upon the latitude; thus, in summer, more of the hardening body will be required. The quantity will necessarily have to be determined by experiment, in different latitudes. In this latitude $\frac{1}{4}$ of spermaceti is added during the hot summer months, and $\frac{1}{6}$ during the winter; or $\frac{1}{8}$ of Japan wax in winter, and $\frac{1}{6}$ or $\frac{1}{4}$ in summer. Curd soap was directed in some formulæ of the *British Pharmacopœia*, 1885. But it must be remembered that there are certain medicinal agents that contribute to the hardening of the cacao butter, as, most dry vegetable or mineral powders, especially iodides of lead and of cadmium, carbonate of lead, oxide of zinc, etc., in which instances no hardening aid is required. On the other hand creosote, chloral hydrate, camphor, carbolic acid, and the essential oils modify the consistence of cacao butter so that together they liquefy at a heat lower than the ordinary fusing point of the butter.

Various instruments have been proposed for making suppositories, and the reader is referred to *Amer. Jour. Pharm.*, 1852, p. 211; 1861, pp. 5 and 202; 1867, p. 121; 1868, pp. 52 and 223; 1869, p. 53; to *Proc. Amer. Pharm. Assoc.*, 1865, p. 65; 1866, p. 155; 1867, p. 167; 1868, p. 111; and to Caspari's, Coblentz's and other well-known works on pharmacy. Three sizes are to be preferred, two for the rectum, of 15 or 20 grains, each, for children, the other of 30 or 40 grains, each, for adults; likewise, one for the vagina, of about 120 grains, each. The weight of the suppositories will, of course, depend upon that of the medicinal agent added to the cacao butter—hence, there will always be a variation in weight of a few grains in the different kinds of suppositories. The ordinary weight of the *U. S. P.* and *Br. Pharm.* is 15 grains. Three varieties of molds have been used: (1) Individual hard-metal, cone-shaped molds; (2) separable solid blocks, hinged or otherwise, having several depressions, so that when apposed they form molds; (3) compression molds, for forming suppositories without the intervention of heat.

Upon the suggestion of Mr. H. S. Wellcome, of London, suppositories are now largely made of which the end to be inserted is formed largest—that is, tapering—bulb-shaped. This insures its retention by the sphincter muscles, much trouble having sometimes been experienced in retaining the ordinary conical suppository. When suppositories are prepared in advance by the pharmacist, they should always be kept in a cool place, and when passed over the counter, the person who receives them should be cautioned against placing the box or bottle containing them in the pocket, or in or near any place of too high a temperature; directions should likewise be given to keep them in a cool place until they are wanted for use, and then to handle them quickly.

Suppositories which contain a cavity from the base to a point near the apex, into which the active ingredient is placed, and the aperture then closed at base, have been recommended by some parties, but such are entirely unfit for use, as the medicinal substance, not being equally diffused throughout, instead of acting gradually and for a length of time, does not act at all until the material of which the suppository is made becomes liquefied, and then it acts suddenly and powerfully, perhaps irritating the parts to a considerable extent, and effecting more injury than benefit.

Preparation.—Dr. Chapman's process is as follows: (1) Melt the cacao butter and Japan wax together, and then thoroughly incorporate the medicinal articles with it, either by rubbing them together in a mortar, or by first triturating the medicinal extract, powder, or tincture, etc., with part of the melted butter upon a warm slab, adding, if necessary, as little as possible of alcohol, oil, glycerin, or water, etc., sufficient quantity to aid in obtaining a thorough incorporation of the materials; and, when well incorporated, triturate this with the remainder of the melted liquid in a mortar, continuing the trituration until the mass becomes quite thick, not, however, so thick as to prevent it from flowing readily into the molds. (2) The metallic block, before the melted mass is poured into the molds, must previously be set upon a lump of ice, and rest there until it has reached the dew point, as manifested by the thin layer of moisture upon its external surface (sometimes called sweating), then, and not till then, the mixture must be poured into the molds, as cool as may be without interfering with its flowing, and allowed to remain in until all the suppositories are hard and movable in the molds. (3) When the suppositories are sufficiently congealed, which requires 2 or 3 minutes, very seldom exceeding 5, pressure with the ball of the thumb upon each suppository, will cause it to move in the mold, at the same time imparting a snapping or cracking sensation; then the block may be turned upside down, and the suppositories will fall out. If the suppositories are allowed to remain in the mold for too long a time, they are liable to split or crack.

The following method is that directed by the *U. S. P.*: "Take of the medicinal ingredient, the prescribed quantity; oil of theobroma, a sufficient quantity. Having weighed out the medicinal ingredient or ingredients, and the quantity of oil of theobroma required, according to the kind of suppository to be prepared (see below), mix the medicinal portion (previously brought to a proper consistence, if necessary) with a small quantity of the oil of theobroma, by rubbing them together, and add the mixture to the remainder of the oil of theobroma, previously melted and cooled to the temperature of 35° C. (95° F.). Then mix thoroughly, without applying more heat, and immediately pour the mixture into suitable molds. The molds must be kept cold by being placed on ice, or by immersion in ice-cold water, before the melted mass is poured in. In the absence of suitable molds, suppositories may be formed by allowing the mixture, prepared as above, to cool, care being taken to keep the ingredients well mixed, and dividing the mass into parts, of a definite weight each, of the proper shape. Unless otherwise specified, suppositories should have the following weights and shapes, corresponding to their several uses: Rectal suppositories should be cone-shaped, and of a weight of about one gramme (1 Gm.) [15.5 grs.]. Urethral suppositories should be pencil-shaped, and of a weight of about one gramme (1 Gm.) [15.5 grs.]. Vaginal suppositories should be globular, and of a weight of about three grammes (3 Gm.) [about 46 grs.]"—(*U. S. P.*). A cold process has been followed in which the ingredients, finely divided, are mixed in a mortar or on a slab, and compressed by hand, spatula, or other compressing instrument.

Formulas.—The following suppositories were official in the *U. S. P.*, 1870:

Suppositoria	Medicinal Ingredients	Mix first with Cacao Butter	Subsequently mix with Cacao Butter
Acidi Carbolici	Carbolic acid, grains xij	Grains lx	Grains cviii
Acidi Tannici	Tannin, grains lx	Grains lx	Grains lx
Aloes	Purified aloes (powdered), grains lx	Grains lx	Grains lx
Asafœtidæ	Tincture asafetida, 1 fluid ounce; spontaneously evaporated	Grains lx	Grains lxxx
Belladonnæ	Alcoholic extract of belladonna, grains vj; water, q. s.	Grains lx	Grains cxiv
Morphiæ	Morphine sulphate, grains vj	Grains lx	Grains cxiv
Opii	Extract of opium, grains xij; water, q. s.	Grains lx	Grains cviij
Plumbi	Acetate of lead, grains xxxvj	Grains lx	Grains lxxxiv
Plumbi et Opii	Acetate of lead, grains xxxvj; extract of opium, grains vj; water, q. s.	Grains lx	Grains lxxx

Make of each formula twelve (12) suppositories. The following was official in the *British Pharmacopœia*, 1885:

Suppositoria Hydrargyri (*Mercurial suppositories*).—Mercurial ointment, 60 grains; oil of theobroma, 120 grains. Mix with sufficient heat, and make into 15-grain suppositories. Each suppository contains 5 grains of ointment of mercury. The following suppositories are official in the *British Pharmacopœia*, 1898:

Suppositoria Acidi Carbolici (*Phenol suppositories*).—Each containing 1 grain of phenol.

Suppositoria Acidi Tannici (*Tannic acid suppositories*).—Each containing 3 grains of tannic acid.

Suppositoria Belladonnæ (*Belladonna suppositories*).—Each containing approximately $\frac{1}{60}$ grain (0.001 gramme) of the alkaloids of belladonna root.

Suppositoria Glycerini (*Glycerin suppositories*).—Each containing 70 per cent of glycerin.

Suppositoria Iodoformi (*Iodoform suppositories*).—Each containing 3 grains (0.2 gramme) of iodoform.

Suppositoria Morphinæ (*Morphine suppositories*).—Each containing ¼ grain (0.017 gramme) of morphine hydrochloride.

Suppositoria Plumbi Composita (*Compound lead suppositories*).—Each containing 3 grains (0.2 gramme) of lead acetate, and 1 grain (0.067 gramme) of opium.

SUPPOSITORIA GLYCERINI (U. S. P.)—SUPPOSITORIES OF GLYCERIN.

Preparation.—"Glycerin, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; sodium carbonate, three grammes (3 Gm.) [46 grs.]; stearic acid, five grammes (5 Gm.) [77 grs.]. To make 10 rectal suppositories. Dissolve the sodium carbonate in the glycerin in a capsule on a water-bath; then add the stearic acid, and heat carefully until this is dissolved, and the escape of carbonic acid gas has ceased. Then pour the melted mass into suitable molds, remove the suppositories when they are cold, and wrap each in tin-foil. These suppositories should be freshly prepared when required"—(*U. S. P.*). The *U. S. P.* suppository contains 90 per cent of glycerin. The hygroscopic nature of glycerin renders it necessary to cover the suppository in some manner, as by paraffin or tin-foil, which latter is recommended in the formula. The official suppository weighs about 102 grains.

Action and Medical Uses.—These suppositories, by the irritating presence of the glycerin, provoke rectal action, causing an alvine evacuation. They are useful in some cases of *constipation* depending upon atony of the lower bowel. They should not be used continuously.

SYMPHYTUM.—COMFREY.

The root of *Symphytum officinale*, Linné.

Nat. Ord.—Boraginaceæ.

Common Name and Synonyms: *Comfrey; Radix symphyti, Radix consolidæ majoris.*

Botanical Source.—Comfrey has an oblong, fleshy, perennial root, black externally, and a pilose, herbaceous stem, 3 or 4 feet high, branching above, and winged by the decurrent bases of the pointed, wavy, rough-edged leaves. The lower leaves and radical are ovate-lanceolate, tapering into a petiole; the upper and floral, lanceolate. Flowers white or of a rose color, and borne in terminal, revolute racemes. Calyx 5-parted, with lanceolate, acuminate sepals; the corolla tubular-campanulate; the limb with 5 recurved teeth. Stamens 5, included; anthers elongated. Style filiform. Nutlets smooth, ovate, fixed by a large excavated (perforate) base. The whole plant is rough with dense hairs (W.—G.).

History, Description, and Chemical Composition.—Comfrey is a native of Europe, but naturalized in this country, growing on low lands and moist places, flowering all summer. The root is medicinal; when fresh it is glabrous, fusiform, branching, 10 or 12 inches in length, by 1 in diameter, and very mucilaginous. The dried root, as found in commerce, is in pieces varying from 1 to 4 or 5 inches long, black, and corrugated externally, dark-whitish and corneous internally, nearly odorless, viscid, and slightly astringent. It contains some tannic acid, a trace of starch, some sugar, and a large amount of mucilage, which is readily extracted by water. *Asparagine* in small amount was obtained from it by Henry and Plisson in 1829.

Action, Medical Uses, and Dosage.—This plant is demulcent and slightly astringent. With other mucilaginous agents, it is considered inert or of but little medical importance by many writers; but this is an erroneous view, the result of deficient investigation. All mucilaginous agents exert an influence on mucous tissues, hence the cure, by their internal use, of many pulmonary and other affections in which these tissues have been chiefly implicated. Physicians must not expect a serious disease to yield to remedies which act on mucous membranes only; and to determine the true value of a medicinal agent, they must first ascertain the true character of the affection, as well as of the tissues involved. Again, mucilaginous agents are always beneficial in *scrofulous* and *anemic habits*. Comfrey root is very useful in *diarrhœa*, *dysentery*, *bronchial irritation*, *coughs*, *hæmoptysis*, other *pulmonary affections*, *leucorrhœa*, and *female debility;* these being principally mucous affections. It is also of some value in *passive hemorrhages* from the bowels, kidneys, or womb. It may be boiled in water, wine, or made into a syrup, and taken in doses of from 1 to 4 fluid ounces of the preparation 2 or 3 times a day. A tincture of the recent root (℥viii to alcohol, 98 per cent, Oj) has been recommended in from 1 to 10-drop doses. Externally, the fresh root, bruised, forms an excellent application to *bruises, ruptures, fresh wounds, sore breasts, ulcers, white swellings*, etc.

SYRUPI.—SYRUPS.

Syrups are liquid medicines, of a viscid consistence. They are solutions of sugar alone, or sugar mixed with honey and dissolved in water, wine, vinegar, or diluted acetic acid. Simple syrup is a solution of sugar in water, and forms the basis of many medicated syrups.

Medicated syrups are those in which one or more medicinal agents enter into the solution, and are commonly prepared by incorporating sugar with vegetable, aqueous or spirituous solutions, expressed juices, etc. When the active principles of the ingredients are dissipated or decomposed by boiling water, or where they are not readily taken up by water, they are frequently dissolved by alcohol, specific gravity 0.935, the alcohol being retained or evaporated subsequently, as may be required; sometimes a tincture of the medicinal agent or agents is added to simple syrup. The stability of a syrup depends on its composition and consistence, the temperature, and the amount of exposure to the air. As many syrups are used in chronic diseases during the absence of febrile or active inflammatory symptoms, the addition of an alcoholic tincture is not then objectionable, unless it be in large proportion; but syrups prepared for febrile or inflammatory difficulties should be entirely free from any spirituous liquor whatever.

If the sugar be in too small amount the syrup will ferment; if in too large amount the sugar will crystallize. The heat employed should be adapted to the character of the active principle; if it be volatile or easily decomposed a gentle heat is required. If it be not injured by heat, concentration may be conducted with a brisk fire, and effected as rapidly as possible. After the syrup has cooled, if a pellicle forms upon its surface, it has been concentrated too much. "Various means have been devised for the preservation of syrups; a little sulphate of potassium, chlorate of potassium, bisulphite of calcium, or sugar of milk, has been recommended for this purpose. One fluid drachm of Hoffman's Anodyne to the pint of syrup will effectually check a tendency to fermentation. The maintenance of a syrup in a regular degree of temperature, say 55° to 60° C. (131° to 140° F.), will tend very much to lessen its liability to ferment. As a general rule, syrups intended to be kept should be bottled while hot, securely corked and sealed, and after cooling should be shaken, that the moisture condensed on the cork may be mixed with the syrup, and not form a diluted layer at the surface" (Mohr and Redwood).

Salicylic acid has of late years been employed to preserve syrups, but if prepared by the cold process to be hereafter mentioned no preservative is required.

Nearly all the compounds that have been proposed for syrups, such as the *Eclectic Alterative, Scrofulous, Stillingia*, and *Pulmonary Syrups*, comprise substances whose medicinal principles are imperfectly soluble in water. The process laid down under the formula for *Compound Syrup of Aralia* (which see) is applicable to this class.

In all these preparations, the principle should be adopted of confining the boiling and evaporation to the weaker portion of the solution, so that those delicate principles which are evaporated or decomposed by heat may be submitted to its action as little as possible.

Owing to the fact that syrups which have been boiled for a long time, and syrups which contain acids, are liable to have a part of their sugar changed to inverted sugar, the cold process of Orynski (1871) has attracted considerable attention, it having been observed that such syrups are less liable to ferment, and that alkaline solutions of copper are more slowly affected by them than when heat has been employed. This process, as employed later by Hunstock, consists in placing the sugar into a cylindrical cone-shaped percolator, in the lower end (neck) of which has been introduced a piece of moistened sponge or cotton, packed neither too tight nor too loose, a cork being inserted into the lower orifice of the vessel. The menstruum, prepared as directed by the official process, is now poured upon the sugar, and the whole is set aside until a portion of the sugar has dissolved and the mass has settled to half its original bulk. The cork is then removed and the syrup allowed to pass drop by drop. Should the liquid fail to dissolve all the sugar, pour upon the final remainder a portion of the filtrate, which will usually complete the solution. This process is especially adapted for syrups made of plants holding volatile principles, or for those whose ingredients are likely to be injured by heat.

Syrups in which vinous fermentation has begun, which may be known by the frothiness due to escaping carbon dioxide and by the vinous odor, may, unless the fermentation has passed beyond the incipient stage, or unless their virtues depend partly or wholly upon volatile principles, be restored by boiling and straining them. Almond and acacia syrups excepted, alteration of non-volatile active constituents seldom takes place at such a stage of decomposition. Glycerin has been proposed as a menstruum for syrups which, when made of sugar, readily decompose. In some cases sugar is used as a preservative on account of its quality of preventing chemical changes. Thus syrup of iodide of iron and Vallett's iron mass both contain sugar for this quality. Syrups, both simple and compound, once constituted an important part of the Eclectic physicians' remedies. But they have been discarded almost wholly, the burden of sugar being of no use in disease and often harmful. In Eclecticism syrups are practically obsolete; yet we give in the pages to follow the formulæ of those peculiar to our school.

SYRUPUS (U. S. P.)—SYRUP.

SYNONYMS: *Syrupus simplex*, *Simple syrup*, *Syrupus albus*, *Syrupus sacchari*.

Preparation.—"Take of sugar, in coarse powder, eight hundred and fifty grammes (850 Gm.) [1 lb. av., 13 ozs., 430 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sugar, with the aid of heat, in four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of distilled water, raise the temperature to the boiling point, strain the liquid, and pass enough distilled water through the strainer to make the product, when cold, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Syrup may also be prepared in the following manner: Press down into the neck of a percolator or funnel of suitable size a tapering piece of coarse, well-cleaned sponge, not too tightly, and in such a manner that the whole sponge shall be within the neck of the percolator, its upper end being about half an inch below its commencement. Place the sugar in the apparatus, make its surface level without shaking or jarring, then carefully pour on four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of distilled water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by distilled water, added in portions, so that all the sugar may be dissolved, and the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Syrup thus prepared has a specific gravity of about 1.317"—(*U. S. P.*).

Description.—Simple syrup, when properly made, is sweet, nearly odorless, transparent, and colorless, of the consistence of thin molasses. Refined sugar should always be used.

Action and Medical Uses.—Simple syrup is nutritious and demulcent. It is employed in various mixtures, pills, medicated syrups, and extemporaneous prescriptions. Locally, it is applied to *abrasions*, *burns*, and *scalds*.

Soda Water Syrups.—The following formulæ and directions for the preparation of soda water syrups, etc., are reproduced from *Elixirs*, by J. U. Lloyd.

Simple syrup made according to the *U. S. P.*, is too thick for use as a soda syrup. It is difficult to mix it with the carbonated water, and it sticks to the glass. For a simple soda syrup, the following formula has stood the test of years:

SIMPLE SYRUP (*Soda syrup*).—Pure white sugar, 35 pounds (av.); distilled water, 20 pints. Pour the water into a kettle, add the sugar, and bring the mixture to a boil, stirring constantly. Then remove from the fire and strain while hot. This syrup will neither crystallize in cold, nor ferment in warm weather. However, the addition of certain vegetable extractives will cause any simple syrup to ferment. Either rock-candy syrup (a purified, uncrystallizable syrup resulting from the manufacture of rock-candy), or simple syrup, made according to the foregoing formula, may be used in the formulæ that follow when "syrup" is commended.

Syrup of Almond or Peach.—Flavoring extract of almond (peach), ½ fluid ounce; syrup, 15½ fluid ounces. Mix them together.

Chocolate Syrup.—Flavoring extract of chocolate, 4 fluid ounces; syrup, 12 fluid ounces. Mix them together. This syrup is brown and unsightly.

Syrup of Coffee. Flavoring extract of coffee, 4 fluid ounces; syrup, 12 fluid ounces. Mix them together.

Syrup of Coffee.—Coffee (Java), 8 ounces (av.); sugar, 20 ounces (av.); boiling water, a sufficient amount. Percolate the coffee with hot water until 10 fluid ounces of percolate are obtained, and in the percolate dissolve the sugar.

Syrup of Ginger.—Flavoring extract of ginger, 1 fluid ounce; syrup, 32 fluid ounces. Mix them together. This syrup is likely to be unsightly from the presence of finely divided resin. It is also too peppery for some persons, and must be made with less ginger than is called for by our formula. The formula that follows is milder, and yields a transparent product.

Syrup of Ginger.—Soluble extract of ginger, 2 fluid ounces; syrup, 30 fluid ounces. Mix them together.

Syrup of Lemon.—Syrup, 1 pint; flavoring extract of lemon, 2 fluid drachms; citric acid, 1 drachm; curcuma color, water, frothing liquid, of each, a sufficient amount. Dissolve the powdered citric acid in ½ fluid ounce of water, add to the syrup, and then add the extract, frothing liquid, and enough curcuma color to bring to a lemon color. By referring to our remarks concerning lemon extract, the operator will find that the quality of syrup of lemon depends upon the quality of the lemon extract employed in making it. Since we give several formulæ, choice thereof is readily made.

Syrup of Nectarine.—Flavoring extract of nectarine, 1 fluid ounce; syrup, 15 fluid ounces. Mix them together.

Syrup of Orange.—Syrup, 1 pint; flavoring extract of orange, 2 fluid drachms; citric acid, 1 drachm; curcuma color, water, frothing liquid, of each, a sufficient amount. Dissolve the powdered citric acid in ½ fluid ounce of water, add to the syrup, and then add the extract, frothing liquid, and enough curcuma color, modified by a small amount of cochineal color, to bring to an orange-yellow color. By referring to our remarks concerning orange extract, the operator will find that the quality of syrup of orange depends upon the quality of the orange extract employed in making it. Since we give several formulæ, choice thereof is readily made.

Syrup of Blood Orange.—Syrup of blood or red orange is not distinguished from the foregoing excepting by its color. To make it, color the syrup of orange with cochineal color until it is of a rich-red color.

Syrup of Pineapple.—Syrup, 1 pint; flavoring extract of pineapple, 1 fluid drachm; curcuma color, frothing liquid, of each, a sufficient amount. Mix the simple syrup and the extract of pineapple, color the liquid appropriately with tincture of curcuma, and then add the frothing liquid.

Syrup of Raspberry.—Flavoring extract of raspberry, 2 fluid drachms; simple syrup, 1 pint; cochineal color, frothing liquid, of each, a sufficient amount. Mix the extract with the syrup, color with an appropriate amount of cochineal color, and add the frothing liquid, if desirable.

Syrup of Rose.—Flavoring extract of rose, 1 fluid ounce; syrup, 1 pint. Mix them together and color red with cochineal color.

Syrup of Sarsaparilla.—Flavoring extract of sarsaparilla, 1 fluid ounce; syrup, 1 pint. Mix them together and color dark-brown with caramel.

Syrup of Strawberry.—Flavoring extract of strawberry, 2 fluid drachms; simple syrup, 1 pint cochineal color, frothing liquid, of each, a sufficient amount. Mix the extract with the syrup, color with an appropriate amount of cochineal color, and add the frothing liquid, if desirable.

Syrup of Vanilla.—Syrup, 1 pint; flavoring extract of vanilla, 2 fluid drachms; caramel, cochineal color, frothing liquid, of each, a sufficient amount. Mix the extract and the syrup, then add caramel and cochineal color enough to give a clear red-brown, and finally add the frothing liquid. By referring to our remarks on flavoring extract of vanilla, it will be seen that the quality of syrup of vanilla depends on the quality of the extract employed in making it. The operator may, therefore, select as his judgment dictates, but our experience is to the effect that the extract made of prime long vanilla is best suited to build up a business and retain it. In like manner, other soda syrups may be extemporaneously prepared by mixing together flavoring extracts and syrup. It is unnecessary for us to consume space with details that will suggest themselves to every druggist.

Cream Syrups. These syrups have long been favorites, and when made of pure, fresh milk are delicious. In former times, they were made with much care and replenished daily. Now we learn that condensed milk is often substituted for fresh milk, and simple syrup is mixed therewith. The formulæ that follow are such as were used thirty years ago, and, in our judgment, have no superiors.

Cream Syrup (Orange Cream).—Milk, 1 quart; sugar, 2½ pounds. Dissolve the sugar in the milk by the aid of a gentle heat, stirring constantly; strain, and when cool, add 4 fluid drachms of flavoring extract of orange and enough curcuma color to bring to a rich cream color. This syrup must be freshly made each day.

Nectar Syrup (Nectar Cream).—Milk, 1 quart; sugar, $2\frac{1}{2}$ pounds. Dissolve the sugar in the milk by the aid of a gentle heat, stirring constantly; strain, and when cool, add 4 fluid drachms of flavoring extract of best vanilla (or nectar) and enough cochineal color to bring to a deep pink. This syrup must be freshly made every day.

Fruit Syrups.—In recent years fruit juices have largely replaced some of the artificial flavors of former times. These juices are manufactured in large amounts by experienced men, and druggists usually find it better to purchase them than to attempt their manipulation. They produce delicious syrups, and, in our opinion, are very much to be preferred to most of the ordinary imitation syrups that are made of artificial ethers. Full directions for making syrups accompany them, and we need not, therefore, consider these substances in detail. While we do not recommend an attempt at manufacturing these juices generally in a small way, we believe it often judicious for the apothecary to make syrups direct from some of the juicy fruits when they are plentiful and in season. The following are suggested if the respective fruit is abundant and cheap; if not, it is better to purchase fruit juices on the market and make the syrup therefrom.

Blackberry (Fruit) Syrup.—Heat ripe blackberries to the boiling point and express the juice. To 4 pints of juice add 6 pounds of sugar, dissolve by heat, and bottle securely while hot. It must be kept in a cool, dark location.

Raspberry (Fruit) Syrup.—Heat ripe berries to the boiling point and express the juice. To 4 pints of juice add 6 pounds of sugar, dissolve by heat, and bottle securely while hot. It must be kept in a cool, dark location.

Strawberry (Fruit) Syrup.—Heat ripe berries to the boiling point and express the juice. To 4 pints of juice add 6 pounds of sugar, dissolve by heat, and bottle securely while hot. It must be kept in a cool, dark location.

Cherry (Fruit) Syrup.—Heat ripe fruit to the boiling point and express the juice. To 4 pints of juice add 6 pounds of sugar, dissolve by heat, and bottle securely while hot. It must be kept in a cool, dark location.

Grape (Fruit) Syrup.—Heat ripe fruit to the boiling point and express the juice. To 4 pints of juice add 6 pounds of sugar, dissolve by heat, and bottle securely while hot. It must be kept in a cool, dark location.

Pineapple (Fruit) Syrup.—Wash and then slice the pineapples thinly, without removing the peel; then mix therewith 1 pound of sugar for each pound of fruit, and occasionally stir the mixture for 2 or 3 days, then squeeze the syrup therefrom and bottle it.

Quince (Fruit) Syrup.—Quarter and seed the quinces without removing the peel. Slice thinly, and mix therewith 1 pound of sugar for each pound of fruit, and occasionally stir the mixture for 2 or 3 days, then add some water if too thick, and squeeze the syrup therefrom and bottle it. Most persons peel such fruits as pineapple and quince, and thereby lose the rich aroma which mostly resides in the peel. Quince especially becomes insipid if peeled. Other fruit syrups can be made of juicy fruits by similar methods.

"Tonic" Syrups.—We can not too strongly condemn the indiscriminate use of nervines in the form of beverages. Perhaps there may be an excuse for the affixing of a name only to a fanciful, harmless syrup, the name reminding one of a remedy, and yet it seems as though the use or imaginary use of medicines should be left to the discretion of physicians.

Such "tonics," even as solution of phosphate of calcium in acid water, so fashionable in some instances at present, may better be left to the discretion of physician prescribers who understand the systemic condition of the "debilitated." It seems to us as though much injury may result in the continued drinking of phosphoric acid and other medicines by persons who do not need such substances, and who simply imagine that they should "take a tonic."

The same remarks apply to "iron tonics" and "calisaya tonics," and other similar syrups; and while "syrup of beef extract" may do no harm, it seems to us enough out of place as a beverage to give even a man in health the horrors and a dislike for beef tea in its proper place. We may, with our views of this matter expressed, be pardoned for omitting formulæ for such compounds.

The following frothing liquids and colors are employed in the above formulæ:

Frothing Liquids.—In some cases it is desirable that a syrup should froth considerably. Judgment, however, must be employed in adding the frothing liquid, as well as drawing the carbonated water into the syrup, for some syrups are naturally inclined to foam too much. Among our formulæ we occasionally direct the use of a frother, and the operator can select from the following that which best suits his taste:

The white of 1 egg added to a quart of the syrup specified.

One ounce of mucilage of acacia added to a quart of the syrup.

Two drachms of tincture of soap bark (quillaya) added to a quart of the syrup.

The first and second of these have been in use for a long time; the last is a comparatively recent addition. That the first and second are both harmless is evident, and we have as yet heard no complaints concerning tincture of quillaya.

Tincture of Soap Bark (Quillaya). Take of ground or powdered quillaya, 4 ounces; alcohol, water of each a sufficient amount. Moisten the quillaya with a mixture of alcohol, 2 ounces; water, 14 ounces; and having allowed the moistened powder to stand 1 hour to expand, pack it loosely in a percolator. Cover with menstruum, and when it appears at the exit of the percolator cork the exit and allow the mixture to macerate from 12 to 24 hours. Then continue the percolation until 1 pint of tincture be obtained.

This tincture is of an opalescent color and is likely to precipitate by age; it should be kept in a cool locality. It can be made clear by increasing the proportion of alcohol in the menstruum, but this increase of alcohol is at the expense of the frothing power of the product. The larger the amount of alcohol the less its comparative value as a froth producer. One ounce of the foregoing tincture is sufficient for a gallon of syrup.

Colors.—Throughout this work *Elixirs*, by J. U. Lloyd various substances for coloring are occasionally commended. They are, or should be, harmless, and are necessary adjuncts, for the public taste must be catered to in the way of bringing certain syrups to resemble the colors of the fruits that they are designed to imitate. It is important that these colors should be innocuous, and luckily the shades desired can be easily obtained. At the present time, beautiful, concentrated red, yellow, green, and other colors, can be purchased of dealers in essential oils, and are warranted free from any poison or objectionable impurity, and may be substituted for those we commend. The colors we direct may be made as follows (natural fruit syrups do not demand artificial colors):

Solution of Cochineal (*Carmine*).—This preparation has been used some years by the writer in preference to any "tincture" of cochineal. The fat in cochineal causes such preparations to putrefy in warm weather; and to extract the fat, by means of ether, from the powdered cochineal, previous to tincturing it, is expensive and tedious. The term "tincture of cochineal" is scarcely appropriate as applied to the aqueous solutions made of cochineal, cream of tartar, and alum, and, as the object is simply to secure a coloring matter, the term might, with equal propriety, be applied to our solution of carmine, made as follows: Carmine, No. 40, 60 grains; distilled water, glycerin, of each, 4 ounces; ammonia water, a sufficient quantity. Powder the carmine and triturate with the water, gradually adding ammonia water until the carmine disappears, and a dark-red liquid, free from insoluble matter, remains. To this add the glycerin and mix. Should this solution ever become murky, a little ammonia water will restore its transparency. Solution of carmine is necessarily alkaline, and can not be employed to color acid liquids. For all neutral or alkaline solutions it is admirable, and for soda water syrups is far preferable to aniline red.

Curcuma (*Turmeric*) (Yellow).—Macerate 4 ounces of good curcuma in a pint of alcohol, shaking occasionally for 7 days, then filter.

Caramel (*Burnt sugar*) (Brown).—In a capacious iron kettle, over a direct fire, melt a pound of sugar, and increase the temperature until empyreumatic vapors have been freely driven off, and the residue has acquired a deep-black color. Then remove from the fire, allow to partially cool, and gradually and cautiously stir 2 pints of hot water into it. This operation must be performed in the open air or over a good flue, for the vapors are very irritating when inhaled. Caution must also be employed in pouring the water into the hot mass, for, if it be very hot, the material will be thrown violently from the kettle by the sudden expansion of steam. If caramel is only wanted in small amount, it is best to purchase it.

SYRUPUS ACACIÆ (U. S. P.)—SYRUP OF ACACIA.

Synonyms: *Syrup of gum Arabic*, *Syrupus gummosus*.

Preparation.—"Mucilage of acacia, recently prepared, twenty-five cubic centimeters (25 Cc.) [406 ♏]; syrup, seventy-five cubic centimeters (75 Cc.) [2 flʒ, 257 ♏]; to make one hundred cubic centimeters (100 Cc.) [3 flʒ, 183 ♏). Mix them. This syrup should be freshly prepared when required"—(*U. S. P.*).

Mucilage of acacia is easily and very quickly decomposed, and the formula of the *U. S. P.* (1870) is, by some, regarded as preferable to the preceding. It is made practically as follows: Dissolve 2 troy ounces of gum Arabic (in pieces) in 8 fluid ounces of water, without heat, add 14 ounces of coarsely-powdered refined sugar, and, by aid of gentle heat, dissolve it, and then strain the product. Momentarily heating the preparation to 100° C. (212° F.) is thought advisable by some.

Action and Medical Uses.—Demulcent for *catarrhal disorders of the throat*, and as a *fever drink*. It may be used as a medium for suspending powders when about to be swallowed.

SYRUPUS ACIDI CITRICI (U. S. P.)—SYRUP OF CITRIC ACID.

Preparation.—"Citric acid, ten grammes (10 Gm.) [154 grs.]; water, ten cubic centimeters (10 Cc.) [162 ♏]; spirit of lemon, ten cubic centimeters (10 Cc.) [162 ♏]; syrup, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 ♏]. Dissolve the citric acid in the water, and mix the solution with five hundred cubic centimeters (500 Cc.) [16 flʒ, 435 ♏] of syrup. Then add the spirit of lemon, and, lastly, enough syrup to make the product measure one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

This syrup is prepared with less trouble than lemon syrup direct from the fruit, and can be preserved much better, but its taste is less agreeable.

Action, Medical Uses, and Dosage.—This syrup, added to water or to carbonic acid water, forms an agreeable cooling beverage for persons laboring under *febrile complaints*, and in certain states of the system requiring acids. From 1 fluid drachm to ½ fluid ounce may be added to ½ pint of the fluid in which it is to be taken.

SYRUPUS ACIDI HYDRIODICI (U. S. P.)—SYRUP OF HYDRIODIC ACID.

"A syrupy liquid containing about 1 per cent, by weight, of absolute hydrochloric acid ($HI=127.53$), or about 1.3 Gm. in 100 Cc."—(*U. S. P.*).

Preparation.—"Potassium iodide, thirteen grammes (13 Gm.) [201 grs.]; potassium hypophosphite, one gramme (1 Gm.) [15.5 grs.]; tartaric acid, twelve grammes (12 Gm.) [185 grs.]; water, fifteen cubic centimeters (15 Cc.) [243 ♏]; diluted alcohol, syrup, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the two potassium salts in the water, and the tartaric acid in twenty-five cubic centimeters (25 Cc.) [406 ♏] of diluted alcohol. Mix the two solutions in a vial, shake it thoroughly, and place it in ice-water for half an hour, occasionally shaking. Then filter the mixture through a small, rapidly-acting, white filter, and carefully wash the vial, and filter with diluted alcohol, until the filtrate ceases to produce more than a faint cloudiness when a drop or two is allowed to fall in silver nitrate test-solution. Reduce the filtrate, by evaporation in a tared capsule, on a water-bath, to fifty grammes (50 Gm.) [1 oz. av., 334 grs.], and mix it, when cold, with enough syrup to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*U. S. P.*).

Hydriodic acid, in aqueous solution, is unstable, and, as sugar tends to preserve the acid, this syrup has been made official. The process is practically that of the *National Formulary* (1st ed.). The potassium hypophosphite, reacting with the tartaric acid, causes a small quantity of hypophosphorous acid to be liberated, which preserves the product from decomposition. Mr. George M. Beringer (*Amer. Jour. Pharm.*, 1894, p. 20) points out that the above quantity of tartaric acid is below the theoretical amount required for the decomposition of the iodide and the hypophosphite, and should be at least 13.19 grammes.

Description and Tests.—"A transparent, colorless, or not more than a pale straw-colored liquid, odorless, and having a sweet and acidulous taste. Specific gravity about 1.313 at 15° C. (59° F.). If a small portion of the syrup be mixed with a little starch T.S., and a few drops of chlorine water then added, the liquid will acquire a deep-blue color. Not more than a faint bluish tint should be produced in the syrup by starch T.S. alone (limit of free iodine). The addition of silver nitrate T.S. to a small portion of the syrup produces a pale-yellow precipitate, nearly insoluble in ammonia water. If 32 (31.88) Gm. of the syrup be exactly neutralized by ammonia water, and then mixed with 2 drops of potassium chromate T.S., it should require about 25 Cc. of decinormal silver nitrate V.S. to produce a permanent red tint (corresponding to about 1 per cent of absolute hydriodic acid)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Uses, same as for *Acidum Hydriodicum*. Dose, ½ to 1 fluid drachm, largely diluted with water.

SYRUPUS ACTÆÆ COMPOSITUS (N. F.)—COMPOUND SYRUP OF ACTÆA.

SYNONYMS: *Syrupus cimicifugæ compositus*, *Compound syrup of cimicifuga* (or *Black cohosh*).

Preparation.—"Fluid extract of cimicifuga (*U. S. P.*), forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏]; fluid extract of glycyrrhiza (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; fluid extract of senega (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; fluid extract of ipecac (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; wild cherry, in moderately fine powder, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; purified talcum (F. 395), fifteen grammes (15 Gm.) [232 grs.]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the wild cherry with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water, and allow it to macerate during 1 hour. Then add to it the fluid extracts and talcum, and stir or agitate the mixture frequently and thoroughly during about 15 minutes. Transfer to a wetted filter, and, when the liquid ceases to drop from the funnel, wash the contents of the filter with water to obtain five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of filtrate. In this dissolve the sugar by agitation, and add enough water, previously passed through the filter, to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Through an oversight of the National Formulary committee, this preparation is made to bear the title *Syrupus Actææ Compositus*, which error was corrected in the *errata* of the first edition of that work, whereby the above title was made a synonym. In the second revision, however, the change seems not to have been made. *Syrupus Cimicifugæ Compositus* is the name to be preferred.

Action, Medical Uses, and Dosage.—This preparation is evidently intended for *pulmonic complaints*. The dose should be from ½ to 1 fluid drachm.

SYRUPUS ÆTHERIS.—SYRUP OF ETHER.

Preparation.—Take of refined sugar, 18 ounces; distilled water, 1 pint; alcohol (of 90 per cent), 13 fluid drachms; pure ether, 5 fluid drachms. Introduce all the articles into a close-stoppered flask, agitate together, until the sugar is dissolved, and keep in the flask well closed. This process furnishes a syrup of a fixed composition, not disturbed by variations of temperature, and holding a sufficient amount of ether in solution, which is not readily lost by evaporation.

Action, Medical Uses, and Dosage.—This syrup will be found an agreeable form of administering ether in all cases where its internal use is indicated. The dose is from ½ to 2 or 3 teaspoonfuls.

SYRUPUS ALLII (U. S. P.)—SYRUP OF GARLIC.

Preparation.—"Fresh garlic, sliced and bruised, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; sugar, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; diluted acetic acid, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Macerate the garlic with three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of diluted acetic acid during 4 days, and express the liquid, avoiding the use of metallic utensils. Then mix the residue with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] more of diluted acetic acid, and again express. Mix the expressed liquids, and filter. Pour the filtrate upon the sugar, contained in a suitable vessel, and stir or agitate until the sugar is dissolved. Lastly, add enough diluted acetic acid to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and mix thoroughly. Keep the syrup in well-stoppered, completely filled bottles, in a cool place. *Syrup of Garlic* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by diluted acetic acid, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*). This produces a syrup which is more or less opalescent.

Action, Medical Uses, and Dosage.—This syrup is useful in *cough* and *chronic catarrhal affections of infants*, acting also as a mild stimulant to the nerves; to a child under 1 year old, 1 fluid drachm may be given for a dose. The active principle of garlic is more readily taken up by vinegar than water. A syrup of onions is often prepared extemporaneously for coughs, by slicing 1 or 2 onions, and laying the slices upon each other with sugar between. This is set by the fire in a saucer or glass vessel, and kept there until the juice of the onion and the sugar have, by the aid of the heat, formed a syrup in the vessel. It may be given freely.

SYRUPUS ALTHÆÆ (U. S. P.)—SYRUP OF ALTHÆA.

SYNONYM: *Syrup of marshmallow.*

Preparation.—"Althæa, cut into small pieces, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [32 fl℥, 391 ♏]. Wash the althæa with cold water, then macerate it with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water, previously mixed with the alcohol, during 1 hour, stirring frequently, and strain without expressing the residue. In the strained liquid dissolve the sugar by agitation, without heat, add the glycerin and enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Keep the syrup in well-stoppered, completely filled bottles, in a cool place"—(*U. S. P.*). This produces a syrup having an agreeable, but faint odor, and a yellowish color. Like syrup of acacia, it is extremely liable to ferment. The glycerin and alcohol present probably retard this change to some extent.

Action, Medical Uses, and Dosage.—Like those of *Syrup of Acacia.*

SYRUPUS AMYGDALÆ (U. S. P.)—SYRUP OF ALMOND.

SYNONYM: *Syrupus emulsivus.*

Preparation.—"Sweet almond, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; bitter almond, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; sugar, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; orange-flower water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; water, one hundred and thirty cubic centimeters (130 Cc.) [4 fl℥, 190 ♏]; syrup, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the almonds, previously blanched, in a mortar, with one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of the sugar and thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of water to a smooth paste. Mix this well with the orange-flower water and two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of syrup, and strain with strong expression. To the residue add one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water, and express again. In the strained liquid dissolve the remainder of the sugar, without heat, adding enough syrup to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Keep the syrup in well-stoppered, completely filled bottles, in a cool place"—(*U. S. P.*).

Action and Medical Uses.—A feebly sedative preparation, used considerably in admixture with diuretics and expectorants in *irritable conditions of the renal and broncho-pulmonic tracts.*

SYRUPUS ARALIÆ COMPOSITUS.—COMPOUND SYRUP OF ARALIA.

Preparation.—Take of the roots of small spikenard, yellow dock, burdock, and ground guaiacum-wood, each, 10 troy ounces; bark of the root of sassafras, of southern prickly ash, elder flowers, blue flag root, each, 8 troy ounces. First grind and mix the articles together, moisten with diluted alcohol and place in a percolator, cover with the same menstruum, and macerate for 2 days. Then gradually add diluted alcohol until 2 pints of percolate have been obtained, which retain and set aside. Continue the percolation until the drug is exhausted and distill or evaporate the alcohol from it. Mix the solutions, add

12 pounds (av.) of refined sugar and water enough to make 16 pints of syrup, using a gentle heat to effect solution of the sugar. Each pint will contain the virtues of 4 ounces of the ingredients. It may be flavored with essence of wintergreen, sassafras, or prickly ash berries, etc.

"In the early editions of this work this preparation was termed Compound Syrup of Sarsaparilla (*Syrupus Sarsaparillæ Compositus*). On account of the difficulty met with among druggists in filling orders for compound syrup of sarsaparilla, when it is not indicated to them what syrup of this name is required (as there are several), I have deemed it best to change the name, that no such difficulty may occur hereafter. This article has also been termed *Alterative syrup*, but it is much superior to the compound formerly known by this name. In the present case I have substituted the roots of *Aralia nudicaulis* for the Honduras sarsaparilla of the former formula, as it is considered by physicians to be the more active agent; those, however, who prefer the Honduras sarsaparilla, will, of course, retain it in their preparation of this syrup" (J. King).

Action, Medical Uses, and Dosage.—"This forms a valuable syrup, which may be used in all cases where an alterative is indicated; in *chronic hepatitis, rheumatism, syphilis, scrofula, cutaneous diseases, ulcers, white swellings, rickets, necrosis*, and every taint of the system. Some physicians add an ounce of the iodide of potassium to every pint of syrup. The dose is from a teaspoonful to a tablespoonful, 3 or 4 times a day, in about a gill of water" (J. King).

SYRUPUS ASAFŒTIDA.—SYRUP OF ASAFETIDA.

Preparation.—Take of asafetida, 1 ounce; boiling water, 1 pint; sugar, 2 pounds. Triturate the asafetida in a mortar with a portion of the boiling water until a uniform paste is formed, then gradually add the remainder of the water, strain, and add the sugar, dissolving it with a gentle heat (R. Petty, *Amer. Jour. Pharm.*, Vol. XXIV, p. 319).

Description.—Good asafetida contains a portion of volatile oil, which would be dissipated were much heat employed in the solution of the sugar. Boiling water instead of cold is employed to take up more of the gum-resin which is permanently dissolved or suspended by the aid of sugar. This syrup is nearly white when first made, but gradually assumes a pinkish tinge; it is quite permanent, keeping for several months without any material change, and has the advantage of being entirely free from alcohol, which is often objectionable with asafetida mixtures.

Action, Medical Uses, and Dosage.—This is an excellent form for the administration of asafetida, being prompt in its action, and not so stimulating as the tincture. The dose is 1 or 2 tablespoonfuls, repeated 3 or 4 times a day. If used in enema, 2 to 4 fluid ounces may be injected into the rectum at one time. Other antispasmodics may be combined with it, as fluid extracts of black cohosh, blue cohosh, ladies'-slipper root, scullcap, valerian, etc., according to indications.

SYRUPUS ASARI COMPOSITUS (N. F.)—COMPOUND SYRUP OF ASARUM.

SYNONYM: *Compound syrup of Canada snakeroot.*

Preparation.—"Asarum, root, in moderately coarse (No. 40) powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; alcohol, one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl℥, 123 ♏︎]; cochineal, in fine powder, one and one-half grammes (1.5 Gm.) [23 grs.]; potassium carbonate, two and one-half grammes (2.5 Gm.) [39 grs.]; wine of ipecac (*U. S. P.*) thirty cubic centimeters (30 Cc.) [1 fl℥. 7 ♏︎]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Mix the asarum intimately with the cochineal and potassium carbonate, previously triturated together. Moisten the powder with a sufficient quantity of a menstruum prepared by mixing the alcohol with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water, and allow it to macerate in a covered vessel for 24 hours. Then transfer it to a small percolator, and pour on the remainder of the menstruum. Allow the percolation to proceed slowly, and then follow up the menstruum by water, until five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of percolate are obtained. To this add the wine of ipecac, and afterward the sugar, and dissolve the latter by agitation. Finally, add enough water, previously passed through the percolator, to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 3½ grains of asarum"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent combines the expectorant qualities of asarum and ipecacuanha. The dose is about 1 fluid drachm.

SYRUPUS AURANTII (U. S. P.)—SYRUP OF ORANGE.

SYNONYM: *Syrup of orange peel.*

Preparation.—"Sweet orange peel, taken from the fresh fruit, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; precipitated calcium phosphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Introduce the sweet orange peel (which should be as free as possible from the white, inner layer, and cut into small shreds) into a flask, and add eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏] of alcohol. Stopper the flask loosely with a notched cork, and apply the heat of a water-bath until the alcohol boils, and maintain it boiling during 5 minutes. Then stopper the flask well, and set it aside to cool. Filter off the liquid, and wash the filter and contents with alcohol until the filtrate measures one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Mix the precipitated calcium phosphate in a mortar, with one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.] of sugar, and add the tincture with constant trituration. To the resulting, pasty mass add three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water, triturating constantly, transfer the whole to a filter, and return the first portions of the filtrate, if necessary, until it runs through clear. In the filtrate dissolve the remainder of the sugar, and add enough water, through the filter, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Pharmaceutical Uses.—This syrup is agreeable in flavor and odor, and has a yellowish color. The volatile oil of the fresh, sweet orange peel, together with coloring matter, is dissolved by the alcohol. It is an excellent flavoring substance for mixtures.

SYRUPUS AURANTII FLORUM (U. S. P.)—SYRUP OF ORANGE FLOWERS.

SYNONYM: *Syrupus aurantii floris.*

Preparation.—"Sugar, eight hundred and fifty grammes (850 Gm.) [1 lb. av., 13 ozs., 430 grs.]; orange-flower water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sugar in four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of orange-flower water by agitation, without heat, add enough orange-flower water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and mix thoroughly. Syrup of orange flowers may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of orange-flower water upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by orange-flower water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—A very slight sedative effect is produced by this syrup upon those delicate individuals whose nervous system is easily excited. Its chief use, however, is in flavoring other medicines.

SYRUPUS CALCII LACTOPHOSPHATIS (U. S. P.)—SYRUP OF CALCIUM LACTOPHOSPHATE.

Preparation.—"Precipitated calcium carbonate, twenty-five grammes (25 Gm.) [386 grs.]; lactic acid, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; phosphoric acid, thirty-six cubic centimeters (36 Cc.) [1 fl℥, 104 ♏]; orange-flower water, twenty-five cubic centimeters (25 Cc.) [406 ♏]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. To the lactic acid, mixed with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water, and contained in a capacious mortar, gradually add the calcium carbonate, in portions, until it is dissolved. Then add the phosphoric acid, and triturate until the precipitate at first formed is dissolved. Add one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of water, and filter, rinsing the mortar with seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏] of water, and passing the rinsings through the filter. To the mixed filtrates add the orange-flower water, and, having added the sugar, dissolve it by agitation, without heat, and strain. Lastly, pass enough water through the strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and mix thoroughly"—(*U. S. P.*). This formula is regarded as a great improvement over the official process of 1880. Diluted lactic acid readily dissolves calcium carbonate, and, by adding phosphoric acid, calcium phosphate is formed, and this is maintained in solution by the presence of lactic acid and the uncombined phosphoric acid. Should precipitation be likely to occur, a very small quantity of hydrochloric acid will prevent such a change.

Action, Medical Uses, and Dosage.—This agent is used as a reconstructive in cases of general and nervous debility. It was a favorite remedy with Prof. A. J. Howe, M. D., as a vehicle for Fowler's solution, to be used in *incipient phthisis*. The dose ranges from 1 to 4 fluid drachms.

Related Preparations.—SYRUPUS CALCII LACTOPHOSPHATIS CUM FERRO (N. F.), *Syrup of calcium lactophosphate with iron, Syrup of lactophosphate of lime with iron.* "Lactate of iron, eight and one-half grammes (8.5 Gm.) [131 grs.]; potassium citrate, eight and one-half grammes (8.5 Gm.) [131 grs.]; water, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; syrup of calcium lactophosphate (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the lactate of iron and potassium citrate in the water with the aid of heat, and add enough syrup of calcium lactophosphate to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains ½ grain of lactate of iron and about ¼ grain of calcium lactate (or about ⅜ grain of so-called calcium lactophosphate)"—(*Nat. Form.*).

SYRUPUS CALCII HYPOPHOSPHITIS (N. F.), *Syrup of calcium hypophosphite, Syrup of hypophosphite of lime.*—"Calcium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; citric acid, one and one-half grammes (1.5 Gm.) [23 grs.]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the calcium hypophosphite and the citric acid in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, filter the solution, add the sugar to the filtrate, and pass enough water through the filter to make the product, after the sugar has been dissolved by agitation, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 2 grains of calcium hypophosphite"—(*Nat. Form.*). Or, dissolve hypophosphite of calcium, 1 ounce, in water, 9½ fluid ounces; filter, add white sugar, 12 ounces; dissolve by aid of heat, and add fluid extract of vanilla, ½ fluid ounce. The dose varies from a teaspoonful to a tablespoonful 3 times a day. A teaspoonful is equivalent to 3½ grains of the calcium salt.

SYRUPUS CALCII ET SODII HYPOPHOSPHITUM (N. F.), *Syrup of calcium and sodium hypophosphites, Syrup of hypophosphite of lime and soda.*—"Calcium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; sodium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; citric acid, one and one-half grammes (1.5 Gm.) [23 grs.]; sugar, seven hundred and seventy-five grammes (775 Gm.) (1 lb. av., 11 ozs., 148 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the two hypophosphites and the citric acid in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, filter the solution, add the sugar to the filtrate, and pass enough water through the filter to make the product, after the sugar has been dissolved by agitation, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 2 grains, each, of calcium hypophosphite and sodium hypophosphite"—(*Nat. Form.*).

SYRUPUS CALCII CHLORHYDROPHOSPHATIS (N. F.), *Syrup of calcium chlorhydrophosphate, Syrup of chlorhydrophosphate of lime.*—"Precipitated calcium phosphate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; spirit of lemon (*U. S. P.*), twenty cubic centimeters (20 Cc.)

[325 ♏]; hydrochloric acid (*U. S. P.*), water, syrup (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the precipitated calcium phosphate with thirty cubic centimeters (30 Cc.) [487 ♏] of water, and dissolve it with the aid of hydrochloric acid, avoiding an excess. Then add the spirit of lemon, filter the liquid, and wash the filter with a mixture of thirty cubic centimeters (30 Cc.) [487 ♏], each, of water and syrup. Lastly, add enough syrup to the filtrate, to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 1 grain of calcium phosphate"—(*Nat. Form.*).

SYRUPUS CALCIS (U. S. P.)—SYRUP OF LIME.

SYNONYMS: *Saccharated solution of lime, Syrupus calcariæ, Liquor calcis saccharatus.*

Preparation.—"Lime, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; sugar, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the lime and sugar thoroughly in a mortar, so as to form a homogeneous powder; then add the mixture to five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of boiling water, contained in a bright copper or tinned iron vessel, boil for 5 minutes, constantly stirring, and then strain. Dilute the strained liquid with an equal volume of water, and filter through white paper. Then evaporate the filtrate, in a tared capsule, to seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.], allow it to cool, add to it enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and mix thoroughly. Keep the syrup in well-stoppered bottles"—(*U. S. P.*).

Description.—In the presence of sugar, water will dissolve a much greater amount of lime than when employed alone, in consequence of the saccharates formed being more soluble than lime itself. This syrup is likely to vary in the quantity of lime present, and no limit is fixed in the official formula for the amount to be contained in the finished product. Syrup of lime is thin, viscid, transparent, and colorless, has a bitter, pronounced alkaline, almost caustic, and sweetish taste, and is strongly alkaline in reaction. It should be preserved in well-closed bottles, for, when exposed to the air, it absorbs carbonic acid gas. It should be well diluted before being administered.

Action, Medical Uses, and Dosage.—This syrup has been proposed as an antidote for *poisoning by oxalic acid*, *carbolic acid*, etc., and is useful in all cases requiring lime-water, but not preferable to the latter. The dose is about ½ to 1 fluid drachm, well diluted with water.

Related Preparation.—SYRUPUS CALCII IODIDI (N. F.), *Syrup of calcium iodide.* "Iodine, seventy-six grammes (76 Gm.) [2 ozs. av., 298 grs.]; iron wire, fine, bright, and finely cut, twenty-eight grammes (28 Gm.) [432 grs.]; precipitated calcium carbonate, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; distilled water, syrup (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the iron wire with fifty-seven grammes (57 Gm). [2 ozs. av., 5 grs.] of the iodine, and one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl℥, 123 ♏] of distilled water, and apply a gentle heat, until the iodine is combined, and the liquid has acquired a greenish color. Filter the liquid through a small filter into a flask containing the remainder of the iodine, wash the filter with sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of distilled water, and heat the solution gently, taking care that no iodine is lost by evaporation. Heat two hundred and fifty cubic centimeters (250 Cc. [8 fl℥, 218 ♏] of distilled water in a capacious capsule to boiling, and add to it small alternate portions, first of the precipitated calcium carbonate, and then of the solution of iodide of iron, in small portions at a time, stirring briskly and waiting until the violence of the reaction moderates before adding a fresh portion. From time to time, add a little distilled water, to replace that lost by evaporation. When all the iron solution has been added, continue heating the mixture until it is quietly boiling, then filter it through a wetted filter, and wash the latter with enough distilled water to make the product, when cold, measure five hundred cubic centimeters (500 Cc. [16 fl℥, 435 ♏]. In this dissolve the sugar by agitation, then make up the volume with syrup to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and strain, if necessary. Each fluid drachm contains about 5 grains of calcium iodide"—(*Nat. Form.*).

SYRUPUS CEANOTHI COMPOSITUS.—COMPOUND SYRUP OF RED-ROOT.

Preparation.—Take of the tops and leaves of Ceanothus americanus, of the bark of the root of Ceanothus americanus, and herb of Lactuca elongata, each, 16 troy ounces; root of Cimicifuga racemosa, 4 troy ounces; root of Asclepias tuberosa and Asarum canadense, each, 2 troy ounces; lobelia herb, and root of Sanguinaria canadensis, each, 1 troy ounce. Proceed as with Compound Syrup of Aralia, making 2 gallons of the finished syrup. This preparation is an improvement on the formula of its introducer, Dr. James Cooper.

Action, Medical Uses, and Dosage.—This syrup has been found very valuable in *coughs, pulmonary and hepatic affections.* The dose is from 1 fluid drachm to ½ fluid ounce, 3 or 4 times a day. In smaller doses, frequently repeated, it forms an excellent expectorant.

SYRUPUS CHLORAL.—SYRUP OF CHLORAL.

Preparation.—"Take of hydrate of chloral, 80 grains; distilled water, 1½ fluid drachms; syrup, a sufficiency. Dissolve the hydrate of chloral in the water, and add the syrup until the mixed product measures 1 fluid ounce. The specific gravity should be about 1.320"—(*Br. Pharm.*, 1885).

Action, Medical Uses, and Dosage.—The uses of this syrup, which is also official in the *British Pharmacopœia*, 1898; are those of chloral hydrate (which see). Each fluid drachm contains 10 grains of chloral hydrate, and the dose is from ½ to 2 fluid drachms.

SYRUPUS CHONDRI COMPOSITUS (N. F.)—COMPOUND SYRUP OF CHONDRUS.

Synonym: *Compound syrup of Irish moss.*

Preparation.—"Irish moss, one gramme (1 Gm.) [15.5 grs.]; fluid extract of ipecac (*U. S. P.*), one cubic centimeter (1 Cc.) [16 ♏]; fluid extract of squill (*U. S. P.*), sixteen cubic centimeters (16 Cc.) [260 ♏]; fluid extract of senega (*U. S. P.*), sixteen cubic centimeters (16 Cc.) [260 ♏]; camphorated tincture of opium (*U. S. P.*), twenty-eight cubic centimeters (28 Cc.) [454 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [232 grs.]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Macerate the Irish moss in sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of water until it is softened, then heat it on a boiling water-bath for 15 minutes, strain it through flannel, without pressure, and wash the flannel and contents with sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of hot water. Mix the fluid extracts and tincture with the purified talcum and three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl℥, 475 ♏] of water, shake the mixture frequently and thoroughly during half an hour, and then filter it through a wetted filter, returning the first portions of the filtrate until it runs through clear. Mix the mucilage of Irish moss with the filtrate, then add the sugar, and pass enough water through the filter to make the product, after the sugar has been dissolved by agitation, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent is demulcent and expectorant. The dose is from ½ to 1 fluid drachm.

SYRUPUS CINNAMOMI (N. F.)—SYRUP OF CINNAMON.

Preparation.—"Cinnamon (cassia), in moderately coarse powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; cinnamon water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of cinnamon water, moisten the cinnamon with a sufficient quantity of this menstruum and allow it to macerate for about 2 hours. Then transfer it to a small percolator, and percolate, in the usual manner, using first the remainder of the menstruum above directed, and afterward cinnamon water. Collect the first five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of the percolate separately, and dissolve in it the sugar. Then collect an additional quantity of percolate, and add it to the syrup, so as to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation is practically identical with that official in the *German Pharmacopœia*"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This syrup is a warm aromatic stomachic, carminative, and astringent. It is chiefly used as an adjuvant to other less pleasant medicines, especially in the treatment of *diarrhœa*, *dysentery*, *hemorrhages*, and where astringents are indicated. It may be given in doses of 1 or 2 fluid drachms.

SYRUPUS COCHLEARIÆ COMPOSITUS.—COMPOUND SYRUP OF HORSERADISH.

Preparation.—Take of the recent root of horseradish, grated, 2 ounces; boneset, leaves and tops, 1 ounce; Canada snakeroot, ½ ounce; boiling water, diluted acetic acid, of each, a sufficient quantity; refined sugar, 2 pounds (av.) Infuse the boneset and Canada snakeroot in ½ pint of the boiling water, and express with strong pressure, adding boiling water to the mass until ½ pint of infusion is obtained; then add the sugar. Add the horseradish to diluted acetic acid, ½ pint; let it stand for 2 days, and then express, adding diluted acetic acid to the mass until ½ pint of the acetous solution is obtained. Add this to the above syrup, and agitate until all the sugar is dissolved.

Action, Medical Uses, and Dosage.—This forms an efficient preparation for *obstinate colds*, *catarrhs*, *hoarseness*, and *chronic irritation of the throat and fauces*. The dose is from 1 to 4 fluid drachms, every 2 or 3 hours. The following compound, known as *Cough* or *Vegetable Elixir*, has been found a most beneficial agent in *chronic pulmonary affections*, *cough*, etc. To 1 gallon of good cider vinegar, add ½ pound each, of balsam of tolu and gum Arabic, dissolve by heat, and add of refined sugar 6 pounds; when all is dissolved, remove from the fire, and add of tincture of opium, 18 fluid ounces. The dose of this is a teaspoonful 3, 4, or 5 times a day, or whenever the cough is severe. Sometimes molasses or honey may be substituted for the sugar.

SYRUPUS COFFEÆ (N. F.)—SYRUP OF COFFEE.

Preparation.—"Coffee, roasted, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; sugar, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; water, a sufficient quantity. Introduce the coffee, reduced to a moderately coarse powder, into a suitable vessel; pour upon it five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of boiling water, then cover it well, and boil for 5 minutes. Allow it to become cold, keeping the vessel well covered; strain off the liquid and pass enough water through the strainer to make the strained liquid, when cold, measure five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]. In this dissolve the sugar, by agitation, without heat, and strain through muslin. *Note.*—It is recommended that a mixture of equal parts of the commercial varieties of coffee, known as 'Java' and 'Mocha,' be employed for this purpose. The coffee may also be exhausted by percolation, but special arrangements are then necessary to maintain the menstruum at the proper temperature"—(*Nat. Form.*).

Uses.—Two tablespoonfuls of this syrup, to a cup of boiling water or milk, will make a cup of good coffee. It is much used in soda water and mineral waters, in which it may be less concentrated, and be diluted with simple syrup (*Amer. Jour. Pharm.*, Vol. XXVIII, p. 372).

SYRUPUS CORYDALIS COMPOSITUS.—COMPOUND SYRUP OF TURKEY-CORN.

Preparation.—Take of the root of turkey-corn, coarsely bruised, 32 troy ounces; the leaves of twin-leaf, blue flag root, each, 16 troy ounces; sheep-laurel leaves, 8 troy ounces. Mix the articles together, and prepare a syrup after the manner of making Compound Syrup of Aralia, using the same proportion of sugar to the finished product. It may also be flavored with some agreeable aromatic essence, as sassafras, wintergreen, prickly ash berries, etc.

Action, Medical Uses, and Dosage.—This is a valuable alterative syrup, and is used with much success in *syphilis, scrofula, liver affections*, and *rheumatism*. Iodide of potassium may be added to it, in the same manner as usually pursued with the compound syrup of stillingia, to which this is by no means second. The dose is 1 fluid drachm, 3 or 4 times a day, in ½ gill of water (J. King).

Related Syrup.—Some sixty years since, a half-breed Indian called Ben Smith, in the state of New York, made a syrup, which gained considerable reputation as a remedy in *syphilitic diseases*, and which sold rapidly for $3.00 per bottle; the following is the formula for its preparation: Take of Indian hemp (*Apocyn. cann.*), Virginia sarsaparilla, inner bark of white pine, each, 1 pound; mezereon, 4 ounces; sheep-laurel, ½ pound; water, 4 gallons; sugar, 8 pounds. Place the plants in the water, boil for a few minutes, and then gradually evaporate, until about 2 gallons of decoction are left, then strain, and add the sugar. To each quart bottle of this syrup he added 40 drops of nitric acid, and 20 grains of tartar emetic dissolved in a sufficient quantity of spirits. The dose was a wineglassful 3 times a day. I have never been able to ascertain the true botanical character of the Virginia sarsaparilla. This syrup has been found as efficient in syphilis, when prepared without the tartar emetic (J. King).

SYRUPUS ERIODICTYI AROMATICUS (N. F.)—AROMATIC SYRUP OF ERIODICTYON.

SYNONYMS: *Aromatic syrup of yerba santa, Syrupus corrigens.*

Preparation.—"Fluid extract of eriodictyon (*U. S. P.*), thirty-two cubic centimeters (32 Cc.) [1 fl℥, 39 ♏]; solution of potassa (*U. S. P.*), twenty-five cubic centimeters (25 Cc.) [406 ♏]; compound tincture of cardamom (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; oil of sassafras, one-half cubic centimeter (0.5 Cc.) [8 ♏]; oil of lemon, one-half cubic centimeter (0.5 Cc.) [8 ♏]; oil of cloves, one cubic centimeter (1 Cc.) [16 ♏]; alcohol, thirty-two cubic centimeters (32 Cc.) [1 fl℥, 39 ♏]; sugar, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the fluid extract of eriodictyon and solution of potassa, then add one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water previously mixed with the compound tincture of cardamom, and afterward add the oils dissolved in the alcohol. Shake the mixture thoroughly, then filter it, and pour enough water through the filter to obtain three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl℥, 327 ♏] of filtrate. Pour this upon the sugar contained in a bottle, and dissolve it by placing the bottle in hot water, frequently agitating. Lastly, cool the product and add enough water, passed through the filter previously used, to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation is chiefly intended as a vehicle, for disguising the taste of quinine or of other bitter substances"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—For uses, see *Eriodictyon*. Largely used as a disguising vehicle for bitter substances. Dose, 1 fluid drachm.

SYRUPUS FERRI IODIDI (U. S. P.)—SYRUP OF FERROUS IODIDE.

SYNONYM: *Syrup of iodide of iron.*

"A syrupy liquid containing about 10 per cent, by weight, of ferrous iodide (FeI_2=308.94), or about 13.4 Gm. in 100 Cc."—(*U. S. P.*).

Preparation.—"Iron, in the form of fine bright wire, and cut into small pieces, twenty-five grammes (25 Gm.) [386 grs.]; iodine, eighty-three grammes (83 Gm.) [2 ozs. av., 406 grs.]; syrup, distilled water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.] Introduce the iron into a flask of thin glass, having a capacity of about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏], add to it one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of distilled water, and afterward the iodine. Shake the mixture occasionally, checking the reaction, if necessary, by the affusion of cold water, and, when the solution has acquired a greenish color, and has lost the odor of iodine, heat it to boiling. Then filter it through a strong, double, rapidly-acting filter placed in a funnel, the point of which dips below the surface of six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.] of syrup contained in a tared vessel. When the liquid has run through, wash the flask and filter with a mixture of twenty-five cubic centimeters (25 Cc.) [406 ♏] each, of syrup and distilled water, previously raised to near 100° C. (212° F.), then withdraw the funnel, add enough syrup to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and mix thoroughly. Keep the syrup in small, well-stoppered and completely filled bottles"—(*U. S. P.*).

By this process the solution of iodide of iron is preserved to a great extent from decomposition by the addition of saccharine matter. The aqueous solution is exceedingly subject to decomposition by exposure to air and light, the ferrous salt passing into basic ferric salt with liberation of iodine. To obviate this tendency to oxidation, M. Frederking, of Riga, and Prof. Procter, of Philadelphia, proposed the addition of saccharine matter, which they found to exert a protective action, and which fact has since been amply confirmed. Hence, the sugar is added to protect the solution of iodide of iron.

Upon standing for a length of time, or if exposed to the action of diffused light or air, syrup of iodide of iron gradually undergoes decomposition, and becomes more or less colored a rusty red. To overcome this difficulty, various means have been suggested and tried. It has been found that placing the well-filled bottle directly in the sunlight will prevent such decomposition, and even it the preparation has already become dark in color such treatment will restore it to its natural hue, though it is probable that the preparation is somewhat changed, some ferric iodate probably being formed in it. Prof. J. F. Judge recommended hypophosphorous acid to decolorize such a changed syrup. Dr. E. R. Squibb has found from 15 to 20 minims of a solution of 15 to 20 grains of hyposulphite of sodium in a fluid ounce of water, to restore the color of syrup of iodide of iron, when the color had not become darker than brown sherry wine. Syrup thus restored is not so apt to change again (*Amer. Jour. Pharm.*, 1868, p. 99). Prof. F. F. Mayer had previously recommended the same for preserving aqueous solutions of iodide of iron (*Proc. Amer. Pharm. Assoc.*, 1859, p. 371). Mr. Thomas B. Groves recommended phosphoric acid for the preservation of syrup of iodide of iron; he adds diluted phosphoric acid, ½ fluid ounce to each 31 fluid ounces of the syrup. The syrup must be completely cooled before the acid is added (*Amer. Jour. Pharm.*, 1868, p. 265).

Description and Tests.—Syrup of iodide of iron is a pale yellowish-green, clear fluid, destitute of any precipitate. If the addition of starch changes it to a blue color, it holds free iodine. Sulphuric acid added to it changes it to a brown color, with evolution of vapors of a violet color on the application of heat. The *U. S. P.* describes it as "a transparent, pale-green liquid, having a sweet, strongly ferruginous taste, and a neutral reaction. Specific gravity about 1.353 at 15° C. (59° F.). On adding a few drops of potassium ferricyanide T.S. to a small portion of the syrup, a blue precipitate will be produced. If mixed with a little starch T.S., and afterward with a few drops of chlorine water, the syrup will acquire a deep-blue color. This color should not be produced in the syrup by starch T.S. alone (absence of free iodine). If 1.55 Gm. (1.5447 Gm.) of the syrup and 10 Cc. of water be introduced into a flask, and the liquid mixed, successively, with 11 Cc. of decinormal silver nitrate V.S., and 5 Cc., each, of diluted nitric acid and ferric ammonium sulphate T.S., it should not require more than about 1 Cc. of decinormal potassium sulphocyanate V.S. to produce a reddish-brown tint which persists after shaking (corresponding to about 10 per cent of ferrous iodide)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The medicinal properties are the same as mentioned under the head of *Saccharated Iodide of Iron;* the dose is from 10 to 40 drops, 3 times a day. It should be well diluted with water, and care should be taken not to allow it to act on the teeth, by washing the mouth immediately after taking a dose.

Related Syrups.—Syrupus Ferri Bromidi (*U. S. P.*, 1880). *Syrup of bromide of iron*, was at one time in some little demand, and may be made by filtering the solution of bromide of iron (as prepared under *Ferri Bromidum*), into 16 fluid ounces of simple syrup, and, after washing ne paper and excess of iron and liberated carbon with a little distilled water, adding enough simple syrup to the mixture to make the whole measure 20 fluid ounces. Several and varying proportions have been suggested for this preparation, but the strength we have adopted seems to be the best, as it produces a syrup similar to the official syrup of iodide of iron, bromine being substituted for iodine. Syrup of bromide of iron has a greenish color when recent, somewhat resembling, in appearance, that of syrup of iodide of iron, and, like this preparation, it decomposes by age. Each fluid ounce contains about 65 grains of bromide of iron.

The following is the process of the *National Formulary:*

Syrupus Ferri Bromidi (N. F.), *Syrup of bromide of iron* (*U. S. P.*, 1880).—A syrupy liquid containing 10 per cent of ferrous bromide ($FeBr_2$=215.4). "Iron, in the form of fine wire, and cut into small pieces, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; bromine, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; sugar, in coarse powder, six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.]; distilled water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Introduce the iron into a flask of thin glass of suitable capacity, add to it two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.] of distilled water, and afterward the bromine. Shake the mixture occasionally, until the reaction ceases and the solution has acquired a green color and has lost the odor of bromine. Place the sugar in a porcelain capsule and filter the solution of bromide of iron into the sugar. Rinse the flask and iron wire with ninety grammes (90 Gm.) [3 ozs. av., 76 grs.] of distilled water and pass the washings through the filter into the sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling point on a sand-bath, and, having strained the syrup through linen into a tared bottle, add enough distilled water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place accessible to daylight"— *Nat. Form.*).

Syrupus Ferri Citro-iodidi (N. F.), *Syrup of citro-iodide of iron, Tasteless syrup of iodide of iron.*—"Iodine, fifty-nine grammes (59 Gm.) [2 ozs. av., 36 grs.]; iron wire, fine, bright, and finely cut, twenty-eight and one-half grammes (28.5 Gm.) [1 oz. av.]; potassium citrate, eighty-eight grammes (88 Gm.) [3 ozs. av., 46 grs.]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the iron with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of distilled water in a flask, add forty-five grammes (45 Gm.) [1 oz. av., 257 grs.] of the iodine, apply a gentle heat and set aside until the iodine is combined and the solution has acquired a green color. Then heat the contents of the flask to boiling, filter the liquid, and wash the filter with thirty cubic centimeters (30 Cc.) [487 ♏] of warm distilled water. Add to the filtrate the remaining fourteen grammes (14 Gm.) [216 grs.] of iodine, and, as soon as solution has been effected, mix with the potassium citrate previously dissolved in one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of distilled water, and agitate the liquid until it has assumed a green color. Pour this upon the sugar contained in a bottle, agitate until solution has been effected, and when the liquid is cold, add enough distilled water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains an amount of iron, corresponding to about 3.6 grains of ferric iodide. *Note.*—The official *Syrupus Ferri Iodidi* contains about 8 grains of *ferrous iodide* (protiodide of iron) in each fluid drachm. The above preparation contains the iron in the *ferric* condition"—(*Nat. Form.*).

SYRUPUS FERRI PHOSPHATIS.—SYRUP OF PHOSPHATE OF IRON.

Preparation.—"Take of granulated sulphate of iron, 224 grains; phosphate of sodium, 200 grains; bicarbonate of sodium, 56 grains; concentrated phosphoric acid, 1¼ fluid ounces; refined sugar, 8 ounces (av.); distilled water, 8 fluid ounces; dissolve the sulphate of iron in about 4 ounces of boiling water, and the phosphate of sodium in a similar quantity of cold water; mix the solutions, then add the bicarbonate of sodium, dissolved in a little water, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with distilled water, till the filtrate ceases to be affected by chloride of barium. Mix the residue on the filter, in a mortar, with the phosphoric acid. As soon as the precipitate is dissolved, filter the solution, add water and the sugar, and dissolve without heat. The product should measure exactly 12 fluid ounces; any water which may be necessary beyond that introduced with the precipitate or with the sugar, being added to form the stated bulk. Its specific gravity is about 1.305. It contains the equivalent of about 1 grain of anhydrous phosphate of iron ($Fe_3[PO_4]_2$) in 1 fluid drachm"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) prepares a compound of the same strength by dissolving iron, in the form of wire, in warm diluted phosphoric acid, and filtering the solution into syrup.

In the first process, where sodium phosphate and ferrous sulphate react upon each other, tribasic ferrous phosphate and sodium sulphate result with formation of free sulphuric acid. This is almost wholly neutralized by the presence of the bicarbonate of sodium, otherwise the acid would hold the ferrous phosphate in solution. The reaction is as follows: $2PO_4HNa_2+3FeSO_4=(PO_4)_2Fe_3+H_2SO_4+2Na_2SO_4$. The precipitated ferrous phosphate is washed, and, during the process, changes from white to blue, through partial oxidation, forming ferroso-ferric phosphate. Such a change is also liable to take place when the syrup is exposed to air, even though the sugar is intended to prevent such a change. The precipitate above mentioned is dissolved in the phosphoric acid, and then made into a syrup. A sherry color sometimes ensues in the finished product, and is due to caramel (Groves), and, at the same time, an insoluble phosphate is deposited, which may be filtered out.

Action, Medical Uses, and Dosage.—This syrup is employed where a chalybeate and nerve tonic combined is required. The dose is 1 fluid drachm.

Other Iron Syrups.—Syrupus Ferri Saccharati Solubilis (N. F.), *Syrup of soluble saccharated iron, Syrupus ferri oxydati solubilis* (*Ger. Pharm.*), *Syrup of saccharated oxide of iron, Syrup of soluble oxide of iron.* I. "Solution of chloride of iron (*U. S. P.*), eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; soda (*U. S. P.*), thirty-two and one-half grammes (32.5 Gm.) [1 oz. av., 64 grs.]; solution of soda (*U. S. P.*), a sufficient quantity; sugar, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; distilled water, syrup (*U. S. P.*), of each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the soda in two hundred and ten cubic centimeters (210 Cc.) [7 fl℥, 49 ♏] of water, add this solution to the solution of chloride of iron previously mixed with seventy grammes (70 Gm.) [2 ozs. av., 205 grs.] of syrup, and set the mixture aside, during 24 hours, in a dark place. Then pour the clear liquid slowly into sixteen hundred cubic centimeters (1600 Cc.) [54 fl℥, 49 ♏] of boiling distilled water, continue the boiling for a few minutes, and then set the mixture aside during 1 day, in a dark place, so that it may become clear by settling. Withdraw the supernatant liquid by means of a siphon, then wash the residue again with sixteen hundred cubic centimeters (1600 Cc.) [54 fl℥, 49 ♏] of boiling distilled water, by decantation. Transfer the magma to a wetted strainer, and wash it with hot distilled water until this runs off colorless, but so that the mass on the strainer still retains a moderately strong alkaline reaction. Then allow the excess of liquid to drain off, transfer the moist magma to a tared porcelain capsule, add the sugar, and heat it on a water-bath, with exclusion of daylight, during 2 hours, replacing from time to time any water lost by evaporation, and adding, if necessary, solution of soda, drop by drop, until the magma is entirely dissolved. Lastly, add enough syrup to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and transfer the product to bottles, which should be completely filled, and stored in a cool and dark place. One hundred grains, or about 75 minims, of this syrup represent approximately 1 grain of metallic iron. *Note.*—The above process is based upon that of the *German Pharmacopœia* (1st ed.). The formula given by the second edition of this work presupposes the keeping in stock of a dry 'Ferrum Oxydatum Saccharatum Solubile' (Saccharated Oxide of Iron), representing 3 per cent of metallic iron. When this is available, the Syrup of Soluble Saccharated Iron may also be prepared by the following formula: II. Saccharated oxide of iron, syrup, water, each, equal parts. Dissolve the saccharated oxide of iron in the mixed liquids"—(*Nat. Form.*).

Syrupus Phosphatum Compositus (N. F.), *Compound syrup of phosphates, Chemical food.*—"Precipitated calcium carbonate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; soluble ferric phosphate (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; ammonium phosphate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; potassium bicarbonate, four grammes (4 Gm.) [62 grs.]; sodium bicarbonate, four grammes (4 Gm.) [62 grs.]; citric acid, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; phosphoric acid (50 per cent), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; orange-flower water, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; tincture of cudbear (F. 418), sixteen cubic centimeters (16 Cc.) [260 ♏]; sugar, five hundred and twenty-five grammes (525 Gm.) [1 lb. av., 2 ozs., 227 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the precipitated calcium carbonate with the potassium and sodium bicarbonates, the citric acid, glycerin, and orange-flower water, and gradually add the phosphoric acid, stirring until solution has been effected. Dissolve the ferric phosphate and the ammonium phosphate in two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of hot water, cool, and add the solution to that previously prepared. Filter the whole through a pellet of absorbent cotton placed in the neck of a funnel, and receive the filtrate in a graduated bottle containing the sugar. Agitate until the latter is dissolved, then add the tincture of cudbear, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains about 2 grains of calcium phosphate, 1 grain, each, of the phosphates of iron and of ammonium, and smaller quantities of potassium and sodium phosphates. *Note.*—Phosphoric acid (50 per cent) may be made by adding seventy grammes (70 Gm.) [2 ozs. av., 205 grs.] of distilled water to one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of phosphoric acid (*U. S. P.*), which contains 85 per cent, by weight, of absolute orthophosphoric acid (H_3PO_4)"—(*Nat. Form.*).

Syrupus Ferri et Mangani Iodidi (N. F.), *Syrup of iodide of iron and manganese.*—"Iodine, eighty-one and one-half grammes (81.5 Gm.) [2 ozs. av., 383 grs.]; iron wire, fine, bright, and finely cut, twenty-six and one-half grammes (26.5 Gm.) [409 grs.]; manganese sulphate, twenty-six and one-half grammes (26.5 Gm.) [409 grs.]; potassium iodide, thirty-one and one-half grammes (31.5 Gm.) [486 grs.]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the iron with two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of distilled water in a flask, add the iodine, and prepare a solution of ferrous iodide, in the usual manner, aiding the process, if necessary, by heating the contents of the flask, at first gently, and finally to boiling. Filter the liquid, through a small filter, directly upon the sugar, contained in a suitable bottle. Dissolve the manganese sulphate in one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏] of distilled water, and the potassium iodide in one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏] of diluted alcohol, mix the two solutions, and filter into the same bottle which contains the sugar and the iron solution. Wash the filter with thirty cubic centimeters (30 Cc.) [487 ♏] of cold distilled water, receiving the washings in the same bottle. Agitate until the sugar is dissolved, and, if necessary, strain. Finally, make up the volume with distilled water to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains about 6 grains of iodide of iron (ferrous) and 3 grains of manganese iodide" (*Nat. Form.*).

Syrupus Ferri Arsenatis (N. F.), *Syrup of arsenate of iron.* "Sodium arsenate (*U. S. P.*), dried to a constant weight at a heat not exceeding 149° C. (300° F.), forty centigrammes (0.40 Gm.) [6 grs.]; citrate of iron (*U. S. P.*), thirty-five centigrammes (0.35 Gm.) [5.5 grs.]; water, thirty cubic centimeters (30 Cc.) [487 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium arsenate and citrate of iron in the water, contained in a test-tube, by the aid of heat. Then mix the solution with enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains about $\frac{1}{30}$ grain of arsenate of iron (ferric). *Note.*—Care should be taken to select perfectly formed crystals of sodium arsenate, which must then be dried completely at 100° Cc. (212° F.), and the quantity required for the above formula must be weighed from the *dried* salt. It is advisable to dry a fresh quantity of the salt each time the above syrup is to be prepared"—(*Nat. Form.*).

SYRUPUS FERRI PYROPHOSPHATIS.—SYRUP OF PYROPHOSPHATE OF IRON.

Preparation.—Take of soluble pyrophosphate of iron, in scales, 150 grains; distilled water, 4 fluid drachms; syrup, 37 fluid ounces. Dissolve the pyrophosphate of iron in the distilled water, filter, and mix the solution with the syrup. One to 2 fluid drachms of the tincture of some aromatic oil should be added to it. There are other formulas for this syrup.

Action, Medical Uses, and Dosage.—This forms a pleasant preparation for the administration of this salt of iron, in all cases where it is indicated (see *Ferri Pyrophosphas*). One fluid drachm contains 2 grains of the pyrophosphate. Its dose is from 1 to 3 teaspoonfuls, repeated 2 or 3 times a day. When required, it may be added to many other tonic and alterative syrups.

Related Preparation.—Syrupus Ferri Lactophosphatis (N. F.), *Syrup of lactophosphate of iron.* "Lactate of iron, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; phosphoric acid (85 per cent, *U. S. P.*), a sufficient quantity; water, thirty cubic centimeters (30 Cc.) [487 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the lactate of iron in the water with the aid of a sufficient quantity of phosphoric acid, avoiding excess, and add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 1 grain of lactate of iron, or about 1½ grains of so-called lactophosphate of iron"—(*Nat. Form.*).

SYRUPUS FERRI PROTOCHLORIDI (N. F.)—SYRUP OF PROTOCHLORIDE OF IRON.

Synonyms: *Syrup of ferrous chloride.*

Preparation.—"Solution of protochloride of iron (F. 222), fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; orange-flower water, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the solution of protochloride of iron with the glycerin and orange-flower water, and add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains about 1 grain of protochloride of iron (ferrous chloride)"—(*Nat. Form.*).

This syrup is a solution of ferrous chloride protected from oxidation by means of sugar. Notwithstanding, this precaution, it loses its pale-green hue upon standing, and changes to a deeper color. Small quantities only should be prepared, and be kept securely stoppered in small, well-filled vials.

Action, Medical Uses, and Dosage.—This syrup is used for the general purposes of the chalybeates. Dose, ½ to 1 fluid drachm.

SYRUPUS FERRI, QUININÆ, ET STRYCHNINÆ PHOSPHATUM (U.S.P.)

SYRUP OF THE PHOSPHATES OF IRON, QUININE, AND STRYCHNINE.

SYNONYMS: *Syrupus ferri phosphorici cum chinino et strychnino, Syrupus Eastoni, Easton's syrup, Aitkin's syrup, Syrup of the triple phosphates, Syrup of the three phosphates.*

Preparation.—"Soluble ferric phosphate, twenty grammes (20 Gm.) [309 grs.]; quinine sulphate, thirty grammes (30 Gm.) [463 grs.]; strychnine, two-tenths of a gramme (0.2 Gm.) [3 grs.]; phosphoric acid, forty-eight cubic centimeters (48 Cc.) [1 fl℥, 299 ♏]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; water, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; syrup, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Heat the soluble ferric phosphate with the water, in a porcelain capsule, until it is dissolved. Then add the phosphoric acid, the quinine sulphate, and the strychnine, and stir, until solution is effected. Filter the liquid into the glycerin, contained in a graduated bottle, add enough syrup to make up the volume to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and mix thoroughly. Lastly, strain, if necessary"—(*U. S. P.*).

This syrup can be readily prepared by the foregoing process. Instead of the freshly precipitated ferrous phosphate formerly used, the above scaled salt, known as sodio-ferric citro-phosphate, is now employed. The phosphoric acid and glycerin are added to preserve the solution from precipitation. Each fluid drachm holds about $\frac{1}{85}$ grain of strychnine, 1⅛ grain of the iron compound, and 1⅔ grain of sulphate of quinine. The syrup slightly deepens in color with age.

Action, Medical Uses, and Dosage.—This preparation is very similar to the Compound Tonic Mixture, or *Misturæ Alterantiæ Composita*, mentioned elsewhere, and may be used to fulfil the same indications. The dose ranges from ½ to 1 fluid drachm, well diluted with water.

SYRUPUS GLYCYRRHIZÆ (N. F.)—SYRUP OF GLYCYRRHIZA.

SYNONYM: *Syrup of liquorice.*

Preparation.—"Pure extract of glycyrrhiza (*U. S. P.*), one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; glycerin, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the pure extract of glycyrrhiza in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, add the sugar, dissolve it by agitation, and strain. Then add the glycerin, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 30 grains of glycyrrhiza"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Glycyrrhiza.*) Dose, ½ to 1 fluid drachm.

SYRUPUS HELIANTHI COMPOSITUS.—COMPOUND SYRUP OF SUNFLOWER SEED.

Preparation.—Take of bruised sunflower seed, 8 troy ounces; sugar, 24 ounces; Holland gin, 2 pints; water, a sufficient quantity. Pour 4 pints of water on the bruised seeds, and bring to a boil, strain, and evaporate the liquid to 24 fluid ounces, in which dissolve the sugar by the aid of heat. Then, when cold, add the Holland gin.

Action, Medical Uses, and Dosage.—Prof. R. S. Newton highly lauds the compound syrup of helianthus in *chronic affections of the lungs, larynx, bronchi*, etc., as an efficient preparation for relieving *cough*, diminishing abnormal mucous secretion, and imparting tone and healthful vigor to the mucous tissues of the air passages. The dose varies from a teaspoonful to a tablespoonful, 3, 4, or more times per day, or whenever cough is severe. Where it is desired to obtain a diuretic effect, ½ ounce, each, of the oils of juniper and of stillingia may be added to the above syrup.

SYRUPUS HYPOPHOSPHITUM (U. S. P.)—SYRUP OF HYPOPHOSPHITES.

SYNONYM: *Syrupus calcii hypophosphitis compositus.*

Preparation.—"Calcium hypophosphite, forty-five grammes (45 Gm.) [1 oz. av., 257 grs.]; potassium hypophosphite, fifteen grammes (15 Gm.) [232 grs.]; sodium hypophosphite, fifteen grammes (15 Gm.) [232 grs.]; diluted hypophosphorus acid, two grammes (2 Gm.) [31 grs.]; sugar, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; spirit of lemon, five cubic centimeters (5 Cc.) [81 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the hypophosphites with four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of water, until they are dissolved, add the spirit of lemon, and the hypophosphorous acid, and filter the liquid. In the filtrate dissolve the sugar by agitation, without heat, and add enough water, through the filter, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Strain, if necessary. Syrup of hypophosphites may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

The hypophosphorous acid is employed in this sweetened solution of the hypophosphites, to complete the solution of the calcium salt, which otherwise does not wholly dissolve. The combined hypophosphites are present to the amount of about 4.3 grains to the fluid drachm, about 2½ grains of which consists of the calcium compound. Heat should be avoided in its preparation.

Action, Medical Uses, and Dosage.—This syrup combines the virtues of the respective hypophosphites employed. Dose, ½ to 1 fluid drachm.

Related Preparations.—SYRUPUS HYPOPHOSPHITUM COMPOSITUS (N. F.), *Compound Syrup of hypophosphites, Compound hypophosphites.* "Calcium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; potassium hypophosphite, seventeen and one-half grammes (17.5 Gm. [270 grs.]; sodium hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; hypophosphite of iron, two and one-fourth grammes (2.25 Gm.) [35 grs.]; manganese hypophosphite, two and one-fourth grammes (2.25 Gm.) [35 grs.]; potassium citrate, five grammes (5 Gm.) [77 grs.]; citric acid, two grammes (2 Gm.) [31 grs.]; quinine hydrochlorate, one and one-eighth grammes (1.125 Gm.) [17 grs.]; tincture of nux vomica (*U. S. P.*), twenty-two cubic centimeters (22 Cc.) [357 ♏]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Rub the hypophosphites of iron and of manganese with the potassium citrate and citric acid to powder, add sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of water, and warm the mixture a few minutes until a clear greenish solution is obtained. Introduce the other hypophosphites and the quinine hydrochlorate, previously triturated together, into a graduated bottle, next add the sugar, the iron and manganese solution first prepared, the tincture of nux vomica, and lastly, enough water to make up the volume, as soon as the sugar is saturated by the liquid, to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Agitate until solution has been effected, and strain, if necessary. Each fluid drachm contains 2 grains of calcium hypophosphite, 1 grain, each, of potassium and sodium hypophosphites, ⅛ grain, each, of the hypophosphites of iron and of manganese, 1/16 grain of quinine hydrochlorate, and 1¼ minims of tincture of nux vomica. *Note.*—This syrup should not be confounded with the official *Syrupus Hypophosphitum* (syrup of the hypophosphites). It is not intended to be perfectly clear, and should be shaken before using"—(*Nat. Form.*).

SYRUPUS SODII HYPOPHOSPHITIS (N. F.), *Syrup of sodium hypophosphite.*—"Sodium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; citric acid, one and one-half grammes (1.5 Gm.) [23 grs.]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium hypophosphite and the citric acid in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, and filter the solution. In this dissolve the sugar by agitation, and pass enough water through the filter, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 2 grains of sodium hypophosphite"—(*Nat. Form.*).

SYRUPUS HYPOPHOSPHITUM CUM FERRO (U. S. P.)—SYRUP OF HYPOPHOSPHITES WITH IRON.

Preparation.—"Ferrous lactate, ten grammes (10 Gm.) [154 grs.]; potassium citrate, ten grammes (10 Gm.) [154 grs.]; syrup of hypophosphites, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the ferrous lactate and potassium citrate with a small quantity of the syrup, gradually added, until they are dissolved. Then strain, and add enough syrup of hypophosphites to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. This preparation should be freshly made, when wanted"—(*U. S. P.*).

Formerly ferrous hypophosphite was employed in preparing this syrup but was found to be unsatisfactory. Ferrous lactate has now been selected as less liable to precipitate with the other salts, and citrate of potassium is added to further assist in holding the salts in perfect solution. The preparation should be well and carefully preserved to prevent oxidation, which is likely to gradually ensue. Avoid heat in preparing this syrup. Each fluid drachm contains about ¾ grain of ferrous lactate, about 1 grain each of potassium and sodium hypophosphites, and about 2½ grains of calcium hypophosphite.

Action, Medical Uses, and Dosage.—This syrup is representative of the hypophosphites and iron compounds, and employed like them. The dose is from ½ to 1 fluid drachm.

Related Preparation.—SYRUPUS FERRI HYPOPHOSPHITIS (N. F.), *Syrup of hypophosphite of iron.* "Hypophosphite of iron, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; potassium citrate, twenty-five grammes (25 Gm.) [386 grs.]; orange-flower water, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the hypophosphite of iron, with the aid of the potassium citrate, in the orange-flower water, and add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains 1 grain of hypophosphite of iron (ferric)"—(*Nat. Form.*).

SYRUPUS IPECACUANHÆ (U. S. P.)—SYRUP OF IPECAC.

Preparation.—"Fluid extract of ipecac, seventy cubic centimeters (70 Cc.) [2 fl℥, 176 ♏]; acetic acid, ten cubic centimeters (10 Cc.) [162 ♏]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 oz., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dilute the fluid extract of ipecac with three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water to which the acetic acid had previously been added, and mix them thoroughly by shaking. Then filter, and pass enough water through the filter to obtain five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of filtrate. To this liquid add the glycerin, dissolve the sugar in the mixture, and add enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly, and strain, if necessary. Syrup of ipecac may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Mix the filtrate obtained as directed in the preceding formula with the glycerin, pour the mixture upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This syrup is emetic and expectorant; it is used principally among children. As an emetic the dose for an adult is 1 or 2 fluid ounces; for a child 1 or 2 years old, 1 or 2 fluid drachms, to be repeated every 10 or 20 minutes till it operates. When used as an expectorant, an adult may take 1 or 2 fluid drachms; a child, from 5 to 20 minims.

SYRUPUS KRAMERIÆ (U. S. P.)—SYRUP OF KRAMERIA.

SYNONYMS: *Syrup of rhatany*, *Syrupus ratanhæ*.

Preparation.—"Fluid extract of krameria, four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]; syrup, five hundred and fifty cubic centimeters (550 Cc.) [18 fl℥, 287 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*). This is a clear syrup, holding 27 minims of the fluid extract of krameria in each fluid drachm.

Action, Medical Uses, and Dosage.—This syrup is usually added to astringent and antacid mixtures, to be administered in the *non-inflammatory diarrhœas* of small children. Dose, ½ to 1 fluid drachm.

SYRUPUS LACTUCARII (U. S. P.)—SYRUP OF LACTUCARIUM.

Preparation.—"Tincture of lactucarium, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; precipitated calcium phosphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sugar, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the precipitated calcium phosphate and one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.] of the sugar, in a mortar, with the tincture of lactucarium gradually added, and afterward with three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water, added in small portions at a time. Filter the mixture, dissolve the remainder of the sugar in the filtrate, and pass enough water through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Syrup of lactucarium may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*). This syrup is transparent, the rubber-like constituents of lactucarium having been removed in the process of tincturing. Of lactucarium it contains about 3 grains in each fluid drachm.

Action, Medical Uses, and Dosage.—(For uses, see *Lactucarium*.) Dose, about 1 fluid drachm.

SYRUPUS LIMONIS.—SYRUP OF LEMON.

Preparation.—"Take of fresh lemon peel, 2 ounces (av.); lemon juice, strained, 1 pint (Imp.); refined sugar, 2¼ pounds (av.). Heat the lemon juice to the boiling point, and, having put it into a covered vessel with the lemon peel, let them stand until they are cold, then filter, and dissolve the sugar in the filtered liquid with the aid of heat. The product should weigh 3½ pounds (av.), and its specific gravity be about 1.340"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs the previous maceration of the lemon peel for 7 days in alcohol of 90 per cent, pressing off the tincture and mixing it with the lemon juice and sugar.

Action, Medical Uses, and Dosage.—When diluted with water, this forms an agreeable drink for *febrile affections* when an acid is indicated. Dose, 1 fluid drachm, well diluted.

SYRUPUS LIQUIDAMBAR.—SYRUP OF SWEET-GUM.

Preparation.—Take of sweet-gum bark, in coarse powder, 5 ounces; refined sugar, 2 pounds (av.); water, a sufficient quantity. Moisten the bark thoroughly with water, let it stand for 24 hours in a close vessel, then transfer it to a percolator, and pour water gradually on it until a pint of filtered liquor is obtained. To this add the sugar in a bottle, and agitate occasionally until it is dissolved (Dr. C. W. Wright).

Action, Medical Uses, and Dosage.—This is a pleasant medicine, which is not apt to be ejected from an irritable stomach. It is very useful in *bowel complaints of children*, *diarrhœa*, *chronic cough*, and *chronic mucous affections* generally. The dose for an adult is a fluid ounce, 3 or 4 times a day; and, in diarrhœa, to be repeated after each evacuation from the bowels when they recur too frequently. Probably the sweet-gum, or resinous exudation, dissolved in alcohol, or made into an emulsion, and then added to syrup, would answer the purpose still better.

SYRUPUS LOBELIÆ.—SYRUP OF LOBELIA.

Preparation.—Take of vinegar of lobelia, 1 pint; sugar, 2 pounds. Dissolve with the aid of a gentle heat, and strain while hot.

Action, Medical Uses, and Dosage.—This forms a pleasant expectorant syrup, and although the volatile properties of lobelia are dissipated by heat, this syrup will be found sufficiently active for practical purposes; the long-continued digestion removes the peculiar, disagreeable taste of the lobelia. It will be found very useful in *infantile catarrh*, *pertussis*, *croup*, *pectoral diseases*, to produce emesis, and to bring the system under the relaxing influence of lobelia. The dose is from 1 fluid drachm to ½ fluid ounce (N. T. Isgrigg, M. D.).

SYRUPUS MANNÆ (N. F.)—SYRUP OF MANNA.

Preparation.—"Manna, in flakes, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; alcohol, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the manna in four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of hot water, add the alcohol, set the liquid aside for 12 hours in a moderately warm place, and filter. Dissolve the sugar in the filtrate, with the aid of a gentle heat, allow the syrup to cool, and add enough water, passed through the filter previously used, to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This product is approximately of the same strength as that which is official in the *German Pharmacopœia*"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Manna.*) Dose, 1 to 2 fluid drachms.

SYRUPUS MARRUBII COMPOSITUS.—COMPOUND SYRUP OF HOARHOUND.

Preparation.—Take of the bark of red-root, roots of elecampane, spikenard, and comfrey, bark of wild cherry, and leaves and tops of hoarhound, each, 16 troy ounces; bloodroot, 8 troy ounces. Grind and mix the articles together. Make a syrup after the process directed for Compound Syrup of Aralia, using the same menstruum and the proportional amount of sugar to produce 24 pints of syrup. Each pint will contain the virtues of 4 ounces of the ingredients. In the earlier Dispensatories, this article was called *Syrupus Araliæ Compositus* (Compound Syrup of Spikenard), but in consequence of the great improvement in the formula, and from the fact that this name has been now bestowed upon another preparation, the name of the article under consideration has been changed to avoid confusion.

Action, Medical Uses, and Dosage.—This is an elegant remedy for *obstinate coughs* of long standing, and *pulmonary affections* generally. It has been called "Pulmonary Balsam," but is superior to the preparation bearing this name in past years. It is often employed advantageously in pulmonary and bronchial difficulties, combined with ¼ part of fluid extract of queen's root. The dose of the syrup is ½ fluid ounce, 3 or 4 times a day.

SYRUPUS MITCHELLÆ COMPOSITUS.—COMPOUND SYRUP OF PARTRIDGEBERRY.

SYNONYM: *Mother's cordial.*

Preparation.—Take of partridgeberry, 16 troy ounces; helonias root, high cranberry bark, blue cohosh root, each, 4 troy ounces. Grind, and mix the articles together; place the whole 1¾ pounds in a convenient vessel, cover them with fourth-proof brandy, and macerate for 3 days. Then transfer the whole to a percolator, and gradually add brandy, until 3 pints of spirituous tincture have been obtained, which reserve. Then continue the percolation with water until the liquid passes tasteless; add to this 2 pounds of refined sugar, and evaporate by a gentle heat to 5 pints; remove from the fire, add the reserved 3 pints of spirituous tincture, and flavor with essence of sassafras. Strictly speaking, this is not a syrup, but a sweetened infusion, yet I place it here, as being nearly in its appropriate class. It is often termed *Mother's cordial*, but is superior to the article to which the name was formerly applied (J. King). This process is not always followed, the brandy being displaced by diluted alcohol.

Action, Medical Uses, and Dosage.—This preparation is a uterine tonic and antispasmodic. It may be used in all cases where the functions of the internal reproductive organs are deranged, as in *amenorrhœa*, *dysmenorrhœa*, *menorrhagia*, *leucorrhœa*, and to overcome the *tendency to habitual abortion*. The dose is from 2 to 4 fluid ounces, 3 times a day. Pregnant women, especially those of a delicate or nervous system, will find it an advantage to take 1 or 2 doses daily, for several weeks previous to parturition, as by the energy it imparts to the uterine nervous system, the labor will be very much facilitated, beside which it frequently removes the cramps to which some are liable during the latter weeks of the utero-gestation. The medicine appears to exert a specific influence on the uterus (J. King).

Related Preparation.—PARTURIENT BALM. A preparation called the "*Parturient Balm*," has also been used and recommended in the above diseases, but I have found it to be of less efficacy; however, as some practitioners employ it, I introduce at this place the formula for its preparation: Take of blue cohosh root, spikenard root, each, 4 pounds (av.); black cohosh root, partridgeberry herb, queen-of-the-meadow root, each, 2 pounds (av.); ladies'-slipper root, comfrey root, each, 1 pound (av.). Proceed to make a syrup according to the directions given for the Compound Syrup of Aralia, making 8 gallons of syrup. The dose of this is from a teaspoonful to a tablespoonful, 3 or 4 times a day (J. King).

SYRUPUS MORI.—SYRUP OF MULBERRIES.

Preparation.—"Take of mulberry juice, 1 pint (Imp.); refined sugar, 2¼ pounds (av.); rectified spirit, 2½ fluid ounces. Heat the mulberry juice to the boiling point, and, when it has cooled, filter it. Dissolve the sugar in the filtered liquid by the aid of heat, and add the spirit. The product should weigh 3 pounds, 6 ounces (av.), and its specific gravity be about 1.330"—(*Br. Pharm.*, 1885).

Raspberry, pineapple, currant, strawberry, blackberry, and other fruit syrups may be made after this method, or by the one followed in making *Syrupus Rubi Idæi*. The object of heating in this instance is to coagulate and separate the albumen present. Only porcelain or enamelled-iron vessels should be used in preparing syrups from acid juices.

Action, Medical Uses, and Dosage.—This syrup is used chiefly to flavor fever drinks and so-called "soda water" (carbonic acid water). The dose, as given in the *British Pharmacopœia*, is 1 fluid drachm.

SYRUPUS MORPHINÆ SULPHATIS (N. F.)—SYRUP OF MORPHINE SULPHATE.

SYNONYMS: *Syrupus morphinæ*, *Syrup of morphine.*

Preparation.—I. "Morphine sulphate, two and two-tenths grammes (2.2 Gm.) [34 grs.]; water, hot, thirty cubic centimeters (30 Cc.) [487 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the morphine sulphate in the hot water, and add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains ⅛ grain of morphine sulphate. *Note.*—This preparation is in considerable use in the southern states. It should, however, never be dispensed in prescriptions, unless it is known to be the preparation intended, or unless it is designated as that of the *National Formulary* (N. F.). When *Syrup of Morphine* is prescribed without any such specific designation or knowledge, it is recommended that the corresponding, but weaker preparation of the *French Pharmacopœia* be dispensed. The official title of this is *Sirop de Chlorhydrate de Morphine* (or *Sirop de Morphine*). This may be prepared approximately of the strength required by the *Codex*, as follows: II. Morphine hydrochlorate, seventeen decigrammes (0.7 Gm.) [11 grs.]; water, thirty cubic centimeters (30 Cc.) [487 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the morphine hydrochlorate in the water, and add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains about $\frac{1}{25}$ grain of morphine hydrochlorate"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Morphinæ Sulphas.*) Dose, ½ to 1 fluid drachm.

Related Preparations.—SYRUPUS MORPHINÆ COMPOSITUS (N. F.), *Compound syrup of morphine.* "Fluid extract of ipecac (*U. S. P.*), two cubic centimeters (2 Cc.) [33 ♏]; fluid extract of senega (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; fluid extract of rhubarb (*U. S. P.*), sixteen cubic centimeters (16 Cc.) [260 ♏]; morphine sulphate, fifty-five centigrammes (0.55 Gm.) [8.5 grs.]; oil of sassafras, one cubic centimeter (1 Cc.) [16 ♏]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the morphine sulphate in about sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of syrup, then add the fluid extracts and the oil of sassafras, and lastly enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the whole thoroughly by shaking. *Note.*—In some sections of the country, this preparation is dispensed when Pectoral Syrup or Jackson's Cough Syrup is demanded or ordered. As the formula differs too much from that originally used by Dr. Jackson, it is recommended that the above preparation be dispensed only when it is designated by the title above given"—(*Nat. Form.*). To the above we will add that it seems to us to have been unwise to have introduced this preparation at all, much less under the name Compound Syrup of Morphine, which title properly belongs to Jackson's Cough Syrup, which is the original Compound Syrup of Morphine.

SYRUPUS PECTORALIS (N. F.), *Pectoral syrup, Jackson's pectoral (or cough) syrup.*—"Morphine hydrochlorate, fifty-five centigrammes (0.55 Gm.) [8.5 grs.]; oil of sassafras, one-half cubic centimeter (0.5 Cc.) [8 ♏]; syrup of acacia (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the morphine hydrochlorate in about sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of the syrup, add the oil of sassafras, and enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains $\frac{1}{32}$ grain of morphine hydrochlorate. *Note.*—The original formula of Dr. Samuel Jackson's cough syrup was as follows: Sassafras pith, 60 grains; acacia, 1 ounce; sugar, 28 ounces (av.); muriate of morphine, 8 grains; water, enough to make 32 fluid ounces. The sassafras pith was afterward uniformly replaced by oil of sassafras, and the other constituents of the syrup have been more or less altered, so that a number of different formulas are in vogue in different sections of the country. It is recommended that the above be followed, if possible, for the sake of uniformity"—(*Nat. Form.*). There must be much confusion in the minds of pharmacists concerning these morphine syrups. Had the *National Formulary* given but one formula for Compound Syrup of Morphine, and made that one also Jackson's Cough Syrup, this could have been avoided. It seems as though the many syrups containing opium (or its chief alkaloid, might be reduced to the advantage of physicians, pharmacists, and the public.

SYRUPUS CODEINÆ (N. F.), *Syrup of codeine.*—"Codeine sulphate, one gramme (1 Gm.) [15.5 grs.]; syrup (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Reduce the codeine sulphate to a fine powder and dissolve it in the syrup, previously warmed. A fluid drachm of this preparation contains about ½ grain of codeine sulphate. *Note.*—The *Syrupus Codeini* of the *French Pharmacopæia*, is a weaker preparation, containing only about ⅛ grain of codeine (alkaloid) in a fluid drachm"—(*Nat. Form.*).

SYRUPUS PAPAVERIS (N. F.)—SYRUP OF POPPY.

Preparation.—I. "Tincture of poppy (F. 416), eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl℥, 282 ♏]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Evaporate the tincture of poppy on a water-bath, at a gentle heat, until its volume is reduced to four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]. In this dissolve the sugar with a gentle heat, strain, and when the syrup is cold, add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—The product is practically identical with the *Syrupus Papaveris* of the *British Pharmacopœia.* The corresponding preparation of the *German Pharmacopœia* (*Syrupus Papaveris,* or *Syrupus Diacodii*) is much weaker, and may be prepared as follows: ℞. Tincture of poppy (F. 416), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; syrup (*U. S. P.*), eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl℥, 282 ♏]. Mix them"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This syrup is anodyne and narcotic, though capable of doing mischief on account of the uncertain opium strength of the poppy capsules employed in preparing the tincture. The dose for small children is placed at ½ fluid drachm.

Related Preparation.—SYRUPUS IPECACUANHÆ ET OPII (N. F.), *Syrup of ipecac and opium, Syrup of Dover's powder.* "Fluid extract of ipecac (*U. S. P.*), eight and one-half cubic centimeters (8.5 Cc.) [138 ♏]; tincture of deodorized opium (*U. S. P.*), eighty-five cubic centimeters (85 Cc.) [2 fl℥, 420 ♏]; sugar, seven hundred and seventy-five grammes (775 Gm.) [1 lb. av., 11 ozs., 148 grs.]; cinnamon water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the fluid extract and tincture with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of cinnamon water, and filter the liquid; to this add the sugar and enough cinnamon water to make the product, after the sugar has been dissolved by agitation, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 5 grains of Dover's powder, or ½ grain, each, of ipecac and opium. *Note.*—In place of the above directed quantities of fluid extract of ipecac and tincture of deodorized opium, eighty-five cubic centimeters (85 Cc.) [2 fl℥, 320 ♏] of the official *Tinctura Ipecacuanhæ et Opii* may be taken"—(*Nat. Form.*).

This preparation may be used like *Dover's powder.* The dose is from 1 to 2 fluid drachms.

SYRUPUS PHYTOLACCÆ COMPOSITUS.—COMPOUND SYRUP OF POKE.

Preparation.—Take of poke-root and bark of American ivy (*Ampelopsis quinquefolia*), each, coarsely bruised, 16 troy ounces; black cohosh root, coarsely bruised, and sheep laurel leaves, each, 8 troy ounces. Prepare a syrup after the manner of making Compound Syrup of Aralia, using the same menstruum and the same proportion of sugar. Make 12 pints. Flavor with some aromatic essence, as sassafras, wintergreen, etc.

Action, Medical Uses, and Dosage.—This syrup is an excellent alterative and antisyphilitic, and is beneficial in *syphilis, scrofula,* and *rheumatism.* If required, iodide of potassium may be added to it, as in the instance of Compound Syrup of Stillingia. The dose is a teaspoonful, 3 or 4 times a day, in ½ gill of water (J. King).

SYRUPUS PICIS LIQUIDÆ (U. S. P.)—SYRUP OF TAR.

Preparation.—"Tar, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; water, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; boiling distilled water, four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; sugar, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the tar intimately with about one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of white sand, pour on the water, and stir frequently during twelve hours; then pour off the water and throw it away. Pour the boiling distilled water upon the residue, stir well and frequently during 15 minutes, add the glycerin, and set the vessel aside for 24 hours, occasionally stirring. Decant the clear solution, and filter. Dissolve the sugar in the filtrate with the aid of a gentle heat; allow the liquid to cool, then strain it, and pass enough distilled water through the strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*)

The official process very properly directs the washing of the tar which removes the acetic acid and other irritant impurities, and the glycerin is intended to prevent turbidity. The official syrup should have a tarry odor, a yellowish hue, and a somewhat bitterish taste. It is of acid reaction and turns brown when treated with alkalies.

Action, Medical Uses, and Dosage.—This forms a very useful remedy in the treatment of *chronic pulmonary* and *bronchial affections*, and also acts as a diuretic in certain *diseases of the bladder and kidneys*. The dose is from a dessert to a tablespoonful, repeated 3 or 4 times a day.

SYRUPUS PINI STROBI COMPOSITUS (N. F.)—COMPOUND SYRUP OF WHITE PINE.

Preparation.—"White pine bark (Pinus Strobus), seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; wild cherry bark, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; spikenard root, ten grammes (10 Gm.) [154 grs.]; balm of Gilead buds, ten grammes (10 Gm.) [154 grs.]; sanguinaria root, eight grammes (8 Gm.) [123 grs.]; sassafras bark, seven grammes (7 Gm.) [108 grs.]; morphine sulphate, one-half gramme (0.5 Gm.) [8 grs.]; chloroform, six cubic centimeters (6 Cc.) [97 ♏]; sugar, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; alcohol, water, syrup (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the vegetable drugs to a moderately coarse (No. 40) powder, moisten the powder with a menstruum composed of 1 volume of alcohol and 3 volumes of water, and macerate for 12 hours. Then percolate with the same menstruum until five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of tincture have been obtained, in which dissolve the sugar and the morphine sulphate; lastly, add the chloroform, and sufficient syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and strain"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent is considerably employed for the general purposes of a "cough syrup." Dose, 1 fluid drachm.

SYRUPUS PRUNI VIRGINIANÆ (U. S. P.)—SYRUP OF WILD CHERRY.

Preparation.—"Wild cherry, in No. 20 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; glycerin, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water. Moisten the wild cherry with a sufficient quantity of the liquid, and macerate for 24 hours in a close vessel; then pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid has disappeared from the surface, follow it by water, until the percolate measures four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]. Dissolve the sugar in the percolate by agitation, without heat, strain, and pass enough water through the strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Syrup of wild cherry may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the percolate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Or, take of wild cherry bark, in rather coarse powder, 5 ounces; moisten it thoroughly with a sufficient quantity of water, and then introduce it, rather closely packed, into a percolator, and gradually add water until a pint of percolate has passed. Place this in a well-stopped bottle, add to it sugar, 28 troy ounces, and form a syrup by agitation. The official process is based upon that proposed by Procter and Turnpenny (1842). The glycerin present (proposed by Schnabel, in 1874) not only prevents fermentation, but obviates all danger of precipitation. This syrup has an agreeable taste and a fine brown-red color.

Action, Medical Uses, and Dosage.—This forms a handsome tonic and sedative syrup, which may be used in all cases where wild cherry bark is indicated or desired. It may be given in doses of from 1 fluid drachm to ½ fluid ounce.

SYRUPUS RHAMNI CATHARTICÆ (N. F.)—SYRUP OF RHAMNUS CATHARTICA.

SYNONYMS: *Syrup of buckthorn berries, Syrupus spinæ cervinæ.*

Preparation.—"Syrup, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; fermented juice of buckthorn berries, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sugar in four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of the juice, with the aid of a gentle heat. allow the syrup to cool, then add enough of the juice to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and strain, if necessary. *Note.*—This preparation is practically identical with that official in the *German Pharmacopœia.* The species of buckthorn to be used is the *Rhamnus cathartica*, Linne, native of Europe, and naturalized, to some extent, in the United States. If the fresh berries can not be obtained, the imported fermented juice may be used in preparing the syrup"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Used chiefly as a purgative for children (see *Rhamnus Cathartica*). Dose, 1 fluid drachm.

SYRUPUS RHEI (U. S. P.)—SYRUP OF RHUBARB.

Preparation.—"Fluid extract of rhubarb one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; spirit of cinnamon, 4 cubic centimeters (4 Cc.) [65 ♏]; potassium carbonate, ten grammes (10 Gm.) [154 grs.]; glycerin, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; water, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; syrup, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the spirit of cinnamon with the fluid extract of rhubarb, and add to it the potassium carbonate dissolved in the water. Then add the glycerin, and, lastly, enough syrup to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*). This syrup has a dark red-brown color.

Action, Medical Uses, and Dosage.—(See *Rheum.*) Dose, ½ to 1 fluid drachm.

SYRUPUS RHEI AROMATICUS (U. S. P.)—AROMATIC SYRUP OF RHUBARB.

Preparation.—"Aromatic tincture of rhubarb, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; syrup, eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*). This preparation is somewhat opaque. and possesses a spicy, bitterish taste, and emits a pleasant aroma.

Action, Medical Uses, and Dosage.—(See *Rheum.*) Dose, ½ to 1 fluid drachm.

SYRUPUS RHEI ET POTASSÆ COMPOSITUS.—COMPOUND SYRUP OF RHUBARB AND POTASSA.

SYNONYM: *Neutralizing cordial.*

Preparation.—Take of best India rhubarb. in coarse powder, and bicarbonate of potassium, each, 16 troy ounces; cinnamon, golden seal, each, 8 troy ounces; refined sugar, 6 pounds (av.); fourth-proof brandy, 2 gallons; oil of peppermint, 2 fluid drachms. Macerate the rhubarb, potassium bicarbonate, cinnamon, and golden seal in the brandy for 2 days, then express the tincture with strong pressure, and add to it the oil of peppermint, previously dissolved in a little alcohol. Break up the cake or compressed residue from the press, and place it in a displacement apparatus, and gradually add warm water, until the strength of the articles is exhausted. Evaporate this solution to 8 pints, and while the liquor is still hot dissolve in it the sugar. Continue the evaporation, if necessary, until when added to the tincture first obtained, it will make 3 gallons, and mix the two solutions together. Strictly speaking, this is not a syrup, but a sweetened tincture (Wm. S. Merrell).

Dr. Hill has kindly furnished me with the formula by which he prepares this syrup, and which many physicians prefer on account of its pleasantness and efficacy. It is as follows: Take of best India rhubarb, in coarse powder, and pure carbonate of potassium, each, 2 ounces; golden seal, cinnamon, each, 1 ounce; refined sugar, 4 pounds; brandy, 1 gallon; oil of peppermint, 20 minims. Macerate the rhubarb, golden seal, and cinnamon in ½ gallon of the brandy for 6 hours with a gentle heat, then transfer the mass to a percolator and displace with the remaining ½ gallon of brandy. The remaining strength, if there be any, can be obtained by adding water until the liquor comes off tasteless. To this add the carbonate of potassium, sugar, and oil of peppermint, this last having been previously rubbed with a sufficient quantity of the sugar to absorb it, and mix the two liquors. The whole of the active properties of the ingredients may be obtained with more certainty by using alcohol (76 per cent) instead of brandy, owing to the great want of uniformity in the quality of the latter (J. King).

The following excellent preparation is recommended by Prof. F. J. Locke, M. D.: Take rhubarb, coarsely ground, peppermint herb, and potassium bicarbonate, of each, 3 ounces; boiling water, 4 pints; diluted alcohol, ½ pint; essence of peppermint, ½ ounce; white sugar, 2 pounds. Pour the boiling water upon the rhubarb, peppermint herb, and potassium bicarbonate, and allow them to macerate for 2 hours in a warm place. Strain, and while still warm add the sugar. After the sugar has dissolved and the liquid is cold, add the diluted alcohol and the essence of peppermint. The dose is from 1 to 4 fluid drachms.

Action, Medical Uses, and Dosage.—This syrup is an agreeable laxative, antacid, and tonic. It is sometimes called *Neutralizing cordial*. It may be used in cases of *obstinate constipation*, *acidity of stomach*, *dyspepsia*, and as a laxative in *pregnancy*, and where *piles* are present. It is one of the principal remedies employed by physicians in *diarrhœa*, *dysentery*, *cholera morbus*, *cholera infantum*, and in the same diseases as the compound powder of rhubarb. Dr. Locke's preparation is exceedingly efficient in *acid and irritative forms of summer diarrhœa* (see *Rheum*). The dose for an adult is a tablespoonful every ½ hour, hour, or 2 hours, according to the urgency of the symptoms; for a child, in proportion to its age.

Related Preparation.—SYRUPUS RHEI ET POTASSII COMPOSITUS (N. F.), *Compound syrup of rhubarb and potassa, Neutralizing cordial*. "Fluid extract of rhubarb (*U. S. P.*), seventeen and one-half cubic centimeters (17.5 Cc.) [284 ♏]; fluid extract of hydrastis (*U. S. P.*), eight and one-half cubic centimeters (8.5 Cc.) [138 ♏]; potassium carbonate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; tincture of cinnamon (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; spirit of peppermint (*U. S. P.*), eight cubic centimeters (8 Cc.) [130 ♏]; syrup (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the potassium carbonate in the syrup, and add the solution to the fluid extracts, tincture, and spirit, previously mixed with six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of diluted alcohol. Mix well, add enough diluted alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter, if necessary"—(*Nat. Form.*). This preparation is designed to replace the old Eclectic neutralizing cordial, and, in some respects, is as important. It will be observed that alcohol is used instead of brandy.

SYRUPUS RHŒADOS.—SYRUP OF RED POPPY.

Preparation.—"Take of fresh red poppy petals, 13 ounces (av.); refined sugar, 2¼ pounds (av.); distilled water, 1 pint (Imp.), or a sufficiency; rectified spirit, 2½ fluid ounces. Add the petals gradually to the water heated in a water-bath, stirring frequently, and afterward, the vessel being removed, infuse for 12 hours. Then press out the liquor, strain, add the sugar, and dissolve by means of heat. When nearly cold add the spirit, and as much distilled water as may be necessary to make up for loss in the process, so that the product shall weigh 3 pounds 10 ounces (av.). Its specific gravity should be about 1.330"—(*Br. Pharm.*, 1885).

The directions in the *British Pharmacopœia* (1898) practically agree with these. This syrup is prone to ferment, but this is retarded by the addition of the alcohol. It has a handsome red color.

Action, Medical Uses, and Dosage.—The proportion of opium present in this syrup is very uncertain, consequently but little reliance is placed upon it as an opiate. It is chiefly used as a coloring agent for mixtures. The dose is about 1 fluid drachm.

SYRUPUS ROSÆ (U. S. P.)—SYRUP OF ROSE.

Preparation.—"Fluid extract of rose, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; syrup, eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl℥, 282 ♏]; to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Syrup of rose has a beautiful red color, and is often used to color mixtures. It has a pleasant, subastringent taste. One fluid drachm of red rose petals is represented in each fluid ounce of syrup.

Uses.—Employed chiefly as a flavoring and coloring agent. Dose, 1 fluid drachm.

SYRUPUS RUBI (U. S. P.)—SYRUP OF RUBUS.

Preparation.—"Fluid extract of rubus, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; syrup, seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This agent, in doses of from 1 to 2 fluid drachms, is a remedy for mild forms of *non-irritable diarrhœa*.

Related Preparation.—SYRUPUS RUBI AROMATICUS (N. F.), *Aromatic syrup of blackberry.* "Rubus (*U. S. P.*), one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; cinnamon fifteen grammes (15 Gm.) [232 grs.]; nutmeg, fifteen grammes (15 Gm.) [232 grs.]; cloves, eight grammes (8 Gm.) [123 grs.]; allspice, eight grammes (8 Gm.) [123 grs.]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; diluted alcohol (*U. S. P.*), blackberry juice, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Reduce the rubus (blackberry root) and the aromatics to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with the diluted alcohol, until two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of percolate are obtained. To this add four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of blackberry juice, and dissolve the sugar in the liquid by agitation. Lastly, add enough blackberry juice to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

SYRUPUS RUBI IDÆI (U. S. P.)—SYRUP OF RASPBERRY.

Preparation.—"Fresh, ripe raspberries, any convenient quantity; sugar, a sufficient quantity. Reduce the raspberries to a pulp, and let this stand, at a temperature of about 20° C. (68° F.), until a small portion of the filtered juice mixes clear with half its volume of alcohol. Then separate the juice by pressing, set it aside, in a cool place, until the liquid portion has become clear, and filter. To every 40 parts by weight of the filtrate (which should not be allowed to remain, unprotected by sugar, more than 2 hours) add 60 parts of sugar, heat the mixture to boiling, avoiding the use of tin vessels, and strain. Keep the product in well-stoppered bottles, in a cool and dark place"—(*U. S. P.*).

Test.—"On shaking separate portions of syrup of raspberries with ether, chloroform, or amylic alcohol, no color should be imparted to these liquids (absence of foreign coloring matters)"—(*U. S. P.*).

In the preparation of fruit syrups, all being prepared alike, the juice is allowed to ferment so as to free it from pectinous and albuminous constituents, which cause it to become opaque. Raspberries readily ferment, so that the process is generally completed in a short time, or in a day, at the most, if put in a position favorable to fermentative action. The process must, however, be carefully watched lest it proceed to acetous fermentation, which greatly impairs the flavor of the product. Neither should it be allowed to mold. Generally a moderate temperature, about 12° to 15° C. (54° to 59° F.), and checking the fermentation when the juice reaches that stage when it can be easily filtered, as directed by the *French Codex*, will insure a good product.

Medical Uses.—Diluted with water this syrup provides a pleasant drink in *fevers*. The syrup may also be used for flavoring purposes.

Related Preparations.—Other syrups prepared like the above, using fresh ripe fruits, are the following: SYRUPUS FRAGARIÆ, *Strawberry syrup;* SYRUPUS CYDONIÆ, *Quince syrup;* SYRUPUS CERASORUM, *Cherry syrup;* SYRUPUS GRANATI, *Pomegranate syrup*, etc. (See *Syrupus Rhamni* and *Syrupus Mori.*)

AQUA RUBI IDÆI, or *Raspberry water*, is prepared by treating 1 part of press cake (left after clarification of the juice) with 2 parts of water and distilling. It has the odor of the fruit. A pleasant *fever drink*.

AQUA FRAGARIÆ.—Prepared like the preceding. A *fever drink* and cosmetic.

ACETUM RUBI IDÆI.—*Raspberry vinegar* may be prepared either by mixing equal parts of raspberry syrup and vinegar, or by taking of raspberry syrup 1 part, and vinegar 2 parts. Diluted with water it forms an agreeable acidulous drink for *fever* patients. The same method is followed in preparing other fruit vinegars.

SYRUPUS RUMICIS COMPOSITUS.—COMPOUND SYRUP OF YELLOW DOCK.

Preparation—Take of yellow dock root, 32 troy ounces; bark of the root of false bittersweet, 16 troy ounces; bark of American ivy (*Ampelopsis quinquefolia*) and figwort (*Scrophularia marilandica*), each, 8 troy ounces; refined sugar, 16 pounds (av.). Prepare after the manner of making Compound Syrup of Aralia, using the same menstruum and the same proportion of sugar. Make 16 pints of syrup. This syrup is sometimes called *Scrofulous Syrup*, but is superior to the article formerly known by this name.

Action, Medical Uses, and Dosage.—This syrup is alterative and antiscrofulous, and was formerly extensively and successfully used in the treatment of *scrofula*, *scrofulous affections*, and many *cutaneous diseases*. Iodide of potassium is frequently added to it, in the proportion of 1 ounce to 1 pint of syrup. The dose is from 1 to 4 fluid drachms, 3 times a day, in about a gill of water; or when the iodide is added, 1 or 2 fluid drachms, in water.

SYRUPUS SANGUINARIÆ (N. F.)—SYRUP OF SANGUINARIA.

SYNONYM: *Syrup of bloodroot.*

Preparation.—Take of bloodroot, in coarse powder, 8 ounces; acetic acid, 4 fluid ounces; water, 5 pints; refined sugar, 2 troy pounds. Macerate the bloodroot for 3 days in 2 fluid ounces of the acetic acid and a pint of the water, then transfer to a percolator, and displace with the remainder of the acetic acid mixed with the balance of the water. Evaporate, by means of a water-bath, to 18 fluid ounces, add the sugar, and form a syrup. By the above process, carefully conducted, the root will be exhausted, and a syrup of a deep-ruby color obtained, opaque in quantity, but transparent in thin strata, having a strongly acrid and bitterish taste.

The *National Formulary* directs its preparation as follows: "Sanguinaria, in No. 20 powder, two hundred and twenty-five grammes (225 Gm.) [7 ozs. av., 410 grs.]; acetic acid (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; sugar, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the acetic acid with three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl℥, 327 ♏] of water, moisten the sanguinaria with a sufficient quantity of this menstruum, and allow it to macerate for 2 hours. Then pack it in a glass percolator, and percolate in the usual manner, first with the remainder of the menstruum previously prepared, and afterward with water, until seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of percolate are obtained, or until the sanguinaria is practically exhausted. Evaporate the percolate, at a moderate heat, to four hundred and fift cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]. In this dissolve the sugar with a gentle heat, if necessary, and add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 13 grains of sanguinaria"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This syrup may be used in all cases where bloodroot is applicable, in doses of from 10 to 60 drops. An excellent cough mixture is composed of equal parts of syrup of squill, syrup of balsam of tolu, syrup of ipecacuanha, syrup of bloodroot, and paregoric; the dose of which is a teaspoonful whenever the cough is troublesome. Syrups of wild cherry bark, bloodroot, balsam of tolu, and fluid extract of stillingia, combined in equal proportions, have been found very useful in *chronic catarrhal* and *bronchial affections*. Prof. E. S. Wayne prepared a good expectorant by dissolving 1 grain of sulphate of sanguinarine in 1 fluid ounce of simple syrup; the dose is ½ fluid drachm, 3 or 4 times a day. It may be added as a valuable adjuvant to other expectorants.

SYRUPUS SARSAPARILLÆ COMPOSITUS (U. S. P.)—COMPOUND SYRUP OF SARSAPARILLA.

SYNONYM: *Syrupus sudorificus.*

Preparation.—"Fluid extract of sarsaparilla, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; fluid extract of glycyrrhiza, fifteen cubic centimeters (15 Cc.) [243 ♏]; fluid extract of senna, fifteen cubic centimeters (15 Cc.) [243 ♏]; sugar, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; oil of sassafras, one-tenth cubic centimeter (0.1 Cc.) [1.6 ♏]; oil of anise, one-tenth cubic centimeter (0.1 Cc.) [1.6 ♏]; oil of gaultheria, one-tenth cubic centimeter (0.1 Cc.) [1.6 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Add the oils (equivalent to about 2 drops, each) to the mixed fluid extracts, and shake the liquid thoroughly. Then add enough water to make up the volume to six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏], and mix well. Set the mixture aside for 1 hour, then filter it. Dissolve the sugar in the filtrate with the aid of a gentle heat, allow the liquid to cool, strain, and add enough water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

History.—This syrup differs from that of 1880 in not containing guaiac and rose petals, and in the introduction of aromatic oils. The original preparation (1820) was patterned after the celebrated French preparation, known as *Sirop de Cuisinier*, which was a sweetened infusion of sarsaparilla, senna, pale rose, anise, and borage flowers.

Action, Medical Uses, and Dosage.—A vehicle for potassium iodide, etc. Used, but probably valueless, in *syphilis*. Dose, ½ fluid ounce.

SYRUPUS SCILLÆ (U. S. P.)—SYRUP OF SQUILL.

Preparation.—"Vinegar of squill, four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]; sugar, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Heat the vinegar of squill to the boiling point, in a glass or porcelain vessel, and filter the liquid while it is hot. Dissolve the sugar in the hot filtrate by agitation, without further heating, strain, and, when the strained liquid is cold, add enough water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*). The object in heating the already prepared vinegar of squill is to coagulate the albuminous substances present, which are subsequently removed by filtration. Avoid metallic vessels in the preparation of this syrup.

Action, Medical Uses, and Dosage.—Syrup of squill is used as an expectorant in *coughs* and *catarrhs*, and as an emetic in affections of the air passages in infants. It is frequently given in combination with tincture of lobelia and other emetic or expectorant agents. A fluid drachm is the usual dose.

SYRUPUS SCILLÆ COMPOSITUS (U. S. P.)—COMPOUND SYRUP OF SQUILL.

SYNONYMS: *Hive syrup*, *Cough syrup*.

Preparation.—"Fluid extract of squill, eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏]; fluid extract of senega, eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏]; antimony and potassium tartrate, two grammes (2 Gm.) [31 grs.]; precipitated calcium phosphate, ten grammes (10 Gm.) [154 grs.]; sugar, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the fluid extracts, evaporate them, in a tared capsule, on a water-bath, to one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; and mix the residue with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. When the mixture is cold, incorporate with it, intimately, the precipitated calcium phosphate, filter, pass enough water through the filter to obtain four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of filtrate, and add to this the antimony and potassium tartrate dissolved in twenty-five cubic centimeters (25 Cc.) [406 ♏] of hot water. Dissolve the sugar in this liquid by agitation, without heat, strain, and add enough water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Compound syrup of squill may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula, and mixed with the solution of antimony and potassium tartrate, upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

This syrup is regarded as much superior to previous official preparations of the same. It is a substitute for the once famous *Cox's Hive Syrup*, which was a decoction of the drugs sweetened with honey. Undoubtedly, a still better syrup could be obtained if vinegar of squill were substituted for the fluid extract, which is an inferior article. Upon evaporation of the alcoholic portion, a pectinous coagulum separates, and is removed by means of the calcium phosphate. More can be removed by repeated filtration, and the antimony salt should not be added until a perfectly transparent filtrate has been obtained. One-eighth grain of tartar emetic is contained in each fluid drachm.

Action, Medical Uses, and Dosage.—According to the dose, this preparation is diaphoretic, expectorant, emetic, and, in large doses, cathartic. It is of some value in *spasmodic laryngitis*. It should, however, be very carefully used, beginning with from 10 to 20-drop doses, every 10 or 15 minutes, until its relaxant and emetic effects are produced. It is seldom used by Eclectic physicians.

SYRUPUS SENEGÆ (U. S. P.)—SYRUP OF SENEGA.

Preparation.—"Fluid extract of senega, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; ammonia water, five cubic centimeters (5 Cc.) [81 ♏]; sugar seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] Mix the fluid extract of senega with three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water, and with the ammonia water, and set the mixture aside for a few hours. Then filter, and pass enough water through the filter to obtain five hundred and fifty cubic centimeters (550 Cc.) [18 fl℥, 287 ♏]. In the filtrate dissolve the sugar by agitation, without heat, strain, and add enough water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Mix thoroughly. Syrup of senega may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Mix thoroughly"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This forms a stimulating expectorant, which is often very useful in *affections of the chest*, etc. It is frequently combined with syrup of squill, tincture of lobelia, syrup of sanguinaria, etc. Its dose is 1 or 2 fluid drachms.

SYRUPUS SENNÆ (U. S. P.)—SYRUP OF SENNA.

Preparation.—"Senna (Alexandria), bruised, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; oil of coriander, five cubic centimeters (5 Cc.) [81 ♏︎]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏︎]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. To the senna add seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏︎] of boiling water, and digest, at a temperature not exceeding 60° C. (140° F), during 24 hours. Then express the liquid, and pass enough water through the residue to obtain six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏︎] of liquid. Strain this, and, when it is cold, mix it with the alcohol in which the oil of coriander had previously been dissolved. Set it aside until the precipitate has subsided, then pour off the clear liquid, filter the remainder, and pass enough water through the filter to obtain five hundred and fifty cubic centimeters (550 Cc.) [18 fl℥, 287 ♏︎]. In the filtrate dissolve the sugar by agitation, without heat, strain, and add enough water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Mix thoroughly"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—A mild purgative. Dose, 1 to 4 fluid drachms.

Related Syrups.—The *Nat. Form.* provides for the following forms of syrup of senna:

SYRUPUS SENNÆ AROMATICUS (N. F.), *Aromatic syrup of senna.*—"Senna, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; jalap, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; rhubarb, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; cinnamon, four grammes (4 Gm.) [62 grs.]; cloves, four grammes (4 Gm.) [62 grs.]; nutmeg, two grammes (2 Gm.) [31 grs.]; oil of lemon, one and one-half cubic centimeters (1.5 Cc.) [24 ♏︎]; sugar, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; diluted alcohol (*U.S.P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Reduce the drugs to a moderately fine (No. 50) powder, add to it the oil of lemon, and percolate it, in the usual manner, with diluted alcohol. Remove the first five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏︎] of the percolate, and dissolve in this the sugar, with the aid of a gentle heat, if necessary, but avoiding loss of alcohol by evaporation. Allow the solution to cool, collect a further portion of percolate, and add it to the syrup, so as to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Each fluid drachm represents 7½ grains of senna, 3 grains of jalap, and 1 grain of rhubarb, with aromatics"—(*Nat. Form.*).

SYRUPUS SENNÆ COMPOSITUS (N. F.), *Compound syrup of senna.*—"Fluid extract of senna (*U. S. P.*), one hundred and thirty-five cubic centimeters (135 Cc.) [4 fl℥, 271 ♏︎]; fluid extract of rhubarb (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏︎]; fluid extract of frangula (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏︎]; oil of gaultheria, four cubic centimeters (4 Cc.) [65 ♏︎]; alcohol, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏︎]; syrup (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎]. Dissolve the oil of gaultheria in the alcohol, and add this to the mixed fluid extracts. Then add enough syrup to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏︎], and mix by agitation. Each fluid drachm represents 8 grains of senna, 2 grains of rhubarb, and 2 grains of frangula"—(*Nat. Form.*).

SYRUPUS STILLINGIÆ.—SYRUP OF QUEEN'S ROOT.

Preparation.—Take of queen's root, 48 troy ounces; prickly ash berries, 24 troy ounces; refined sugar, 18 pounds (av.). Prepare a syrup after the manner directed for making Compound Syrup of Aralia, using the same menstruum and the same proportion of sugar. Make 18 pints of syrup.

Action, Medical Uses, and Dosage.—This has been found highly beneficial in *bronchial* and *laryngeal affections*, also in obstinate cases of *rheumatism*, and wherever a stimulating alterative is required. The dose is from 1 fluid drachm to ½ fluid ounce, 3, 4, or 5 times a day, according to the urgency of the symptoms. It should be taken in water.

SYRUPUS STILLINGIÆ COMPOSITUS.—COMPOUND SYRUP OF QUEEN'S ROOT.

Preparation.—Take of queen's root, and root of turkey corn, each, 32 troy ounces; blue flag root, elder flowers, and pipsissewa leaves, each, 16 troy ounces; coriander and prickly ash berries, each, 8 troy ounces. Prepare a syrup after the manner of making Compound Syrup of Aralia, using the same menstruum and the same proportion of sugar. Make 32 pints of syrup. This syrup is the old Eclectic preparation that gave the reputation to this compound and served as a basis for the present formula in the *U. S. P.*

Action, Medical Uses, and Dosage.—This is a most powerful and effective alterative, and is extensively used by many practitioners in *syphilitic*, *scrofulous*, *osseous*, *mercurial*, *hepatic*, and *glandular diseases*, or in cases where an alterative is indicated. It is most commonly given with an ounce of iodide of potassium added to each pint of the syrup. The dose is 1 fluid drachm, 3 or 4 times a day, in ½ gill of water; but where the iodide is omitted, the dose is from 1 fluid drachm to 1 fluid ounce, 3 or 4 times a day, also in water.

Related Preparation.—SYRUPUS STILLINGIÆ COMPOSITUS (N. F.), *Compound syrup of stillingia.* "Compound fluid extract of stillingia (F. 176), two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [232 grs.]; sugar, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the compound fluid extract of stillingia with the purified talcum, and afterward with two hundred and seventy-five cubic centimeters (275 Cc.) [9 fl℥, 143 ♏] of water, and shake them together thoroughly. Then pour the mixture upon a wetted filter, add the sugar to the filtrate, and pass enough water through the filter to make the product, after the sugar has been dissolved by agitation, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 15 minims of compound fluid extract of stillingia (see F. 176)"—*Nat. Form.*).

SYRUPUS TOLUTANUS (U. S. P.)—SYRUP OF TOLU.

Preparation.—"Balsam of tolu, ten grammes (10 Gm.) [154 grs.]; precipitated calcium phosphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sugar, eight hundred and fifty grammes (850 Gm.) [1 lb. av., 13 ozs., 430 grs.]; alcohol, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the balsam of tolu in the alcohol, in a small flask or bottle, with the aid of a gentle heat. Mix the precipitated calcium phosphate with one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.] of the sugar, in a mortar, thoroughly incorporate with it the solution of the balsam, and set the mortar aside, in a moderately warm place, until the alcohol has evaporated. Then triturate the residue well with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, gradually added, and filter the mixture through a wetted filter, returning the first portions of the filtrate until it runs through clear. To the filtrate, heated to a temperature of about 60° C. (140° F.), add the remainder of the sugar, and dissolve it by agitation. Then allow the syrup to cool, strain it, and pass enough water through the filter and strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly. Syrup of tolu may also be made in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Or, take of balsam of tolu, carbonate of magnesium, each, ½ ounce; alcohol, 1 fluid ounce; refined sugar, 2½ pounds; water, a sufficient quantity. Triturate the balsam of tolu and carbonate of magnesium together, with 1 ounce of the sugar, gradually adding the alcohol, and then water enough to make the whole measure 12 fluid ounces. Filter, add water enough to make 1 pint of filtrate, to which add the rest of the sugar, and dissolve by a very gentle heat. If required, strain the syrup, while hot, through a damp cotton-flannel bag (Prof. Procter). This forms a beautiful, clear syrup, free from turbidity, possessing a decided taste of the balsam, with most of its medicinal virtues.

A more decided flavor and fragrance would be insured if the alcohol were not driven off as directed in the official process. In that case the amount of sugar should be correspondingly decreased. The alcohol would better impart the properties of tolu to the syrup than water, which takes up but very little of the resin, oils, etc., upon which the drug depends for its aroma and flavor.

Action, Medical Uses, and Dosage.—This syrup is used in *coughs*, and to give a pleasant taste to medicines. The dose is from ½ fluid drachm to 2, or even 4 fluid drachms.

SYRUPUS ZINGIBERIS (U. S. P.)—SYRUP OF GINGER.

Preparation.—"Fluid extract of ginger, thirty cubic centimeters (30 Cc). [487 ♏]; precipitated calcium phosphate, fifteen grammes (15 Gm.) [232 grs.]; sugar, eight hundred and fifty grammes (850 Gm.) [1 lb. av., 13 ozs., 430 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the fluid extract of ginger with the precipitated calcium phosphate, and expose the mixture in a warm place until the alcohol has evaporated. Then triturate the residue with four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of water, and filter. In the filtrate dissolve the sugar by agitation, without heat, strain, and pass enough water through the filter to make the product measure one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Mix thoroughly. Syrup of ginger may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under syrup (see *Syrupus*). Pour the filtrate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

"Take of strong tincture of ginger, 6 fluid drachms; syrup, sufficient to produce 20 fluid ounces (Imp.). Mix with agitation"—(*Br. Pharm.*, 1885). This produces a milky syrup.

Take of Jamaica ginger, in a uniform coarse powder, 4 ounces; water, deodorized alcohol, each, a sufficient quantity; carbonate of magnesium, 1 ounce; refined sugar, 20 pounds. Pack the ginger in a percolator, and slowly pour on it the alcohol, until 8 fluid ounces of tincture have passed; evaporate this spontaneously, or at 48.8° C. (120° F.), until it is reduced to 3 fluid ounces. Triturate it with the carbonate of magnesium and 2 ounces of the sugar, gradually adding 2 pints of water. Filter, and add enough water to make 8 pints of filtrate, to which add the rest of the sugar, in a covered vessel, and dissolve by a very gentle heat. If necessary, strain the syrup, while hot, through a damp cotton-flannel bag (Prof. Procter). This forms a beautiful, clear syrup, free from turbidity, possessing a decided taste of the ginger, with most of its medicinal virtues. That made by the official process is yellowish, and has the strong pungency and characteristic odor of ginger.

Action, Medical Uses, and Dosage.—Syrup of ginger is used as a remedy in *atonic bowel complaints of children*, and as a stimulating aromatic addition to various medicinal preparations. The dose is from ½ fluid drachm to 2, 3, or 4 fluid drachms.

TABACUM (U. S. P.)—TOBACCO.

"The commercial, dried leaves of *Nicotiana Tabacum*, Linné"—(*U. S. P.*).

Nat. Ord.—Solanaceæ.

Common Name and Synonym: *Leaf tobacco; Tabaci folia.*

Illustration: Bentley and Trimen, *Med. Plants*, 191.

Botanical Source.—This is an annual herb, with a long, fibrous root, and an erect, round, hairy, viscid stem, branched toward the top, and from 4 to 6 feet in height. The alternate leaves are sessile, ovate or lanceolate, acuminate, decurrent, viscid, pale green, 1 or 2 feet long, and 6 or 8 inches broad. The under surface of the tobacco leaf is marked by a prominent, thick midrib, sending off, at acute angles, lateral veins, which terminate near the margin of the leaf in a curved manner. The flowers are rose-colored, and produced in panicles at the ends of the stems and branches. The bracts are linear and acute. The calyx is urceolate, hairy, glutinous, half as long as the corolla, and ends in 5 acute segments. Corolla funnel-shaped, swelling toward the top, the border dull-red, expanding, with 5 acute, crimped lobes. Stamens 5; filaments inclined to one side, with oblong anthers. Ovary ovate; style long and slender; stigma capitate and cloven. Capsule ovate, invested with the calyx, 2-celled, 2-valved, but opening crosswise at top, and loculicidal. The seeds are very numerous, small, somewhat reniform, and attached to a fleshy receptacle (L.—W.—R.).

ig. 239.

Nicotiana Tabacum.

History.—Tobacco is a native of the warmer parts of America, and was first exported to England, in 1586, by Sir Walter Raleigh. According to the authors of the *Pharmacographia*, it was carried to Europe by the Spaniards on their return from discovering America (1492), and employed for its medicinal effects. At present, it is raised in many parts of the world, and especially in the middle states of this country. The strongest and more commonly used tobacco is raised in Virginia, but the Cuban or Havana leaf is preferred by smokers. The plant flowers in July. In cultivating tobacco the seeds are thickly sown in beds of prepared soil; the young plants are reset in the last month of spring, into fields, where they are placed in rows at distances of 2, 3, or 4 feet apart, and, in order to obviate the flowering and consequent formation of seed, the tops are removed from time to time. Close vigilance is required until the plant is ready for harvest, which is generally in the last summer month, when the matured plants are cut off just above their roots, hung up in bundles under sheds to dry, after which the leaves are removed from the stalks and packed in hogsheads or boxes for the market. There are several varieties of this plant, all of which appear to possess analogous virtues. Soil and the peculiar method adopted in raising this plant, as well as the various methods of curing the leaf, will influence the quality of the final product. (For a detailed account of the production and treatment of the more important tobacco grades of commerce, see L. Janke, *Forschungsberichte über Lebensmittel*, 1897, pp. 58–69.)

Description.—Commercial tobacco is usually of a dark-brown or orange-brown color, though its shades differ, of a powerful, heavy, disagreeable odor, and a peculiar, bitter, sickening taste, followed by a very disagreeable sense of acridity in the fauces. The dark leaves are much stronger and more powerful in their action than the light-colored. The *U. S. P.* describes dried tobacco leaves as follows: "Up to 50 Cm. (20 inches) long, oval or ovate-lanceolate, acute, entire, brown, friable, glandular-hairy, of a heavy, peculiar odor, and a nauseous, bitter, and acrid taste"—(*U. S. P.*). Water or alcohol extract the virtues of dried tobacco leaves. Continued boiling materially impairs their activity.

Chemical Composition.—The aroma of dried tobacco leaves is due to a small quantity of *tobacco camphor* or *nicotianin* (Vauquelin, 1809; Hermbstädt, 1823). It is volatile with steam, forms white, scaly crystals, is of neutral reaction, little soluble in water, soluble in alcohol and ether. The toxic properties of tobacco leaves are due to the alkaloid *nicotine*, discovered by Posselt and Reimann, in 1828, yet the quality of tobacco for smoking purposes does not depend on the quantity of nicotine present. The latter varies in the different grades of leaf from 0.4 to as high as 8 per cent. Smoking tobacco contains less (about 0.4 to 1.3 per cent), owing to partial volatilization of nicotine in the curing process. The alkaloid exists in the leaves combined with malic and citric acids, of which 10 to 14 per cent is present in dried leaves. These acids are supposed to be chiefly combined with potassium. The dried leaves yield a large amount of ash (18 to 27 per cent). Potassium nitrate is among the mineral constituents, occurring especially in the midrib, and may amount to as much as 10 per cent (Flückiger, *Pharmacognosie des Pflanzenreichs*, 3d ed., 1891, p. 715). Other constituents of the fresh leaves are albuminous matters (25 per cent), gum, (5 per cent), resin (4 to 6 per cent), tannic acid, sugar (*tabacose*, Attfield, 1884), wax, calcium oxalate, etc. The poisonous constituents of tobacco smoke are small amounts of carbon monoxide, hydrogen sulphide, and hydrogen cyanide, somewhat larger quantities of *picoline bases* (methyl pyridines), and considerable amounts of nicotine (R. Kissling, see *Amer. Jour. Pharm.*, 1882, pp. 492 and 628; and H. Thoms, *Berichte d. Deutsch. Pharm. Ges.*, 1900, p. 19).

NICOTINE (*Nicotia*, $C_{10}H_{14}N_2$), when freshly distilled, is a colorless, mobile liquid, of an intense, peculiar odor, differing from the accustomed tobacco odor, and an acrid, burning taste. It is very poisonous. Exposed to air and light, it turns dark, and partly resinifies. It is slowly volatilized at ordinary temperature, and can be distilled with the vapors of boiling water. Heated by itself, it boils, with decomposition, at about 240° C. (464° F.), but does not decompose in an atmosphere of hydrogen. It begins to distill at a much lower temperature (146° C., or 294.8° F.). It is miscible with water, alcohol, ether, chloroform, and fatty oils, the solutions being strongly alkaline. Nicotine is heavier than water, and forms salts with acids, which do not easily crystallize. It is a pyridine derivative, forming, upon oxidation, *nicotinic acid* (*beta-pyridine-carbonic acid*) ($C_5H_4N.COOH$). (Also see A. Pinner's researches, *Archiv der Pharm.*, 1893, p. 378, and 1895, p. 572.) Nicotine may be obtained by adding to a concentrated tobacco extract, solution of caustic soda or lime, distilling with steam, extracting the distillate with ether, and carefully evaporating the solvent. (For another method, that of Schloesing, see this *Dispensatory*, preceding edition.) R. Kissling (*Fresenius' Zeitschrift f. Analyt. Chem.*, 1882, pp. 64–90) assays tobacco by agitating 20 grammes, in powder form, with alcoholic caustic soda, exhausting the mixture with ether, carefully distilling off the greater part of the solvent, adding diluted caustic soda to the residue, distilling off the nicotine with steam, and titrating each 100 Cc. of the distillate with volumetric sulphuric acid solution, using rosolic acid for indicator. (For other methods, see *Archiv der Pharm.*, 1893, p. 658; and *Jour. Amer. Chem. Soc. Proc.*, 1899, p. 32.)

Action, Medical Uses, and Dosage.—Tobacco and, in a greater degree, its alkaloid, nicotine, exhibit powerful acro-narcotic properties. Applied to the nose, it occasions sneezing and increased mucous flow. Internally, in small amounts, they produce acrid heat in the throat, gastric warmth, nausea, and sometimes purging. Salivation and diuresis are increased. They allay general unrest and quiet mental inquietude, and give to the patient a sense of languid repose. Larger doses, however, produce a hot, acrid, and raw feeling in the throat and fauces, extreme nausea, vomiting, diarrhœa, and great prostration of muscular and nervous power. Muscular relaxation, with trembling of the extremities, is marked; great anxiety, mental confusion, feeble pulse, pale countenance, and marked depression of heart-action, are prominent among the effects. The body is bathed in cold sweat, the breathing oppressed and laborious, there is photophobia and impaired hearing, the limbs are helpless, and faintness, followed by unconsciousness, may supervene. These effects may occur from the use of tobacco in any form, whether internally or externally applied. Those accustomed to the disgusting habit of chewing or smoking tobacco, become so tolerant of the effects of the weed as not to become affected, or but slightly so, in the manner described. Even in these there is, however, more or less nervous impairment, which becomes manifest when the weed is withdrawn for a day or more. The pernicious habit of cigarette smoking, now under the ban of the law, in regard to minors, in many localities, has done incalculable harm—a rapid pulse, irritable heart (tobacco heart), disordered innervation, nervous prostration, general debility, emaciation, dyspepsia, and a train of other evils, being the result of intemperance in the use of this plant. Toxic (tobacco) amblyopia is frequently produced by the excessive use of tobacco. In chronic tobacco poisoning, there may be epithelial cancer of the mouth, tongue, or lips, or other destructive ulcers of the mouth, follicular pharyngitis, bronchorrhœa, feeble and rapid cardiac action, color-blindness, etc.

Nicotine acts chiefly upon the sympathetic and spinal nervous systems, and, when it kills, does so by paralysis of the heart, or respiratory paralysis (asphyxia). In point of toxic power, nicotine is asserted to be second only to prussic acid. A single drop has killed a rabbit in 3½ minutes (Taylor). Among celebrated murders, that of a brother killed with nicotine, by Count and Countess Bocarmé (*Ann. d'Hyg.*, 1851), is a matter of historical record. A child of 3 years was killed from blowing bubbles from an old pipe which had not been used for a year, but had been washed previous to being used by the child. The symptoms were those of narcotic poisoning (Taylor, *Med. Jurisp.*, p. 204). In poisoning by tobacco, the use of stimulants may be resorted to. Among these may be mentioned strychnine, whiskey, and ether, subcutaneously; aromatic spirit of ammonia, tannin and iodides (chemical antagonists), camphor, digitalis, strophanthus, internally; and external heat.

Tobacco infusion is more apt to affect the heart, and its smoke to act on the nervous system—the former being followed by great feebleness of the pulse, fluttering of the heart, faintness, alarm, etc., while the latter occasions nausea and vomiting, followed by drowsiness. Medicinally, it is a sedative, emetic, diuretic, expectorant, discutient, antispasmodic, errhine, antiseptic, and sialagogue. Tobacco should be seldom employed internally, as we have other agents much safer and fully as effectual to meet every desired indication. However, a tincture of the fresh plant has been advised as a sedative in *respiratory disorders of children*, and a water (*Aqua Nicotianæ Tabacum Spirituosæ Rademacheri;* see Scudder's *Spec. Med.*, p. 187, for formula) has been advised in the *brain complications of fevers*, in both wandering and fixed *acute rheumatism*, in *brain and spinal cord affections*, and in *cholera morbus* and *Asiatic cholera*. The alkaloid nicotine, and, in some instances, tobacco, have been most potent in the relief of *tetanus*. The larger doses may be employed—from ½ to 1 drop of nicotine, hypodermatically. For other purposes only the small doses hereinafter advised should be given.

Tobacco is seldom used as an emetic, except in cases where, from extreme insensibility of the stomach, ordinary emetics will not operate. The smoke injected into the rectum, or the leaf itself, in the shape of a suppository, and introduced into the rectum, or an enema of tobacco, has been beneficial in *strangulated hernia*, *obstinate constipation from spasm of the bowels*, in *retention of urine from spasmodic urethral stricture*, *hysterical convulsions*, *worms*, and in *spasms caused by lead;* likewise in *spasmodic croup*, *spasmodic asthma*, and *constipation*, with inflammation of peritoneum, to produce evacuations of the bowels, moderating reaction, and dispelling tympanites. To use the infusion of smoke, blow the smoke into milk or water and inject. *Hiccough* has been relieved by swallowing tobacco smoke. In *spasmodic croup* and *spasm of the rima glottidis*, a plaster made of Scotch snuff and lard, and applied to the throat and chest, has proved very effectual; or a cataplasm of the leaves may be employed. Inhalation of tobacco smoke sometimes relieves a tickling, irritable *cough*, produced by irritation or other nervous action in the larynx or trachea; *spasmodic laryngitis* has also been similarly relieved. An ointment of tobacco has been found valuable in several forms of *cutaneous disease*, as *scabies*, *urticaria*, etc. *Fresh cuts* may be treated with tobacco moistened from time to time with alcohol. The leaves, in combination with belladonna or stramonium leaves, will be found an excellent application to old, obstinate *ulcers*, *painful tumors*, and for spasmodic affections. A reputed cure for *piles*, is the application and maintenance there, for 3 or 4 hours, of a wet leaf to the parts. The inspissated juice has cured *facial neuralgia*, being rubbed along the track of the affected nerve. Topically, the leaves or an infusion, applied by means of a compress, allay pain in *rheumatism*, *gout*, *orchitis*, *epididymitis*, *buboes*, and other *glandular inflammations*, *scirrhous and scrofulous tumors*, *phimosis*, *paraphimosis*, *boils*, *painful hemorrhoids*, and *erysipelatous inflammations*. An enema of tobacco has given relief in *dysentery*, but extreme caution should be observed in its use. An ointment (tobacco, 1 drachm, to lard, 1 ounce), has been advised to relax *rigid os uteri* during *parturition*. *Rectal ascarides* and *lumbricoid worms* have been expelled by the inflation of the rectum with tobacco smoke, or by injection of the infusion. It has also been used to destroy *maggots* in the nose and ear. In using tobacco at all, great caution should always be observed, and if it produce great depression (as it is apt to do very suddenly), or too lasting a sedative effect, stimulants, as ammonia or brandy, should be administered. The quantity for an injection ought not to exceed 20 grains at first; if this fails, cautiously increase it, for even $\frac{1}{2}$ drachm has often proved fatal. If the injection does not come away in 5 minutes, it should be assisted by throwing up a large quantity of warm water. A wine of tobacco may be used in from 1 to 20-drop doses. Nicotine is too dangerous for general use. The beginning dose should not exceed $\frac{1}{100}$ grain, although as high as 1 grain has been recommended. The dose of tobacco, as an emetic, is 5 grains.

Related Species and Preparation.—Other species of Nicotiana have been cultivated for their leaves. Some which figured as distinct species, are now regarded as varieties of *Nicotiana Tabacum*. Among these are *N. petiolata*, Agardh; *N. fruticosa*, Linné; *N. macrophylla*, Lehman, etc. The species said to be cultivated in Cuba, yielding Havana leaf, is the *Nicotiana repanda*, Willdenow, though Vidal denies this, stating that only N. Tabacum is there grown. *Shiras* or *Persian tobacco* is reputed the product of *N. persica*, Linné. That known as *tumbaki* (of Turkish and Persian tobacco) has in the past been attributed to *N. rustica* and *N. persica*, but is now said to be the product of *N. Tabacum* (*Kew Bulletin*, 1891). *Latakia tobacco*, formerly said to be the product of *N. rustica*, is now held to be the flowering heads and capsules of *N. Tabacum* flavored by being exposed to the smoke of *Pinus halipensis*, Aiton (Dyer).

Dynamyne.—This name was given by Lloyd Brothers to a preparation which contains the alkaloids of tobacco. It is a green-colored, hydro-alcoholic liquid, and is designed for external use only. The name was selected at the request of the late Prof. A. J. Howe, M. D., who desired a characteristic term for a preparation he prescribed extensively and valued highly. Dynamyne, when well diluted with water, is destructive to many plant insects, but does not appear to materially affect the plants to which it is applied. Owing to its toxic nature, care should be exercised in handling or inhaling it. Dynamyne is an agent of great value, and is fast becoming established as a remedy to relieve *pain*, both deep-seated and superficial. A solution of 1 to 4 fluid drachms of dynamyne in 1 pint of water, may be applied to *localized inflammations*, to relieve the *pains of neuralgia, rheumatism, felons, abscesses, pleurodynia*, etc., and many other conditions in which the local effects of tobacco, in a more pronounced degree, are desired. It should not be administered internally.

TAMARINDUS (U. S. P.)—TAMARIND.

"The preserved pulp of the fruit of *Tamarindus indica*, Linné"—(*U. S. P.*) (*Tamarindus officinalis*, Hooker).

Nat. Ord.—Leguminosæ.

Common Names: *Tamarind*, *Tamarind pulp*.

Illustration: Bentley and Trimen, *Med. Plants*, 92.

Botanical Source.—This is a large tree with many spreading branches, a stout, straight trunk, and a rough, ash-gray bark, usually attaining the height of 30 or 40 feet. The leaves are alternate and abruptly pinnated; the leaflets in 12 to 15 pairs, opposite, subsessile, small, obtuse, entire, smooth on both sides, tapering a little, of a greenish-yellow color, and about 6 lines long by 2 broad; the inferior pair are larger. The petioles are from 4 to 6 inches long, and channelled; the stipules small and deciduous. In a cold, damp atmosphere, and also after sunset the leaflets close themselves. The flowers are yellow, veined with red, and in terminal and lateral racemes. Bracts obovate, colored, 1-flowered, and deciduous. Corolla somewhat papilionaceous, erect, unilateral, the length of the calyx, and 3-cleft. Segments ovate, acute, concave. Calyx 4-leaved, cruciate, expanding, tubular at base and deciduous; limb bilabiate and reflexed; upper lip tri-partite; lower broad and 2-toothed. The vexillum, or middle petal, is oblong, and its margins involute and curled; wings oval and margins curled. Keel 2 short, subulate processes under the stamens. Stamens 10, 7 very short and sterile, the others longer, monadelphous, bearing incumbent anthers. Ovary stalked, linear, with the subulate style much incurved; stigma obtuse. The legume is oblong, pendulous, nearly linear, generally curved, somewhat compressed, filled with a firm, acid pulp, covered with a hard, scabrous bark, which never separates into valves; under the bark run 3 fibers, one down the upper concave margin, and the other two at equal distances from the inferior or convex edge. The seeds number from 6 to 12, are somewhat trapeziform, compressed, covered with a smooth, hard, brown shell, and inserted into the convex side of the pericarp (L.—W. I.).

History and Description.—The tamarind tree inhabits both the East and West Indies and Africa. The pods of the West Indian tree are shorter than the other, and fewer seeded. The part used is the fruit, which, when recent, has a pleasant acid taste. They are generally brought to this country as a kind of preserve, made by removing the epicarp, arranging the fruit in layers in a cask, and filling the interstices with syrup at 100° C. (212° F.). As met with in this country, they are reddish-brown, have a sweet and agreeably acid taste, and consist of acid-syrup, seeds, *endocarp* and fibers; the acidity of the syrup is due to its admixture with the sarcocarp or pulp. This is the method pursued in the West Indies. The Egyptians compress them into cakes and dry them in the sun, while, in India, they are compressed into masses, sugar being added in some instances. The East Indian variety is not so sweet as the official drug from the West Indies, is of a darker color and much tougher. The Egyptian grade occurs in black-brown cakes, circular and flattish, and often are moldy. These two varieties are not in American markets. The seeds should be solid and corneous, not soft and expanded, the fibers should be tough, and the whole appearance of the mass should be fresh and syrupy, not dried up from loss or lack of syrup, and without a moldy odor. Sometimes, from being prepared in copper vessels, they may prove dangerous from containing copper, which should not be present.

As required by the official standard, tamarind should be "a reddish-brown, sweet, subacid, pulpy mass, containing strong, somewhat branching fibers, and polished, brown, flattish-quadrangular seeds, each enclosed in a tough membrane; taste sweet and refreshingly acidulous. A piece of bright iron, left for 30 minutes in contact with the pulp previously somewhat diluted with water, should not exhibit any reddish deposit of copper"—(*U. S. P.*).

Chemical Composition.—The constituents of tamarind pulp are sugar (about 12.5 per cent), tartaric, citric, and malic acids, and potassium bitartrate, pectin, gum, etc. (Vauquelin). K. Müller (1882), examining nine specimens, found about 1.5 per cent of seeds, and in an exceptional case 38 per cent of seeds present and from 22 to 32 per cent of water; the moist pulp freed from the seeds contained potassium bitartrate (4.66 to 6.01 per cent), tartaric acid (5.29 to 8.68 per cent) and citric acid (0.64 to 3.95 per cent). The presence of formic, acetic, and butyric acids is probably due to slight fermentation.

Action, Medical Uses, and Dosage.—Tamarind pulp is used to allay thirst, and is nutritive and refrigerant; in large quantity, laxative. On this account it forms a useful and agreeable drink in *febrile* and *inflammatory diseases;* and with persons recovering from sickness, to keep their bowels regular, it may form a portion of their diet. A convenient cooling laxative is TAMARIND-WHEY, made by boiling 1 ounce of the pulp in 1 pint of milk, and straining the product. Combined with senna, or resinous cathartics, it is said to diminish their cathartic operation (P.). Dose, from 1 drachm to 2 ounces. A decoction of tamarind flowers is reputed almost a specific for *hemorrhoids.*

Specific Indications and Uses.—(The flowers.) Hemorrhoids, with persistent burning and itching about the anus, and accompanied with constipation.

TANACETUM (U. S. P.)—TANSY.

"The leaves and tops of *Tanacetum vulgare,* Linne"—(*U. S. P.*) (*Chrysanthemum Tanacetum,* Karsch).

Nat. Ord.—Compositæ.

COMMON NAME: *Tansy.*

Botanical Source.—Tansy has a perennial, moderately creeping root, and an erect, herbaceous, somewhat 6-sided, leafy, solid, striated, smooth stem, 1 to 3 feet in height, branched above into a handsome corymb of flowers. The leaves are smoothish, dark-green, and doubly and deeply pinnatifid; the segments oblong-lanceolate, pinnatifid, and incisely serrate; the margined petiole cut-toothed. The flowers are golden-yellow, in dense, terminal, many-headed, fastigiate corymbs; disk florets 5-cleft and perfect; ray florets few, trifid, and pistillate. Scales of the involucre scarious at the apex, small, obtuse, and imbricated. Pappus short, equal, membranous, and 5-lobed; the achenia with a quadrangular, entire crown. There is a variety called *Double tansy* (*Tanacetum crispum*), with crisped and dense leaves (L.—W.—G.).

History and Description. Tansy is indigenous to Europe, but has been introduced into this country. It is cultivated by many, and also grows spontaneously in old grounds, along roads, etc., flowering in the latter part of summer. The whole plant is medicinal. It has an unpleasant, aromatic odor, and a strong, rather pungent and bitter taste, which properties it partly owes to a yellow or greenish volatile oil. The medicinal virtues of the plant are extracted by alcohol, ether, chloroform, and by water in infusion. Drying impairs much of its activity. The *U. S. P.* describes tansy as follows: "Leaves about 15 Cm. (6 inches) long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark-green, and glandular; flower-heads corymbose, with an imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets; odor strongly aromatic; taste pungent and bitter"—(*U. S. P.*). Though well known to the ancients, it is not known when tansy came into medical use. According to an Egyptian legend, its properties were discovered by the deity Isis.

Fig. 240.

Tanacetum vulgare.

Chemical Composition.—The principal constituent of the herb is the volatile oil, or *oil of tansy* (see *Oleum Tanaceti*). In addition, a bitter, amorphous principle, *tanacetin* ($C_{11}H_{16}O_4$), is present (Leroy, 1845; Leppig, 1882), occurring chiefly in the flowers. It is soluble in water and alcohol, insoluble in ether, although Roder states (*Archiv der Pharm.*, Vol. XCVII, 1846, p. 109) that it is very little soluble in water. The herb also contains tannic acid, resin, malic acid (probably the *tanacetic acid* of Peschier), tartaric, citric, and oxalic acids, etc.

Action, Medical Uses, and Dosage.—Oil of tansy is a poisonous agent, killing by coma and asphyxiation. The effects are different according to the amount taken. The symptoms may be chiefly gastro-intestinal, or they may be spent mainly upon the nervous system. Thus vomiting and purging, with colicky pains were present in one case, the patient dying in collapse, but the mind remained clear to the last. In other cases there have been increased frequency of the pulse, pupillary dilatation, insensibility, convulsions, with frothing at the mouth, and, occasionally, death is preceded by paralysis of motion, swallowing, and respiration. Doses above 15 or 20 drops are highly dangerous.

Tansy is tonic, emmenagogue, and diaphoretic. In small doses, the cold infusion will be found useful in convalescence from exhausting diseases, in *dyspepsia*, with troublesome *flatulence*, *hysteria*, *jaundice*, and *worms*. A warm infusion is diaphoretic and emmenagogue, and has been found beneficial in *intermittent fever*, *suppressed menstruation*, *tardy labor-pains*, and as a preventive for the paroxysms of *gout*. The seeds are reputed the most efficient for *worms*. The oil is likewise used as an anthelmintic, and as an abortive, but for the last purpose it is highly dangerous and generally ineffectual. Tansy is much employed in the form of fomentation to *swellings* and *tumors*, *local inflammations*, etc., and applied to the bowels in *amenorrhœa*, and *painful dysmenorrhœa*. The vinous infusion is said to be beneficial in *strangury*, and other *urinary obstructions*, and in *debility of the kidneys*. By means of a spray or inhalation, a solution of a strong tincture (1 to 4 or 10) is valuable in *diphtheria*, *acute inflammations of the throat*, and in *epidemic catarrh* (Scudder). The dose of the powder is from 30 to 60 grains, every 3 or 4 hours; of the infusion, from 1 to 4 fluid ounces; of the tincture of fresh tansy (℥viii to alcohol, 76 per cent, Oj), 1 to 30 drops; of the oil, from 2 to 10 drops. A very pleasant compound tincture may be made by adding tansy, 2 ounces; swamp milkweed, 1 ounce; unicorn root and prickly ash berries, of each, ½ ounce; to 2 pints of diluted alcohol. Let them macerate for 14 days, and filter. This is useful as a vermifuge and tonic, and may be given to a child 2 or 3 years old, in doses of a teaspoonful, 3 or 4 times a day, in sweetened water.

Related Species.—*Tanacetum Balsamita*, Linné (*Balsamita suaveolens*, Persoon; *Pyrethrum Tanacetum*, De Candolle). This south European perennial is known as the *Costmary*. Its taste is bitter, and its odor strongly aromatic. It is official in the *French Codex*, and is employed for the same purposes as tansy.

Tanacetum umbelliferum, *Sweet pellitory*.—India. Contains an organic pigment, acid, wax, fat, glucose, inulin, and a small quantity of *pyrethrin* (compare *Pyrethrum*) (D. Hooper, *Pharm. Jour. Trans.*, Vol. XXI, p. 143).

TARAXACUM (U. S. P.)—TARAXACUM.

"The root of *Taraxacum officinale*, Weber, gathered in autumn"—(*U. S. P.*) (*Leontodon Taraxacum*, Linné; *Taraxacum Dens-leonis*, Desfontaines; *Taraxacum vulgare*, Schrank).

Nat. Ord.—Compositæ.

Common Names and Synonym: *Dandelion, Dandelion root; Taroxaci radix.*

Illustration: Bentley and Trimen, *Med. Plants*, 159.

Botanical Source.—This plant is an herb with a perennial, tap-shaped, very milky root, with a dull-brownish epidermis. The leaves are radical, numerous, spreading, of a bright, shining green, quite smooth, tapering downward, sessile, pinnatifid, with runcinate, sharp, unequally toothed lobes. The scape or flower-stem is longer than the leaves, erect, round, smooth, brittle, naked, hollow, 5 or 6 inches in height, and bears a single, yellow head. The flowers are of a uniform golden-yellow, in round heads, 1½ inches in diameter, expanding in the morning and fine weather only. Involucre double; external scales small, closely pressed, and spreading or reflexed; internal ones in one row, erect, and linear; all frequently callous-horned at the apex. Florets numerous, strap-shaped, equal, and 5-toothed. Stamens with hair-like filaments. Receptacle naked, convex, and dotted. Ovary obovate; style slender and cylindrical; stigmas 2, revolute. Achenia oblong, ribbed, roughened on the ribs, apex prolonged into a very slender, thread-like beak, bearing the pappus of copious, soft, and white capillary bristles. After blossoming the inner involucre closes for a time, the slender beak elongates and raises up the pappus while the fruit is forming, the whole involucre is then reflexed, exposing to the wind the naked fruits, with the pappus displayed in an open globular head, nearly 2 inches in diameter (L.—G.—W.).

History and Description.—This plant is a native of Greece, but is now found growing abundantly in Europe and this country, in fields, gardens, and along roadsides, flowering from April to November. There are some other species recognized by botanists, that appear to possess the same medicinal powers. The young leaves are frequently used as a salad or greens. The whole plant, when broken or wounded, exudes a white, bitter juice, the sensible qualities of which are said to be greater during period of inflorescence. The root only is the official part, and should be collected while the plant is in flower, or preferably in autumn. When recent, it is from 3 to 5 inches or more in length, from 3 to 9 lines in diameter, tap-shaped, fleshy, dull-yellow or brownish externally, white internally, inodorous, and bitter. As found dried in pharmacy, it is considerably diminished in size, having lost more than half its weight, and corrugated lengthwise. As required by the *U. S. P.*, it is slightly conical, about 30 Cm. (12 inches) long, and 1 or 2 Cm. (⅖ to ⅘ inch) thick above, crowned with several short, thickish heads, somewhat branched, dark-brown, longitudinally wrinkled, when dry breaking with a short fracture, showing a yellowish, porous central axis, surrounded by a thick, white bark, containing numerous milk-vessels, arranged in concentric circles; inodorous, bitter. It should be free from the root of *Cichorium Intybus*, Linné (*Nat. Ord.*—Compositæ), which closely resembles it, but is usually paler, and has the milk-vessels in radiating lines"—(*U. S. P.*). Dandelion root should preferably be used in the recent state. Drying, as well as long boiling, impairs its virtues. Alcohol or boiling water extracts its properties.

Chemical Composition.—Taraxacum root contains *inulin*, the quantities of which vary considerably with the season. Dragendorff (1870) found 24 per cent in root collected in October, and only 1.74 per cent in root collected in March, shortly before blooming, at which season the milky juice is abundant. The root also contains variable quantities of reducing sugar (17 per cent in March), and *lævulin* (18.7 per cent). (See constituents at various seasons, by L. E. Sayre, in *Proc. Amer. Pharm. Assoc.*, 1893, p. 82; also paper, by Charles Symes, in *Pharm. Jour. Trans.*, Vol. X, 1872, p. 361.) Other constituents of taraxacum root are a resin, soluble in chloroform and ether, insoluble in alcohol; a resin soluble in alcohol; *taraxacerin* of Kromayer (1861), a white waxy substance, crystallizing in cauliflower-like formations, and *taraxacin* (Polex, 1839), a bitter, amorphous principle, which, in concentrated solutions, forms precipitates with a number of alkaloidal reagents. Kromayer obtained these two principles from the inspissated milky juice of the root (*leontodonium*) by treating it with hot water. This leaves *taraxacerin* undissolved, which may then be obtained pure by recrystallization from hot alcohol. Prof. Sayre (*Proc. Amer. Pharm. Assoc.*, 1897, p. 223) assigns to it the formula $C_9H_{15}O$. The aqueous extract of leontodonium contains the bitter principle: this is abstracted by charcoal, and the latter boiled out with alcohol. The latter is distilled off, the residue dissolved in water, precipitated by means of basic lead acetate, the lead removed from the filtrate by hydrogen sulphide, and the solution evaporated to dryness, and an acrid resin removed by ether. The residue is bitter *taraxacin*. (For a bibliography of taraxacum, see L. E. Sayre, *Proc. Amer. Pharm. Assoc.*, 1876, p. 165.) A. van Zwaluwenburg and M. Gomberg (*Proc. Amer. Pharm. Assoc.*, 1899, p. 305) also observed the presence of minute quantities of a substance giving alkaloidal reactions; however, the authors doubt its alkaloidal nature. Other constituents of taraxacum root, at least of partly fermented extracts, are calcium lactate and *mannite*. The leaves and stems, according to Marmé (1864), contain the sugar *inosite*. The incinerated root leaves 5 to 7 per cent of ash.

Action, Medical Uses, and Dosage.—Dandelion root, when dried, possesses but little medicinal virtue; when recent, it is a stomachic and tonic, with slightly diuretic and aperient actions. It has long been supposed to exert an influence upon the biliary organs, removing *torpor* and *engorgement of the liver* as well as of the spleen. It is also reputed beneficial in *dropsies*, owing to want of action of the abdominal organs, in *uterine obstructions*, *chronic diseases of the skin*, and *impairment of the digestive functions*. It should not be used by those whose digestive organs are weak, as it is apt to occasion dyspepsia, flatulence, pain, and diarrhœa. The addition of cream of tartar to its decoction will render it more diuretic and laxative. Prof. King states that, as far as his experience with this article had gone, he thought its virtues had been overrated. Nevertheless, it is a slow, but efficient agent when properly prepared for use. The existence of an irritable condition of the stomach or bowels, or acute inflammation, contraindicate its employment. Dose of the decoction, 1 to 2 fluid ounces; of the extract, from 5 to 30 grains; of a strong tincture of the fresh root (℥viii to alcohol, 76 per cent, Oj), from 1 to 30 drops.

Specific Indications and Uses.—Loss of appetite, weak digestion, hepatic torpor, and constipation.

TAXUS.—YEW.

The leaves and fruit of *Taxus baccata*, Linné.

Nat. Ord.—Coniferæ.

COMMON NAME: *Yew tree.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 253.

Botanical Source and History.—The common yew is a large evergreen tree, native throughout Europe, and very commonly planted as an ornamental tree in church yards, cemeteries, etc., especially in England. It is of very slow growth, and has a hard, close-grained wood that is much used by cabinet-makers. The branches are long and horizontal, the lowest ones proceeding from the trunk at only a few feet from the ground. The bark is of a dark-brown color, and does not split longitudinally, like the bark of most trees, but scales off in thin plates. The flowers appear in early spring, and the male and female are borne on separate trees. The male are in axillary aments, and consist, each, of a thickened axis, having anther-bearing bracts on the upper half, surrounded at the base by imbricated scales. The female flowers are, each, a single sessile, naked, ovule, without either style or stigma, surrounded at the base by a circular disk, which becomes fleshy in the fruit. The fruit is a single oval seed, covered, excepting at the apex, by a thick, fleshy, red cup, and resembles an abortive acorn surrounded by its cup. The cups of the yew fruit are sweetish, though unpleasant to the taste, often, however, being eaten by children. The leaves are very numerous, linear, about ½ inch long, and $\frac{1}{12}$ inch wide, sharp, dark-green above, lighter beneath, alternate, and are curved outwardly and upwardly.

Fig. 241.

Taxus baccata.

An American variety (var. *Canadensis*, Gray) of the *Taxus baccata*, is a small shrub, found growing in shady, moist places in Canada and the northern parts of the United States.

History.—Excepting the pulp of the fruit, all parts of the yew tree are poisonous. Pliny, Dioscorides, and other ancient writers, mention the poisonous properties of the leaves and seed, and it has been recorded that wine, preserved in casks made of its wood, has occasioned the death of those who drank it. Strabon states that the Gauls used the juice of the leaves as a poison for their arrows. More recent observations have confirmed the statements as to its toxic character; and we frequently read of animals and birds that have been poisoned by the leaves and berries. It is likewise stated that the exhalation emanating from the tree may occasion vertigo, lethargy, and a kind of drunkenness, and that even death may ensue to those who carelessly sleep beneath its branches. Prof. Redwood read a paper before the Pharmaceutical Society of Great Britain (1877), citing the fatal result from drinking a decoction of the leaves.

Chemical Composition.—The poisonons principle of yew resides in an alkaloid *taxine*, first isolated from the leaves by H. Lucas (*Archiv der Pharm.*, 1856, Vol. CXXXV, p. 145), and later from the leaves and fruits by Marmé (*Amer. Jour. Pharm.*, 1876, p. 353), and by A. Hilger and Fr. Brande (*ibid.*, 1890, p. 297). According to Marmé, it is a white crystalline powder, little soluble in water, soluble in ether, alcohol, chloroform, etc.; insoluble in petroleum-ether. It melts at 80° C. (176° F.), and produces a red color with concentrated sulphuric acid. Amato and Caparelli (*ibid.*, 1881, p. 56) obtained from the leaves a probably similar alkaloid, volatile oil, and a non-nitrogenous, crystalline substance, which they called *milouin*.

Action, Medical Uses, and Dosage.—The symptoms occasioned by the juice or extract of the leaves, vary according to the quantity that has been taken. In large doses, there is pallor, vertigo, spasm, and symptoms of collapse, with gastric and enteric irritation, enfeebled and deranged cardiac action, coma, and death. Not unfrequently, very large doses are followed by a prompt diminution of the vital forces, or by positive syncope, in either case speedily terminating in death, without any of the severe symptoms of irritation being manifested. Post-mortem investigations have found some indications of inflammation of the stomach and bowels, of active renal congestion, and of diminished heart-power, with a greater or lesser deprivation of the coagulable quality of the blood. It has been used in the attempt to produce abortion, but always fruitlessly, and in some instances has proved a fatal experiment. In cases of poisoning by the ingestion of this article, it should be promptly removed from the stomach by emesis, after which milk or other bland drinks may be administered, at the same time sustaining the strength, if necessary, by the prudent exhibition of stimulants. The red berries are not injurious. Percy, in former times, prepared a jelly and a syrup from them, which he used in *cough*, *chronic bronchitis*, and to relieve the *pain in calculous nephritis*. The leaves have likewise been recommended in certain maladies, which it is unnecessary to name, as we have no satisfactory evidence of their efficacy. The leaves have been given in doses of 1 to 5 grains; or the infusion may be given corresponding in dosage.

TELA ARANEÆ.—SPIDER'S WEB.

The freshly spun web, free from dust, of the *Tegenaria domestica*, or common house-spider, or as often employed in this country, the web of *Tegenaria medicinalis*.

COMMON NAMES: *Spider's web*, *Cobweb*.

Source, History, and Preparation. The medicinal species of spider, from which the web is obtained, are the *Tegenaria medicinalis* and *Tegenaria domestica*, belonging to the division *Homoganglíata*, class *Arachnida*. The former are found in angles of walls, corners of fences, old houses, barns, etc., where they weave a large, angular, nearly horizontal web, at the upper part of which is a tube in which they keep themselves perfectly at rest, until the web has ensnared a fly or other prey. The field spider's web is said to be of no account, medicinally, while that of the house spider is considered very useful. It is the web of the latter that is preferred by the Homœopaths who introduced spider-web into practice, and who employ it in a trituration. The common house-spider is brownish or blackish in color, and is found in dark places in cellars, dwellings, barns, etc. In Eclectic practice the tincture of the web has been preferred to the trituration. It may be prepared as follows: Cover 2 ounces of clean recently spun web with 1 pint of strong alcohol, and allow it to macerate 10 days. Filter. This remedy was introduced into Eclectic practice as a cure for intermittent fever. There are various opinions among physicians, as to the *modus operandi* of cobweb, some attributing it entirely to the control of the imagination, while others view it in a different light, and entertain favorable opinions of it as a powerful therapeutical agent.

Action, Medical Uses, and Dosage.—Febrifuge, sedative, and antispasmodic. Said to have been found useful in the cure of *intermittents* when all other agents have failed; also recommended in several nervous affections, to relieve pain, lessen spasmodic action, and cause sleep, without any deleterious narcotic influences. Dr. Robert Jackson used it in the *delirium*, *pains*, *spasms*, and *subsultus*, common in *continued fevers*, in dry, nervous *coughs*, *hiccough*, etc. It has also been reputed efficient in *hysteria*, *periodical headache*, *chorea*, *asthma*, *morbid wakefulness* and *restlessness*, and *muscular spasms*. For a series of cases in which this drug acted efficiently, see report of Dr. Pierce, *Ec. Med. Jour.*, Nov., 1886. Of it he writes: "Its specific indications are: Masked periodical diseases in hectic broken-down patients; in all diseases that come up suddenly with cool, clammy skin and perspiration, and cool extremities; in nocturnal orgasm in either sex; numbness of the extremities when sitting still or lying down. It relieves spasms of arterioles, and stimulates capillary circulation. It relieves hyperæsthesia of the cerebro-spinal nerves and the great sympathetic, that depends upon debility. It is the greatest heart stimulant in the materia medica, and lobelia is only second to it." The dose is 5 or 6 grains, rolled up in the form of a pill, and repeated 3 or 4 times a day; or, preferably, specific Tela araneæ in doses of from 1 to 10 drops. The web has been applied to fresh *wounds* to check *hemorrhage*, and used as a plug to the nostrils in cases of long-continued and obstinate *epistaxis*. The small silver-headed spider, given in a dough pill, is said to be a prompt and efficient cure for *ague*.

TEPHROSIA.—HOARY PEA.

The root of *Tephrosia virginiana*, Persoon (*Galega virginiana*, Linné).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Turkey pea*, *Devil's shoestring*, *Goat's rue*, *Hoary pea*, and *Cat gut*.

ILLUSTRATION: Meehan's *Native Flowers and Ferns*, Vol. I, Plate 81.

Botanical Source.—This plant is indigenous, with a perennial root, and a simple, erect, villous stem, 1 to 2 feet high. Its leaves are unequally pinnate; the leaflets numerous, 15 to 29, crowded, linear-oblong, acuminate, straight-veined, the odd one oblong-obcordate—they are about 1 inch in length by 2 or 3 lines in breadth; petiolules about 1 line long. Stipules subulate, $\frac{1}{3}$ of an inch long, and deciduous. The flowers are large, yellowish-white, marked with red-purple, and borne in a dense, terminal, subsessile raceme. The calyx is very villous, with 5, nearly equal, subulate teeth. The banner is roundish, usually silky outside, and white; the keels obtuse, rose-colored, cohering with the red wings. Legume flat, linear, falcate, villous, and many-seeded (W.—G.).

Closely allied to this is the *Tephrosia onobrychoides*, Nuttall. Pilose with somewhat rusty hairs. Stem stout, erect, flexuous, more or less branched, and about 2 feet high. Leaflets 13 to 17, nearly smooth above, silky-hirsute beneath, cuneate-oblong, obtuse or retuse, and mucronate at the end, 1 inch or more long, one-fourth as wide; stipules free, subulate. The raceme is very long (1 or 2 feet), terminal, nearly opposite the leaves, and many-flowered; the flowers being small, red, and white. Calyx villose-hispid, teeth triangular, the lowest subulate, exceeding the others. Legume 2 inches long, slightly falcate, and 8 to 12-seeded (W.).

History and Description.—Each of the above plants is known in the south by the common name of *Devil's shoestring*. Several varieties of the plant are found growing in dry sandy soils from Canada to Florida, and from Illinois and Missouri to Texas, all of which, probably, possess similar medicinal powers. The two plants above described are the ones more commonly used. They flower in June and July. The root is of a light-drab color, from $1\frac{1}{2}$ to 2 feet or more in length, and varying in thickness from $\frac{1}{8}$ to $\frac{3}{8}$ of an inch; it is crooked, not much branched, gradually tapering, with a very few scattering fibers. Internally its color is whitish-yellow. The root is hard, breaks with a short cottony fracture, as may be seen by examining the fractured end with a pocket lens, has a faint spicy odor, and a spicy, faintly sweetish and slightly astringent taste, succeeded by a moderate degree of pungency. It yields its virtues to water or alcohol. It has not been chemically examined (see *Galega*).

Action, Medical Uses, and Dosage.—The root of this plant alone, or in combination with other agents, has been reputed a very efficient remedy in *syphilis;* many southern practitioners have spoken of it to me in the highest terms as an antisyphilitic. The decoction is also much used as a vermifuge, and is said to be as efficient and powerful as spigelia. According to Dr. B. O. Jones, the plant is a mild, stimulating tonic, having a slight action on the bowels, and the secretive organs generally, and applicable in the treatment of many diseases, especially in a certain stage of *typhoid fever*, where there is little use of active medicine. He recommends the following compound fluid extract of tephrosia: Take of Tephrosia virginiana (the plant), 8 ounces; Rumex acutus (dock), 2 ounces; water, 4 quarts. Place the plants in the water, and boil until reduced to 1 quart. Strain, and when intended to be kept, mix with an equal bulk of brandy or diluted alcohol, and half its weight of sugar, macerate for several days, and strain through muslin. The dose is from $\frac{1}{2}$ to 1 fluid ounce, 2, 3, or 4 times a day (*Amer. Jour. Pharm.*, Vol. XXVIII, p. 218) (J. King).

Related Species.—*Tephrosia Appolinea*, De Candolle (*Galega Appolinea*, Delile). Native of Egypt, south Europe. Leaves of this species have been observed as an adulterant of senna, and are sometimes substituted for the latter. Leaflets contain indigo (Hogg).

Tephrosia purpurea, Persoon.—India. Root laxative and tonic (Dymock). *T. spinosa*, Persoon, has similar properties. Both are quite extensively used in India for *dyspepsia* and *chronic diarrhœa.*

Tephrosia Colonila and *T. tinctoria.*—Orient. Contain indigo.

Tephrosia toxicaria.—Africa, and cultivated in Jamaica. It is put into the water of streams to intoxicate fish. *T. piscatoria* has similar uses.

Tephrosia leptostachya, De Candolle.—Senegambia. Leaves and root purgative.

TEREBENUM (U. S. P.)—TEREBENE.

FORMULA: $C_{10}H_{16}$. MOLECULAR WEIGHT: 135.7.

"A liquid consisting chiefly of pinene, and containing not more than very small proportions of terpinene and dipentene. Terebene should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

History and Preparation.—Terebene is prepared by the repeated action of sulphuric acid upon oil of turpentine until its optical rotation has disappeared. It was first prepared in this manner by Deville, in 1841, although Soubeiran and Capitaine, one year before, applied the name "terebene" to an optically inactive terpene hydrocarbon, prepared in a different manner. Terebene was subsequently studied by Riban (1873), Armstrong and Tilden (1879), and others, and more recently by Power and Kleber (*Pharm. Rundschau*, 1894, pp. 16–19), whose conclusions do not agree with the pharmacopœial characteristics for terebene, as given above. Hager (*Handbuch d. Pharm. Praxis*, Vol. II, 1886, p. 1121) directs to place 1000 parts of (French) oil of turpentine into a retort, and cool it by means of ice-cold water, then add 50 parts of concentrated sulphuric acid, drop by drop, and with gentle agitation. Distill from a sand or oil-bath, taking care not to exceed a temperature of 210° C. (410° F.). The distillate contains some unaltered oil of turpentine. Repeat the process with the distillate, after adding $\frac{1}{20}$ of its weight of sulphuric acid. The second distillate is shaken with solution of sodium carbonate, the oil is separated and rectified. It still contains traces of optically active oil of turpentine, but a third distillation is impracticable, as it involves too much loss of material (see Dr. H. W. Jayne, p. 1919).

Description, Chemical Composition, and Tests.—The *U. S. P.* describes terebene as a "colorless, or slightly yellowish, thin liquid, having a rather agreeable, thyme-like odor, and an aromatic, somewhat terebinthinate taste. Specific gravity about 0.862 at 15° C. (59° F.). Only slightly soluble in water, but soluble in an equal volume of alcohol, glacial acetic acid, or carbon disulphide. It boils at 156° to 160° C. (312.8° to 320° F.). On exposure to light and air, terebene gradually becomes resinified, and acquires an acid reaction. In its chemical properties it resembles oil of turpentine. Terebene should possess its characteristic, agreeable odor, should not redden moistened blue litmus paper (absence of acids), and should not have more than a very slight action on polarized light (limit of unaltered oil of turpentine). When evaporated, it should not leave more than a very slight residue (absence of more than traces of resinous matters)"—(*U. S. P.*). The presence of resin is undesirable, as it is supposed to cause cutaneous eruptions (see *Amer. Jour. Pharm.*, 1886, p. 521).

In contradiction to some of the above statements, the researches of Power and Kleber (*loc. cit.*), as well as those of H. W. Jayne and G. H. Chase (*Amer. Jour. Pharm.*, 1887, p. 65, and 1894, p. 225), have shown that, with pure terebene, only a small fraction distills below 160° C. (320° F.)—*i. e.*, contains no (inactive) pinene. Most of the product distills between 178° and 182° C. (352.4° and 359.6° F.), and consists of the hydrocarbons *dipentene* and *terpinene*. Power and Kleber suggest the following corrected definition of terebene: "An optically inactive liquid, obtained by the action of concentrated sulphuric acid on oil of turpentine and subsequent rectification, and consisting for the most part of the hydrocarbons dipentene and terpinene, with some cymol and camphene. Specific gravity about 0.855 at 15° C. (59° F.), boiling point between 170° and 185° C. (338° and 365° F.)." Such a mixture can not be considered as resembling oil of turpentine in its chemical properties. In examining commercial specimens, it was found that those giving off fractions below 160° C. (320° F.), also possessed an optical rotation, and contained unaltered oil of turpentine. On the other hand, a specimen, almost devoid of optical rotation, was shown to be merely a mixture of (dextro-rotatory) American and (lævo-rotatory) French oil of turpentine.

Action, Medical Uses, and Dosage.—Terebene is reputed germicide, antiseptic, deodorant, and expectorant. It kills the yeast plant and renders vaccine virus innocuous. It was introduced into practice by Dr. Wm. Murrell, of London, as a remedy for "*winter cough*." In this form of *chronic bronchitis*, it has been very effectual, and is useful also in the secondary stages of *acute bronchial affections*, with mucous profluvia. In these affections it acts much like the turpentines. Terpene relieves *flatulent dyspepsia*. Applied to *wounds*, *ulcers*, *burns*, etc., it acts as a deodorant and protector, favoring rapid healing. It may be applied in full strength or diluted with olive oil (1 to 5 or 6). The dose of terebene is from 3 to 20 drops, 3 times a day, the average dose being 6 minims. It may be given upon a lump of sugar or upon bread-crumb (see Murrell, *Mat. Med. and Therap.*, 1896).

TEREBINTHINA (U. S. P.)—TURPENTINE.

A concrete oleoresin obtained from *Pinus palustris*, Miller (*Pinus australis*, Michaux), and from other species of *Pinus*.

Nat. Ord.—Coniferæ.

COMMON NAMES: (Of Pinus palustris) *Broom pine*, *Swamp pine*, *Yellow-pitch pine*, *Long-leaved pine;* (Of oleoresin) *White turpentine*, *Thus americanum*, or *Frankincense* (*Br. Pharm.*, 1898).

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 258 (*Pinus Tæda*, 259).

Botanical Source.—This tree is the *Pinus australis* of Michaux. Its trunk is from 60 to 80 feet high, about 40 or 50 feet of which distance, below the branches, has a diameter varying from 12 to 20 inches. The bark of the tree is slightly furrowed. The leaves are in threes, of a bright-green color, about a foot long, and conglomerate at the ends of the branches; the sheaths or stipules are pinnatifid, scaly, and persistent; the buds very long, whitish. Sterile aments violet-colored, 2 inches long. Strobiles or cones subcylindrical, muricate, with small recurved spines, and from 8 to 10 inches long. Seeds with a thin, white testa (W.).

This is a native tree, found in the middle, southern, and western states, in sandy plains and woods, but chiefly from Virginia to Florida, within 100 miles of the coast. Its timber is strong, compact, and durable, and is much used by carpenters and workers in wood. From this tree is obtained the principal supply of *naval stores*, *i. e.*, resin, tar, etc., used in this and other countries.

Pinus Tæda, Linné, *Loblolly*, or *Old-field pine.*—A tree 80 or more feet high, with a trunk often 3 feet in diameter. The top is wide and spreading. The leaves are pale-green, about 6 to 10 inches long, borne in threes, the fascicles being invested with long, nearly entire sheaths. The fruit is an ovate-oblong cone, shorter than the leaves, and deflexed, the scales being armed with a strong, inflexed spine. *Pinus Tæda* inhabits old, dry, abandoned fields, and the barren, sandy soils from Virginia to Florida. An abundance of turpentine flows from it, but not so large a quantity is collected from it as from the first-named species. It is recognized in the *British Pharmacopœia* as one of the sources of turpentine, named by that authority THUS AMERICANUM, or *Frankincense*.

Collection and Description.—In the southern states, turpentine is uniformly collected on the so-called *turpentine farms* by cutting a slanting cavity (*box*) into the tree, less than 1 foot above the ground. About the first of March, when the resin begins to flow, V-shaped strips of the bark above the box are removed, and, from time to time, when the edges of the cut bark become clogged, narrower strips are cut. The resin collects in the box during the warm season, especially in June, July, and August. That collected in the first year is called *virgin dip*. When the boxes are full, the turpentine is ladeled out into barrels, which are sent to the still in order to obtain from it oil of turpentine and resin (colophony). An inferior resin, called *scrape*, is that which is hardened and covers the denuded surface of the tree. Distilling of the oleoresin is carried out in the woods; the stills consist of copper retorts set into a brick furnace, each holding from 15 to 20 barrels of crude material. The resin is distilled with addition of water, the oil of turpentine (see *Oleum Terebinthinæ*) being condensed in a large condensing-worm surrounded by cold water. The residue in the retort is finally drawn off, and constitutes *resin* (see *Resina*), or *rosin* (*colophony*), commercially distinguished as W. W. (water white), W. G. (window glass), the best grade, or N., the next best, M. K., etc. In the southern states, four consecutive seasons of bleeding exhaust the trees, and, as the margin of profit from one tree is exceedingly small, an immense acreage is annually invaded and devastated in order to keep the industry at a profitable level (*United States Government Report*, 1892; see Bastin and Trimble, *Amer. Jour. Pharm.*, 1896, pp. 242–253; also see L. J. Vance, *ibid.*, 1895, p. 537, from *Garden and Forest*, 1895).

Ten thousand trees yield the first year 280 barrels of dip (each, 240 pounds) and 70 barrels of scrape; 1 barrel of dip yields 6½ gallons of spirits of turpentine, while 1 barrel of scrape yields only 3 gallons. The total result of the first year is 2000 to 2100 gallons of spirits of turpentine and 260 barrels of rosin (W. G.). The yield of dip decreases in subsequent years, while that of scrape increases, and is highest in the second year. The rosin of the fourth year's make is almost black, opaque, and generally inferior. In France, where a finer grade of turpentine is obtained from *Pinus Pinaster*, Solander, the trees last from 40 to 50 years, and longer, owing to a more economic management of the industry. The oleoresin is collected in cups, and the oil of turpentine distilled off by direct steam. The hardened oleoresin, which covers the scars, is scraped off, and is known as *galipot*. The turpentine of the American market has a yellowish tint, a rather agreeable odor, and a bitter, terebinthinate taste. It is readily dissolved in alcohol or ether (excepting mechanical impurities), and combines with the fixed oils. The *U. S. P.* describes terebinthina as "in yellowish, opaque, tough masses, brittle in the cold, crumbly-crystalline in the interior, of a terebinthinate odor and taste. The alcoholic solution has an acid reaction"—(*U. S. P.*). Chemically, it is a combination of resin (see *Resina*) and oil of turpentine (see *Oleum Terebinthinæ*). (For *Venice turpentine*, *Chios turpentine*, etc., see *Terebinthina Canadensis;* also see R. G. Dunwody, *Amer. Jour. Pharm.*, 1890, p. 284; and E. L. Murray, *ibid.*, p. 393, for interesting notes on turpentine.)

Action, Medical Uses, and Dosage.—The turpentines act as local irritants, occasioning heat, redness, and even inflammation of the skin. Taken internally, they act more especially on the mucous tissues, lessening excessive morbid discharges. They have a diuretic influence on the urinary apparatus, imparting to the urine an odor like that of violets. They also act as stimulants on the general system, quickening the pulse, increasing the temperature of the surface, and causing a sensation of warmth at the stomach. They likewise act as anthelmintics. In large doses, they act upon the bowels, or, if this effect is not produced, they are apt to cause loss of appetite, nausea, vomiting, griping, strangury, or bloody urine. They have been used in *gonorrhœa*, *gleet*, *chronic affections of the kidneys and bladder*, *leucorrhœa*, *chronic affections of the mucous membrane of the air passages*, *chronic rheumatism*, *hemorrhoids*, *intestinal ulcerations*, *tympanites*, *amenorrhœa*, *chronic mucous diarrhœa*, etc. Externally, they are detergents and digestives, and have sometimes been applied to *indolent and ill-conditioned ulcers;* also as rubefacients and stimulants. Their peculiar influence upon the body is chiefly owing to their essential oil. They also enter into various plasters and ointments, especially the white turpentine. An adhesive and strengthening plaster may be made as follows: Take of caoutchouc, reduced to fine shreds, 5 pounds, steep it in hot water to soften, then remove from the water, dry as quickly as possible, place in a vessel, and cover with oil of turpentine, which must be increased in quantity as the caoutchouc absorbs it. When the gum is sufficiently dissolved, press it through a fine sieve, and add to it the following mixtures: (1) White turpentine, melted and dissolved in a sufficient quantity of oil of turpentine to make it thin enough to strain; (2) capsicum, 4 ounces, heated in a quart of oil of turpentine, which must be filtered and gradually added and ground with a pound of litharge, and to which balsam of Peru, 6 ounces, is to be added. This plaster may be spread on paper, linen, or leather. The dose of the turpentines is from 10 to 60 grains, in the form of pill, emulsion, or electuary. They may be made into pills, when too soft, by the addition of powdered liquorice root, magnesia, etc. An emulsion may be made by rubbing them with yolk of egg, or mucilage of gum Arabic, sugar, and some aromatic water; sugar and honey mixed with them form an electuary (see also *Oleum Terebinthinæ*).

Related Products.—ANIMÉ, or *Gum animé*. There are two substances of this name, one derived from India, and known as *East Indian animé*, which does not enter our commerce, and one from South America, known as *South American animé*. The former is waxy in luster, friable, of a reddish or yellowish color, and has somewhat the odor of fennel. It is employed in Ceylon to check the alcoholic fermentation in *jaggery*, a spirituous beverage. It is thought to be derived from *Vateria Indica*. The South American kind forms irregular pieces of a lemon to a reddish-brown hue, translucent, covered with a whitish powder, friable, and pulverizable, and softens when masticated. It has an odor suggestive of olibanum. It consists of essential oil and two resinous bodies, one soluble and the other insoluble in cold alcohol. Claimed to be the product of *Hymenæa Courbaril*, Linné, a leguminous plant, but is probably derived from a *Burseracea*.

CARUBA DI GUIDEN.—Gall-like excrescences, the result of stings of an hemiptera, found upon species of *Pistacia*, notably the *Pistacia Terebinthus*. They are reputed useful in *asthma* and *chronic bronchitis*, being pulverized and burned in a vessel, or smoked in a pipe, so that the terebinthinous fumes may be inhaled.

TEREBINTHINA CANADENSIS (U. S. P.)—CANADA TURPENTINE.

"A liquid oleoresin obtained from *Abies balsamea* (Linné), Miller"—(*U. S. P.*) (*Pinus balsamea*, Linné; *Picea balsamea*, Loudon).

Nat. Ord.—Coniferæ.

COMMON NAMES: (Of oleoresin) *Canada balsam*, *Balsam of fir;* (Of tree) *Balsam fir*, *Balm of Gilead fir*, *Balsam spruce*, *Hemlock fir*.

ILLUSTRATION: (Of *Abies balsamea*) Bentley and Trimen, *Med. Plants*, 263.

Botanical Source.—This is a small, handsome tree, rarely above 30 feet high, and having a regular pyramidal head. The leaves range from $\frac{1}{2}$ to $\frac{3}{4}$ inch in length, evergreen, linear, obtuse, bright-green above, silvery-white underneath, with a grooved line above, and an elevated one beneath. The male flowers are yellow, numerous, axillary, solitary, and about as long as the leaves; the female catkins are lateral, cylindrical, erect, and green; the bracts are obovate, tipped with a point, somewhat minutely toothed, and shorter than the broad, compact scales. The cones are 2 or 3 inches in length, about 1 inch broad, erect, cylindric, lateral, reflexed on the margin, shining, and purplish (G. W.).

History.—This tree inhabits the northern portions of the United States and British North America, also lower latitudes on highly elevated situations. The juice procured from it is known by the names of *Canada balsam*, *Balsam of fir*, *Canada turpentine*, etc. It may be obtained by making incisions into the tree, but more generally by collecting the fluid, which is discharged from the cavities containing this oleoresin, which forms between the wood and the bark. Large amounts are gathered in the province of Quebec. After allowing the trees to rest for 2 or 3 years, they are again punctured but yield less oleoresin than when first tapped. *Abies Fraseri*, Pursh, of the mountains from New England to North Carolina also yields balsam of fir, as well as *Abies canadensis*, Michaux (compare *Pix Canadensis*).

Description.—Canada balsam is described by the *U. S. P.* as "a yellowish, or faintly greenish, transparent, viscid liquid, of an agreeable, terebinthinate odor, and a bitterish, slightly acrid taste. When exposed to the air, it gradually dries, forming a transparent mass. It is completely soluble in ether, chloroform or benzol"—(*U. S. P.*). Alcohol does not completely dissolve it, while ether and oil of turpentine dissolve it, and solution of potassa forms a soluble soap with part of its resin. Canada balsam is extensively used in microscopic investigations, as a cement, to impart a greater transparency to certain objects, and to preserve and mount objects. It is also employed in the construction of Nicol's prism, an essential part of polarizing microscopes.

Chemical Composition.—According to Flückiger, this balsam (or rather oleoresin) consists of resin soluble in alcohol and ether (60 per cent), resin soluble in ether, insoluble in alcohol (16 per cent), and volatile oil (about 24 per cent). The latter, distilled from fresh leaves and cones of *Abies balsamea*, Miller, was proved by C. G. Hunkel (*Amer. Jour. Pharm.*, 1895, p. 9) and H. L. Emmerich (*ibid.*, p. 135) to contain *lævo-pinene* and *lævo-bornyl-acetate*.

Action, Medical Uses, and Dosage.—In large doses, Canada balsam acts upon the bowels, and is apt to cause nausea. In small doses it increases the urinary secretion, and also acts as a stimulant to the general system. Its vermifuge properties are inferior to those of the oil of turpentine. From its direct stimulating action on mucous tissues, it has been found a very efficient internal remedy in *gonorrhœa*, *gleet*, *chronic mucous inflammation of the bladder*, *chronic laryngitis*, *bronchitis*, *catarrh*, *mucous diarrhœa*, *hemorrhoids*, and *rheumatic affections*. In gonorrhœa, where the use of copaiba is not desirable, I have found Canada balsam an excellent substitute in the following combination, viz.: Take of Canada balsam, 2 fluid ounces; oil of turpentine, 4 fluid drachms; spirits of nitric ether, 8 fluid ounces; pulverized camphor, 2 drachms. Mix these together. The dose is 1 fluid drachm, 3 times a day. In cases where the inflammatory symptoms have been subdued, pulverized kino, 2 drachms, may also be added (J. King).

Applied to the skin, Canada balsam produces redness and slight irritation; and is frequently employed as a stimulant to *indolent* and *erysipelatous ulcers;* it likewise enters into the composition of several salves and irritating plasters. The dose of Canada balsam varies from 5 to 20 grains, which may be repeated 2 or 3 times a day. It may be administered in emulsion, or in pill form. When mixed with about $\frac{1}{28}$ part of its own weight of calcined magnesia, Canada balsam solidifies in about 12 hours (P.).

European and Rarer Turpentines.—COMMON TURPENTINE (*Terebinthina communis*) is derived from *Pinus sylvestris*, Linné, that official in the *German Pharmacopœia* is obtained from *Pinus Pinaster*, Solander (*Pinus maritima*, Poiret), the source of *French* or *Bordeaux turpentine*, and from *Pinus Laricio*, Poiret, which yields *Austrian turpentine*.

The *French Codex* recognizes STRASBOURG TURPENTINE from *Pinus Picea*, Linné, BORDEAUX or COMMON TURPENTINE, VENICE and CHIO TURPENTINE. (Also see *Pix Burgundica*, *Pix Canadensis*, *Terebinthina*, *Resina*, etc.)

CHIAN TURPENTINE (*Terebinthina Chia; Terebinthina Cypria*) is obtained from the *Pistacia Terebinthus*, Linné, growing in western Asia and in the basin of the Mediterranean. It takes its name from the island of Chio or Scio, where most of it is collected. The use of Chian turpentine by Paracelsus as a cancer remedy was revived in 1880 by Mr. Clay, of England, who strongly recommended it for *uterine cancer*, others, however, declare it wholly inefficient. It is yellowish, greenish, or bluish-green, translucent, viscid, and thick like molasses. Its odor is rather pleasant and suggestive of fennel, and its taste less acrid than most of the turpentines. It gradually hardens by age, and is often adulterated with the cheaper turpentines.

VENICE TURPENTINE (*Terebenthina veneta*, *Terebenthina laricis*, or *laricina*), is furnished by the *Larix europæa*, De Candolle, or *Pinus Larix*, Linné. It is procured chiefly in Switzerland, Tyrol, and the French province—Dauphiny. When pure, it is limpid, with a yellow color, sometimes having a green tint, tenacious, and thick like molasses. Its odor is sweet, citron-like, and its taste hot, pungent, and somewhat bitter. It requires an exposure to the air for many years before it becomes hard and brittle. It contains from 18 to 25 per cent of oil of turpentine, dissolves slowly but freely in alcohol, and is dissolved by the caustic alkalies. It does not harden with magnesia, and is dissolved by glacial acetic acid, amylic alcohol, and acetone. The article sold under the name of Venice turpentine in this country is often a factitious product. Uses, those of the turpentines.

Hungarian Turpentine (*Terebinthina hungarica*) exudes in the spring-time from the cut-off tops of the *Pinus Pumilio*, Hænke. It is yellowish, thin, and clear, warm to the taste and aromatic in odor.

The *Balsam pine* (*Abies Menziensii*, Lindley) of the Pacific slope yields a pale-yellow, fluid turpentine, upon puncturing the vesicles in the bark. Upon standing, a granular substance slowly deposits and the product assumes a solid, opaque form. In Mexico, the *Pinus Teocotl*, Schlechtendal, furnishes turpentine. In Japan, the *Pinus densiflora* yields *akamatsu*, and the *Pinus thunbergii* yields *kuromatsu*. They contain 18 per cent of an oil, differing somewhat from that of European turpentine, and about 80 per cent of resin, not differing from that of the latter. *Pinus dammara*, Lambert, of the East India Islands, yields *Dammara turpentine*, a product which quickly becomes hard; and a glutinous milky product is derived from *Dombeya excelsa*, of Chili, and is known as *Dombeya turpentine*.

Related Drugs and Products.—Turiones, or Gemmæ Pini (*Pine shoots*). The shoots of *Pinus sylvestris* when about 2 inches long. They are coated with an oleoresinous exudate, and have a bitter resinous and sub-acrid taste, and a pleasant terebinthinate odor. They enter into the composition of a *Compound tincture of pine shoots* and a *Syrup of pine shoots*, the first a German, the second a French, pharmacal preparation.

Caranna.—A soft oleoresin from the *Icica Carrana*, Kunth, and related trees of Central and South America. It is greenish-brown in color, has a bitter taste and aromatic odor.

Tacamahaca.—From the American tropics; is derived from *Icica heptaphylla*, Aublet, and other related trees. It is brownish or yellowish, clear, glossy when broken, bitter in taste, and has an aroma which is increased by burning. A product of the same name is procured in India and the East India Islands from *Calophyllum Tacamahaca*, Willdenow (*Calophyllum Inophyllum*, Linné). The seeds of the latter yielded van Itallie (*Jahresb. der Pharm.*, 1888, p. 41) 72 per cent of a greenish, butyraceous fixed oil (*weandee* or *bitter oil*), its odor resembling that of fenugreek; it is used in India in the treatment of *rheumatism*.

TERPINI HYDRAS (U. S. P.)—TERPIN HYDRATE

Formula: $C_{10}H_{18}(OH)_2+H_2O$. Molecular Weight: 189.58.

"The hydrate of the diatomic alcohol terpin. Terpin hydrate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—This compound is formed when *pinene* is kept in prolonged contact with diluted mineral acids (see *Oleum Terebinthinæ*). It is more frequently obtained by the action of alcoholic nitric acid upon oil of turpentine. Mr. Edward T. Hahn (*Amer. Jour. Pharm.*, 1897, p. 74) follows the proportions directed by Carl Hempel, and recommends the use of methyl alcohol in the place of ethyl alcohol.

Description and Tests.—Terpin ($C_{10}H_{18}[OH]_2$) is a saturated terpene derivative, according to the modern nomenclature, being classed among the *terpanes;* its special name is *terpa*-1, 4-*diol* (see instructive article, by Dr. E. Kremers, on *Hydrocymenes and Derivatives*, in *Proc. Amer. Pharm. Assoc.*, 1894, p. 251). When acted upon by diluted sulphuric or phosphoric acids, or by glacial acetic acid, terpin loses 1 molecule of water, being converted into the unsaturated alcohol *terpineol* ($C_{10}H_{18}O$), of which several isomers exist. Upon treatment with glacial acetic acid, it loses another molecule of water, the hydrocarbon *dipentene* being formed. The *U. S. P.* describes terpin hydrate as occurring in "colorless, lustrous, rhombic prisms, nearly odorless, and having a slightly aromatic and somewhat bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in about 250 parts of water, and in 10 parts of alcohol; in 32 parts of boiling water, and in 2 parts of boiling alcohol; also soluble in about 100 parts of ether, 200 parts of chloroform, or 1 part of boiling glacial acetic acid. Terpin hydrate melts at 116° to 117° C. (240.8° to 242.6° F.), with the loss of water, and, at the temperature of boiling water, sublimes in fine needles. When heated in a flask, adapted for distillation, it first loses water. At 258° C. (496.4° F.) anhydrous terpin distills over without decomposition, soon solidifying to a crystalline, hygroscopic mass, which melts at 102° to 105° C. (215.6° to 221° F.). When strongly heated on platinum foil, it burns with a bright, smoky flame, leaving no residue. Terpin hydrate is dissolved by sulphuric acid with an orange-yellow color. If to its hot, aqueous solution a few drops of sulphuric acid be added, the liquid will become turbid and develop a strongly aromatic odor. Terpin hydrate should not have the odor of turpentine, and its hot, aqueous solution should not redden blue litmus paper (absence of adhering acid)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Terpin, which is hydrated oil of turpentine, acts upon the bronchial and renal tracts after the manner of balsam, and imparts to the secretions of the latter a peculiar odor. Excessive doses will cause strangury, renal congestion, hæmaturia, and albuminuria. It is employed as a remedy for *chronic inflammations of the bronchiæ and kidneys. Chronic nephritis*, with heart complications, and *degeneration of the cardiac muscle, albuminous urine*, and *anasarca*, are said to be cases for its exhibition, using it with care. Terpin hydrate is also used to prevent *flatulent distension of the abdomen*, and to assist the expulsion of *flatus* when already present. *Hay-fever* is said to be relieved by it, and it is reputed a good palliative in *pertussis*. Like the terebinthinates, it is of value in *gleet* and in *chronic cystitis*. The dose is from 1 to 3 grains, 3 or 4 times a day, being best administered in pill, tablet, or emulsion.

Related Product.—Terpineol. A mixture of several terpenes with varying proportions of terpinol ($C_{10}H_{17}OH$) and alcohol. It is produced by boiling together terpin and diluted hydrochloric or sulphuric acid. It is a colorless, oleaginous fluid, having a hyacinthine odor, and a specific gravity of 0.852. Insoluble in water, soluble in alcohol and ether. Employed in doses of from 3 to 5 grains, 4 times a day, as an expectorant, in *chronic catarrh*, with bronchial irritation, with lack of secretions; also in *bronchitis*. It is best administered in pill or capsule. Pure liquid *terpineol* is a colorless, oily, viscid fluid, having the odor of fresh lilacs; it is optically inactive, has a specific gravity of 0.940, and boils between 216° and 218° C. (420.8° and 424.4°F.) (Schimmel & Co., 1896). (As to the more recent chemistry of terpineol, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 200.)

TEUCRIUM.—GERMANDER.

The herb of *Teucrium Marum*, Linné.

Nat. Ord.—Labiatæ.

Common Names and Synonym: *Cat thyme, Germander, Herb mastich, Syrian herb mastich; Herba mari veri.*

Botanical Source.—This is a shrubby, much-branched plant, about 10 inches in height. Its oval or lance-ovate, petiolate leaves are about ½ inch in length, are whitish, woolly beneath, and have an entire, revolute margin. From the axils of the bracts, the single, rose-hued flowers project, forming a unilateral, spicate raceme. These flowers are of the characteristic kind distinguishing the genus. having a long lower lip, and a short, deeply-cleft upper lip, and from this division project the 4 stamens. It has a pungent, bitter taste, and a pronounced camphoraceous odor.

History and Chemical Composition.—Most of the species of the genus Teucrium are indigenous to Europe. All of them are bitter or bitterish, and have aromatic properties. The species under consideration, and those named below, owe their activities to tannin, a small amount of a bitter body, an essential oil, and a camphor-like body, volatile with boiling water.

Action, Medical Uses, and Dosage.—The many species of Teucrium possess stimulant and tonic properties in varying degrees. Besides these properties, the *Teucrium Marum* is credited with diuretic, diaphoretic, and emmenagogue qualities. It has been used in *amenorrhœa, leucorrhœa*, and *chronic bronchitis*, and with varying success in *chlorosis, gout, dropsy*, and *scrofula*. It is asserted to be of much value in *whooping-cough*, and, in powder, has been employed to cure *nasal polypi*. Dose of the powder, 20 to 40 grains, or the same quantity may be given in infusion.

Related Species.—*Teucrium Scordium*, Linné (*Herba scordii*), *Water germander*.—Europe. Flowers in whorls of 2 to 4, rose-colored. When fresh, it has a garlicky odor, and bitter, sharp taste. Formerly much employed internally in *chronic eruptive skin diseases*, simple and syphilitic, and in *dyspeptic conditions;* and internally and topically to *pruritis ani* and *hæmorrhoids*. Regarding *teucrin*, a sterilized, aqueo-alcoholic extract of this plant, see Mosetig-Moorhof, *Amer. Jour. Pharm.*, 1893, p. 171, from *Pharm. Centralhalle*.

Teucrium Chamædrys, Linné, *Chamædrys*. Europe. Flowers purple-red. Formerly employed in *rheumatism, gout*, and *scrofula*, and allied disorders, and in *intermittent fever* and *uterine affections*. It was a constituent of the famous gout remedy, *Portland powder*, composed of the leaves of *Ajuga Chamæpitys*, the leaves and tops of *Erythræa Centaureum* and *Teucrium Chamædrys*, and the roots of *Gentiana lutea* and *Aristolochia rotunda*, all in equal parts.

Teucrium Polium, Linné, *Polymountain.*—Europe. Said to be of value in *Asiatic cholera. Teucrium montanum*, Linné, has yellow flowers.

Teucrium canadense, Linné, *Germander*, *Wood sage.*—Indigenous in damp places in the United States. Flowers in a spike, and purplish. Stimulant and tonic. "Thought to exert a beneficial influence in nervous affections, as *hysteria*, *epilepsy*, *restlessness* (nervousness), and *inability to sleep*"—(*Spec. Med.*, p. 258).

Ajuga reptans, Linné, *Bugle.*—Europe. Blue flowers; bitter and feebly aromatic. *Ajuga pyramidalis*, Linné, *Mountain bugle*, has similar properties. Both have tonic and astringent properties. They were once employed in *hemorrhagic conditions*, *consumption*, and *biliary disorders.*

Ajuga Iva, Schreber (*Teucrium Iva*, Linné), *French ground pine.*—Resembles the next species, but has woolly, toothed, linear leaves, and red flowers. It has the odor of musk.

Ajuga Chamæpitys, Pursh (*Nat. Ord.*—Lamiaceæ), *Chamæpitys*, *Ground pine.*—A labiate plant with an annual, diffused stem, with 3-cleft leaves, and solitary, axillary flowers, shorter than the leaves, having stamens longer than the upper leaf, surmounted by reniform, 1-celled anthers. This herb inhabits Europe and several sections of the United States, where it is also known by the names *Bugle* or *Germander*. The parts used are the leaves and tops, which have a slightly terebinthinate, not unpleasant smell, and a rough taste, which properties are imparted to diluted alcohol. An essential oil, somewhat terebinthinate, is furnished by distillation. The leaves of this plant are somewhat excitant, and exert an influence on the urinary organs. They have proved efficient in *menstrual derangements* and *arthritic affections;* and are said to be of service in *dropsy*, *jaundice*, *strangury*, and *visceral obstructions*. From 30 to 60 grains of the pulverized leaves may be administered every 2 or 3 hours; but their vinous tincture is preferred in doses of from ½ to 1 fluid drachm.

THALICTRUM.—RUE ANEMONE.

The herb of *Thalictrum anemonoides*, Michaux (*Anemone thalictroides*, Linné).

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Rue anemone*, *Anemone rue.*

ILLUSTRATION: *Botanical Magazine*, 866.

Botanical Source and History.—This is a little plant about 6 or 8 inches high, common in open woods throughout the middle and eastern United States. The root consists of a cluster of oblong tubers, bearing a few radical biternate leaves, and a flowering stem. The cauline leaves are clustered in a whorl at the top of the stem, forming an involucre at the base of the flowers. The flowers, which are centrifugal in development, have from 8 to 10 colored sepals, varying in color from a pale-pink to a pure white. This pretty little plant is one of the earliest spring flowers, blooming in March and April. It has been the subject of considerable diversity of opinion among botanists, concerning its position in the Natural System, being intermediate in character between the two genera, Anemone and Thalictrum; with the flower of the former, it has the fruit of the latter, and while the arrangement of the leaves is like that of the genus Anemone, their shape accords with that of the different species of Thalictrum. Linnæus, who was the first to give the plant a specific name, called it "*Anemone thalictroides*," which name it retained until Michaux transferred it to the genus Thalictrum under the name *Thalictrum anemonoides*. This change was accepted by De Candolle, and is now adopted by Gray and Bentham and Hooker. Pursh described a 1-flowered variety, but it is not generally considered distinct. Nothing is known of the chemical composition of any part of this plant.

Thalictrum flavus, Linné, and *Thalictrum majus*, Europe, are known in England as *Poor man's rhubarb*. From the root of *Thalictrum macrocarpum*, a plant growing in the Pyrenees, a neutral, crystallizable, yellow body, *macrocarpin*, and a crystallizable, white alkaloid, *thalictrine*, resembling aconitine, have been obtained by Hanriot and Doassans (*Amer. Jour. Pharm.*, 1881, p. 336).

Action, Medical Uses, and Dosage.—But little is known concerning the therapeutical properties of this plant. Dr. S. E. Barber, of Connsville, Mo., informs us that he has found it to be a valuable remedy in external and internal *hemorrhoids*, not accompanied with hemorrhage. The method of using it is to simply eat 3 or 4 of the small root-tubers, 3 times a day. We used some of the tubers, which he sent to us, in two cases of *blind piles*, and with apparent success. If further and more extensive trial of these tubers should confirm these conclusions as to their efficacy, it is probable that a fluid preparation could be made from them, possessing the same properties, and in a more convenient form (J. King).

THALLINÆ SULPHAS.—THALLINE SULPHATE.

FORMULA: $(C_9H_{10}[OCH_3]N)_2H_2SO_4+2H_2O$. MOLECULAR WEIGHT: 459.06.

Preparation and History.—The base thalline, discovered in 1884 by Skraup, is a derivative of quinoline (C_9H_7N), namely, *tetra-hydropara-methoxy-quinoline* ($C_9H_6[OCH_3]N.[H_4]$). As quinoline is prepared from aniline ($C_6H_5.NH_2$) by "Skraup's synthesis," so is thalline prepared from a substituted aniline, namely, *para-anisidine* ($C_6H_4[OCH_3].NH_2$) (see brief directions in *Amer. Jour. Pharm.*, 1886, p. 383). The intermediary product obtained is *para-methoxy-quinoline*, or *paraquinanisol*, from which thalline is obtained by reduction with tin and hydrochloric acid. *Thalline* has its name (meaning "green") from the deep emerald-green coloration it produces with ferric chloride or other oxidizing agents. It crystallizes in thick, white prisms, is sparingly soluble in water and light petroleum, readily soluble in alcohol, ether and benzene. It melts between 42° and 43° C. (107.6° and 109.4° F.), and is soluble in acids, with which it forms crystallizable salts.

Description.—Thalline sulphate is a white or whitish powder, consisting of a granular aggregation of crystals, permanent in the air, but gradually turning brown when exposed to light; resembling anise or coumarin in smell, and possessing a sharp, saline, bitter, and sickening taste. It is freely soluble in boiling water, while of cold water 7 parts, and of alcohol 100 parts are required for solution; the solutions, when exposed to light and air, turn brown. Upon adding a small amount of ferric chloride (or other oxidizer) to an aqueous solution of the salt, an emerald-green hue is produced, unaffected by sulphuric acid, but changing under the influence of reducing agents to purple, red, or yellow. The salt forms, with strong sulphuric acid, a colorless solution, which becomes deep-red upon the addition of a small quantity of nitric acid, the color gradually fading to yellow-red. The aqueous solution of the salt has an acid reaction, and yields precipitates with solution of iodine, with tannic acid, and with barium nitrate.

Action, Medical Uses, and Dosage.—Thalline is a prompt and certain antipyretic, but its use is attended with such deleterious effects that the consensus of opinion, even among those who favor the use of the synthetic antipyretics, is general in condemning its use as a medicine. While it produces a fall of temperature, it does not appear to shorten the course of febrile diseases, and may occasion vomiting and purging, albuminuria, or fatal syncope. Renal infarction, death of the glands, and fatty degenerations have been observed under its use upon animals (Ehrlich). It destroys the blood corpuscles, producing a condition of extreme anemia, which alone is sufficient to condemn it. The 1 or 2 per cent solution is said to be effectual as an injection in *gleet*. The hourly dose of the salts employed (the sulphate and tartrate) is ½ grain.

Related Compounds.—THALLINÆ TARTRAS, *Thalline tartrate*. A granular, crystalline, white powder, having the taste and odor of the sulphate, but requiring 10 parts of cold water for its solution. Ether scarcely dissolves it, alcohol somewhat better. Its solutions redden litmus, and the salt fuses at 155° C. (311° F.). (See also *Thallinæ Sulphas.*)

KAIRIN (*Kairine*).—Two synthetical compounds, discovered by O. Fischer, in 1882, are known as *Kairin A* and *Kairin M*. The first is *ethyl-kairin* the hydrochloride of oxyquinoline ethyl tetrahydride, ($C_9H_{10}[C_2H_5]NO.HCl$). It is the one referred to when simply kairin is mentioned. It forms odorless and colorless crystals, or usually occurs as a grayish-white, crystalline powder, having a bitter and salty taste. It is soluble in water (6 parts) and alcohol (20 parts). Treated with ferric chloride it turns deep-brown, striking purple upon the addition of sulphuric acid. Kairin M is the corresponding methyl compound ($C_9H_{10}[CH_3]NO.HCl$), methyl iodide, instead of ethyl iodide, being used in its preparation. Kairin is open to many of the objections to the thalline compounds. It is an antipyretic, but is a dangerous heart depressant. It should have no place in therapeutics.

Kairolin A (*Kairoline*) and *Kairolin M* are compounds resembling the preceding, and are the acid sulphates, respectively, of ethyl and methyl quinoline-tetrahydride. Kairolin differs from kairin in not containing oxygen. (See graphic formulæ of Kairin, Kairolin, Thalline, Antipyrin, etc., in *Pharm. Centralhalle*, 1887, p. 160.)

THAPSIA.—THAPSIA.

The root and prepared resin of *Thapsia garganica*, Linné.

Nat. Ord.—Umbelliferæ.

Botanical Source.—This plant is a herbaceous perennial, from 2 to 4 feet high. It has a round, smooth stem, and 3 pinnately-compound leaves, which are borne on sheathing leaf-stalks. The flowers are in large, compound umbels, and the yellow petals are elliptical, and with an inflexed point. The fruit consists of 2 dorsally-compressed carpels, which are 9-ribbed, with the 2 side-ribs winged. The root is large, from 1 to 2 feet long, and from 2 to 3 inches in diameter at the thickest part.

History and Chemical Composition.—This plant is a native of Spain and other parts of southern Europe, and also found in northern Africa. According to Dioscorides, it derives its name from the island of Thapsos, in which it was first discovered; in the time of Theophrastus, it was found in abundance on the promontory, called Gargano, hence its species name of *Garganica*. It contains an acrid, milky juice when fresh, and yields a resin when dried. The root is the part employed in medicine, and has long been in use with the Arabs. The resin of the African variety (*Thapsia Sylphium* of Viviani) is a strong irritant, both the resin and dried root being exported from Algeria in considerable amounts. The resin is obtained by extracting the dry root with alcohol, distilling the tincture, and washing the residue with water (Reboulleau and Bertherand, 1857). It is soluble in alcohol, ether, and carbon disulphide; becomes plastic at 16° C. (60.8° F.), has an amber-yellow color, and a specific gravity somewhat greater than that of water. It is said to be a component of a plaster made in France, and sold under the name *Thapsia Plaster*. Desnoix prepares this plaster as follows: Rosin, 15 parts; elemi, 12½ parts; yellow wax, 18 parts; turpentine, 5 parts; resin of thapsia, 3½ parts. Melt the rosin, elemi, and wax together, and then add the turpentine and thapsia resin. Strain through linen, and spread upon leather (*Dorvault, L'Officine*, 1872, p. 883). Thapsia also contains an irritating, volatile substance, which affects the exposed skin of those distilling the alcoholic tincture, and who have, consequently, to exercise much care during the operation. M. Yvon (*Pharm. Jour. Trans.*, Vol. VIII, 1877, p. 162) found *Thapsia Sylphium* to possess this property in a marked degree, while *T. garganica* did not exhibit it. F. Canzoneri (1883) obtained from the dried root of *Thapsia garganica*, by percotion with ether, a syrupy acid resin of strongly vesicating properties. It was differentiated into liquid *octoic* or *caprylic acid* ($C_8H_{16}O_2$), crystallizable *thapsic acid* ($C_{16}H_{30}N_4$), and a non-nitrogenous, neutral, vesicating substance (*Amer. Jour. Pharm.*, 1884, p. 325).

Action and Medical Uses.—The properties of this plant reside in its resin, which has been employed as a vesicating or irritating plaster in *rheumatic, neuralgic*, and other *local pains*, and in all cases in which a counter-irritant is indicated. According to its mode of preparation, and the length of time it is allowed to remain upon the part, its effect may be varied from that of a slight redness to the production of an intense irritation with the formation of vesicles; its action being, in this respect, similar to that of euphorbium, croton oil, mezereon, and other counter-irritants. It is more commonly employed in combination with other agents, to modify its more active effects. The tincture of the resin may be painted upon oilcloth, adhesive plaster, or other material, and used as a local counter-irritant. Internally, this agent is not employed, though it is stated to possess emeto-cathartic properties.

THEA.—TEA.

The leaves of *Thea chinensis*, Sims (*Camellia theifera*, Griffith; *Camellia Thea*, Link).

Nat. Ord.—Ternstrœmiaceæ.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 34.

Botanical Source.—The tea plant, *Thea chinensis*, is an evergreen shrub, when uncultivated, attaining as much as 30 feet in height, but seldom reaching more than 6 or 7 feet when under cultivation. There are several varieties of this plant, among them *Thea viridis* (green tea) and *Thea bohea* (black tea). The commercial terms, green and black tea, do not refer to this botanical distinction. The several botanical varieties were formerly regarded as distinct species.

Thea viridis has many alternate, bright-brown and smooth branches, which are green and downy when young. The leaves are alternate, bright deep-green, oval or oval-lanceolate, short-stalked, very convex, serrated, entire toward the base, and at the apex, which is acuminate and emarginate; shining on both sides, blistered when old, and slightly downy beneath. The flowers are small, white, axillary, and solitary, with a rather heavy odor. Corolla of 5 to 9 petals, unequal, the outer one being shorter. Calyx without bracts, 5-cleft; segments imbricated and equal. Stamens numerous, smooth, adhering to the very base of the petals; filaments white and awl-shaped; anthers rounded, reniform, and opening at the base. Ovary ovate and pubescent; style simple at the base and trifid above. Capsule spheroidal, 3-celled, and often, by abortion, 1 or 2-celled; cells opening at the apex, 1 or, rarely, 2-seeded. Seeds spheroidal, wingless (L.).

Fig. 242.

Thea chinensis.

Thea bohea, very much like the preceding, but the leaves are flatter, smaller, darker green, with small serratures, and terminating gradually in a point, and not at all acuminate or emarginate (L.). Flowers axillary and several together.

History, Preparation, and Description.—The tea plant is a native of eastern Asia, and was brought to Europe during the second half of the seventeenth century. It is extensively cultivated in China and Japan, also in Assam, Java, Bengal, Ceylon, Sicily, Portugal, Brazil, Jamaica, etc. It may also be successfully cultivated in South Carolina (see *Amer. Jour. Pharm.*, 1898, p. 251). China and Japan furnish the bulk of the tea of commerce. According to investigations by Robert Fortune (1852) and other travellers, it appears that all the teas are collected from the same species, but their quality is subject to climatic influences, and dependent also on the soil, culture, and preparation. The tender tops of the shrub yield the finest teas, while the lower leaves yield the common kinds. The first crop also yields finer teas than subsequent crops, which are successively of poorer quality to the fifth or sixth crop. The accompanying illustration, from Col. Money's *Tea Cultivation* (abstracted in *Food and Food Adulterants*, by Wiley, Spencer, and Ewell, *Bulletin No.* 13, *United States Department of Agriculture*, Part VII), shows a branch with leaves of different age, each representing a commercial grade of tea, as indicated. Distinction is made in commerce between *green tea* and *black tea*, the difference depending solely on the manner in which the leaves are treated in order to develop the aroma and taste of tea. Fresh tea leaves are non-aromatic, and have merely an astringent taste.

Fig. 243.

a. Flowery Pekoe.
b. Orange Pekoe.
c. Pekoe.
d. Souchong 1st.
e. Souchong 2d.
f. Congou.
a. b. When mixed together Pekoe.
a, b, c, d, e. (When mixed together) Pekoe Souchong
If there be another leaf below *f*, and it be taken, it is named and would make Bohea
Each of these leaves was first a flowery Pekoe leaf, i. e., it then became *b*, then *c*, and so on
At the base of the leaves *c, d, e, f* exist buds 1, 2, 3, 4, from which new shoots spring.

Green Teas are prepared by exposing the leaves to the sun's rays for 1 or 2 hours. In Japan they are treated with steam; subsequently they are roasted in iron pans over a charcoal fire; then they are rolled by hand on a bamboo table, and quickly dried in the roasting pan. This procedure "fixes" the green color of the tea. During the latter process, such additions as Prussian blue and gypsum are frequently made for the purpose of "improving" the green color (R. Fortune, *The Tea Districts of China and India*, 3d ed., Vol. II, 1853, p. 69, London). Commercial grades of green teas are *Twankay*, *Young Hyson*, *Hyson-skin*, *Imperial*, *Gunpowder*, etc.

Black Teas are obtained by a process of fermentatian. The leaves are allowed to lie on bamboo trays for about 12 hours, during which time they wither;

then they are agitated by hand, and again allowed to lie in heaps for an hour or longer. Finally the leaves are alternately heated in pans and rolled on tables, this being repeated several times. After the last drying, the tea is sorted by means of sieves, and divided chiefly into three classes, depending on the size of the leaves—namely, *Pekoe* (the leaf buds), *Souchong*, and *Bohea* (see illustration, p. 1928). Other commercial grades of black tea are *Congou*, *Caper*, and *Oolong*, etc. The rolling of the leaves is now frequently done by machinery, especially in Ceylon. This practice is preferable to the old method of peforming the rolling with the hands, or even with the feet, as witnessed, for example, by Prof. Tichomirow (see below). It has been customary in tea-growing districts to improve the flavor of inferior teas by mixing them temporarily with certain fragrant flowers, such as of *Jasminum Sambac*, Aiton; *Aglaia odorata*, Loureiro; *Gardenia pictorum*, Hasskarl, etc., and afterward separating them out again. This statement, however, is discredited by Prof. Tichomirow, though he has seen special and high-grade green teas encased in boxes containing a layer of the flowers of *Aglaia odorata*. The leaves of the green tea have a dark bluish-green color, a pleasant, somewhat fragrant odor, and a bitterish, slightly astringent, herbaceous taste. They impart their peculiar taste and odor to boiling water by infusion, forming an agreeable and invigorating drink. The leaves of black tea are much darker-colored than those of the green, and their taste and odor is not so pleasant. They form a brownish infusion with boiling water. In Ceylon, black tea alone is manufactured, while in Japan only green tea can be produced, because the Japanese variety of tea does not bear fermentation (Flückiger, *Pharmacognosie*, 1891).

BRICK TEA.—A *tablet tea* is manufactured at Hankow, China, from common tea-dust, by steaming it and pressing it into wooden molds. A smaller and high-grade tablet is made from fine tea-dust by pressing it (dry) into steel molds by means of machinery. These grades are consumed throughout Russian Siberia. *Brick tea* is made from leaves and stalks of the tea shrub, which are powdered, sifted, steamed, and pressed into bricks of the size of an ordinary brick. This tea is used in Chinese Mongolia and Thibet (*Bull. Kew Gardens*, 1890, p. 109). (For a most interesting and detailed account of the cultivation of tea in Ceylon and China, see Prof W. A. Tichomirow, *Pharm. Zeitschrift f. Russland*, 1892, p. 209, etc.)

Chemical Composition and Tests.—The aroma of tea leaves is due to a small quantity of volatile oil (0.6 to 1 per cent, Mulder). Other important constituents are *theine* (*caffeine*), varying in commercial specimens from 1 to 5 per cent, usually from 1 to 2½ per cent; large quantities of *tannic acid*, identical with gallotannic acid, from 7 to 21 per cent; gallic acid, oxalic acid, and *quercetin*, albuminous and coloring matters, and ash (3 to 7 per cent), of which about one-half is soluble in water. *Boheic acid* ($C_{14}H_{20}O_{12}$), a deliquescent, amorphous substance, soluble in alcohol and water, was observed in black tea by Rochleder (1848). It forms a precipitate with lead acetate. A. Kossel (1888) found, in tea extract, *theophylline* ($C_7H_8N_4O_2+H_2O$), isomeric with *theobromine* (see *Theobroma*), and melting at 264° C. (497.2° F.), and the base *adenine* ($C_5H_5N_5$).

The seeds of Assam tea, according to Boorsma, contain two saponin-like substances—*assamic acid* and *assamin* (*Proc. Amer. Pharm. Assoc.*, 1892, p. 784). David Hooper found the seeds to contain 9 per cent of total saponin, and 22.9 per cent of fixed oil, yet the latter can not be obtained free from the poisonous saponin (*Pharm. Jour. Trans.*, Vol. XXV, 1895, p. 605)

Black tea, according to analysis of Y. Kozai (*United States Bulletin No.* 13, *loc. cit.*), contains less tannic acid than green tea, prepared from the same lot of fresh leaves. It evidently decomposes during fermentation. The amount of theine is practically the same in both. *Theine* ($C_8H_{10}N_4O_2+H_2O$) was discovered in tea by Oudry (1827), and found identical with caffeine, in 1838, by Mulder and C. Jobst. (For its characteristics, see *Caffeina*.)

The "strength" of tea is not necessarily proportionate to the amount of *theine* present. David Hooper (*Jahresb. der Pharm.*, 1890, p. 181) determined the tannin in 65 specimens of India and Ceylon teas, and found them (dried) to vary from 10 to 21 per cent; the finest grades contained the most tannin. P. Dvorkovitch, however (*Amer. Jour. Pharm.*, 1892, p. 48), concludes that the quality or strength of tea is determined by the proportion of theine to total tannin, including that which is altered in the fermentation process. In the finest teas, the proportion of theine is large. Of great practical value and, of course, much simpler than the chemical analysis, is the infusion test, as carried out by experienced tea brokers. It consists in merely allowing the sample to lie in contact with a definite quantity of boiling water (about 1 in 40) for 5 minutes, and judging the quality of the infusion by its taste and flavor. This procedure removes only 20 per cent of extractive matter, while, if the tea were completely exhausted, about 35 to 40 per cent would be yielded, including all the tannin, which would make the decoction unpalatable and harmful. Messrs. Paul and Cownley have shown (*Amer. Jour. Pharm.*, 1887, p. 627, from *Pharm. Jour. Trans.*) that, in making tea, about one-half of the total theine is removed. In one instance the residue still contained 1.7 per cent of theine, while in another instance, where exhaustion was carried as far as practicable, as much as 0.13 per cent of theine remained in the "exhausted" tea leaves. D. Hooper (*loc. cit.*) found that 5 minutes' infusion with boiling water will remove about one-third of the total tannin. (For the determination of *theine* in tea, see Paul and Cownley, *loc. cit.*) Petit and Terrat believe that chloroform or diluted alcohol (60 to 80 per cent) completely and readily abstract theine from tea, provided the latter be previously moistened (*Proc. Amer. Pharm. Assoc.*, 1896, p. 602; also see P. Dvorkovitch, *loc. cit.*).

Tea is much subject to adulteration. Certain substances are mixed with it in order to give it a better appearance (*facing*), *e. g.*, Prussian blue, indigo, turmeric, gypsum, graphite, magnetic oxide of iron, etc. The improvement of the flavor has been mentioned. Catechu has been added to increase the astringency. Another practice is to substitute partially extracted tea leaves (see methods of detection, by A. Tichomirow, *Amer. Jour. Pharm.*, 1893, p. 302). Leaves of other plants which come into consideration as possible adulterants, and which are figured in the above *United States Government Report*, are those of maté, Paraguay tea (*Ilex Paraguayensis*), camellia (*C. japonica*), hawthorn, box-elder, horse chestnut, sycamore, rose, plum, elm, ash, willow, beech, oak, Missouri or golden currant, birch, poplar, raspberry, and Jersey tea (*Ceanothus Americanus*), also *Vaccinium Arctostaphylos* (see *Bull. Kew Gardens*, 1895, p. 61; also see *Related Products*, p. 1931).

Action, Medical Uses, and Dosage.—Tea is a mild stimulant and astringent. Used in moderation, the infusion, when not too strong, is a harmless and refreshing beverage. As to its effects upon the constitution, there is quite a diversity of opinion, but it is very probable that, with healthy persons, no pernicious influences arise from its use, unless taken in large quantities, or very strong. When made into a weak infusion, it is very agreeable to the invalid, and may be used in *fevers* and *inflammatory diseases*, when it is desired to check sleep. In *colds*, *catarrhs*, and slight attacks of *rheumatism*, warm tea is taken as a diluent, diuretic, and diaphoretic. It frequently relieves *headache*, and allays the *irritation of the stomach* produced by intemperance of the previous day. With some persons, however, tea produces very unpleasant nervous symptoms, as tremors, anxiety, headache, sleeplessness, etc. Tea is said to be a sedative to the heart and blood vessels, and Liebig considers it to possess considerable nutritive power. Black tea is generally preferred by those of weak or delicate nerves, on account of its being less apt to produce disagreeable nervous symptoms. Externally, the infusion has been used with advantage as a collyrium. The essential oil of tea exerts a most powerfully stimulating and intoxicating effect. In China, tea is seldom used till it is a year old, on account of the well-known intoxicating effects of new tea, due probably to the larger proportion of essential oil contained in the freshly-dried leaf (W. A. Miller). According to Dr. Lewin, the effects of theine and caffeine are identical, with the exception that the first is a less powerful toxic than the latter, requiring double the doses to produce the same effect, and likewise occasions convulsive movements in the limbs, which have not been noticed from the action of the latter (*Arch. de Phys., Norm., et Path.*, 1868).

Later investigators, however, consider theine and caffeine physiologically identical with each other, as well as with theobromine, cocaine, and guaranine. While their principles are thus identical, it is equally true that coffee and tea differ considerably in their effects and, of the two, the latter is more apt to harm the nervous system. Both tea and coffee induce wakefulness, but that of the former may partake of the character of a distressing insomnia, while the latter induces a pleasant, dreamy wakefulness. Both, however, in proper amounts, produce a feeling of mild exhilaration and well-being. Immoderate quantities of tea long-continued, may give rise to dyspepsia, constipation, headache, nervous unrest, hysteria, cardiac palpitation, and other irregularities, tremors, neuralgia, difficult breathing, ringing in the ears, physical and mental exhaustion, and other deleterious effects. The infusion of tea may be used freely; the fluid extract in doses of ½ to 1 fluid drachm, well diluted with water.

Related Products.—LIE TEA. "This substance, as its name implies, is an imitation of tea, usually containing fragments or dust of the genuine leaves, foreign leaves, and mineral matters, held together by means of a starch solution, and colored by one of the facing preparations. It is stated that gunpowder and imperial teas are more subject to this form of adulteration. Of the samples of tea examined by the Department of Agriculture, all were free from lie tea. According to Hassall, the percentage of ash in lie tea ranges from 13.05 to 52.92 for black teas, and 13.13 to 56.34 for green teas. The same authority also found black teas containing from 6 to 17.7 per cent of lie tea, and green teas containing 1.38 to 48.46 per cent of this adulterant. To detect lie tea, treat the suspected sample with boiling water. If it contains this adulterant, portions will break up into dust and leaf fragments" (*Food and Food Adulterants*, Wiley).

BUSH TEA (*Honig thee*).—South Africa. Species of *Cyclopia*, probably *C. brachypoda* and *C. longifolia*, are utilized by the inhabitants of Cape Colony as a substitute for tea (see *Pharm. Jour. Trans.*, Vol. XI, 1881, pp. 549 and 569). H. G. Greenish showed that it contained *cyclopin* ($C_{25}H_{28}O_{13}$), a glucosid, yielding sugar and *cyclopia-red*. No theine could be detected.

TEA OIL.—The Chinese use *tea oil* for lamps and as an article of food. It is pale-yellow, nearly odorless, of specific gravity 0.927, burns with a clear, white flame, is soluble in ether, but insoluble in alcohol and water. It is obtained, by warm pressure, from the seeds of various species of the genus *Camellia*, as the *C. japonica*, *C. oleifera*, Abel; *Thea oleosa*, Loureiro; or *C. sasangua*, Thunberg. The press-cake contains a poisonous, saponin-like substance (see *Bull. Kew Gardens*, 1888, p. 264).

Camellia drupifera, Loureiro, yields a similar oil.

Thea Japonica, Baillon (*Thea Camellia*, Hoffmann; *Camellia Japonica*, Linné).—This Japanese shrub, cultivated here for its ornamental beauty, yields poisonous seeds. Martin and Katsuyama (1878) obtained an acrid, semisolid, fixed oil, tannin, and a poisonous glucosid, *camellin*, somewhat soluble in hot water, little soluble in ether, easily soluble in alcohol.

THEOBROMA.—CACAO.

The seeds of *Theobroma Cacao*, Linne.

Nat. Ord.—Sterculiaceæ.

COMMON NAMES: *Cacao*, *Cocoa* (incorrectly), or *Chocolate tree*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 38.

Botanical Source.—The genuine cacao tree is a small and handsome evergreen tree, growing in South America and the West Indies, from 12 to 25 feet high, and branching at the top; when cultivated it is not allowed to grow so high. The stem is erect, straight, 4 to 6 feet high; the wood light and white; the bark thin, somewhat smooth, and brownish. The leaves are alternate, petiolate, lanceolate-oblong, ribbed, veined, entire, smooth on both sides, dark-green, 8 to 10 inches long, the younger ones rose-colored; the petioles terete, thinner in the middle, with 2 small, linear, awl-shaped stipules at base. The flowers are very small, clustered, axillary, but emanate from the sides of the stems; they are white, with a reddish tint, and scentless. Pedicels uniflorous and filiform. The calyx consists of 5 sepals, and is deciduous; the divisions are ovally lanceolate, angustate, and pointed. Petals 5, vaulted at the base, ligulate above. Stamens, linear, awl-shaped, urceolate, the 5 sterile ones much longer than the 5 fruitful ones, and alternate with the petals; the 5 fruitful ones opposite the petals, and bearing 2 anthers. The style is 5-cleft at the apex; the stigmas simple. Ovary free, sessile, oval, elongated, 10-grooved, downy, with 8 ovules in 2 rows in each of the compartments. Fruit indehiscent, ovate-oblong, 5-celled, and covered with a ligneous, leather-like bark, emanating from the sides of the stems. The seeds are numerous, compressed, ½ inch long, reddish-brown externally,

Fig. 244.

Theobroma Cacao.

dark-brown internally, and imbedded in a whitish, sweetish, buttery pulp. (On the anatomical structure of cacao seed, see A. Tschirch, *Archiv. der Pharm.*, 1887, p. 605.)

Source, History, and Preparation.—This tree was extensively cultivated in Mexico, Central and South America for many years, indeed long before the discovery of America, and at one time formed the currency of the natives, who made an immense consumption of it in various ways. At present it is chiefly cultivated in Brazil, Costa Rica, Guayaquil, Ecuador, Venezuela, Peru, Guatemala, the island of Trinidad, and most of the other West India Islands; also in Africa, Ceylon, Samoa, and other parts of the globe. The cocoa or chocolate nuts of commerce are the seed taken from the fruit and deprived of a slimy covering. There are many varieties of this seed brought into the market, named, according to the place from which they have been imported, *e. g.*, Puerto Cabello, Cauca, Maracaibo, Caracas, Surinam, Java, Domingo, Bahia, etc.

Cacao seeds are prepared for commerce either by simple drying, in which case they retain their bitterness and astringency; or they are cured by a sweating process by which their bitter and astringent properties are much modified, and the color of the seed changed. The seeds are placed into closed boxes for a certain length of time, or buried in the ground for a few days; the best process is to allow the seeds to lie for a week in heaps covered with green leaves, such as plantain leaves, etc., after which time they are dried. Also see directions given by W. Cradwick, of Jamaica, for curing cacao seeds on a domestic scale, in *Amer. Jour. Pharm.*, 1895, p. 530.

Description.—The best cacao seeds are large, full and heavy, smooth, of a beautiful, light chestnut-brown color, free of foreign matter, well sieved, dry, not musty, without disagreeable or rancid smell, but of an agreeable odor, and a mild somewhat bitter and fatty taste, with but little astringency. When the kernels are separated from the shell and broken, they should be shining and violet-brown, not traversed by white streaks. It is said that under the most favorable circumstances cacao can not be preserved for more than three years. The *cracked cocoa*, or *cocoa nibs* of commerce is coarsely ground cacao previously roasted. Commercial *cocoa* may also consist of the powdered press-cake obtained when the oil or butter of cacao is partially removed by pressure. *Chocolate* is prepared by first roasting the seed, then removing their husks as soon as the requisite degree of aroma and of friability is obtained, allowed to cool, and cracked or ground between heated stones, which causes them to assume the consistence of paste, which is molded into rectangular cakes. When roasted cacao seeds are ground with about an equal amount of sugar and certain aromatics, the product constitutes *sweet chocolate*. Those who manufacture chocolate have various methods of preparing, sweetening, and aromatizing it. *Cacao shells* are also an article of commerce, being used in preparing a table beverage resembling chocolate or cocoa in taste, but being naturally weaker than these.

Chemical Composition.—Cacao seeds contain fat (40 to 50 per cent) (*oil of cacao, cacao butter;* see *Oleum Theobromatis*), the base *theobromine* ($C_7H_8N_4O_2$), small quantities of *caffeine* (*theine*), starch (from 1.3 to 7.5 per cent, Ridenour, *Amer. Jour. Pharm.*, 1895, p. 209), a red coloring matter (*cacao-red*), albuminous matter (6 to 18 per cent), and ash (2 to 4 per cent), etc.

In 18 commercial specimens of cacao, A. Eminger (*Forschungsberichte über Lebensmittel*, 1896, p. 275; also see *Amer. Jour. Pharm.*, 1897, p. 113) found theobromine to vary from 0.88 to 2.34 per cent, caffeine from 0.05 to 0.36 per cent. According to E. Knebel (1892), the presence of cacao-red is due to the decomposition of a glucosid under the influence of a diastatic ferment, resulting in dextrose, cacao-red, theobromine, and caffeine (compare *Kola*).

THEOBROMINE was discovered in cacao seeds by Woskresensky in 1841. It is also a constituent of Kola nuts (see *Kola*). It crystallizes in small rhombic needles, has a bitter taste and sublimes without decomposition at about 290° C. (554° F.). Its solubilities, as revised by Eminger (*loc. cit.*), are as follows: It requires 736.5 parts of water at 18° C. (64.4° F.), 136 parts at boiling temperature, 5399 parts of alcohol (90 per cent) at 18° C. (64.4° F.), 440 parts at boiling heat, and 818 parts of absolute alcohol at the boiling point; 21,000 parts of ether at 17° C. (62.6° F.); 4856 parts of methyl alcohol at 18° C. (64.4° F.); 5808 parts of chloroform at 18° C. (64.4° F.), and 2710 parts at the boiling point. It is insoluble in carbon tetrachloride (CCl_4) at 18° C. (64.4° F.), while caffeine at this temperature is soluble at the ratio of 1:1000. The author bases upon this a method of quantitative separation of caffeine from theobromine, which was before possible only by precipitating theobromine by means of nitrate of silver in ammoniated solution (compare W. Kunze, *Amer. Jour. Pharm.*, 1899, 145). Theobromine is insoluble in petroleum-ether. Its aqueous solution is neutral, but it forms crystallizable salts with acids. Chemically it is *dimethylxanthin* (E. Fischer, 1882). A. Eminger assays cacao for theobromine by extracting the fat with petroleum-ether, boiling the residue with a 3 to 4 per cent sulphuric acid to produce the insoluble cacao-red (theobromine is not affected), neutralizing the residue with barium hydroxide, evaporating to dryness with sand, extracting theobromine and caffeine with chloroform, and separating both by means of carbon tetrachloride in the cold. This process avoids warming with bases which more or less destroy theobromine. (On the analysis of 12 commercial samples of prepared cocoa, see Florence Yaple, in *Amer. Jour. Pharm.*, 1895, p. 318.)

Cacao shells were found by T. S. Clarkson (*Amer. Jour. Pharm.*, 1887, p. 277) to contain 0.9 per cent alkaloid, 10.9 per cent nitrogenous matter, 5.32 per cent of fat, a resin soluble in ether and alcohol, and having the odor of cacao, 5.6 per cent of mucilage, and 9.07 per cent of ash, containing aluminum.

Action, Medical Uses, and Dosage.—CHOCOLATE, when scraped into a coarse powder, and boiled in milk, or milk and water, is much used as an occasional substitute for coffee, and for a drink at meals. It is a very useful nutritive article of diet for invalids, persons convalescing from acute diseases, and others with whom its oily constituent does not disagree, as is apt to be the case with dyspeptics. BUTTER OF CACAO is a bland article, rather agreeable to the taste, and highly nutritious; it has been used as a substitute for, or an alternate with, cod-liver oil, and as an article of diet during the last days of pregnancy. It has also been employed in the formation of suppositories and pessaries, for *rectal, vaginal, and other difficulties* (see *Suppositories*). It likewise enters into preparations for *rough* or *chafed skin, chapped lips, sore nipples*, various cosmetics, pomatums, and fancy soaps; and has also been used for coating pills.

Theobromine when absorbed acts powerfully as a diuretic, and has a stimulant or exciting action which is not possessed by chocolate itself. It is, however, quite difficult of absorption, and is without effect upon the heart and circulation. It enters into the compound known as *Diuretin*, which, in certain conditions, is an active diuretic.

THUJA.—ARBOR VITÆ.

The branchlets and leaves of *Thuja occidentalis*, Linné.

Nat. Ord.—Coniferæ.

COMMON NAMES: *Arbor vitæ*, *Yellow cedar*, *False white cedar*, *Tree of life*.

Botanical Source.—This evergreen tree is indigenous to this country, growing wild in various parts of the United States, from Canada to the Carolinas, on the rocky borders of streams and lakes, and in swamps, flowering in May. It abounds especially in Canada and the northern states. The trunk of the tree is crooked, rapidly diminishing in size upward, throwing out recurved branches from base to summit; branches ancipital, flat, and broad. The wood is very light and soft, but exceedingly durable. The leaves are evergreen, rhomboid-ovate, with a gland on the back, squamose, appressed, and imbricated in 4 rows. The cones are terminal, oblong, and nodding; the scales pointless and 1-seeded; the seeds broadly winged (W.—G.).

History and Description.—The thuja, a well-known coniferous tree, attains a height of from 20 to 50 feet in its native habitat, which is in cold and wet swamps, growing among the tamarac and other allied species, or in wet, rocky situations. It is commonly known as Yellow cedar and (wrongly) White cedar, the latter name properly belonging to another tree, the *Cupressus thujoides*. It is best known to the public in general, when cultivated for ornamental gardening, as it frequently is, as the arbor vitæ, or "tree of life." When thus cultivated and neatly trimmed, it has a much more compact appearance than in the wild state, as in the latter the branches and leaves have a somewhat loose and straggling appearance. The wood is light, fine-grained, and soft, being somewhat resinous, and is very durable. The twigs and small leaflets of this tree furnish the drug of commerce.

Fig. 245.

Thuja occidentalis.

Thuja has been used in medicine to a slight extent for two centuries at least. Boerhaave lauded the distilled water of thuja as a remedy for dropsy. Homœopathy is indebted to Hahnemann for its introduction into that school. Schoepf states that it is useful in coughs, fevers, scurvy, and rheumatism. Peter Kalm, a Swedish traveller and collector of American plants, after whom our drug Kalmia is named, states that, in Canada, the bruised leaves were applied locally to relieve the pains of rheumatism. Parkinson advised the eating of the leaves and young sprouts on buttered bread to bring about the "expectoration of tenacious and vitiated humors." In the early part of the present century, the oil of thuja was employed as an anthelmintic and tænicide. Its use for this purpose, however, is dangerous, owing to its liability to produce a violent irritation of the gastro-intestinal tract.

The use of thuja by the Eclectic profession is of comparatively recent date. The first published account of its use by one of our school is in the *Eclectic Medical Journal* for 1862, though it was, undoubtedly, personally used by other Eclectics. In an editorial, the editor, Dr. Scudder, gives the experience of Dr. Dickey, of Preble County, Ohio, who used it as a discutient in scrofulous enlargements of the lymphatic glands. Equal parts of powdered Podophyllum peltatum were incorporated with thuja sprouts, and made into a poultice with milk. The same treatment was pursued in severe neuralgia and rheumatic complaints, affording great relief. In one case, in which the patient had been bed-ridden for over a year, in consequence of severe pain and weakness in the lumbar region, a speedy and complete cure was effected. How much of the relief came from the heat and moisture of the poultice does not appear, but as the doctor had exhausted his therapeutic resources, it is fair to presume that the relief was in part, at least, due to the thuja. The leaves and twigs are employed. They have a pleasant benzoinic odor, and a pungent, bitterish, aromatic taste. A yellowish, green, pungent, aromatic, essential oil may be procured from them by distillation. Water or alcohol extracts their virtues.

Chemical Composition.—The leaves and tops of thuja yield, by distillation with steam, about 0.5 to 1 per cent of volatile oil (*Oleum Thujæ, Oil of Arbor Vitæ*). It is colorless or green-yellow, has a bitter taste, and a strong, camphoraceous odor, resembling that of tansy. According to Jahns (1883) and Wallach (1892–1894), it contains chiefly *dextro-pinene*, *lævo-fenchone*, and *dextro-thujone* (see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 344). Other constituents of the leaves of thuja are a bitter glucosid, *pinipicrin* (also contained in Pinus sylvestris), and a peculiar, astringent, yellow coloring matter, *thujin* ($C_{20}H_{22}O_{12}$, Rochleder and Kawalier, 1858), which is also a glucosid, closely related to *quercitrin;* with diluted acids, it splits into sugar and *thujigenin* ($C_{14}H_{12}O_7$), the latter takes up water and becomes *thujetin* ($C_{14}H_{14}O_8$). With barium hydroxide, thujin is decomposed into sugar and *thujetic acid* ($C_{28}H_{22}O_{13}$). (For experimental details regarding these bodies, see Husemann and Hilger, *Pflanzenstoffe*, 1882, p. 331).

Action, Medical Uses, and Dosage. Thuja was occasionally employed by doctors in the earlier years, but few new uses for it were developed. Like nearly all the drugs, which are not so dangerously active as to force themselves on the practitioner's notice, it only needed some conspicuous authority to announce the virtues of the remedy. The late Prof. Howe believed the drug valuable. It would seem that he was especially partial to the conifers. He reintroduced Pinus canadensis and thuja. Its present extensive use is largely due to his advocacy of the drug. It is true that Prof. King described thuja in the earlier editions of the *American Dispensatory*, and stated that a decoction of the leaves had been used in *remittent and intermittent fevers, coughs, rheumatic and scorbutic affections*, and gave the usual notice respecting its power to remove *warts*. With the exception of the latter use, this gave nothing further than Schoepf's statement.

Prof. Howe was desirous of seeing the remedy fully tested, so he began with the drug to determine its true value. In the *Eclectic Medical Journal* for 1880, p. 331, he gives a brief compilation of Eclectic uses of the drug, and concludes with his knowledge of it, and a notice of his intended lines of investigation. He says: "A tincture of fresh leaves of thuja will, locally applied, according to my experience, remove *warts* from the face and hands, *condylomata* about the nates, but will not destroy swiftly growing *venereal warts.* It will deaden *fungous granulations*, and utterly destroy them in some instances. But the best action of the drug is in overcoming the growing and spreading progress of *epithelioma*. I have seen it repress and overcome *fungoid and ulcerous epitheliomata* in an astonishingly happy manner." He further intimates that he shall try it in *croupous and diphtheritic cases*, and states that he shall inject some of the tincture into the *tunica vaginalis testis* for the cure of *hydrocele*, and may try it on the granulations of *trachoma*. Finally, he would see what could be done to a *bulging nævus* with it. Having carried out the last intention, he records his success (*Ec. Med. Jour.*, 1880, p. 391): "In the treatment of nævi, I feel that a specific has been brought out. I do not expect that it will take out the scarlet color of those vascular patches, called mother's mark, but that the agent will cause to shrink to insignificance those *puffy nævi*, which once called for the ligation of arteries. The thuja treatment is so safe and simple that a surgical operation is uncalled for, the operating surgeon losing by the discovery." Later, in the *Eclectic Annual*, he stated that, externally applied, it would lessen the size of a *nævus* or *mother's mark*. Many failures have been recorded in its use for the latter purpose. Thuja comes highly recommended as a dressing for *sloughing wounds*, *ulcers*, *bedsores*, senile and other forms of *gangrene*, serving a useful purpose in overcoming the horrible stench arising therefrom. It may likewise be used in *carcinomatous ulcerations*. Some even claim that it has power to check the latter disorder, but in all probability, this is claiming too much for the drug. It is frequently valuable to restrain *hemorrhages* occasioned by *malignant growths*.

Thuja is antiseptic and stimulant. Its general action is very much like that of the terebinthinates, and is said to resemble savin more than any other drug of this class. For this reason, it has been employed, as before stated, in *amenorrhœa*, with pelvic atony, and also in *catarrhal diseases of the female generative organs*. We have used it with good results as a topical application to thick, spongy, or tender os uteri, with leucorrhœal discharge. It is asserted that thuja has brought on abortion, acting not so much as a direct abortivant, but as a gastro-intestinal irritant, producing violent intestinal disturbances, giving rise, indirectly, to miscarriage. Thuja is a remedy for blood changes and glandular disorders. Tissue degenerations in the epithelial structures appear to be influenced by it. Good results have come from using an inhalation of thuja in *bronchial diseases* and *catarrhal affections* of a chronic type. We would suggest its inhalation in *fetid bronchitis* and *bronchorrhœa*. The preparation should be dropped on hot water and inhaled. It is first stimulant, afterward subastringent. It has successfully combatted *hemoptysis*. Its inhalation is serviceable in *diphtheria* and *membranous croup*. Rectal troubles, such as *fissured anus* and *hemorrhoids*, have been frequently cured with thuja. When it is thought necessary to inject a pile tumor, thuja may be used in preference to carbolic acid. It cures by inducing atrophy. In fissured anus, it is said that the drug at first aggravates the trouble, but, if persisted in, soon effects a permanent cure. Locally, or by hypodermatic injection, it has given good, but only temporary, results in *vascular rectum*, where, from a paralytic condition, the lower segment of the rectum bulges and sags, amounting almost to a prolapsus. Thuja is well known as Prof. Howe's specific for the cure of *hydrocele*. His method was to add to 1 ounce of warm, sterilized water 1 drachm of Lloyd's thuja. After tapping the sac, 2 drachms of this solution were then sent, hypodermatically, into the *tunica vaginalis testis*. The fluid was then squeezed into every part of the sac. At first some pain and considerable swelling results, but in a few days, if the work has been properly done, a permanent cure is accomplished. Alarming swelling has been reported in some instances operated upon in this manner, as well as some failures recorded. As before stated, Prof. Howe intimated that thuja might be applied to *trachomic lids*. Later, Dr. D. Thomas Long, of Topeka, Kan., employed a preparation of it in unctuous condition, now known as Long's thuja, with great success in the treatment of this disorder. The patient may be given a small box of the unguent and taught how to use it. Each application causes considerable smarting for a short time, accompanied by lachrymation, which, however, very quickly subsides, leaving no unpleasant after-effects. We have had excellent results in *chronic trachoma* from this treatment. Constitutional or tonic treatment may also be required. Perhaps, one of the best known properties ascribed to this drug, is its power to remove *warts*, whether of the hands, face, or genitals. Nearly every writer who has mentioned this drug, has reported success in this direction. Our experience from the local application of thuja to warts has been negative. Subcutaneous injection of it around the base of the growth has been recommended, and might be more effective than the preceding. Fearn (*Ec. Med. Gleaner*, 1894, from *Calif. Med. Jour.*) advises it where excrescences are sensitive and moist, with a foul-smelling secretion. Prof. Lyman Watkins, M. D., reports success with it in *urethral caruncle*. Several physicians have called attention to the fact that specific thuja proves an efficient remedy for *nocturnal enuresis*. Dr. Price (*Ec. Med. Jour.*, 1892) records interesting cases cured with this drug. Thuja was used first in 5-drop doses at bedtime, afterward reduced to 3 drops. Old men, with enlarged and greatly irritated prostate inducing a constant dribbling of urine, consequently staining the clothing and entailing much unpleasantness, are benefited by 5-drop doses of thuja. Another interesting report is that of Dr. George Herring (*Homœopathic World*), who employed it for *irritability of the bladder*, in gouty and eczematous patients. One case in particular mentioned by him, was that of an old man of 87 years, who was nearly exhausted from weakness consequent upon broken rest and frequent rising at night to empty his bladder. Thuja (first dilution), in 2-drop doses, brought complete relief. Prof. Howe (*Ec. Annual*) states that thuja, in 5 or 6-drop doses, will generally cure *enuresis* of children, and will alleviate *senile dribbling of urine*, if no paralysis exists. It has been successfully employed in *gleet*, when the continuance of the discharge was dependent on *granular urethritis*. A favorite injection for *gonorrhœa*, particularly in the latter stages, and for *gleet*, is composed of aqueous thuja, 1 part; Lloyd's colorless hydrastis, 1 part; water, 4 parts. The proportions may be varied as desired. It gives tone to the bladder walls, and is particularly of value in dribbling or expulsion of urine in plethoric women, with relaxed bladder tissues, where even a cough or slight muscular exertion causes an expulsion of urine. Thuja is a topical remedy of unsurpassed value in *syphilitic chancroid*. For this purpose the aqueous thuja is to be preferred. If applied early it relieves the pain, checks discharges, and promotes rapid healing. It acts best where softness and moisture are present. The parts should be cleansed with a borax wash before each application. Upon hard chancres it has little or no effect. This form of thuja is also valuable as an application to *post-nasal catarrh*, and to shrink *nasal polypi* and other *growths in the nose and nasopharynx*. Locally and internally, it gives excellent results in *chronic tonsillar affections*, and in the milder forms of *faucial and pharyngeal diphtheria*. It is also of value in some *chronic skin affections*, showing a tendency to vegetations. Dr. Foltz (*Dynam. Therap.*) states that specific thuja ($\frac{1}{5}$ to $\frac{1}{3}$-drop doses) acts upon the deep ocular tissues, and has been used in *scleritis*, *episcleritis*, *sclerochoroiditis*, and *syphilitic iritis*, with gummata on the iris; also externally and internally for the removal of *tarsal tumors*. Dose of specific thuja, from 1 to 20 drops; of aqueous thuja, 1 to 30 drops. Externally, Long's thuja, specific thuja, and aqueous thuja may be applied full strength, or diluted as required.

Specific Indications and Uses.—Enlarged prostate, with dribbling of urine in the aged; urine easily expelled upon coughing or slight muscular exertion; vesical irritation and atony; enuresis of children; verrucous vegetations; trachoma; chancroid.

Related Drug.—CYPRESS OIL. From *Cupressus sempervirens*. Lauded in *whooping-cough*. Used by sprinkling upon the clothing, bed, etc., of the patient.

THYMOL (U. S. P.)—THYMOL.

FORMULA: $C_{10}H_{14}O$. MOLECULAR WEIGHT: 149.66.

"A phenol occuring in the volatile oils of *Thymus vulgaris*, Linné, *Monarda punctata*, Linné (*Nat. Ord.*—Labiatæ), and *Carum Ajowan* (Roxburgh), Bentham et Hooker (*Nat. Ord.*—Umbelliferæ). It should be kept in well-stoppered bottles"—(*U. S. P.*).

SYNONYMS: *Acidum thymicum, Thymic acid.*

Source, History, and Preparation.—Thymol was discovered by Caspar Neumann in 1719. It was purified, in 1853, by M. Lallemand, who gave it the name "thymol," and ascribed the formula (old notation) $C_{20}H_{14}O_2$, the same being accepted at the present day as correct, corresponding to $C_{10}H_{14}O$ of the new notation. Thymol is a phenol (*iso-propyl-meta-cresol*), and is isomeric with carvacrol (*iso-propyl-ortho-cresol*). It is found in oil of thyme, oil of horsemint, and oil of *Carum Ajowan*, De Candolle (*Ptychotis Ajowan*), a plant from the East Indies; the thymol of commerce being derived from thyme oil. The yield of thymol from this source, however, is comparatively small and quite variable (from less than 1 to 38 per cent; see *Amer. Jour. Pharm.*, 1882, p. 521). Larger quantities of thymol occur in the oil of horsemint (see *Monarda*). Thymol exists in oil of thyme, associated with two hydrocarbons of greater volatility, cymol ($C_{10}H_{14}$), and thymene ($C_{10}H_{16}$) (see *Oleum Thymi*). Thymol may be obtained by fractionally distilling the pure oil of thyme; cymene and thymene pass over, and afterward the thymol, which may be purified by crystallization from alcohol; or, the thyme oil may be agitated with solution of caustic soda, the hydrocarbons forming the upper layer are removed, and the lower solution containing the thymolate of sodium is neutralized with hydrochloric acid, when thymol will rise to the surface, and may be purified by crystallization from its alcoholic solution.

Description.—Thymol, as described by the *U. S. P.*, forms "large, colorless, translucent crystals of the hexagonal system, having an aromatic, thyme-like odor, and a pungent, aromatic taste, with a very slight caustic effect upon the lips. Its specific gravity, as a solid, is 1.069 at 15° C. (59° F.), but when liquefied by fusion it is lighter than water. It melts at 50° to 51° C. (122° to 123.8° F.), remaining liquid at considerably lower temperatures. When triturated with about equal quantities of camphor, menthol, or chloral, it liquefies. Soluble in about 1200 parts of water at 15° C. (59° F.), and in less than its own weight of alcohol, ether, or chloroform; also readily soluble in carbon disulphide, glacial acetic acid, and in fixed or volatile oils. Its alcoholic solution is optically inactive"—(*U. S. P.*). Being a phenol, thymol readily dissolves in caustic alkalies and is regenerated by acids, even carbonic acid (see *Preparation*, above). Thymol also dissolves in 120 parts of glycerin. In making solutions of thymol with glycerin and water, it is best to triturate the thymol in a mortar with a small portion of alcohol, until it is dissolved, then add the desired menstruum. Thymol boils at 230° C. (446° F.) (Doveri and Lallemand).

Tests.—"If a very small crystal of thymol be dissolved in 1 Cc. of glacial acetic acid, and then 6 drops of sulphuric acid and 1 drop of nitric acid be added, the liquid will assume a deep bluish-green color. If 1 Gm. of thymol be heated in a test-tube, in a water-bath, with 5 Cc. of a 10 per cent solution of sodium hydrate, a clear, colorless, or very slightly reddish solution should be formed, which becomes darker on standing, but without the separation of oily drops (absence of *thymen*, or lævogyrate *pinene* ($C_{10}H_{16}$). If to this a few drops of chloroform be added, and the mixture agitated, a violet color will be produced. When a crystal of thymol is heated in an open capsule, or in a watch-glass, on a water-bath, it should gradually volatilize, leaving no residue (absence of *paraffin*, *spermaceti*, etc.)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Thymol is an antiseptic and disinfectant, and is considered by many who have experimented with it, to be superior, in these respects, to carbolic acid. By destroying the vitality of organized and living ferments, it prevents the occurrence of putrefaction, and arrests it when it has commenced. A small quantity of thymol added to albumen, milk, solutions of gum, or of gelatin, will preserve them for several months; and urine will be kept intact for several weeks. In contact with putrid pus, it promptly removes any odor emanating from this substance, and keeps it without change until complete desiccation occurs. Applied to *wounds*, *ulcers*, or *abscesses*, in the form of a weak solution, it promptly modifies their condition, and accelerates cicatrization. Fifteen grains of thymol dissolved in 2 pints of distilled water, forms an invaluable disinfectant; this has been found effective in disinfecting sick rooms, and as a local application to prevent *septicemia* during the parturient period, as well as at other times when there is reason to fear its development. M. Paquet has preserved viscera, portions of limbs, etc., free from the least trace of putrefaction for several months, by means of the following solution: Take of thymol, tannin, each, 1 drachm; anilin, ½ drachm; glycerin, 3 ounces. Mix. When employed in the dressing of ulcers, etc., the following solution has been recommended by M. Giraldes: Take of thymol, from ½ to 1 drachm; alcohol, 3 fluid ounces; distilled water, 30 fluid ounces. Mix. This has been found to act efficiently, even in cases in which iodine and other analogous topical applications had been fruitlessly employed. It is not necessary to employ too strong a solution, as pure thymol possesses caustic properties. M. Paquet has derived great benefit in dressing ulcers by the following: Take of thymol, ½ drachm; alcohol (85 per cent), 2 fluid drachms; distilled water, 33 fluid ounces. Mix. These solutions may be applied on lint, or by spray. Concentrated thymol may be advantageously substituted for nitric acid, or nitrate of silver, in cauterization of the dental nerves; its odor is not so disagreeable as that of carbolic acid.

Thymol has been employed in inhalations, by Bouillhon, Paquet, and others, in *bronchial* and other *affections of the respiratory organs*, attended with gangrenous exhalations. The respiratory mucous membranes become excited, the expectoration is diminished, becomes thinner and less tenacious, contains a much smaller amount of mucin, and is more freely passed. It suppresses the gangrenous odor, and prevents the diseased bronchial surfaces and the abnormal secretions covering them, from undergoing butyric fermentation, thus checking a poisoning of the blood. Ten drops of a thick, concentrated solution of thymol are placed in a small glass flask, furnished with a cork, through which pass two bent glass tubes, one descending nearly to the bottom of the flask, the other being short. This latter is held in the patient's mouth, who will aspire the air charged with the vapor of the thymol. These inhalations should be continued for 4 or 5 minutes, each time, and be repeated 8 or 10 times per day. Ten drops of the solution will suffice for inhalation during 4 or 5 days. If, during the inhalation, a slight sense of pricking is experienced in the posterior region of the pharynx, the inhalation should be suspended until this sensation passes off, and then be again continued. M. Lewin considers thymol very useful in *diphtheria* and other similar diseases dependent upon the action of living organisms; also in arresting the hypersecretion of various mucous membranes. In cases in which fermentation occurs in the stomach with dilatation of this organ, he states that thymol acts promptly in arresting the accompanying vomitings, and gradually effects a contraction of this dilated cavity.

M. Baelz, who has made some comparative experiments with thymol and salicylic acid (in the service of M. Wunderlich) upon persons in health, and also those affected with *typhoid fever*, *articular rheumatism*, *phthisis*, and *pyelitis*, states that in doses of ⅛ of a grain, repeated several times, no effect was observed; in order to obtain an appreciable therapeutical result, it was necessary to give daily from 25 to 30 grains. Upon coming in contact with the bucco-pharyngeal mucous membrane, the medicine occasioned a pricking sensation and a disagreeable taste; there was seldom any nausea, and vomiting occurred but once among 36 persons. Upon increasing the dose, a slight, but transient, sense of heat was experienced in the epigastrium; and, in some cases, a diarrhœa analogous to that in typhoid fever. In the majority of cases, half an hour or an hour after the gestion of thymol, more or less limited and profuse sweats appeared, but in all cases less than those occasioned by salicylic acid or jaborandi. An increase in the quantity of urine was frequently noticed; and the urine presented a dark, greenish color, as if it contained blood, and appeared a yellowish-brown when illuminated by reflected light. A solution of perchloride of iron added to the urine rendered it cloudy, and of a whitish-gray color. When the gray predominated, it reminded one of an icteric urine, or even of a nephritic urine mixed with blood; the absence of albumen, however, prevented any mistake as to the latter cause. The nervous phenomena were represented by tinnitus aurium, deafness, and a sense of constriction at the temples (*Archiv der Heilkunde*, Vol. XIV, Parts III and IV). In doses of from 30 to 60 grains, M. Baelz considers its action, as an antipyretic, decidedly inferior to that of salicylic acid.

Dr. B. Kussner has found that from 3 to 5 drops of a 1 per cent solution of thymol is beneficial in *diarrhœa of children*. Thymol injected into the veins lowers the temperature and induces stupor. Animals poisoned with it pass into a deep coma; after death their blood is dark and fluid, but no fatty degeneration of internal organs is observed (*Med. Press and Circ.*). Prof. Webster reports a satisfactory use of thymol in expelling *tapeworm*. A cathartic is administered at night, and 10 grains of thymol administered in the morning every 15 minutes until the worm is expelled. As it is a powerful depressant, it must be carefully used. It is a remedy for *chyluria*.

The preferable forms, for the internal administration of thymol are either to dissolve it in an alcoholic drink, or to form it into a thick, emulsioned fluid; but, thus far, the employment of this agent has been confined chiefly to its use as a topical application, and to utilize its antiseptic properties. The advantages derived from its internal administration have been very limited. The following has been advised as a method of preparing it into pills, the soap being indispensable to assure the division of the thymol: Take of thymol, 3 grains; medicinal soap, 6 grains; excipient, a sufficient quantity. Mix thoroughly, and divide into 20 pills. An ointment has likewise been advantageously employed, by thoroughly triturating together from 2 to 20 drops of a thick, alcoholic solution of thymol with 1 ounce of petrolatum or pure lard. This has been used as a local application in *burns*, *eczema*, *psoriasis*, *tinea*, *lichen*, and other *cutaneous affections*, and as a parasiticide. When much hyperemia is present, it must not be applied until this has been allayed. A very powerful antiseptic may be made thus: 1 part of thymol and 12 parts of chloral hydrate are triturated together, and then an equal quantity of camphor added, when the mixture assumes a liquid form; these proportions may be varied, if deemed necessary. Thymol enters into various antiseptic compounds used as local applications, for *catarrhal conditions*, etc.

Derivative.—THYMACETIN ($CH_3.CO.NH.C_6H_2[OC_2H_5].[CH_3].[C_3H_7]$). This substance is analogous to *phenacetin*, inasmuch as the phenol of the latter is substituted by thymol. It is a crystalline white powder, but little soluble in water. In doses of about 7 grains it is credited with hypnotic power. Analgesic properties are also possessed by it. Functional *nervous* and *neuralgic headaches*, and *mental and other nervous disorders* have been successfully treated with it. The dose ranges from 3 to 15 grains. It combines the properties of phenacetin with the antiseptic power of thymol.

Related Preparation.—LISTERINE. Listerine is an agreeable non-irritant and non-escharotic antiseptic preparation composed of the essential antiseptic constituents of thyme, eucalyptus, gaultheria, baptisia, and Mentha arvensis combined with refined benzo-boracic acid. Listerine is a transparent amber-colored fluid becoming cloudy or opaque below 60° F., but clearing again as the temperature reaches that figure. It has a fragrant, aromatic odor, a pungent taste, and in reaction is slightly acid. It mixes clear with water in all proportions. It is very extensively employed in the antiseptic treatment of operative and accidental *wounds*, and as a general cleansing agent in medical and dental practice. Its range of usefulness is practically unlimited in *surgery*, *gynæcology*, *urino-genital disorders*, and *dental practice*, being used as a deodorant and antiseptic wash. Internally it is administered in many *fermentative gastro-intestinal affections* requiring the stimulant and antiseptic properties of such a combination. It may be used freely, full strength or diluted, as a gargle mouth-wash, spray, injection or inhalation. The dose for internal use is 1 fluid drachm, 3 or 4 times a day, full strength or diluted with water. Listerine is a specialty of the Lambert Pharmacal Company of St. Louis.

THYMUS.—THYME.

The herb of *Thymus vulgaris*, Linne.

Nat. Ord.—Labiateæ.

COMMON NAME: *Thyme*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 205.

Botanical Source.—*Thymus vulgaris*, Linné. Thyme is a small under shrub, with erect, suffruticose, numerous, branched stems, procumbent at base, and 6 to 10 inches in height. The leaves are oblong-ovate and lanceolate, numerous, and revolute at the sides. The flowers are bluish-purple, small, and borne in terminal, leafy, whorled spikes (W.).

Thymus Serpyllus, Linné, *Wild thyme*, or *Mother of thyme*, with a decumbent stem, flat, entire, elliptical punctate, obtuse, and petiolate leaves, ciliate at base, and purple, spotted, capitate flowers, has similar virtues to the above (W.). A variety of this species is the *Thymus citriodora*, Schreber (*Lemon thyme*), having a pleasant, lemon-melissa odor.

History, Description, and Chemical Composition.—These two plants are natives of Europe, introduced into this country, and extensively cultivated in gardens as culinary plants, especially the *T. vulgaris.* They blossom during the summer. The whole herb is used. It should be collected when in flower, and carefully dried. It has a strong, pungent, spicy, rather pleasant taste and odor, both of which are retained by careful drying. These properties are due to a reddish-brown volatile oil (*red oil of thyme*), procured by distilling the plant with water. Its specific gravity is similar to that of the oil of origanum, for which it is frequently substituted. The rectified oil is known as *white oil of thyme* (see *Oleum Thymi* and *Thymol*). The herb yields its virtues to alcohol, or to boiling water by infusion.

Fig. 246.

Thymus vulgaris.

Action, Medical Uses, and Dosage.—Thyme is tonic, carminative, emmenagogue, and antispasmodic. The cold infusion is useful in *dyspepsia*, with weak and irritable stomach, and as a stimulating tonic in convalescence from exhausting diseases. The warm infusion is beneficial in *hysteria*, *dysmenorrhœa*, *flatulence*, *colic*, *headache*, and to promote perspiration. Occasionally the leaves have been used externally, in fomentation. The oil is valuable as a local application to *neuralgic and rheumatic pains;* and, internally, to fulfil any of the indications for which the plant is used. Dose of the infusion, from 1 to 3 fluid ounces; of the oil, from 2 to 10 drops on sugar, or in emulsion. Thyme, scullcap, and rue, of each, 2 ounces; peony and black cohosh, of each, 1 ounce; macerated for 14 days in diluted alcohol, and then filtered, forms a good preparation for *nervous and spasmodic diseases of children.* It may be given in teaspoonful doses to a child 3 years old, repeating it 3 or 4 times a day, sweetening and diluting it, if desired. A strong infusion of the *Thymus Serpyllus*, slightly sweetened, and mixed with gum Arabic, is stated by M. Joset to be a valuable remedy for *whooping-cough*, *convulsive and catarrhal coughs*, and *stridulous sore throat*, the favorable result occurring at the end of a very few days. It may be taken *ad libitum.*

TILIA.—LINDEN FLOWERS.

The inflorescence of various species of *Tilia.*

Nat. Ord.—Tiliaceæ.

Common Names: *Linden*, *Basswood*, *Linn tree*, *White wood.*

Botanical Source and History.—The various linden species, bearing the above names, are all stately trees, from 40 to 100 feet in height, having a tough, fibrous bark, and a very soft, white, woody portion, yielding a very soft and light charcoal. The leaves are cordate, petiolate, alternate, serrate, and often oblique at base.

Tilia americana, Linné, has thick and smooth leaves (*T. glabra* of Ventenat), or has thinner leaves, softly pubescent underneath (*T. pubescens* of Aiton), and many-flowered cymes. The latter variety grows in the southern states, and the smooth leaved kind inhabits the United States and Canada.

Tilia heterophylla, Ventenat (*T. laxifolia*, Pursh; *T. alba*, Michaux) has bright-green leaves, smooth on upper surface, but silvery-white underneath. Pennsylvania, Ohio, and Mississippi valleys, and south.

Fig. 247.

Tilia americana.

Tilia ulmifolia, Scopoli (*T. microphylla*, Ventenat; *T. parvifolia*, Ehrhart).—Leaves pale-green beneath, and smooth, except in the vein-angles, where they are pubescent. About 7-flowered cymes. This and the next species constitute the *Tilia europæa* of Linne.

Tilia platyphyllos, Scopoli (*T. pauciflora*, Hayne; *T. grandiflora*, Ehrhart).—Cymes 3-flowered; leaves softly pubescent on under surface, and larger than those of preceding species.

Description.—Linden flowers are borne in cymes, which are axillary, and the peduncles are partly united to a greenish-yellow, linear, leaf-like bract. The petals are 5 and whitish, or approach yellow, are oblong, or lanceolate, generally notched. The calyx is 5-parted. The stamens are numerous and hypogynous, somewhat united at their bases so as to form 5 clusters (in the last two species), while in the others the stamens are connected at their bases with a petaloid scale opposite the petal. Ovary 5-celled; style 1; stigma 5-lobed; fruit a spherical, nut-like capsule, 1-celled, and 1 or 2-seeded. When fresh, the odor is agreeable; when dry, faint. The taste is mucilaginous and sweetish.

Chemical Composition.—Linden flowers contain sugar, tannin, mucilaginous matter, fatty substance, wax, yellow coloring matter, and a volatile oil, to which their fragrant odor is due. Upon the leaves of the European species, Boussingault detected a sweet exudate, having the composition of Mt. Sinai manna. A glucosid, *tiliacin*, has been isolated from the leaves of the linden, as well as from *Cirsium arvense* (P. A. Latschinow, *Amer. Jour. Pharm.*, 1890, p. 296).

Action, Medical Uses, and Dosage.—The European species (*Tilia europæa*) is a common domestic remedy in Europe for the relief of many *nervous and catarrhal disorders*. The leaves, flowers, and buds are employed, and their properties may be regarded as stimulant, lenitive, tonic, and nervine. The infusion is generally preferred, and may be given to allay irritation and restlessness, and to promote rest and sleep. The hot infusion is employed to check *diarrhœa* from cold, and in the various forms of *colds* and *catarrhal conditions*, while, either hot or cold, it may be used in *restlessness*, *nervous headaches*, *painful and difficult digestion*, and *mild hysteria*. The effects upon the nervous system are sometimes obtained by an enema, or bath, prepared from the flowers. The infusion is prepared from 30 or 40 grains of the flowers and 1 pint of water. It forms an agreeable vehicle for other medicines. A strong tincture may be prepared of the flowers (℥viij) and strong alcohol (Oj). Dose, 1 to 20 minims. The other species undoubtedly possess similar properties.

TINCTURÆ.—TINCTURES.

History.—Tinctures are obtained by subjecting certain medicinal substances to the action of alcohol, ether, etc., for the purpose of extracting their active principles. Some are prepared by simple maceration, or by percolation, at ordinary temperature, while others require certain degrees of temperature. When alcohol, or diluted alcohol, is employed as a solvent, the preparation is termed simply a *Tincture;* though sometimes a small portion of acid or alkali is added to facilitate its solvent action. Occasionally, spirit of ammonia or ether are employed as the solvents, furnishing *Ammoniated tinctures* and *Ethereal tinctures*. Tinctures are also prepared by means of gin, brandy, wine, etc., as the solvent. The former are termed *Spirituous tinctures*, and those with wine, *Vinous tinctures*, or *Medicated wines*. When the substance to be dissolved is insoluble in water, rectified spirit (alcohol of specific gravity 0.820) is preferred as the menstruum; when it is soluble in both alcohol and water, diluted or proof-spirit is preferred. The former is applicable to resins, volatile oils, oleoresins, camphor, etc., in which the addition of water would diminish or entirely prevent the solvent power of the alcohol. The latter is proper where the drugs contain gum-resins, tannates, extractive, saline matters, etc. A *Simple tincture* contains the active principles of a single substance; a *Compound tincture* contains the active principles of several articles. The term *Saturated tincture* is a misnomer, the supposition once being that the resultant products were saturated with the active constituents of the drugs. *Essential* or *Concentrated tinctures* are terms once given to *Alcoholic fluid extracts*. The term *Hydro-alcoholic tincture* is applied to those prepared with dilute, or even weaker, alcohol. *Alcoolatures*, or *Preserved juices*, are mixtures of expressed plant juices with alcohol. *Succi* of the *British Pharmacopœia*, are prepared with 3 parts, by measure, of the juice of the plant to 1 of spirit. The action of light, as well as of air, sometimes has a deleterious influence upon tinctures. In order to preserve them from evaporation, and thereby maintaining a uniform degree of strength, and also from decomposition or deterioration, all tinctures should be kept in bottles well closed with accurately-fitting stoppers, and in a cool place not exposed to sunlight.

Preparation.—I. By Maceration. The article or articles should be reduced to a powder of a proper degree of fineness, or, where this can not be done, should be sliced or bruised, and then be placed in alcohol or diluted alcohol, as may be required, and allowed to macerate, in a close glass bottle, usually for 14 days, with occasional agitation, after which they are expressed, if necessary, and the tincture filtered through paper. Tinctures of drugs rich in oleoresins, the majority of gum-resins, resins, and balsams, are best prepared by this method.

II. By Percolation.—The article or articles should be reduced to a powder of a proper degree of fineness, or, where this can not be done, should be sliced, bruised, or rasped, etc. They are then to be first covered with the menstruum with which the tincture is to be made, and allowed to stand until they are moistened throughout, which step generally requires from 24 to 36 hours. The whole is then transferred to a percolator, and the menstruum gradually poured on, and allowed to percolate or filter until the requisite amount has passed (see section on *Percolation*, under *Fluid Extracts*). The preparation of tinctures by percolation, is, with a few exceptions, the method now generally pursued by all pharmacists of this country. The *National Formulary* gives the following directions for preparing unofficial tinctures:

Tincturæ (N. F.), *Tinctures.*—General Process. "All tinctures, for which no working formula is provided by the *United States Pharmacopœia*, the *National Formulary*, or some other work of authority, and the strength of which is not otherwise specified by the prescriber, should be prepared in the following proportions: *The drug*, properly comminuted, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; *the menstruum*, enough to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—The choice of the menstruum will depend upon the nature of the drug, and, in some cases, upon the uses to which the tincture is to be applied. In general, it may be stated that, if the useful constituents are soluble in alcohol, and but slightly or not at all soluble in water, strong alcohol should be used as a menstruum. Whenever it is possible, and consistent with the intended use of the preparation, the alcoholic strength of the menstruum should be made to approach that of diluted alcohol, the object being not only to exhaust the drug of all its useful constituents, but also to retain them in solution. If the drug is fibrous, and can be dried or powdered without injury or loss of useful constituents, percolation is preferable. If the drug is resinous, and partly or almost wholly soluble in the menstruum, or if it is fibrous and can not well be powdered without undergoing injury, maceration should be resorted to. In the latter case, the drug, comminuted as much as possible, should be kept in contact with the full quantity of the menstruum for two weeks, or until the soluble matters are extracted, the liquid portion strained off, and the remainder of the tincture contained in the residue on the strainer carefully displaced by washing with a fresh portion of the menstruum until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained for every one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.] of drug used in the operation. The preparation of tinctures from fluid extracts, instead of from the original drugs themselves, is not recommended. In some special cases, however, when the crude drug is not accessible, or when a tincture, which is not at hand and otherwise unobtainable, is required for immediate use, it may be prepared, extemporaneously, from the corresponding fluid extract, provided that the latter is known to fully represent the active constituents of the drug which are intended to be contained in the tincture"—(*Nat. Form.*). The following general directions are given by the *National Formulary* for the preparation of *Ethereal tinctures:*

Tincturæ Æthereæ (N. F.), *Ethereal tinctures.*—General Formula. "*The drug*, properly comminuted, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; alcohol, ether (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Percolate the drug in the usual manner, but with proper precautions to avoid loss of menstruum by evaporation, with a mixture of one (1) volume of ether, and two (2) volumes of alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of percolate are obtained. *Note.*—This formula is to be used, when ethereal tinctures of belladonna, castor, digitalis, lobelia, valerian, or of other drugs, are to be prepared"—(*Nat. Form.*).

For extensive systematic work on the standardization of tinctures, see Messrs. Farr and Wright, *Pharm. Jour. Trans.*, Vol. XXIV, 1893–94, pp. 177–180; and *Proc. Amer. Pharm. Assoc.*, 1891 to 1895).

TINCTURA ACONITI (U. S. P.)—TINCTURE OF ACONITE.

SYNONYMS: *Tinctura aconiti radicis* (*U. S. P.*, 1870), *Tincture of aconite root.*

Preparation.—"Aconite, in No. 60 powder, three hundred and fifty grammes (350 Gm. [12 ozs. av., 151 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of alcohol to three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water. Having moistened the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of menstruum, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Special care should be observed in the selection of aconite root, and it should be thoroughly powdered and the percolation carefully conducted. It yields a yellow-brown tincture, which, when added to water, renders the latter milky through precipitation of aconite resin.

Action, Medical Uses, and Dosage.—(See *Aconitum.*) This is a much stronger preparation than the tincture of the leaves, and care should be employed not to use the two tinctures indiscriminately. It may be used for the same purpose, but in smaller doses, commencing with a fraction of a drop, in a teaspoonful of water, and gradually increasing it to 5 drops.

Related Tinctures.—TINCTURA ACONITI, Fleming (N. F.), *Fleming's tincture of aconite.* (1) "Aconite (root), in fine powder, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the aconite with enough alcohol to render it distinctly damp and to maintain it so after 24 hours maceration in a well-covered vessel. Then pack it tightly in a percolator, and percolate it slowly, in the usual manner, with alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained. *Note.*—This preparation is still prescribed by many physicians. It is recommended that their attention be directed to the official fluid extract and tincture of aconite, so that the above preparation may be gradually abandoned. When this preparation is required for immediate use, and it is not otherwise available, it may be prepared in the following manner (see note to F. 396): (2) Fluid extract of aconite (*U. S. P.*), seventy cubic centimeters (70 Cc.) [2 fl℥, 176 ♏]; alcohol, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]. Mix them"—(*Nat. Form.*). Dose, ¼ to 1 drop.

TINCTURA ACONITI FOLIORUM, *Tincture of aconite leaves.*—Take of the recently dried leaves of aconite, finely powdered, 2 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 1 pint of tincture. Tincture of aconite leaves possesses all the properties of Aconitum napellus, and may be used whenever the drug is indicated, in doses of from 1 to 15 drops. It should not be confounded with the tincture of the root, which is a much more powerful preparation and is the preparation now generally employed.

TINCTURA ALOES (U. S. P.)—TINCTURE OF ALOES.

Preparation.—"Purified aloes, in moderately fine powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; liquorice root, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powders, and, having moistened the mixture with eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏] of diluted alcohol, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This is a cathartic and tonic, but is seldom used on account of its disagreeable taste, aloes being preferred in the pill form. As a cathartic, the dose is from ½ to 1½ fluid ounces. As a local application, on lint, it has been found useful in *old sores, ulcers, wounds*, etc.

TINCTURA ALOES ET MYRRHÆ (U. S. P.)—TINCTURE OF ALOES AND MYRRH.

SYNONYMS: *Elixir proprietatis paracelsi, Tinctura aloes composita.*

Preparation.—"Purified aloes, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; myrrh, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; liquorice root, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of seven hundred add fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol to two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water. Having mixed the aloes, myrrh, and liquorice root, reduce them to a moderately coarse (No. 40) powder. Moisten the powder with sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of the menstruum, and macerate for 24 hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This is a deep red-brown tincture, precipitating when added to water. Older formulas contained saffron.

Action, Medical Uses, and Dosage.—This tincture is emmenagogue and cathartic; it has been beneficially employed in *anemic* and other *abnormal conditions of the female system*, connected with *derangement of the menstrual secretion*, and with *constipation*. It will likewise be found useful as a stimulating laxative, in cold, sluggish states of the system, unconnected with any menstrual difficulty. The dose is 1 or 2 fluid drachms.

TINCTURA ARALIÆ SPINOSÆ.—TINCTURE OF ARALIA SPINOSA.

SYNONYM: *Tincture of prickly elder.*

Preparation.—Take of prickly elder bark, in fine powder, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This tincture is tonic, stimulant, and alterative, and is an efficient remedy in *chronic rheumatism, pulmonary affections, colic, flatulence, cholera morbus*, and *Asiatic cholera*. It is useful in *syphilis*, in combination with the tincture of turkey-corn. During the prevalence of *cholera*, in 1849–50–51, it was added to emetic and cathartic medicines, for the purpose of preventing any tendency toward excessive discharges from the bowels. It also serves as a local stimulating application, when properly diluted with strong infusion of golden seal, in cases of *chronic ophthalmia*. The dose is from 10 to 60 drops, 3 or 4 times a day (J. King).

TINCTURA ARNICÆ FLORUM (U. S. P.)—TINCTURE OF ARNICA FLOWERS.

SYNONYM: *Tinctura arnicæ* (*U. S. P.*, 1870), *Tincture of leopard's bane.*

Preparation.—"Arnica flowers, in No. 20 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pack the powder firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). A yellow-brown preparation, striking opalescent with water.

Action, Medical Uses, and Dosage.—This tincture is principally used as a local application to *sprains, bruises, wounds*, etc., but it may also be used internally in all cases where arnica would be applicable. The dose is from 1 to 30 drops.

TINCTURA ARNICÆ RADICIS (U. S. P.)—TINCTURE OF ARNICA ROOT.

Preparation.—"Arnica root, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of the menstruum, and macerate for 24 hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Arnica.*) Dose, 1 to 30 minims.

TINCTURA ASAFŒTIDÆ (U. S. P.)—TINCTURE OF ASAFETIDA.

Preparation.—"Asafetida, bruised, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the asafetida with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, and macerate for 7 days, in a closed vessel; then filter through paper, adding through the filter, enough alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This tincture has a yellowish or brownish-red color. Added to water, the resin separates, and the mixture becomes whitish.

Action, Medical Uses, and Dosage.—This tincture has all the efficiency of asafetida. The dose is from 30 to 60 drops.

Related Tincture.—TINCTURA ASAFŒTIDÆ COMPOSITA, *Compound tincture of asafetida.* Take of asafetida, lupulin, stramonium seeds, bruised, valerian root, in fine powder, each, 1 ounce; alcohol, 3 pints. Macerate for 14 days; express and filter. This tincture was formerly used principally in *epilepsy*, though it will be found useful in *hysteria*, *chorea*, and other *derangements of the nervous system*. The dose is a fluid drachm, repeated every 2 or 3 hours, in severe cases; and in ordinary cases, 3 times a day, to be taken in water, tea, or wine (J. King).

TINCTURA AURANTII AMARI (U. S. P.)—TINCTURE OF BITTER ORANGE PEEL.

SYNONYMS: *Tinctura aurantii*, *Tincture of orange peel.*

Preparation.—"Bitter orange peel, in No. 30 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol to four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of the menstruum, and macerate for 24 hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Uses and Dosage.—Used principally as a flavoring agent. Dose, 1 to 2 fluid drachms.

TINCTURA AURANTII DULCIS (U. S. P.)—TINCTURE OF SWEET ORANGE PEEL.

Preparation.—"Sweet orange peel, taken from the fresh fruit, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the orange peel (which should be as free as possible from the inner, white layer), previously cut into small pieces, with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]

of alcohol. and macerate for 24 hours; then pack it moderately in a conical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has a golden color and fine aroma. The fresh peel may be grated, avoiding the white portion, or it may be carefully peeled off with a sharp knife.

Uses.—Employed exclusively as a flavoring agent.

TINCTURA AURANTII RECENTIS.—Tincture of Fresh Orange Peel.

Preparation.—"Take of bitter orange, rectified spirit, of each, a sufficiency. Carefully cut from the orange the colored part of the rind in thin slices, and macerate 6 ounces of this in 18 fluid ounces of the spirit for a week, with frequent agitation. Then pour off the liquid, press the dregs, mix the liquid products, and filter. Finally, if necessary, add spirit to make 1 pint"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs for Tinctura Aurantii (*Tincture of orange*), to Take of "fresh bitter orange peel, cut small, 5 ounces (Imp.), or 250 grammes (Metric); alcohol (90 per cent), 1 pint, or 1000 cubic centimeters. Prepare by the maceration process"—(*Br. Pharm.*, 1898).

Uses and Dosage.—This tincture, like the other tinctures of orange, is used as a flavoring ingredient. It is stronger than that prepared from the dried peel. Dose, 1 to 2 fluid drachms.

TINCTURA BELLADONNÆ FOLIORUM (U. S. P.)—Tincture of Belladonna Leaves.

Synonyms: *Tincture of belladonna, Tinctura belladonnæ* (*U. S. P.*, 1880).

Preparation—"Belladonna leaves, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This tincture possesses all the virtues of belladonna, when prepared from the leaves, recently dried. The dose is from 5 to 10 drops. The imported leaves are of such uncertain strength that a tincture made from the alcoholic extract would be more trustworthy. Its uses are those of belladonna.

TINCTURA BENZOINI (U. S. P.)—Tincture of Benzoin.

Preparation.—"Benzoin, in moderately coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powder with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, and macerate for 7 days. in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This tincture is of a brown-red color, and is acid in reaction. With water it produces an opalescent mixture. The cosmetic preparation, known as Lac Virginis, or *Virgin's milk*, is prepared by mixing various amounts of rose water (from 20 to 100 parts) with 1 part of tincture of benzoin.

Action, Medical Uses, and Dosage.—This agent was formerly extensively used in catarrhal affections of the breathing and urinary organs and digestive tube. By atomization, or by inhalation with steam, it sometimes gives relief in *acute and chronic laryngitis and bronchitis*, particularly if there be fetid expectoration. Tincture of benzoin is stimulant and protecting in the early stage of *coryza*. It has been applied with advantage to *irritable ulcers, bed-sores, sore nipples*, and, with glycerin, to *chapped hands and face*, for *freckles*, and other *cutaneous eruptions, excoriations*, and *abrasions*, and irritable condition of the parts about the anus; also to allay the itching of *eczema, urticaria*, and *chilblains*.

TINCTURA BENZOINI COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF BENZOIN.

SYNONYMS: *Tinctura balsamica, Elixir traumaticum, Balsamum commendatoris.*

Preparation.—"Benzoin, in coarse powder, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; purified aloes, in coarse powder, twenty grammes (20 Gm.) [309 grs.]; storax, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; balsam of tolu, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the benzoin, aloes, storax, and balsam of tolu with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, and digest the mixture, at a temperature not exceeding 65° C. (149° F.), for 2 hours in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture, when cold, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). Compound tincture of benzoin has a deep brownish-red color, and an acid reaction. When added to water, it produces an opaque mixture.

Action, Medical Uses, and Dosage.—A preparation similar to this has been known under various names, as *Balsamum traumaticum, Jesuits' drops, Wound balsam, Commander's balsam, Friar's balsam*, etc. It is used as an expectorant in *old coughs* and *catarrhs.* Compound tincture of benzoin is advised by inhalation, with steam, for the relief of *acute and chronic laryngitis*, and in *chronic bronchial irritation*, with free and fetid secretion. It was formerly used as a stimulating application to *obstinate ulcers.* Internally, the dose is from ½ to 1 or 2 fluid drachms. *Turlington's balsam*, a well-known remedy, was composed of benzoin, 6 ounces; liquid storax, 2 ounces; socotrine aloes, ½ ounce; Peruvian balsam, 1 ounce; myrrh, ½ ounce; angelica root, 2 drachms; balsam of tolu, 2 ounces; extract of liquorice, 2 ounces; alcohol, 4 pints. Mix, digest for 10 days, and strain (*Jour. of Phila. Col. of Pharm.*, Vol. V, p. 28). It is an improper application to fresh wounds, though it is often applied to *excoriations* and *abrasions*, and to *sore nipples*, as a protective. It sometimes relieves the itching of *chilblains, eczema*, and *urticaria*, and, combined with glycerin, is a useful application for *chapped hands and face.* This balsam is designed to represent the once popular preparation known by the above-given names, and as *Swedish, Persian, Wade's, St. Victor's*, and *Vervain's balsams.*

TINCTURA BRYONIÆ (U. S. P.)—TINCTURE OF BRYONIA.

Preparation.—"Bryonia, recently dried, and in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture should preferably be prepared with diluted alcohol, as the bitter principle is soluble in water. The tincture has a bitterish taste, and a brownish-yellow color.

Action, Medical Uses, and Dosage.—(See *Bryonia.*) The dose of this preparation, for its specific uses, should be small—from a fraction of a drop to 2 drops. By some it is employed as a purgative, in doses of from 20 to 90 drops. It is never used in the latter manner in Eclectic practice.

TINCTURA BUCHU.—TINCTURE OF BUCHU.

Preparation.—"Take of buchu leaves, in No. 20 powder, 2½ ounces (av.); proof-spirit, 1 pint (Imp.)"—(*Br. Pharm.*, 1885). Prepare as directed under *Tinctura Sennæ*). This produces a green-brown tincture, possessing the sensible properties of buchu. The preparation of the *British Pharmacopœia* (1898) is similar, except that 4 ounces of the leaves are directed, and alcohol (60 per cent), a sufficient quantity to make 1 pint of tincture.

Action, Medical Uses, and Dosage.—(See *Buchu.*) This preparation is less eligible than the infusion. Dose, 1 to 3 fluid drachms, well diluted with water.

TINCTURA CACTI.—TINCTURE OF CACTUS.

Preparation.—Take of the fresh flowers and stems of Cactus grandiflorus, cut into small pieces, 4 troy ounces; alcohol (95 per cent), 1 pint. Mix together, and macerate for 14 days, frequently agitating; then filter with expression.

Action, Medical Uses, and Dosage.—Used in the diseases named under *Cactus.* The dose is from 1 to 10 drops, 3 times a day, in water; or, 2 fluid drachms may be added to 3 fluid ounces of water, of which the dose is a teaspoonful, 3 or 4 times a day.

TINCTURA CALENDULÆ (U. S. P.)—TINCTURE OF CALENDULA.

SYNONYM: *Tincture of marigold.*

Preparation.—"Calendula, in No. 20 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Freshly dried and powdered flowering calendula must be used in preparing this tincture. A weaker alcohol allows precipitation to occur. A non-alcoholic preparation is made by means of glycerin instead of alcohol.

Action and Medical Uses.—(See *Calendula.*) This tincture is used locally to *cuts*, *wounds*, etc, after the manner of employing tincture of arnica.

TINCTURA CALUMBÆ (U. S. P.)—TINCTURE OF CALUMBA.

SYNONYMS: *Tinctura colombæ*, *Tincture of colombo.*

Preparation.—"Calumba, in No. 20 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol to four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). If diluted alcohol be employed, a tincture is obtained which deposits a greater amount of precipitate than when strong alcohol is used. This tincture has a brownish-yellow color.

Action, Medical Uses, and Dosage.—This tincture forms a bitter tonic; it may be added to liquid tonic preparations, whenever it is required, to slightly augment their tonic action. The dose is from 1 to 4 fluid drachms.

TINCTURA CANNABIS INDICÆ (U. S. P.)—TINCTURE OF INDIAN CANNABIS.

SYNONYMS: *Tincture of India hemp*, *Tincture of Indian hemp*, *Tincture of hemp*, *Tinctura cannabis* (*U. S. P.*, 1870).

Preparation.—"Indian cannabis, in No. 40 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This forms a powerful sedative narcotic, which has been used in *neuralgia*, *cholera*, and other symptoms where the India hemp has been recommended, with much success. The dose is 5 drops, gradually increased to 20 or 40, according to its influence. The extract and fluid extract are, however, more frequently employed than the simple tincture.

TINCTURA CANTHARIDIS (U. S. P.)—TINCTURE OF CANTHARIDES.

Synonym: *Tincture of Spanish flies.*

Preparation.—"Cantharides, in No. 60 powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of alcohol, and pack it firmly in a cylindrical percolator; then gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has a green-yellow color. When prepared with diluted alcohol, the color is brownish-yellow, and the tincture deposits a precipitate. It possesses the characteristic odor of cantharides and a pungent taste.

Action, Medical Uses, and Dosage.—This is the best form for the administration of cantharides, in *chronic gonorrhœa*, *gleet*, *amenorrhœa*, and some *urinary derangements*. Externally, it is sometimes used as a rubefacient, but care should be taken to avoid its vesicating action. The dose is from 1 to 20 drops, every 3 or 4 hours.

TINCTURA CAPSICI (U. S. P.)—TINCTURE OF CAPSICUM.

Synonym: *Tincture of cayenne pepper.*

Preparation.—"Capsicum, in No. 30 powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏] of alcohol to fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏] of water. Having moistened the powder with forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏] of the menstruum, pack it firmly in a cylindrical percolator; then gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Tincture of cayenne pepper is a useful and permanent stimulant, and may be administered in *depressed states of the system*, with torpor of the stomach, as with *inebriates*, and in *typhoid stages of febrile diseases;* also to prevent the nausea which oil of turpentine is apt to occasion. It is also useful in *gangrenous sore throat*, and to remove *relaxation of the uvula*, applied to the part on a camel's-hair pencil, or as a gargle. For this purpose it may be diluted, if required, with mucilage of elm bark. It is also an excellent application to the eye in cases of *chronic ophthalmia*. It is frequently applied locally, with advantage, in cases of *swellings*, *rheumatic pains*, *partial paralysis*, *atrophied muscles*, etc. The dose is from 10 to 60 drops in water, 3, 4, or 5 times a day, according to the urgency of the case (see *Capsicum*).

TINCTURA CARDAMOMI (U. S. P.)—TINCTURE OF CARDAMOM.

Preparation.—"Cardamom, in No. 30 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has the characteristic taste and odor of cardamom, and is of a brownish-yellow color.

Action, Medical Uses, and Dosage.—This tincture is aromatic and carminative, and is useful in *mild colic*, *flatulency*, *nausea*, *gastric debility*, etc. It is also advantageously added as a pleasant aromatic to several mixtures, tinctures, infusions, etc. The dose is 1 or 2 fluid drachms.

TINCTURA CARDAMOMI COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF CARDAMOM.

Preparation.—"Cardamom, twenty grammes (20 Gm.) [309 grs.]; cassia cinnamon, twenty grammes (20 Gm.) [309 grs.]; caraway, ten grammes (10 Gm.) [154 grs.]; cochineal, five grammes (5 Gm.) [77 grs.]; glycerin, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the cardamom, cinnamon, caraway, and cochineal, and reduce them to a moderately coarse (No. 40) powder. Having moistened the powder with twenty-five cubic centimeters (25 Cc.) [406 ♏] of diluted alcohol, pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏] of tincture are obtained; then add the glycerin, and mix them"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This is a very pleasant aromatic tincture, and is used for the same purpose as the tincture of cardamom, and in the same doses.

TINCTURA CASCARILLÆ.—TINCTURE OF CASCARILLA.

Preparation.—"Take of cascarilla bark, in No. 40 powder, 2½ ounces (av.); proof-spirit, 1 pint (Imp.)"—(*Br. Pharm.*, 1885). Prepare as directed for *Tinctura Sennæ.* This tincture is red-brown in color. The *British Pharmacopœia* (1898) directs the employment of 4 ounces of cascarilla bark, and of alcohol (70 per cent), a sufficient quantity to make 1 pint of tincture.

Action, Medical Uses, and Dosage.—(See *Cascarilla.*) Dose, 20 to 120 drops.

TINCTURA CASTOREI.—TINCTURE OF CASTOR.

Preparation.—Take of castor, 10 drachms; alcohol, 1 pint. Form into a tincture by maceration, as explained under *Tincturæ*, and make 1 pint of tincture. This tincture has a dark red-brown color, and, with water, becomes opalescent. If water be in large quantity, a milky turbidity follows, and a reddish-brown, resin-like matter is deposited. If allowed to stand, it becomes somewhat transparent and nearly colorless.

Action, Medical Uses, and Dosage.—This tincture should always be prepared from the Russian castor, if possible. Its properties are the same as the castor in substance (see *Castor*), and may be given in doses of from 20 minims to 2 fluid drachms.

Related Tincture.—TINCTURA CASTOREI AMMONIATA, *Ammoniated tincture of castor.* Take of castor, 2½ ounces; asafetida, in small fragments, 10 drachms; spirit of ammonia, 2 pints (Imp.). Digest for 7 days in a well-closed vessel, strain, and strongly express the residuum, and filter (*Ed.*). This is antispasmodic and stimulant; useful in various *affections of the nervous system, hysteria, spasmodic affections of the stomach*, etc. Inflammation contraindicates its use. It may be given in doses of ½ to 2 fluid drachms.

TINCTURA CATECHU COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF CATECHU.

Preparation.—"Catechu, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; cassia cinnamon, in No. 40 powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powders, and, without moistening, pack the mixture firmly in a cylindrical percolator; then gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.)

[33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture may also be made by maceration. It has a dark brown-red color, and is acid to test-paper. On long keeping it is apt to gelatinize, and thus become inert.

Action, Medical Uses, and Dosage.—This forms an astringent tincture, useful in *chronic diarrhœa*, *chronic dysentery*, etc. The dose is from ½ to 3 fluid drachms. It may be administered in some mucilage, sweetened water, or port wine.

TINCTURA CAULOPHYLLI COMPOSITA.—COMPOUND TINCTURE OF CAULOPHYLLUM.

SYNONYM: *Compound tincture of blue cohosh.*

Preparation.—Take of blue cohosh root, in fine powder, 2 ounces; ergot, water-pepper, in fine powder, each, 1 ounce; oil of savin, ½ fluid ounce; alcohol, 1½ pints, or a sufficient quantity. Add the powders to the alcohol, and form into tincture by maceration or percolation; adding, lastly, the oil of savin, the whole making 1½ pints of tincture.

Action, Medical Uses, and Dosage.—This forms an emmenagogue tincture, very useful in *amenorrhœa*, *dysmenorrhœa*, and other *uterine affections*. The dose is from 15 drops to 1 fluid drachm, 2 or 3 times a day.

TINCTURA CHIRATÆ (U. S. P.)—TINCTURE OF CHIRATA.

SYNONYM: *Tincture of chiretta.*

Preparation.—"Chirata, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Chirata.*) Dose, ½ to 2 fluid drachms.

TINCTURA CHLOROFORMI COMPOSITA.—COMPOUND TINCTURE OF CHLOROFORM.

Preparation.—"Take of chloroform, 2 fluid ounces; rectified spirit, 8 fluid ounces; compound tincture of cardamom, 10 fluid ounces. Mix."—(*British Pharmacopœia*, 1885).

Action, Medical Uses, and Dosage.—(See *Chloroformum.*) Dose, 10 to 60 drops, well diluted with water.

TINCTURA CHLOROFORMI ET MORPHINÆ.—TINCTURE OF CHLOROFORM AND MORPHINE.

Preparation.—"Take of chloroform, 1 fluid ounce; ether, 2 fluid drachms; rectified spirit, 1 fluid ounce; hydrochlorate of morphine, 8 grains; diluted hydrocyanic acid, ½ fluid ounce; oil of peppermint, 4 minims; liquid extract of liquorice, 1 fluid ounce; treacle, 1 fluid ounce; syrup, a sufficiency. Diffuse the hydrochlorate of morphine and oil of peppermint in the spirit, and add the chloroform and ether. Mix the liquid extract of liquorice and treacle with 3 fluid ounces of syrup, add this to the previously formed solution, mix them thoroughly, add the hydrocyanic acid, and increase the volume to 8 fluid ounces by further addition of syrup"—(*Br. Pharm.*, 1885).

This preparation contains in a 10-minim dose, chloroform, 1¼ minims; ether, ¼ minim; rectified spirit, 1¼ minims, morphine hydrochlorate, 1/48 grain; diluted hydrocyanic acid, 5/8 minim; oil of peppermint, 1/80 minim; and liquid extract of liquorice, 1¼ minims (also see *Related Compounds*, p. 1952).

Action, Medical Uses, and Dosage.—This agent is an anodyne, and may be used in various forms of *colic*, in *cough*, and *delirium tremens*. Dose, 10 to 60 minims.

Related Preparations.—Mistura Chloroformi et Opii (N. F.), *Mixture of chloroform and opium, Chloroform anodyne.* "Purified chloroform, 2 fluid ounces; oil of peppermint, 16 minims; tincture of Indian cannabis, 2 fluid ounces; tincture of quillaja (N. F.), 2 fluid ounces; fluid extract of belladonna, 128 minims; deodorized tincture of opium, 2¾ fluid ounces; tincture of capsicum, 1 fluid ounce; purified extract of glycyrrhiza, 240 grains; water, ½ fluid ounce; syrup, enough to make 16 fluid ounces. Triturate the purified extract of glycyrrhiza with the water and 1 fluid ounce of the syrup until it is dissolved. Mix the fluid extract of belladonna, deodorized tincture of opium and tincture of capsicum, and add them to the solution first prepared. Then mix the chloroform, oil of peppermint, tincture of Indian cannabis, and tincture of quillaja, and add them to the mixture. Finally, add enough syrup to make 16 fluid ounces, and mix the whole thoroughly together. This mixture should be shaken, whenever any of it is to be dispensed. Each fluid drachm represents 7½ minims of chloroform, 7½ minims of tincture of Indian cannabis, 3¾ minims of tincture of capsicum, 1 minim of fluid extract of belladonna, and about 1 grain of opium. *Note.*—This preparation is intended to fulfil the same purposes as the *Tinctura Chloroformi et Morphinæ* of the *British Pharmacopœia*, though the composition of the latter differs materially from that of the mixture above given"—(*Nat. Form.*).

Tinctura Chloroformi et Morphinæ Composita, *Compound tincture of chloroform and morphine.*—Take of "chloroform, 1½ fluid ounces (Imp.), or 75 cubic centimeters (Metric); morphine hydrochloride, 87½ grains, or 10 grammes; diluted hydrocyanic acid, 1 fluid ounce, or 50 cubic centimeters; tincture of capsicum, ½ fluid ounce, or 25 cubic centimeters; tincture of Indian hemp, 2 fluid ounces, or 100 cubic centimeters; oil of peppermint, 14 fluid ounces, or 1.5 cubic centimeters; glycerin, 5 fluid ounces, or 250 cubic centimeters; alcohol (90 per cent), a sufficient quantity. Mix the chloroform, tincture of capsicum, tincture of Indian hemp, oil of peppermint, and glycerin, with 9 fluid ounces of the alcohol, and dissolve the morphine hydrochloride in the mixture; add the diluted hydrocyanic acid; then mix with enough of the alcohol to form 1 pint (or 1000 cubic centimeters) of the compound tincture. Dose, 5 to 15 minims. This preparation contains in a 10-minim dose, ¾ minim of chloroform, ½ minim of diluted hydrocyanic acid, and $\frac{1}{11}$ grain of morphine hydrochloride; that is more than 4 times the proportion of morphine hydrochloride present in the corresponding preparation of the *British Pharmacopœia* of 1885"—(*Br. Pharm.*, 1898). (See also *Mistura Chloroformi et Cannabis Indicæ Composita* (N. F.), which is also called *Chloroform Anodyne.*)

TINCTURA CIMICIFUGÆ (U. S. P.)—TINCTURE OF CIMICIFUGA.

Synonyms: *Tincture of black snakeroot*, *Tincture of black cohosh*, *Tincture of actæa.*

Preparation.—"Cimicifuga, in No. 60 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This tincture may be used wherever black cohosh is indicated, as in *pulmonary*, *rheumatic*, *scrofulous*, *uterine*, *ophthalmic and neuralgic affections* (see *Cimicifuga*). The dose is 10 drops, gradually increased to 1 fluid drachm; if it affects the head or nervous system, the dose may be diminished (J. King).

TINCTURA CIMICIFUGÆ COMPOSITA.—COMPOUND TINCTURE OF CIMICIFUGA.

Synonym: *Compound tincture of black cohosh.*

Preparation.—Take of the tincture of black cohosh, 4 fluid ounces; tincture of bloodroot, 2 fluid ounces; tincture of poke-root, 1 fluid ounce. Mix together

Action, Medical Uses, and Dosage.—This is a valuable alterative and expectorant, and appears to exert a specific influence on the lungs, rendering the breathing easy, diminishing the frequency of the pulse, and the general excitability of the system. It is used in *pulmonary affections*, *hemoptysis*, *hepatic diseases*, *dyspepsia*, *laryngitis*, etc. The dose is from 10 drops to 1 fluid drachm, every 2 or 3 hours, according to the indications. A very slight degree of nausea produced and maintained by it, will be found to result in the most decided benefit (J. King).

TINCTURA CINCHONÆ (U. S. P.)—TINCTURE OF CINCHONA.

Synonyms: *Tincture of Peruvian bark, Tincture of yellow cinchona.*

Preparation.—"Cinchona, in No. 60 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs]; glycerin, seventy-five cubic centimeters (75 Cc) [2 fl℥, 257 ♏]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with six hundred and seventy-five cubic centimeters (675 Cc.) [22 fl℥, 396 ♏] of alcohol and two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water. Having moistened the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of the menstruum, macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, and pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of alcohol and water, made in the same proportions as before, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). If too weak in alcohol, this tincture precipitates cinchona-red, together with cinchona alkaloids, in combination with kinic acid. The change is, in a measure, prevented, or at least retarded, by the addition of glycerin. This addition was suggested by Mr. A. B. Taylor (1865), who, upon experimentation, showed that the best menstruum for this tincture was one composed of 2 parts of alcohol and 1 part, each, of water and glycerin. The tincture has a reddish-brown color.

Action, Medical Uses, and Dosage.—This tincture is commonly used as an adjuvant to other preparations of cinchona or of quinine. It may be given in doses varying from 1 fluid drachm to ½ fluid ounce. However, it is seldom used alone.

Related Tincture.—Tinctura Cinchonæ Detannata (N. F.), *Detannated tincture of cinchona.* "Fluid extract of cinchona (*U.S.P.*), one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl℥, 123 ♏]; alcohol, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; solution of tersulphate of iron (*U. S. P.*), three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl℥, 327 ♏]; water of ammonia (*U. S. P.*), three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl℥, 327 ♏]; water, diluted alcohol (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. To the water of ammonia, diluted with fifteen hundred cubic centimeters (1500 Cc.) [50 fl℥, 346 ♏] of water, gradually add the solution of tersulphate of iron, previously diluted with twenty-five hundred cubic centimeters (2500 Cc.) [84 fl℥, 257 ♏] of water, under constant stirring. Pour this mixture, containing ferric hydrate as a precipitate, upon a wet muslin strainer (which has been tared, after having been wetted and deprived of excess of water by moderate pressure), and, when the liquid has drained off, return the precipitate to the vessel, and mix it intimately with about four thousand cubic centimeters (4000 Cc.) [135 fl℥, 122 ♏] of water. Again drain it on the strainer, transfer it once more to the vessel, and treat it as before. Finally drain and press the precipitate on the strainer until it weighs five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 278 grs.]. Mix the fluid extract of cinchona with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol, and add the ferric hydrate, previously prepared. Agitate the mixture frequently, until the tincture is deprived of tannin, which may be known by the absence of a blackish-green color when a small portion of the clear tincture is treated with a drop or two of tincture of chloride of iron. Insert a plug of absorbent cotton into a suitable percolator, and introduce the mixture. As soon as the liquid has disappeared from the surface, pour on enough diluted alcohol to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation is practically identical, in strength of cinchona (without the tannin), with the official *Tinctura Cinchonæ*"—(*Nat. Form.*).

TINCTURA CINCHONÆ COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF CINCHONA.

Synonyms: *Compound tincture of Peruvian bark, Huxham's tincture of bark.*

Preparation.—"Red cinchona, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; bitter orange peel, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; serpentaria, twenty grammes (20 Gm.) [309 grs.]; glycerin, seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of alcohol and seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏] of water. Having mixed the cinchona, bitter orange peel, and serpentaria, reduce them to a fine (No. 60) powder. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of alcohol and water, made in the same proportions as before, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This aromatic tincture has a deep reddish-brown color, and an astringent, bitter taste. It is liable to precipitate, like tincture of cinchona, but this is, in a measure, retarded by the glycerin present.

Action, Medical Uses, and Dosage.—This tincture is an efficient stomachic bitters, and may be used wherever a mild tonic of this character is desired. The dose is 2 or 3 fluid drachms, or more.

Related Tinctures.—Tinctura Cinchonæ Composita, *Compound tincture of Peruvian bark.* The following is the old London formula modified by Prof. King: "Take of calisaya bark, in fine powder, 4 ounces; bitter orange peel, 3 ounces; Virginia snakeroot, in moderately fine powder, 6 drachms; saffron, in coarse powder, 2 drachms; cochineal, in fine powder, 1 drachm; good diluted alcohol, 20 fluid ounces, or a sufficient quantity"—(*Lond.*). Form it into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 20 fluid ounces of tincture. This tincture is generally known as *Huxham's tincture of bark.* Prof. King preferred brandy as the menstruum.

Tinctura Antiperiodica (N. F.), *Antiperiodic tincture*, *Warburg's tincture.*—I. *Without aloes.* "Rhubarb, thirty-six grammes (36 Gm.) [1 oz. av., 118 grs.]; angelica seed, thirty-six grammes (36 Gm.) [1 oz. av., 118 grs.]; elecampane, eighteen grammes (18 Gm.) [278 grs.]; saffron, eighteen grammes (18 Gm.) [278 grs.]; fennel, eighteen grammes (18 Gm.) [278 grs.]; gentian, nine grammes (9 Gm.) [139 grs.]; zedoary root, nine grammes (9 Gm.) [139 grs.]; cubeb, nine grammes (9 Gm.) [139 grs.]; myrrh, nine grammes (9 Gm.) [139 grs.]; white agaric, nine grammes (9 Gm.) [139 grs.]; camphor, nine grammes (9 Gm.) [139 grs.]; quinine sulphate, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; diluted alcohol (*U. S. P.*), a sufficient quantity to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. Reduce the fibrous vegetable drugs to a coarse (No. 20) powder, mix this with the myrrh and camphor, previously powdered, and digest the whole, during 12 hours, in a suitable, well-covered vessel, with forty-two hundred and fifty cubic centimeters (4250 Cc.) [143 fl℥, 140 ♏] of diluted alcohol, on a water-bath, avoiding, as much as possible, any loss of alcohol by evaporation. Then strain off the liquid with pressure, dissolve the quinine sulphate in the strained liquid, with a gentle heat, if necessary, filter, and pass enough diluted alcohol, first through the strainer and then through the filter, to make the product measure five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. Each fluid ounce contains 10 grains of quinine sulphate. *Note.*—This preparation, made *without aloes*, is intended to serve as a stock tincture, from which the regular 'Warburg's Tincture' is to be made, when required. 'Warburg's Tincture without Aloes' is also often prescribed or asked for, and in this case the above preparation is to be dispensed. The original formula directed by Dr. Warburg, contained the old *Confectio Damocratis* as one of the ingredients. The latter is a very complex preparation, many of the constituents being unobtainable at the present day. It has, therefore, been omitted. II. *With aloes.*—Extract of aloes (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; antiperiodic tincture, without aloes, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the extract in the tincture. *Note.*—When 'Warburg's Tincture,' without any further specification, is ordered, this preparation (containing aloes) is to be dispensed"—(*Nat. Form.*).

TINCTURA CINCHONÆ FERRATA.—FERRATED TINCTURE OF CINCHONA

Synonym: *Ferrated tincture of Peruvian bark.*

Preparation.—Take of the compound tincture of Peruvian bark, 1 pint; hydroxide of iron, recently precipitated, ½ ounce; ammonio-citrate of iron, 256 grains. To the compound tincture add the hydroxide, and digest until all the cinchotannin, whether pure, oxidized, or combined, is completely eliminated. Then filter, and wash the tannate and excess of oxide with boiling alcohol, to remove any trace of alkaloid which may have been precipitated with the tannin; this alcoholic solution may be evaporated to dryness, the product dissolved in a little water, acidulated with citric acid, and added to the filtered liquor along with the ammonio-citrate of iron (Samuel Simes).

Action, Medical Uses, and Dosage.—This forms an exceedingly agreeable and energetic invigorative, admirably adapted in the cases of weak and languid habits of children and females, where the body is in a pallid or flaccid state, and very susceptible of fatigue or morbid action. It does not solely depend on the quinine and iron it contains for its value as a curative agent; the grateful and by no means inefficient adjuvants, the orange peel, snakeroot, and other proximate principles of cinchona, independent of quinine, are by no means to be overlooked, and can not be replaced by salts of quinine and iron alone, however scientific their artificial combinations may appear. Each fluid ounce contains 16 grains of ammonio-citrate of iron. The dose is 1 or 2 fluid drachms, 3 or 4 times a day (Samuel Simes).

TINCTURA CINNAMOMI (U. S. P.)—TINCTURE OF CINNAMON.

Preparation.—"Ceylon cinnamon, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; glycerin, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [32 fl℥, 391 ♏]. Mix the glycerin with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol and two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water. Having moistened the powder with fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏] of the menstruum, pack it in a conical percolator, gradually pour on the remainder of the menstruum, and afterward more of a mixture of alcohol and water, made in the same proportions as before, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This aromatic tincture is of a reddish-brown color, and sweet in taste. If made with diluted alcohol, and without the presence of glycerin, it is liable to gelatinize. This the *U. S. P.* has attempted to avoid by the use of glycerin and alcohol.

Action, Medical Uses, and Dosage.—Tincture of cinnamon is an aromatic astringent, and may be used in *chronic diarrhœa*, *menorrhagia*, *uterine hæmorrhage*, and as an adjunct to other astringent solutions; 1, 2, or 4 fluid drachms, as required, may be administered for a dose, in sweetened or mucilaginous liquid.

Related Preparation.—TINCTURA AROMATICA (N. F.), *Aromatic tincture.* "Cinnamon (cassia), eighty-five grammes (85 Gm.) [3 ozs. av.]; ginger, thirty-six grammes (36 Gm.) [1 oz. av., 118 grs.]; galangal root, eighteen grammes (18 Gm.) [278 grs.]; cloves, eighteen grammes (18 Gm.) [278 grs.]; cardamom, eighteen grammes (18 Gm.) [278 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the drugs to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with a mixture of two (2) volumes of alcohol and one (1) volume of water, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of percolate are obtained. *Note.*—This preparation is practically identical with that which is official in the *German Pharmacopœia.* Galangal is the root of *Alpinia officinarum*, Hance"—(*Nat. Form.*). This tincture may be used for its stimulant and carminative effects in *flatulence*, etc.

TINCTURA CINNAMOMI COMPOSITA.—COMPOUND TINCTURE OF CINNAMON.

Preparation.—Take of cinnamon, finely powdered, 1 ounce; cardamom, prickly ash berries, ginger, finely powdered, of each, 3 drachms; diluted alcohol, 2 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, making 2 pints of tincture.

Action, Medical Uses, and Dosage.—This is a very warm and agreeable aromatic tincture, beneficial in *flatulence*, *debility*, or *spasm of the stomach*, and *chronic diarrhœa.* The dose is 1 or 2 fluid drachms, in sweetened water.

TINCTURA COCCI CACTI.—TINCTURE OF COCHINEAL.

Preparation.—"Take of cochineal, in fine powder, 2½ ounces (av.); proof-spirit, 1 pint. Macerate for 7 days in a closed vessel, with occasional agitation. Strain, press, filter, and add sufficient proof-spirit to make 1 pint (Imp.)"—(*Br. Pharm.*, 1885). Or, use diluted alcohol and form into a tincture by maceration, as explained under *Tincturæ*, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This tincture is calmative and antispasmodic, and may be given in *pertussis*, *asthma*, *hysteria*, and *nervous diseases*, in doses of from 20 drops to a fluid drachm. It is now chiefly employed for coloring (deep-red) various fluid mixtures, although a solution of 1 drachm of No. 40 carmine, in a mixture of glycerin (4 ounces), water (12 ounces), and ammonia water (sufficient quantity) is to be preferred for this purpose.

Other Coloring Tinctures.—Tinctura Persionis (N. F.), *Tincture of cudbear.* "Cudbear, in fine powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pack the cudbear in a suitable percolator, and percolate it with a mixture of one (1) volume of alcohol and two (2) volumes of water, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained. *Note.*—This preparation is intended as a coloring agent, when a bright-red tint or color is to be produced, particularly in acid liquids"—(*Nat. Form.*).

Tinctura Persionis Composita (N. F.), *Compound tincture of cudbear.*—"Cudbear, twenty grammes (20 Gm.) [309 grs.]; caramel, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Mix one (1) volume of alcohol with two (2) volumes of water. Macerate the cudbear with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of the menstruum, during 12 hours, agitating occasionally, and then filter through paper, and add the caramel, previously dissolved in one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏] of water. Then pass enough of the before-mentioned menstruum through the filter to make the whole measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation is intended as a coloring agent, when a brownish-red tint or color is to be produced"—(*Nat. Form.*).

TINCTURA COLCHICI COMPOSITA.—COMPOUND TINCTURE OF COLCHICUM.

Preparation.—Take of colchicum seed, in fine powder, 2 ounces; black cohosh root, in fine powder, 3 ounces; diluted alcohol, 2 pints, or a sufficient quantity. Form it into a tincture by maceration or percolation, and make 2 pints of tincture. Or, it may be made by adding together equal parts of the tinctures of colchicum seed and black cohosh root.

Action, Medical Uses, and Dosage.—This forms an excellent agent in *inflammatory rheumatism* and *gout*, and has proved a superior remedy in *phlegmasia dolens*, or the *swelled leg of parturient women*. The dose is from 10 to 60 drops, or more, as circumstances indicate, every 1, 2, 3, or 4 hours. Iodide of potassium, 15 grains to 1 ounce of the tincture, may frequently be added with advantage (J. King).

TINCTURA COLCHICI SEMINIS (U. S. P.)—TINCTURE OF COLCHICUM SEED.

Synonyms: *Tincture of colchicum*, *Tinctura colchici* (*U. S. P.*, 1880).

Preparation.—"Colchicum seed, in No. 30 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol and four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, macerate for 24 hours; then pack it moderately in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This produces a bitter, brown-yellow tincture, striking opalescent with water.

Action, Medical Uses, and Dosage.—This tincture may be used wherever colchicum is indicated. It is also employed as an external application in *gouty, neuralgic, and rheumatic pains*. The dose is from 30 drops, cautiously increased to 1 or 2 fluid drachms.

TINCTURA CONII.—TINCTURE OF HEMLOCK.

Preparation.—"Take of hemlock fruit, finely comminuted, 2½ ounces (av.); proof-spirit, 1 pint (Imp.)"—(*Br. Pharm.*, 1885). Prepare as directed for *Tinctura*

Sennæ. The *British Pharmacopœia* (1898) directs the use of conium fruit, recently reduced to No. 40 powder, 4 ounces (Imp.), and alcohol (70 per cent), a sufficient quantity to make 1 pint of tincture.

The juice of conium is considered a more effectual preparation than the preceding. The *U. S. P.* (1880) directed a percolated tincture of conium prepared practically as follows: Tinctura Conii, *Tincture of conium.* "Conium (fruit), in No. 30 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; diluted hydrochloric acid, four grammes (4 Gm.) [62 grs.]; diluted alcohol, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Moisten the powder with fifty grammes (50 Gm.) [1 oz. av., 334 grs.] of diluted alcohol, previously mixed with the diluted hydrochloric acid, and macerate for 24 hours; then pack it moderately in a conical glass percolator, and gradually pour diluted alcohol upon it, until one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.] of tincture are obtained"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Conium.*) Dose, 10 to 40 minims.

TINCTURA CORYDALIS.—TINCTURE OF CORYDALIS.

Synonym: *Tincture of turkey-corn.*

Preparation.—Take of the root of turkey-corn, in fine powder, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This forms an efficient alterative tonic, useful in all cases where simple tonics are indicated, and highly beneficial in *syphilitic and scrofulous affections* (see *Corydalis*). The dose is from 20 drops to 2 fluid drachms, 3 or 4 times a day.

TINCTURA CORYDALIS COMPOSITA.—COMPOUND TINCTURE OF CORYDALIS.

Synonym: *Scudder's alterative.*

Preparation.—Take of the roots of turkey-corn, yellow dock, bark of tag alder, and leaves and roots of figwort, each, in fine powder, 1 troy ounce; alcohol, a sufficient quantity. Form into a tincture by percolation, and after 10 fluid ounces have percolated through, add water, a sufficient quantity, until 19 fluid ounces of tincture have been obtained.

To mandrake root in fine powder, 1 troy ounce; add boiling water, 4 fluid ounces, and allow it to macerate in a hot place for 2 hours; then express, or obtain 4 fluid ounces of infusion, to which add white sugar, 4 troy ounces. To the syrup thus prepared, add the preceding tincture, and make 24 fluid ounces of the preparation. Prof. Scudder aimed in this preparation to obtain the alterative constituents of podophyllum, free or nearly so, of the cathartic resin.

Action, Medical Uses, and Dosage.—This is an excellent alterative, prepared according to Prof. Scudder's formula. He believed that water extracted more of the alterative properties of mandrake than alcohol. It has been employed with advantage in *scrofula, syphilis, cutaneous diseases, hepatic affections*, in *glandular affections* where there is a tendency to hypertrophy and suppuration, and in other cases where an alterative is required. The dose is from 1 fluid drachm to ½ fluid ounce, 3 or 4 times a day (J. King).

TINCTURA COTO (N. F.)—TINCTURE OF COTO.

Preparation.—"Coto bark, bruised, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Macerate the coto with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of alcohol during 7 days; then pour off the liquid, press the residue, and filter the united liquids through paper. Lastly, wash the residue transferred to the filter with enough alcohol to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—Coto bark is derived from an undetermined tree, probably belonging to the natural order Lauraceæ, and is obtained from Bolivia. There are two varieties known, one as 'coto,' and the other as 'para-coto' bark. True coto bark is, at times, difficult to obtain in the market, and the para-coto bark is then frequently substituted for it. While they possess some useful properties in common, yet they differ materially in other respects. Hence, the para-coto bark should not be substituted for the true coto bark"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Coto.*) Dose, 1 to 2 fluid drachms.

TINCTURA CROCI (U. S. P.)—TINCTURE OF SAFFRON.

Preparation.—"Saffron, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the saffron with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture preserves the saffron characteristics and is of a beautiful orange-yellow color.

Action, Medical Uses, and Dosage.—(See *Crocus.*) Sometimes used to color medicinal preparations. Dose, 1 to 2 fluid drachms.

TINCTURA CUBEBÆ (U. S. P.)—TINCTURE OF CUBEB.

Synonym: *Tincture of cubebs.*

Preparation.—"Cubeb, in No. 30 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Formerly, tincture of cubeb was a comparatively weak preparation, but the present official tincture has been increased to double the strength of the 1880 preparation. Diluted alcohol was formerly used, but as this but imperfectly extracted the oil and resin, stronger alcohol was substituted which better dissolved these bodies. The tincture has a green-brown color, and when added to water produces a milky turbidity.

Action, Medical Uses, and Dosage.—(See *Cubeba.*) Dose, 10 drops to 2 fluid drachms.

TINCTURA DIGITALIS (U. S. P.)—TINCTURE OF DIGITALIS.

Synonym: *Tincture of foxglove.*

Preparation.—"Digitalis, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Care should be exercised in the selection of digitalis. The resulting tincture has the odor of the drug, a bitter taste, and a greenish-brown color.

Action, Medical Uses, and Dosage.—This preparation possesses the virtues of foxglove, and affords an excellent mode of exhibiting that drug (see *Digitalis*). The dose is from 1 to 20 drops, 2 or 3 times a day, and increased, if required, with much care.

TINCTURA ERGOTÆ.—TINCTURE OF ERGOT.

Synonym: *Tinctura secale cornuti.*

Preparation.—"Take of ergot, finely comminuted, 5 ounces (av.); proof-spirit, 1 pint (Imp.). Prepare as directed for *Tinctura Sennæ*"—(*Br. Pharm.*, 1885).

Action, Medical Uses, and Dosage.—This tincture may be used in all cases where the action of ergot is indicated or desired. The dose is 10 drops to 2 fluid drachms.

Related Preparation.—TINCTURA ERGOTÆ AMMONIATA, *Ammoniated tincture of ergot.* Take of "ergot, in No. 20 powder, 5 ounces (Imp.), or 250 grammes (Metric); solution of ammonia, 2 fluid ounces, or 100 cubic centimeters; alcohol (60 per cent), a sufficient quantity. Mix the solution of ammonia with 18 fluid ounces (or 900 cubic centimeters) of the alcohol; moisten the powder with 2 fluid ounces (or 100 cubic centimeters) of this mixture, and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add enough of the alcohol to form 1 pint (or 1000 cubic centimeters) of the tincture. Set aside for 24 hours; filter. Dose, ½ to 1 fluid drachm"—(*Br. Pharm.*, 1898).

TINCTURA FERRI ACETATIS.—TINCTURE OF ACETATE OF IRON.

Preparation.—Take of sulphate of iron, 8 ounces; distilled water, ½ pint; pure sulphuric acid, 6 fluid drachms; pure nitric acid, ½ fluid ounce; acetate of potassium, 8 ounces; rectified spirit, ½ gallon. (The above weights are avoirdupois, and the measures Imperial.) To 9 fluid ounces of the water, add the sulphuric acid, and in the mixture, with the aid of heat, dissolve the sulphate of iron. Add next the nitric acid, first diluted with the remaining fluid ounce of water, and evaporate the resulting solution to the consistence of a thick syrup. Dissolve this in 1 quart (2 pints, Imp.), and the acetate of potassium in the remainder of the spirit, and, having mixed the solutions, and shaken the mixture repeatedly in a large bottle, let the whole be thrown upon a calico filter. When any further liquid ceases to trickle through, subject the filter, with its contents, to expression, and, having cleared the turbid tincture thus procured by filtration through paper, let it be added to that already obtained. The specific gravity of this tincture is 0.891 (*Dub.*).

"Take of strong solution of acetate of iron, 5 fluid ounces; acetic acid, 1 fluid ounce; rectified spirit, 5 fluid ounces; distilled water, 9 fluid ounces. Mix, and then add sufficient distilled water to make 1 pint. Preserve in a stoppered bottle"—(*Br. Pharm.*, 1885; not in that of 1898).

In the first formula, by the mutual action of sulphate of iron, sulphuric acid, and nitric acid, a solution of ferric sulphate is obtained. This is decomposed by the acetate of potassium, the products being ferric acetate and potassium sulphate; the former remains in the liquid, the latter is precipitated. Tincture of acetate of iron is a transparent, claret-colored tincture, having a strong, chalybeate taste.

Action, Medical Uses, and Dosage.—This is tonic and astringent, and, besides its internal administration as a chalybeate, it forms an excellent vaginal enema for *leucorrhœa*, when properly diluted with water. It is one of the best of internal styptics. Following the indications given below, it will be found an admirable remedy in diseased conditions requiring an acid preparation of iron other than that containing hydrochloric acid. Thus it proves useful in *female diseases*, the *prostration of typhoid and other adynamic fevers*, *scurvy*, *low cachectic states*, *constitutional syphilis*, and *anemic conditions*. The dose of it is from 10 drops to 1 fluid drachm, given in a sufficient quantity of water, the smaller doses (1 to 10 drops) being preferred for specific effects.

Specific Indications and Uses.—Pale, transparent skin; bluish coloration of tissues; blueness of veins; dull, heavy pain in back of head.

TINCTURA FERRI CHLORIDI (U. S. P.)—TINCTURE OF FERRIC CHLORIDE.

"A hydro-alcoholic solution of ferric chloride (Fe_2Cl_6 = 323.98) containing about 13.6 per cent of the anhydrous salt, and corresponding to about 4.7 (4.69) per cent of metallic iron"—(*U. S. P.*).

SYNONYMS: *Tinctura ferri sesquichloridi*, *Tincture of chloride of iron*, *Tincture of perchloride of iron*, *Tincture of muriate of iron*, *Tinctura ferri muriatis*, *Muriated tincture of iron.*

Preparation.—"Solution of ferric chloride, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the solution with enough alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Let the tincture stand, in a closely-covered vessel, at least 3 months; then transfer it to glass-stoppered bottles, and keep it protected from light"—(*U. S. P.*). When this mixture is allowed to stand, a variety of reactions take place; the alcohol reduces ferric chloride to ferrous chloride, very markedly so in direct sunlight (see experiments, by M. W. Coleman, in *Amer. Jour. Pharm.*, 1883, p. 387). Free chlorine is also formed when the tincture is exposed to sunlight, and this element, acting upon the alcohol, forms ethereal chlorine compounds. The aqueous solution of ferric chloride is permanent.

This tincture is a "bright, brownish liquid, having a slightly ethereal odor, a very astringent, styptic taste, and an acid reaction. Specific gravity about 0.960 at 15° C. (59° F.)"—(*U. S. P.*). It stains white paper yellow, and has an odor of hydrochloric ether. On exposure to the air, a small deposit of iron compound may take place, slightly diminishing the strength of the tincture, but a small quantity of hydrochloric acid added will redissolve this deposit. When the tincture is evaporated, a dark orange-colored residue is obtained, which is hardly crystallizable and is deliquescent. Tincture of chloride of iron is incompatible with vegetable astringent infusions, gum Arabic solution, alkalies and their carbonates.

Tests.—"The tincture yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S. After the tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferricyanide T.S., showing the presence of some ferrous salt, due to reduction. If the iron be completely precipitated from a portion of the tincture by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or dark-colored precipitate with hydrogen sulphide T.S. (absence of zinc or copper), nor should it leave a fixed residue on evaporation and gentle ignition (absence of salts of the fixed alkalies). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute portion of the tincture, the crystal should not become colored brown, nor should there be a brownish-black zone developed around it (absence of nitric acid). On diluting 1 Cc. of the tincture with water to 12 Cc., and boiling, the liquid should remain clear (absence of oxychloride). If 1.12 (1.1176) Gm. of the tincture be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 9.4 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Tincture of chloride of iron is tonic, alterative, diuretic, astringent, and restorative. (For the general uses of iron, see *Ferrum*.) This agent is one of the strongest of the iron preparations, and is to be used chiefly in atonic conditions. Large doses of it are apt to disorder the stomach. However, it has been shown that small doses of chalybeates are preferable to large doses. In administering this agent, it is well to give it through a glass tube, avoiding, as much as possible, contact with the teeth, and afterward rinsing the mouth with sodium bicarbonate solution, unless a local effect upon the tissues of the mouth and throat is the object sought. The specific indications should be closely followed to give good results. The deep-red coloration of mucous tissues, and deep-red color in local diseases, are the direct indications to its use. Sometimes the coloration is so deep as to appear a solid blue, and there may be dull pain in the back of the head. When the trouble is located in the mucous tissues, as in diphtheria and other disorders, the local manifestations of which are in the mouth or throat, the tongue, fauces, and pharyngeal vault are somewhat full, and have a deep-red, glistening, erysipelatoid appearance. Tincture of chloride of iron has long been given in *anemia*, and the train of disorders depending upon such a condition. It is particularly valuable in the anemia following great loss of blood, the quality of the blood not being specially impaired, but the quantity deficient. It is also of great value when anemia is progressive, and due to alteration in the red blood corpuscles, or when the result of prolonged disease. It is frequently a valuable chalybeate in *chlorotic anemia*. As a tonic, it is very useful in *scrofula, rachitis, tabes mesenterica, extensive ulcerative or suppurative processes*, with *colliquative sweating* and *hectic fever, tabes dorsalis, asthenic dropsies*, from loss of blood, and in *amenorrhœa*, with anemia. *Leucorrhœa*, with anemia, *gonorrhœa* (latter stages), *gleet, retention of urine from spasmodic stricture* (10 drops, frequently repeated), *chronic mucous discharges from the urinary organs, dysuria, irritability of the bladder*, in females especially, *diabetes*, and in the *diarrhœa of phthisis and low forms of fevers* it is a useful drug. The dose in these disorders should be from 10 to 20 drops, in plenty of water, 2 or 3 times a day.

This agent is of great value in *passive hemorrhage* from bladder and kidneys (5 drops every 3 hours). It has been employed in *post-partum hemorrhage*, but is not equal to ergot and cinnamon. In *phthisis*, it checks hemorrhage, diarrhœa, profuse expectoration, and lessens night sweats. In *chronic dysentery* and *chronic cholera infantum*, with marked relaxation, it has sometimes proved serviceable. It sometimes relieves the *dysmenorrhœa* of anemic subjects. In genito-urinary disorders, it is contraindicated, as a rule, by *active* inflammation. Some prefer the ethereal tincture (see *Related Tinctures*) in renal disorders, and the dose is much smaller (3 to 5 drops).

In urinary affections, tincture of iron is frequently combined with uva ursi, buchu, or opium. In *pyelitis*, it lessens the quantity of pus, and, by its diuretic action, tends to lessen the danger of dropsy. In *chronic nephritis*, with *albuminuria*, it is a very important remedy, as it is in the latter stage of *scarlatina*, with albumen in the urine. In *chronic ague*, tincture of iron may be given in conjunction with antiperiodics, if anemia is present. Tincture of iron has long been regarded as an efficient agent in *diphtheria*. The tissues are swollen and deep-red. It is often combined as follows: ℞ Tincture of chloride of iron, flʒj; potassium chlorate, grs. xv; water, fl℥ii. From ½ to 1 teaspoonful, every 2 hours, according to age of child. A gargle of the diluted tincture may also be used. Tincture of iron is often of service in disorders produced by the absorption of septic material. It sustains strength, and is often antagonistic to the poison itself.

The most direct specific results from this agent have been obtained in the treatment of *erysipelas*. It is not the remedy for all cases, but for those showing a deep-red, glistening surface, and having but a moderate amount of burning, and showing deep-redness of tongue. In these cases it reduces fever, allays pain and inflammation, increases the urinary flow, cleans the tongue, and gives rest. From 5 to 30 drops, well diluted, should be given every ½ hour, and the surface should be painted with the pure tincture, or the tincture diluted with glycerin (Scudder). Prof. Locke advises the following for local use: ℞ Tincture of chloride of iron, flʒss; glycerin, flʒjss. Mix. Paint upon the parts and cover with cotton. As a general tonic, after severe *gastric, nervous, malarial*, or other *debilitating diseases*, the following combination has been advised: ℞ Tincture of chloride of iron, flʒiii; diluted phosphoric acid, flʒiv; glycerin, fl℥i; simple elixir, q.s. to make fl℥iii. Mix. Sig. One teaspoonful, in water, every 2 or 3 hours (Ellingwood).

"Externally, it has proved useful in destroying *venereal warts*, and is one of the best applications that can be applied to a *venereal chancre;* in this last, it should be applied by means of a feather, and a piece of lint, moistened with it, should be kept in constant contact with the surface of the ulcer. As an application to chancre, it is the only one that I have made for the last 28 years (except the nitric acid during its pustular stage), and is, in my opinion, decidedly the best local remedy for this kind of ulcer that can be used. Occasionally, it causes severe pain, when it should be diluted with as little water as possible; but, in the majority of instances, after the first or second application, patients hardly notice it. It keeps the chancre clean, its surface soft, and changes the poisonous character of the virus, so that its absorption is followed by no bad result. As the chancre soon becomes so changed, by the use of this tincture, that it is frequently difficult to detect it from the healthy surrounding integuments, the practitioner must be careful not to be misled by this appearance, and cease his internal treatment too soon. I have used this tincture, as above named, since the year 1836, and, as far as I know, am the first one in the profession who employed it in this manner, or made its value known in the above diseases" (J. King). Diluted with water, tincture of iron may be used as a stimulating dressing for *sluggish ulcers*, and to reduce *excessive granulations*.

Specific Indications and Uses.—Erysipelatous redness, with glistening surfaces, deep-redness of mucous tissues, approaching a solid blue in color; dull pain in back of head; swollen, reddened tissues.

Related Tinctures.—TINCTURA FERRI CHLORIDI ÆTHEREA (N. F.), *Ethereal tincture of chloride of iron, Bestucheff's tincture, Lamotte's drops.* "Solution of chloride of iron (*U. S. P.*), forty-five cubic centimeters (45 Cc.) [1 fl℥, 250 ♏]; ether (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the solution of chloride of iron with six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol, add the ether, and lastly, enough alcohol to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Introduce the tincture into bottles made of white (flint) glass, which should not be entirely filled. Cork them tightly, and expose them to the rays of the sun, until the tincture has been completely decolorized. Then remove the bottles to a shady place, and open them occasionally, until the contents have again assumed a yellow color. Lastly, transfer the tincture to bottles, which should be well stoppered and kept in a cool and dark place. Each fluid drachm represents about ½ grain of metallic iron. *Note.*—This preparation is practically identical with that official in the *German Pharmacopœia*"—(*Nat. Form.*). Dose, 1 to 10 minims, well diluted.

TINCTURA FERRI CITRO-CHLORIDI (N. F.), *Tincture of citro-chloride of iron, Tasteless tincture of chloride of iron, Tasteless tincture of iron.*—"Solution of chloride of iron (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; sodium citrate, four hundred and sixty grammes (460 Gm.) [16 ozs. av., 99 grs.]; alcohol, one hundred and sixty cubic centimeters (160 Cc.) [5 fl℥, 197 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the solution of chloride of iron with two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water, and dissolve in this mixture the sodium citrate, with the aid of a gentle heat. Then add the alcohol, and, when the solution has become cold, make up the volume with water to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Set the product aside in a cold place for a few days, if convenient, so that the excess of saline matter may separate. Then filter, and pass enough cold water through the filter to restore the original volume. Each fluid drachm contains an amount of iron equivalent to about 7½ grains of dry chloride of iron (ferric). *Note.*—This preparation is practically identical in the strength of iron, but not in the quantity of alcohol, with the official *Tinctura Ferri Chloridi*"—(*Nat. Form.*).

TINCTURA FERRI POMATA (N. F.), *Tincture of ferrated extract of apples. Tinctura ferri malatis crudi, Tincture of crude malate of iron.*—"Ferrated tincture of apples (F. 156), one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, one hundred cubic centimeters (100 Cc. [3 fl℥, 183 ♏]; cinnamon water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the ferrated extract of apples in seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of cinnamon water, add the alcohol, filter, and pass enough cinnamon water through the filter to make one thousand cubic centimeters (33 fl℥, 391 ♏]. Each fluid drachm represents about ⅜ grain of metallic iron. *Note.*—This preparation is practically identical with that official in the *German Pharmacopœia*"—(*Nat. Form.*).

Other Iron Preparations.—FERRATIN. This is an organic preparation of iron, the natural ferruginous element of all food (animal and vegetable) deposited in the liver and other organs of the body, "as reserve iron for blood formation," discovered and introduced by Prof. Schmiedeberg, of Strassburg. It is a reddish powder, without odor or taste, prepared by exposing a mixture of albumen and tartrate of iron to a slight heat in the presence of an alkali. It does not readily dissolve in water, but is rendered soluble by the addition of sodium bicarbonate. It contains about 7 per cent of iron, is absorbed to the extent of 20 per cent (Marfori, and others), and has the advantage over other iron salts in that they must first be converted into ferratin before being assimilated. Scarcely any of the salt, when taken, is eliminated by the kidneys or bowels. It is a blood food, for administration when the proportion of red blood corpuscles is unduly low, as in *anemia*, *chlorosis*, *nervous affections*, *heart and kidney diseases*, and *convalescence from acute diseases*. Ferratin is a specialty of C. F. Boehringer & Soehne, of New York City.

FERRO-SALICYLATA.—This specialty of the Wm. S. Merrell Chemical Co., of Cincinnati, Ohio, contains salicylic acid (from oil of wintergreen), tincture of chloride of iron, in tasteless form, and ammonium citrate. This agent is used in *acute rheumatism*, especially the articular variety, and in persons of delicate or anemic habit, and in those poorly-nourished and broken down in general health.

TINCTURA GALLÆ (U. S. P.)—TINCTURE OF NUTGALL.

SYNONYM: *Tincture of galls.*

Preparation.—"Nutgall, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters

(1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of alcohol. Pack the powder, without moistening it, in a conical glass percolator; then gradually pour upon it the menstruum, and, afterward, alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This is a powerfully astringent, yellow-brown tincture, acid to test paper. With ferric compounds it strikes a blue-black color. The formation of gallic acid is retarded by the glycerin.

Action, Medical Uses, and Dosage. (See *Galla.*) Dose, ½ to 2 fluid drachms. Employed chiefly externally as an astringent.

TINCTURA GELSEMII (U. S. P.)—TINCTURE OF GELSEMIUM.

SYNONYM: *Tincture of yellow jessamine.*

Preparation.—"Gelsemium, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Or, take of the fresh root of yellow jessamine, cut into small pieces, 4 troy ounces; diluted alcohol, 1 pint. Macerate for 14 days; express and filter. This forms a tincture of a beautiful violet tint; it has a peculiar odor, somewhat resembling that of new honey, and a faint, peculiar, not unpleasant taste.

The official tincture has the bitter taste and nauseous odor of gelsemium, and is of a brownish-yellow color. It renders water milky. Gelsemium tincture has been found of greatest therapeutic efficiency in Eclectic medicine when prepared from the green root. Therefore the second formula is to be preferred to the official process.

Action, Medical Uses, and Dosage.—This tincture possesses the active properties of the root, and may be given as a febrifuge in *intermittent, remittent, typhus, typhoid*, and many other *fevers;* it is likewise beneficial in *neuralgia, nervous headache, toothache*, etc. And combined with tincture of cimicifuga, or tincture of colchicum, it proves decidedly efficient in *rheumatism* and *gout*. In *rigidity of the os uteri* (with thin, sharp edges), *puerperal convulsions, puerperal peritonitis*, and *painful dysmenorrhœa*, I consider this among the best agents in the materia medica. I have employed it in all these various conditions, and with the most marked success. It is, in most cases, preferable to lobelia as a relaxant, when the cervix is thin, sharp, and rigid, as it does not occasion any nausea or vomiting. Lobelia is applicable when the cervix is full, thick, and rigid. To one young lady laboring under a most agonizing *dysmenorrhœa*, I administered a teaspoonful of the tincture every ½ hour for 4 hours, before it produced its influence upon her; after which smaller doses sufficed to maintain its effect, and she suffered no further pain during the menstruation. While it produces a relaxation of the rigid os uteri, it seems to exert an influence on the uterine contractility, promoting the action of the organ. The dose of the tincture of gelsemium is from 5 drops to ½ fluid drachm, according to circumstances, and the urgency of the case. The dose of a fluid drachm is seldom required and should be used with extreme caution. The effects of an overdose may be removed by holding aqua ammoniæ to the nostrils, with the internal administration of stimulants (J. King).

TINCTURA GENTIANÆ COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF GENTIAN.

Preparation.—"Gentian, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; bitter orange peel, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; cardamom, ten grammes (10 Gm.) [154 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the gentian, orange peel, and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix alcohol and water in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol to four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of menstruum, macerate for 24 hours; then pack it in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This produces a bitter, brown-yellow tincture having a pleasant aromatic odor.

Action, Medical Uses, and Dosage.—An aromatic, bitter, and stomachic; inferior, however, to the preparation of same name given below. Dose, 30 to 120 drops.

Related Tincture.—Tinctura Gentianæ Composita, *Compound tincture of gentian.* Take of gentian, colombo, swamp milkweed, rhubarb, prickly-ash berries, sassafras, each, 1 ounce; good French brandy, 4 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 4 pints of tincture. This is a mild aperient, stimulant, and tonic, and is especially adapted to children with *debilitated stomachs* or *disordered condition of the digestive organs*, after the administration of anthelmintics for the removal of *worms*, and during convalescence from exhausting diseases, as *summer complaint*, *diarrhœa*, *dysentery*, *fevers*, etc. The dose is from 10 drops to 1 teaspoonful, 3 or 4 times a day, in sweetened water (J. King).

Tinctura Amara (N. F.), *Bitter tincture, Stomachic tincture, Bitter stomachic drops, Stomach drops.*—"Gentian, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; centaury, herb, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; bitter orange peel, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; orange berries, seventeen grammes (17 Gm.) [262 grs.]; zedoary, root, seventeen grammes (17 Gm.) [262 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the drugs to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with a mixture of 2 volumes of alcohol and 1 volume of water, until one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏] of percolate are obtained. *Note.*—Centaury is the herb of *Erythræa Centaurium*, Persoon. Orange berries are the unripe fruit of *Citrus vulgaris*, Risso, collected while small. Zedoary is the rhizome of *Curcuma Zedoaria*, Roscoe. The product obtained by the above formula is practically identical with that which is official in the *German Pharmacopœia*"—(*Nat. Form.*).

TINCTURA GUAIACI (U. S. P.)—TINCTURE OF GUAIAC.

Synonym: *Tincture of guaiacum.*

Preparation.—"Guaiac, in coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powder with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, and macerate, for 7 days, in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This tincture is used in *gout*, *rheumatism*, *dysentery*, *amenorrhœa*, and *dysmenorrhœa* (see *Guaiacum*). The dose is from 1 to 3 fluid drachms, 3 or 4 times a day, given in mucilage, milk, or sweetened water.

Related Tinctures.—Dewees' Tincture of Guaiacum (*Tinctura guaiaci alkalini*), recommended in *suppression of the menses* and *dysmenorrhœa*, is made as follows: Take of the best guaiac, in powder, 4 ounces; carbonate of sodium or potassium, 1½ drachms; pimenta, in powder, 1 ounce; diluted alcohol, 1 pound. Digest for a few days. Dose, a teaspoonful, 3 times a day, to be gradually increased, if necessary (Dewees, on *Diseases of Females*, 1826, p. 81). Or, as modified by the *National Formulary*:

Tinctura Guaiaci Composita (N. F.), *Compound tincture of guaiac, Dewees' tincture of guaiac.*—"Guaiac (*U. S. P.*), one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; potassium carbonate, six grammes (6 Gm.) [93 grs.]; pimenta, in moderately fine powder, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; pumice, in fine powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; alcohol, four hundred and thirty-five cubic centimeters (435 Cc.) [14 fl℥, 340 ♏]; water, four hundred and thirty-five cubic centimeters (435 Cc.) [14 fl℥, 340 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the guaiac and potassium carbonate with the pimenta and the pumice, and afterward gradually with the alcohol. Next add slowly four hundred and thirty-five cubic centimeters (435 Cc.) [14 fl℥, 340 ♏] of cold water, and triturate the mixture thoroughly. Then filter, and pass enough diluted alcohol through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 7½ grains of guaiac"—(*Nat. Form.*).

Tinctura Guaiaci Aromatica, *Aromatic tincture of guaiacum, Greenhow's cholera mixture.* Take of guaiacum, cloves, and cinnamon, each, in moderately fine powder, 1 ounce; brandy, 2 pints. Macerate for 14 days; then filter. This tincture is an excellent aromatic stimulant, astringent, and diaphoretic. It was extensively used in Cincinnati, by practitioners, during the *cholera* of 1849-50-51, and with excellent effect. The late Prof. T. V. Morrow, M. D., considered it as one of the best agents in the treatment of that disease. The dose is from a teaspoonful to a tablespoonful, in sweetened water, every 15 or 20 minutes, until relief is obtained The addition of an ounce of prickly ash berries to this tincture will materially enhance its efficacy (J. King).

Tinctura Antacrida (N. F.), *Antacrid tincture, Dysmenorrhœa mixture, Fenner's guaiac mixture.* "Corrosive chloride of mercury, five and one-half grammes (5.5 Gm.) [85 grs.]; guaiac (*U. S. P.*), in fine powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; Canada turpentine, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; oil of sassafras, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Introduce the guaiac and the Canada turpentine into a flask, together with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol, cork the flask loosely, and heat the contents, on a water-bath, slowly to boiling. Then cool the flask, and filter the contents through a small filter. Dissolve the corrosive chloride of mercury in thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of alcohol, and add this solution, as well as the oil of sassafras, to the filtrate. Lastly, pass enough alcohol through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm contains nearly ⅓ grain of corrosive chloride of mercury. *Note.*—The dose of this preparation is about 10 to 20 minims"—(*Nat. Form.*).

TINCTURA GUAIACI AMMONIATA (U. S. P.)—AMMONIATED TINCTURE OF GUAIAC.

Synonym: *Tinctura guaiaci composita.*

Preparation.—"Guaiac, in coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; aromatic spirit of ammonia, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powder with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of aromatic spirit of ammonia, and macerate for 7 days, in a closed vessel; then filter through paper in a well-covered funnel, and add, through the filter, aromatic spirit of ammonia, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture resembles simple tincture of guaiac, except that it possesses the taste and odor of ammonia.

Action, Medical Uses, and Dosage.—(See *Guaiacum.*) This tincture is extensively employed, locally and internally, to abort *acute tonsilitis.* It may be given in drachm doses, in milk, emulsion, or white wine.

TINCTURÆ HERBARUM RECENTIUM (U. S. P.)—TINCTURES OF FRESH HERBS.

"These tinctures, when not otherwise directed, are to be prepared by the following formula: Take of the fresh herb, bruised or crushed, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; alcohol, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Macerate the herb with the alcohol for 14 days; then express the liquid and filter"—(*U. S. P.*).

This formula was introduced to insure, as nearly as possible, uniformity in the preparation of these tinctures. It is particularly adapted to drugs holding volatile or evanescent constituents, which are dissipated upon exposure in drying. Tinctures of rhus, gelsemium, thuja, salix nigra aments, pulsatilla, etc., may be prepared in this way. Homœopathic tinctures, introduced by Hahnemann, are of this character. The following are the general directions for preparing Mother Tinctures:

"Homœopathic mother tinctures are prepared: (1) By expressing the juice from freshly-gathered plants, and mixing that juice with an equal bulk of alcohol, allowing it to stand 8 days in a dark, cool place, and finally filtering the product; (2) by mixing 2 parts of alcohol with 3 parts of the comminuted plant, straining the liquid through new muslin, and proceeding further as above directed; (3) by taking 2 parts of alcohol to 1 part of the comminuted plant and macerating them together for 8 days in a well-filled bottle, and lastly, decanting, straining, and filtering; (4) by taking alcohol, 5 parts, to the comminuted drug (vegetable or animal), 1 part, macerating 8 days, shaking twice daily, and lastly, decanting, straining, and filtering the product" (Locke's *Syl. of Mat. Med.*),

TINCTURA HUMULI (U. S. P.)—TINCTURE OF HOPS.

Preparation.—"Hops, well dried, and in No. 20 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture possesses the odor and taste of hops, and has a yellow-brown color. On account of the bulky character of hops, they must be first reduced to powder. In order to do this, they must be air-dried (not artificially), and then rubbed in a mortar with sand, which will effectually accomplish their comminution. Drying somewhat diminishes the activity of hops. A tincture of lupulin is more uniform in character than this preparation.

Action, Medical Uses, and Dosage.—(See *Humulus.*) Dose, ½ to 3 fluidrachms.

TINCTURA HYDRASTIS (U. S. P.)—TINCTURE OF HYDRASTIS.

SYNONYM: *Tincture of golden seal.*

Preparation.—"Hydrastis, in No. 60 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture may also be made by maceration. It has a brownish-yellow color, and the characteristic bitter taste of golden seal.

Action, Medical Uses, and Dosage.—This tincture is tonic, and will be found beneficial in *chronic gastric affections*, *hepatic diseases*, *chronic diarrhœa*, and *general debility*. Diluted and applied locally, it forms an efficient remedy in *leucorrhœa* and *ophthalmia*. The dose is from 10 to 60 drops, 2 or 3 times a day, in water (J. King).

TINCTURA HYDRASTIS COMPOSITA.—COMPOUND TINCTURE OF HYDRASTIS.

SYNONYM: *Compound tincture of golden seal.*

Preparation.—Take of golden seal root, lobelia seed, each, in moderately fine powder, 2 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture. Or, it may be made by adding together equal parts of the tinctures of golden seal and lobelia.

Action, Medical Uses, and Dosage.—(See uses of *Lobelia* and *Hydrastis.*) This is a valuable application to diseased mucous surfaces. It is highly recommended in *chronic catarrh*, to be snuffed up into the nostrils, or applied by means of a camel's-hair pencil. It is also useful, when diluted with water, in *chronic ophthalmic diseases* (J. King).

TINCTURA HYOSCYAMI (U. S. P.)—TINCTURE OF HYOSCYAMUS.

Preparation.—"Hyoscyamus, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture is greenish-brown in color, and possesses the characteristic bitter taste and narcotic odor of the crude drug.

Action, Medical Uses, and Dosage.—(See *Hyoscyamus.*) This tincture is sedative and soporific, and is frequently used in cases where opium does not agree, or where its constipating effects are not desired. Sometimes tincture of henbane purges; when this is the case, a small portion of laudanum may be added to it. The dose is from ½ to 1 fluid drachm.

TINCTURA HYPERICI.—TINCTURE OF HYPERICUM.

Synonym: *Tincture of St. John's wort.*

Preparation.—Take of the blossoms of St. John's wort (recent), 5 ounces; alcohol, 1 pint. Macerate for 14 days; express and filter.

Action, Medical Uses, and Dosage.—This tincture may be used to fulfil the indications of the plant, but its principal use is as a local application to *wounds, bruises, ulcers, swellings, tumors, ecchymoses*, etc. As a local application, it is equal to arnica. The dose internally, is from ½ to 1 fluid drachm.

TINCTURA IGNATIÆ (N. F.)—TINCTURE OF IGNATIA.

Synonym: *Tincture of St. Ignatius' bean.*

Preparation.—"Ignatia, in No. 60 powder, ten grammes (10 Gm.) [154 grs.]; alcohol, water, of each, a sufficient quantity. Mix alcohol and water in the protion of eight (8) parts, by weight, of alcohol to one (1) part of water. Moisten the powder with ten grammes (10 Gm.) [154 grs.] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the ignatia is exhausted. Reserve the first ninety grammes (90 Gm.) [3 ozs. av., 76 grs.], evaporate the remainder to ten grammes (10 Gm.) [154 grs.] and mix with the reserved portion. Of this tincture, take any convenient number of parts, and, by means of a water-bath, evaporate it to dryness. Weigh the resulting extract, and from its weight calculate the quantity of extract contained in the one hundred (100) parts of tincture obtained; then dissolve the dried extract in the remainder of the tincture, and add enough of the above menstruum to make the product weigh so many parts that each one hundred (100) parts of tincture shall contain one (1) part of dry extract. Lastly, mix thoroughly, and filter through paper. Tincture of ignatia thus prepared represents about 10 grammes of ignatia in 100 grammes"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Administered in *nervous affections*, and wherever a tincture is indicated. The dose is 1 to 10 drops, 3 times a day.

TINCTURA IODI (U. S. P.)—TINCTURE OF IODINE.

Synonym: *Tinctura iodinii* (*U. S. P.*, 1870).

Preparation.—"Iodine, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the iodine rapidly, in a mortar, to a coarse powder, and transfer it at once to a graduated bottle. Rinse the mortar with several successive portions of alcohol, and pour the rinsings into the bottle. Then add alcohol, shaking the bottle occasionally, until the iodine is dissolved, and the finished tincture measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]" (*U. S. P.*). Prof. A. B. Stevens (*Proc. Amer. Pharm. Assoc.*, 1897, p. 451) proposes to obtain this tincture by percolation of the iodine with alcohol, in a long glass tube, the iodine being previously triturated with coarsely-powdered glass or sand. Tincture of iodine should be placed in closely-stopped vials. It is inferior to the compound tincture of iodine (see p. 1968), on account of being decomposed by the action of light, or of air, through the reaction of iodine and alcohol upon each, giving rise to hydriodic acid (see A. B. Stevens, *loc. cit.*), free iodine, etc. This change takes place at ordinary temperatures, but is accelerated by heat. Besides, it is more apt to irritate the stomach, from the deposition of solid iodine when the tincture is taken in water. In preparing the tincture, the iodine should be well dried. It has a deep-brown color, becomes gradually decomposed upon standing, or on the addition of water. When decomposition, above referred to, has ensued, the tincture no longer precipitates iodine. The tincture, when evaporated, should leave no fixed residue. It should not be prepared in large quantities.

Tests.—"If 6.3 Cc. of the tincture be mixed with a solution of 2 Gm. of potassium iodide in 25 Cc. of water, and a little starch T.S. added, it should require, for complete decoloration, about 35 Cc. of decinormal sodium hyposulphite V.S. (corresponding to about 7 Gm. of iodine in 100 Cc.)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Iodinum.*) This preparation is seldom administered internally, on account of the tendency to deposition of iodine, and consequent irritation produced by the crude iodine. When given, the dose is 10 drops, gradually increased to 30, 2 or 3 times a day, to be administered in water sweetened with loaf-sugar, or in wine. Thirty drops (15 minims) are about equal to 1 grain of iodine. Its principal use is, externally, in *cutaneous scrofula*, *erysipelatous diseases*, *pernio*, *eczema*, *pityriasis*, and other *diseases of the skin*, *acute rheumatism*, *ulcers*, etc. It may be applied by means of a camel's-hair pencil (J. King).

Related Preparations.—TINCTURA IODINII COMPOSITA, *Compound tincture of iodine.* Take of iodine, 1 ounce; iodide of potassium, 2 ounces; alcohol, 2 pints. Macerate till they are dissolved, and filter. The filtering ordered in this formula is unnecessary, and may be dispensed with. This tincture agrees in strength with that of the *U. S. P.*, 1870, which was discarded on account of being so frequently confounded with compound solution of iodine (see *Liquor Iodi Compositus*). This tincture may be used internally for all the purposes to which iodine is applicable. Unlike the tincture of iodine, it is not decomposed when water is added to it. The dose is 5 drops, 3 times a day, gradually increased to 30, if required.

TINCTURA IODI, CHURCHILL (N. F.), *Churchill's tincture of iodine.*—"Iodine, one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 grs.]; potassium iodide, thirty-three grammes (33 Gm. [1 oz. av., 72 grs.]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the potassium iodide in the water, then add the iodine, and lastly, enough alcohol to make the tincture, when completed, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—Churchill's Tincture of Iodine should not be confounded with Churchill's Iodine Caustic (*Liquor Iodi Causticus*)"—(*Nat. Form.*).

TINCTURA IODI DECOLORATA (N. F.), *Decolorized tincture of iodine.*—"Iodine, eighty-three grammes (83 Gm.) [2 ozs. av., 406 grs.]; sodium hyposulphite, eighty-three grammes (83 Gm. [2 ozs. av., 406 grs.]; water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; stronger water of ammonia (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Digest the iodine, sodium hyposulphite, and water, at a gentle heat, until a perfect solution, of a dark reddish-brown color, is produced. Then add one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏] of alcohol, and afterward, the stronger water of ammonia. Shake a few minutes until no more bubbles of gas escape, and the liquid has become colorless, with a whitish precipitate (of sulphur) suspended in it. Cool it, if necessary, and add enough alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Place the bottle containing it in a refrigerator for a few hours, or longer, if convenient, then filter, in a covered funnel, and preserve the liquid for use. *Note.*—On prolonged standing, a crystalline precipitate of sodium tetrathionate will usually form in the liquid. This may be removed by filtration"—(*Nat. Form.*). This is not a solution of iodine, but of iodine compounds; hence, the term tincture of iodine is a misnomer.

TINCTURA IPECACUANHÆ ET OPII (U. S. P.)—TINCTURE OF IPECAC AND OPIUM.

Preparation.—"Tincture of deodorized opium, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]; fluid extract of ipecac, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Evaporate the tincture of deodorized opium, in a tared capsule, on a water-bath, until it weighs eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]. When it has become cold, add to it the fluid extract of ipecac, filter the mixture, and pass enough diluted alcohol through the filter to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This tincture is intended to give a uniform preparation similar to the fluids known as "*Liquid Dover's powder*," or *Tincture of Dover's powder*.

Action, Medical Uses, and Dosage.—The uses of this preparation are those of *Dover's powder*. Dose, 10 minims, which represent 1 grain each of opium and ipecacuanha.

TINCTURA IRIDIS.—TINCTURE OF IRIS.

Synonym: *Tincture of blue flag.*

Preparation.—Take of blue flag root (recent), in fine powder, 3 ounces; alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tinctura*, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—The tincture of blue flag possesses the same alterative and cathartic properties as the root, and may be used in all cases as a substitute for the powder, in doses of from 10 to 60 drops, according to the effect desired, 2 or 3 times a day. Six fluid drachms, each, of the tinctures of blue flag and mandrake roots, with 2 fluid drachms of a saturated tincture of nux vomica, form an efficient remedy in *obstinate constipation, hepatic torpor, derangements of the spleen, sick headache, want of appetite, syphilitic affections, gleet, recent stricture of the urethra, impotency from masturbation, recent disease of the prostate*, etc. The mixture may be given in doses of from 10 to 15 drops, in water, 2 or 3 times a day (J. King).

TINCTURA JABORANDI.—TINCTURE OF JABORANDI.

Preparation.—"Take of jaborandi, in No. 40 powder, 5 ounces (av.); proof-spirit, 1 pint (Imp.)"—(*Br. Pharm.*, 1885). Prepare as directed for *Tinctura Sennæ*. The *British Pharmacopœia* (1898) directs: Take of "jaborandi leaves, in No. 40 powder, 4 ounces (Imp.), or 200 grammes (Metric); alcohol (45 per cent), a sufficient quantity. Moisten the powder with 2½ fluid ounces (or 125 cubic centimeters) of alcohol, and complete the percolation process. The resulting tincture should measure 1 pint, or 1000 cubic centimeters"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—(See *Pilocarpus*.) Dose, 10 to 60 minims.

TINCTURA JALAPÆ (N. F.)—TINCTURE OF JALAP.

Preparation.—"Jalap, in fine powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix 2 volumes of alcohol with 1 volume of water. Percolate the jalap with this mixture, in the usual manner, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained. *Note.*—This preparation was official in the *U. S. P.* of 1870"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Jalapa*.) Seldom used, except as an addition to other purgatives. Dose, ½ to 2 fluid drachms.

Related Tincture.—Tinctura Jalapæ Composita (N. F.), *Compound tincture of jalap*. "Jalap, in fine powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; scammony, in powder, thirty-two grammes (32 Gm.) [1 oz. av., 56 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix 2 volumes of alcohol with 1 volume of water. Mix the powders with half their weight of sand; moisten the mixture with a sufficient quantity of the menstruum, pack it in a percolator, and percolate it with the menstruum, in the usual manner, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*Nat. Form.*).

TINCTURA KALMIÆ.—TINCTURE OF KALMIA.

Synonym: *Tincture of sheep laurel.*

Preparation.—Take of sheep laurel leaves, in coarse powder, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This preparation is sedative and alterative, and may be successfully used in *jaundice, syphilitic diseases, palpitation of the heart, neuralgia of the eye*, etc., in doses of 10 drops, carefully and gradually increased to 30. In *obstinate syphilitic affections*, I frequently add a portion of this tincture to the compound syrup of stillingia, with marked advantage. Externally, the tincture is beneficial in *itch*, and some other *cutaneous affections* (J. King).

TINCTURA KINO (U. S. P.)—TINCTURE OF KINO.

Preparation.—"Kino, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; glycerin, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; water, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with the water and six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol. Rub the kino, in a mortar, adding gradually a sufficient quantity of the menstruum, until a smooth paste is produced. Transfer this to a bottle, add the remainder of the menstruum, and macerate for 24 hours, with occasional agitation. Then filter through paper, adding, through the filter, enough alcohol to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Keep the tincture in small, completely-filled and well-stoppered bottles, in a cool place"—(*U. S. P.*). The substitution of glycerin for a portion of water was suggested by Haselden (1860) as tending to prevent gelatinization.

Action, Medical Uses, and Dosage.—Tincture of kino is astringent, and is principally used, in doses of 1 or 2 fluid drachms, in *diarrhœa*, *cholera morbus*, *cholera*, etc. It is frequently added to astringent mixtures (see *Kino*).

Related Tincture.—TINCTURA KINO COMPOSITA (N. F.), *Compound tincture of kino.* "Tincture of kino (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; tincture of opium (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; spirit of camphor (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; oil of cloves, one and one-half cubic centimeters (1.5 Cc.) [24 ♏]; cochineal, in powder, nine grammes (9 Gm.) [139 grs.]; aromatic spirit of ammonia (*U. S. P.*), eight cubic centimeters (8 Cc.) [130 ♏]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the cochineal with the aromatic spirit of ammonia, and gradually add seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of diluted alcohol. Then add the two tinctures, the spirit of camphor, and the oil of cloves, and filter the mixture through paper. Lastly, pass enough diluted alcohol through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about ½ grain, each, of kino and of powdered opium"—(*Nat. Form.*).

TINCTURA KRAMERIÆ (U. S. P.)—TINCTURE OF KRAMERIA.

SYNONYM: *Tincture of rhatany.*

Preparation.—"Krameria, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This forms a strongly astringent, brownish-red tincture, liable to precipitate rhatany-red, and sometimes gelatinizing. Prepare it in small amounts, and keep it in well-filled bottles. Glycerin, as a part of the menstruum, will aid in preserving it.

Action, Medical Uses, and Dosage.—This is useful in *chronic diarrhœa*, and other cases where an astringent is required. It likewise forms an excellent local application to the gums, where they are tender, spongy, and bleed. The dose is 1 or 2 fluid drachms, in sweetened water or wine, if not contraindicated, 3 or 4 times a day.

TINCTURA LACTUCARII (U. S. P.)—TINCTURE OF LACTUCARIUM.

Preparation.—"Lactucarium, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; water, alcohol, benzin, diluted alcohol, each, a sufficient quantity. Beat the lactucarium in an iron mortar, with clean sand, to a coarse powder, and introduce it into a bottle; add two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏] of benzin, cork the bottle tightly, and set it aside for 48 hours, frequently agitating the mixture. Pour the mixture on a double filter, and allow it to drain. Wash the residue by gradually adding fifteen hundred cubic centimeters (1500 Cc.) [50 fl℥, 346 ♏] of benzin. Allow the lactucarium to dry by exposing it to a current of air. When it is dry, and free from the odor of benzin, reduce it to powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the glycerin with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, and five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol, and moisten the powder with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of the mixture. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours; then allow the percolation to proceed very slowly, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until the lactucarium is exhausted. Reserve the first seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of the percolate, evaporate the remainder, on a water-bath, at a temperature not exceeding 70° C. (158° F.), to two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏], and mix this with the reserved portion. Filter, and add enough diluted alcohol through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). About 7½ grains of lactucarium are contained in 16 minims of this tincture.

Uses.—Tincture of lactucarium is employed in the preparation of *Syrup of Lactucarium*, and, for this purpose, must be freed from caoutchouc, which it contains. This is accomplished by the benzin, and rendered fit to form an unclouded syrup. A pure benzin should be selected, and the percolate should pass very slowly. Tincture of lactucarium is less efficient than syrup of lactucarium, and is but little valued in Eclectic practice.

TINCTURA LARICIS COMPOSITA.—COMPOUND TINCTURE OF LARCH.

SYNONYMS: *Tinctura pinus pendulæ composita, Compound tincture of tamarac.*

Preparation.—Take of tamarac bark, juniper berries, of each, in fine powder, 6 ounces; prickly ash bark, in fine powder, 4 ounces; wild cherry bark, seneca snakeroot, of each, in fine powder, 3 ounces; tansy, coarsely powdered, 1 ounce; whiskey, 5 pints; molasses, 1½ pints; hydro-alcoholic extract of mandrake, 1½ ounces; water, a sufficient quantity. Let the medicinal herbs, roots, and barks be mixed together. To the mixture add 3 pints of the whiskey, and let it stand 24 hours; then place the whole in a percolator, and percolate with whiskey until 24 pints are obtained. To this add the molasses and the hydro-alcoholic extract of mandrake, which last must be thoroughly dissolved.

Action, Medical Uses, and Dosage.—Although not properly a tincture, yet to avoid a new class of pharmaceutic agents (*bitters*), I place this compound among the tinctures. It is an improvement upon the old preparation called *Bone's Bitters*, and is generally preferred by physicians. It possesses nearly four times the strength of that heretofore made, and, consequently, must be taken in a much smaller dose, a desideratum with all medicines containing alcohol. The whiskey and juniper berries are less expensive, and more readily obtainable than the pure Holland gin recommended in the original, and likewise render the preparation more actively diuretic; and the substitution of the extract of mandrake for the bitter and, to many patients, unbearable taste of aloes, renders it much more valuable as a cholagogue, alterative, and aperient. It forms an excellent alterative tonic and aperient for *dyspeptic affections, menstrual derangements, hepatic torpor, constipation, urinary difficulties*, etc. The dose is ½ fluid ounce, 3 times a day, about an hour previous to each meal (J. King).

Related Tincture. TINCTURA LARICIS, *Tincture of larch.* "Take of larch bark, in No. 40 powder, 2½ ounces (av.); rectified spirit, 1 pint (Imp.)."—*Br. Pharm.*, 1885; not in edition of 1898). Prepare as directed under *Tinctura Sennæ*. Unless carefully preserved, this tincture decomposes; it has a reddish-brown color. This agent is used for the same purposes as many of the terebinthinates. Dose, 10 to 30 minims.

TINCTURA LAVANDULÆ COMPOSITA (U. S. P.)—COMPOUND TINCTURE OF LAVENDER.

SYNONYMS: *Compound spirit of lavender, Spiritus lavandulæ compositus, Lavender drops.*

Preparation.—"Oil of lavender flowers, eight cubic centimeters (8 Cc.) [130 ♏]; oil of rosemary, two cubic centimeters (2 Cc.) [32 ♏]; cassia cinnamon, in coarse powder, twenty grammes (20 Gm.) [309 grs.]; cloves, five grammes (5 Gm.) [77 grs.]; nutmeg, ten grammes (10 Gm.) [154 grs.]; red saunders, in coarse powder, ten grammes (10 Gm.) [154 grs.]; alcohol, seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oils in the alcohol, and add the water. Crush the nutmeg in a mortar, mix it with the cinnamon, cloves, and red saunders, and reduce the mixture, by grinding, to a coarse (No. 20) powder. Moisten the mixture with a sufficient quantity of the alcoholic solution of the oils, pack it firmly in a cylindrical percolator, gradually pour upon it the remainder of the alcoholic solution, and, afterward, diluted alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This forms a red tincture of agreeable odor and taste; the addition of water renders it turbid.

Action, Medical Uses, and Dosage.—This forms a delightful preparation, which is much employed as a remedy for *flatulence*, *hysteria*, *gastric uneasiness*, *nausea*, and *general languor*, or *faintness*. It is also used as an adjuvant and corrigent of other medicines. The dose is from 30 drops to 1 or 2 fluid drachms, given in sweetened water, or on sugar (J. King).

TINCTURA LEPTANDRÆ.—TINCTURE OF BLACK ROOT.

Preparation.—Take of black root, in moderately fine powder, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—(See *Leptandra.*) This preparation is aperient and cholagogue, and is employed in various *derangements of the biliary organs*. It is also added to medicines for *summer complaint*, *chronic diarrhœa*, *remittent fever*, etc. The dose is from ½ to 2 fluid drachms, 2 or 3 times a day (J. King).

TINCTURA LIMONIS.—TINCTURE OF LEMON PEEL.

Preparation.—"Take of fresh lemon peel, cut small, 2½ ounces (av.); proof-spirit, 1 pint (Imp.). Macerate for 7 days in a closed vessel, with occasional agitation; strain, press, and filter; then add sufficient proof-spirit to make 1 pint"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) prepares this tincture from 5 ounces (Imp.) of fresh lemon peel with 1 pint of alcohol (90 per cent). Dose, from ½ to 1 fluid drachm.

Action, Medical Uses, and Dosage.—(See *Limon.*) Used chiefly in flavoring medicines. Dose, of first preparation, ½ to 2 fluid drachms.

TINCTURA LOBELIÆ (U. S. P.)—TINCTURE OF LOBELIA.

Preparation.—"Lobelia, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Tincture of lobelia has the characteristic acrid and bitterish taste of lobelia, and a somewhat heavy odor. It is of a greenish-brown color.

Action, Medical Uses, and Dosage.—This tincture possesses the same properties as lobelia; the dose is from 30 to 60 drops as a nauseant; and ½ fluid ounce, or more, as an emetic. A tincture prepared of equal parts of vinegar and alcohol, instead of diluted alcohol, is preferable to the above, in cases where it is not to be kept for a length of time. Externally, the tincture of lobelia is beneficial as a local application in *erysipelas*, *tetter*, and similar *cutaneous eruptions*, *stings of insects*, and in the *poisoning by rhus*, having been successfully used by our practitioners in these affections, for more than 60 years past (J. King).

Related Tincture.—TINCTURA LOBELIÆ ÆTHEREA, *Ethereal tincture of lobelia*. "Take of lobelia, in No. 40 powder, 4 ounces (Imp.); spirit of ether, a sufficient quantity. Moisten the powder with 2 fluid ounces of spirit of ether, and complete the percolation process. The resulting tincture should measure 1 pint. Dose, 5 to 15 minims. This preparation is made with rather more than 1⅓ times the proportion of lobelia ordered for the corresponding preparation in the *British Pharmacopœia* of 1885"—*Br. Pharm.*, 1898).

TINCTURA LOBELIÆ COMPOSITA.—COMPOUND TINCTURE OF LOBELIA.

SYNONYM: *Dr. J. King's expectorant tincture.*

Preparation.—Take of lobelia (herb), bloodroot, skunk-cabbage root, wild ginger root, and pleurisy root, each, in moderately fine powder, 1 ounce; water (or vinegar), 1 pint; alcohol, 3 pints, or a sufficient quantity. Form a tincture by maceration or percolation, as explained under *Tincturæ*, and make 4 pints of tincture.

Action, Medical Uses, and Dosage.—This tincture forms an excellent emetic for children and infants, and may be safely used in *croup*, *whooping-cough*, *bronchitis*, *asthma*, *convulsions*, and in all cases where an emetic is required. It will likewise be found beneficial as an expectorant, or nauseant in *coughs*, *pleuritic affections*, *asthma*, *pertussis*, and whenever expectorants are indicated It is a most valuable compound.

In *croup*, for children 1 year old, give ½ tablespoonful in a tablespoonful of syrup or molasses, and repeat it every 15 minutes, until it vomits; after which a teaspoonful may be given every hour or two, as required—the vomit to be repeated 2 or 3 times a day. A child from 2 to 6 months old, may take from ½ to 1 teaspoonful for a dose; less than 2 months old, from 15 to 25 drops, to be repeated every 10 minutes, if vomiting is required. Children from 3 to 6 years old, may take 1 tablespoonful, in molasses or warm water, every 10 minutes, until it vomits. Warm boneset tea ought always to be given in order to facilitate its operation as an emetic. For *cough*, *asthma*, etc., to promote expectoration and remove tightness across the chest; and in all ordinary cases where an expectorant is required, adults may take 1 or 2 teaspoonfuls in ½ wineglassful of slippery-elm tea, 3 to 5 times a day, or as often as required. Children from 1 to 10 years old, may take from ½ to 1 teaspoonful in the same manner; and for those less than 1 year, from 10 to 30 drops. Should the above doses vomit, they should be lessened, except when vomiting is desired. The stomach and bowels must be kept regular in all cases, by gentle medicines (J. King).

TINCTURA LOBELIÆ ET CAPSICI COMPOSITA.—COMPOUND TINCTURE OF LOBELIA AND CAPSICUM.

SYNONYM: *Antispasmodic tincture.*

Preparation.—Take of lobelia, capsicum, and skunk-cabbage root, each, in moderately fine powder, 2 ounces; diluted alcohol, 2 pints, or a sufficient quantity. Form into a tincture by maceration and percolation, as explained under *Tincturæ*, and make 2 pints of tincture; or, it may be made by combining together equal parts of the saturated tinctures of lobelia, capsicum, and skunk-cabbage root.

Action, Medical Uses, and Dosage.—This tincture is a powerful antispasmodic and relaxant, and will be found highly efficient in *cramps*, *spasms*, *convulsions*, *tetanus*, etc. The dose is from ½ teaspoonful to 1 teaspoonful, every 10 or 20 minutes, as often as the urgency of the case requires.

In *hysteria*, *convulsions*, and *tetanus*, in which swallowing is difficult, it may be poured into the corner of the mouth, and repeated as often as necessary; it will find its way into the stomach; generally, the effect is almost instantaneous. This valuable preparation should always be in the possession of every physician. In *rigidity of the os uteri* (with thick doughy edges), 1 teaspoonful administered by mouth, or by enema into the rectum, and repeated in 15 or 20 minutes, will be found to produce a state of softness and dilatability (J. King).

TINCTURA LUPULINI.—TINCTURE OF LUPULIN.

Preparation.—"Take of lupulin, 4 troy ounces; alcohol, a sufficient quantity. Pack the lupulin in a cylindrical percolator, and gradually pour alcohol upon it, until 2 pints of tincture are obtained"—(*U. S. P.*, 1870).

Action, Medical Uses, and Dosage.—Lupulin is the active principle of hops, and as the quantity of it varies in different specimens of hops, a tincture of it is decidedly preferable to one made of hops. It may be employed with advantage in *coughs*, *after-pains*, and in all cases where opium is inadmissible. (For further uses, see *Lupulinum*.) The dose is 1 or 2 fluid drachms, in mucilage, or sweetened fluid of some kind.

TINCTURA MATICO (U. S. P.)—TINCTURE OF MATICO.

Preparation.—"Matico, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the matico with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has a green-brown color. When prepared with strong alcohol (which is the better menstruum), it has a brown-green hue.

Action, Medical Uses, and Dosage.—(See *Matico*.) Dose, ½ to 2 fluid drachms.

TINCTURA MOSCHI (U. S. P.)—TINCTURE OF MUSK.

Preparation.—"Musk, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]; water, four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the musk in a mortar, first, with a little of the water, until a smooth mixture is made, and then with the remainder of the water. Transfer the whole to a bottle, add the alcohol, and macerate the mixture for 7 days, occasionally shaking the bottle. Then filter through paper, adding, through the filter, enough diluted alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This produces a pale-brown tincture, striking faintly opalescent with water. When made with a weaker alcohol, the odor is strong, the color deep red-brown, and, when mixed with water, the mixture remains transparent. A grain of musk is contained in 20 minims.

Action, Medical Uses, and Dosage.—(See *Moschus*.) Dose, ½ to 2 fluid drachms.

TINCTURA MENTHÆ VIRIDIS.—TINCTURE OF MENTHA VIRIDIS.

Synonyms: *Tincture of spearmint*, *Spirits of mint*.

Preparation.—Take of the fresh herb of spearmint, a sufficient quantity to fill a glass jar, and cover with good Holland gin. Macerate for 7 days; express and filter (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This tincture is diuretic and stimulant. It may be beneficially employed in *strangury*, *retention of urine*, *gravel*, and various *chronic nephritic diseases*. The dose is 2 to 4 ounces, 3 times a day, but, in severe and painful cases, it may be repeated every ½ or 1 hour, until relief is obtained. Externally, it forms an excellent application to *hemorrhoids*, when in a state of inflammation. Cotton must be moistened with it, and applied to the parts.

TINCTURA MYRRHÆ (U. S. P.)—TINCTURE OF MYRRH.

Preparation.—"Myrrh, in moderately coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powder with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of alcohol, and macerate for 7 days in a closed vessel; then filter through paper, adding, through the filter, enough alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). A brown or red-yellow tincture, of a bitter, balsamic taste and an aromatic odor. When added to water, resin is precipitated.

Action, Medical Uses, and Dosage.—Tincture of myrrh is used as a stimulating application to *obstinate, fetid ulcers*, and to promote the *exfoliation of carious bones* (Coxe). It is also useful as a wash, either alone or diluted with water, in *ulceration of the mouth and throat, spongy and bleeding gums*, etc. Internally, it has been used in *chronic cough, catarrh*, etc., as a stimulating expectorant; also as an emmenagogue. The dose is from ½ to 1 fluid drachm.

TINCTURA MYRRHÆ COMPOSITA.—COMPOUND TINCTURE OF MYRRH.

Preparation.—Take of myrrh, in rather fine powder, 8 ounces; capsicum, in fine powder, 2 ounces; alcohol, 1 gallon, or a sufficient quantity. Form into a tincture by maceration, as explained under *Tincturæ*, and make 1 gallon of tincture.

Action, Medical Uses, and Dosage.—This preparation, frequently termed *Hot Drops*, from its resemblance to a compound of similar composition formerly in use, is rarely employed internally. Occasionally, however, it is used in doses of from ½ to 1 fluid drachm, in sweetened water, in cases of *nausea, gastric distress*, especially after a hearty meal, *flatulence*, etc. Its internal employment is contraindicated when inflammation is present. It is principally used externally, when it proves an excellent local application to *sprains, bruises, fresh wounds, cuts, rheumatism, offensive ulcers*, etc.

Related Preparations.—Practically the same as the preceding is the TINCTURA CAPSICI ET MYRRHÆ (N. F.), *Tincture of capsicum and myrrh, Hot drops*. "Capsicum, in No. 20 powder, thirty-two grammes (32 Gm.) [1 oz. av., 56 grs.]; myrrh, in moderately coarse powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the powders with an equal bulk of clean, fine sand, and percolate them, in the usual manner, with a mixture of nine (9) volumes of alcohol and one (1) volume of water, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of percolate are obtained. *Note.*—This preparation is known in some parts of this country by the old Thompsonian name 'Number Six'"—(*Nat. Form.*).

TINCTURA NUCIS VOMICÆ (U. S. P.)—TINCTURE OF NUX VOMICA.

Preparation.—"Extract of nux vomica, dried at 100° C. (212° F.), twenty grammes (20 Gm.) [309 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the extract of nux vomica (which should contain fifteen [15] per cent of alkaloids) in a sufficient quantity of a mixture of three (3) volumes of alcohol and one (1) volume of water, to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This produces a very bitter, yellowish tincture, striking opalescent with water.

Test.—"If 100 Cc. of tincture of nux vomica be evaporated to dryness, and the residue tested by the process of assay given under *Extractum Nucis Vomicæ*, it should be found to contain 0.3 Gm. of alkaloids"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This tincture possesses the properties of nux vomica (which see). Its extreme bitterness is a great objection to the employment of this tincture. It is occasionally employed in doses of from 5 to 10 or 20 drops, and as an external application in *local paralytic affections*.

Related Tincture.—Tinctura Strychninæ Composita, *Compound tincture of strychnine*. Take of strychnine, in crystals, 16 grains; distilled water, alcohol, each, 7½ fluid ounces; acetic acid, compound tincture of cardamom, each, ½ fluid ounce. Dissolve the strychnine in the alcohol and acetic acid mixed together, and then add the remaining articles. This tincture is useful in *impaired spinal energy*, or *spinal exhaustion*, whether the result of excessive study muscular effort, sexual indulgence, masturbation, etc. It is likewise efficient in *paralysis, constipation, debility of the generative organs, malarial diseases, chronic splenitis*, and *recent diseases of the prostate gland*. It is contraindicated in irritation of the spinal nerves. Two fluid drachms of the tincture contain ⅛ grain of strychnine. The dose is from 10 to 30 drops, 3 times a day.

TINTCURA OPII (U. S. P.)—TINCTURE OF OPIUM.

Synonyms: *Laudanum, Tinctura meconii, Tinctura thebaica.*

Preparation.—"Powdered opium, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; precipitated calcium phosphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; water, four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏]; alcohol, four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the powders, in a mortar, with the water previously heated to the temperature of 90° C. (194° F.), until a smooth mixture is made, and macerate for 12 hours; then add the alcohol, mix thoroughly, and transfer the whole to a cylindrical percolator. Return to the percolator the first portion of the percolate, until it runs through clear, and, when the liquid ceases to drop, gradually pour on diluted alcohol, continuing the percolation slowly, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

History and Description.—This tincture is universally known in this and other English-speaking countries as *laudanum*. It has been known throughout Europe as *Laudanum Liquidum Simplex*, in contradistinction to solid opium preparations, which were also called by the name *laudanum*, usually with some qualifying term, as *Laudanum Antihystericum*, etc. Tincture of opium has a deep red-brown color, and the characteristic odor and taste of opium. Lest concentration take place, through evaporation of its alcohol, it should be kept in securely-stoppered bottles. Each fluid drachm represents 5.7 grains of dry opium, or 1 grain of opium in about 10.5 minims of the tincture.

In preparing this tincture, it is essential that well-dried opium should be used, to insure a full-strength product, and it should be in a finely-powdered form. The admixture with calcium phosphate aids in its percolation, which could not otherwise be readily accomplished with diluted alcohol. The percolate passes slowly, and about 60 per cent of the opium constituents are obtained in solution by the use of the diluted alcohol. The Pharmacopœia directs the drug to be macerated 12 hours previous to percolation. Twice that length of time, however, will better insure the complete disintegration of the opium. After completion of the percolation, water should abstract nothing from the dried residue, and only mere traces of alkaloids, or their compounds, should be abstracted by diluted acids.

Valuation.—"If 100 Cc. of tincture of opium be assayed by the process immediately following, it should yield from 1.3 to 1.5 Gm. of crystallized morphine"—(*U. S. P.*).

Assay of Tincture of Opium.—"Tincture of opium, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; ammonia water, three and five-tenths cubic centimeters (3.5 Cc.) [57 ♏]; alcohol, ether, water, each, a sufficient quantity. Evaporate the tincture to about 20 Cc., add 40 Cc. of water, mix thoroughly, and set the liquid aside for an hour, occasionally stirring, and disintegrate the resinous flakes adhering to the capsule. Then filter, and wash the filter and residue with water, until all soluble matters are extracted, collecting the washings separately. Evaporate in a tared capsule, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 14 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 20 Gm. Then add 10 Gm. (or 12.2 Cc.) of alcohol, shake well, add 25 Cc. of ether, and shake again. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during 10 minutes, and then set it aside, in a moderately cool place, for at least 6 hours, or over night. Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel 2 rapidly-acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother water, and afterward wash them, drop by drop from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc., or more, if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them. The weight found represents the amount of crystallized morphine obtained from 100 Cc. of the tincture"—(*U.S.P.*).

Action, Medical Uses, and Dosage.—This tincture, occasionally termed *Tinctura Thebaica*, possesses the medicinal virtues of opium, and may be used in all cases where the drug is indicated, in doses of from 5 to 30 drops (see *Opium*).

Related Preparations.—TINCTURA OPII ACETATA. If diluted acetic acid be employed instead of water, it will form a much better tincture of opium, and one less liable to vary in strength (TINCTURA OPII ACETATA, or *Acetated Tincture of Opium*), and which may be given in the same doses as above. It is, however, seldom prescribed at the present day. The *U. S. P.* (1870) directed 2 troy ounces of dry-powdered opium to be macerated for 7 days in a mixture of 8 fluid ounces of alcohol and 12 fluid ounces of distilled vinegar; express and filter. Twenty fluid ounces are obtained. One grain of opium is contained in each 10 minims.

TINCTURA OPII MURIATICA.—In a mixture of hydrochloric acid, 1 fluid ounce, and water, 15 fluid ounces, macerate 1 ounce of powdered opium for 14 days, and filter. Then add sufficient water to make 1 pint of tincture. No alcohol is present. This is not quite half as strong as tincture of opium.

TINCTURA PAPAVERIS (N. F.), *Tincture of poppy.*—"Poppy capsules, freed from seeds, and in coarse powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 flʒ, 109 ♏]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 ♏]. Digest the poppy capsules with three thousand cubic centimeters (3000 Cc.) [101 flʒ, 212 ♏] of boiling water during 2 hours, then express and strain. Evaporate the strained liquid to five hundred cubic centimeters (500 Cc.) [16 flʒ, 435 ♏], mix it with two hundred and fifty cubic centimeters (250 Cc.) [8 flʒ, 218 ♏] of alcohol, and set the mixture aside, well covered, until it is quite cold. Then filter, add the glycerin to the filtrate, and pass enough of a mixture of two (2) volumes of water and one (1) volume of alcohol through the filter, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 ♏]. Each fluid drachm represents 30 grains of poppy (capsule) freed from seeds"—(*Nat. Form.*).

TINCTURA OPII DEODORATI (U. S. P.)—TINCTURE OF DEODORIZED OPIUM.

SYNONYM: *Tinctura opii deodorata* (*U. S. P.*, 1880).

Preparation.—"Powdered opium, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; precipitated calcium phosphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; ether, two hundred cubic centimeters (200 Cc.) [6 flʒ, 366 ♏]; alcohol, two hundred cubic centimeters (200 Cc.) [6 flʒ, 366 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 ♏]. Rub the powders in a mortar with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water, previously heated to the temperature of 90° C. (194° F.), until a smooth mixture is made, and macerate for 12 hours; then pour the mixture on a filter, or transfer it to a cylindrical percolator, and gradually pour on water until the opium is practically exhausted. Reduce the percolate, by evaporation on a water-bath, to one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏], and, when it has cooled, shake it repeatedly with the ether in a bottle. When the ethereal solution has separated by standing, pour it off, and evaporate the remaining liquid until all traces of ether have disappeared. Mix the residue with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, and filter the mixture through paper. When the liquid has ceased to pass, add enough water, through the filter, to make the filtered liquid measure eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]. Lastly, add the alcohol, and mix them"—(*U. S. P.*).

Test.—"If 100 Cc. of tincture of deodorized opium be assayed by the process given under *Tinctura Opii*, it should yield from 1.3 to 1.5 Gm. of crystallized morphine"—(*U. S. P.*).

Several *elixirs of opium* and a denarcotized tincture of opium are upon the market, which this preparation is designed to displace. Tincture of denarcotized opium contains the same amount of opium as tincture of opium, *i.e.*, 1 grain in about every 10.5 minims It is not so dark in color as laudanum. The drug is deprived of its narcotine and odor-giving principles by means of the ether employed. This is successfully, though somewhat difficultly, performed by following the official directions. The trouble is due to the formation of an emulsion produced by shaking together the concentrated aqueous preparation and the ether. This may be avoided, according to Prof. Maisch, if the opium be first denarcotized and deodorized, and an infusion made and evaporated to the necessary quantity, and the requisite amount of alcohol added to bring the tincture to the desired strength. Benzin has been suggested to denarcotize and deodorize this preparation, but it is not suitable, as it leaves its own disagreeable odor.

Action, Medical Uses, and Dosage.—(See *Opium.*) Dose, from 10 to 20 minims.

Related Preparation.—The following was offered to the profession by Eugene Dupuy, a pharmacist of New York, as a substitute for *McMunn's Elixir of Opium*. It is said that none of the unpleasant effects attributed to laudanum have as yet attended its administration: Take of opium, 10 drachms, make it into a thin pulp, with a sufficient quantity of water; then allow the mixture to stand in a cool place 48 hours, after which transfer it to an elongated glass funnel containing filtering paper, and add a superstratum of water equivalent to the bulk of the whole mass. When 12 ounces of liquid have filtered, add to the filtered solution alcohol (95 per cent), 4 ounces. The solution is an aqueous solution of opium, nearly free from narcotine, preserved by alcohol, and contains about two-thirds of the substance of the opium—the residue consisting chiefly of resin, narcotine, caoutchouc, ligneous matter, etc.

TINCTURA OPII CAMPHORATA (U. S. P.)—CAMPHORATED TINCTURE OF OPIUM.

SYNONYMS: *Paregoric*, *Elixir paregoricum*, *Paregoric elixir.*

Preparation.—"Powdered opium, four grammes (4 Gm.) [62 grs.]; benzoic acid, four grammes (4 Gm.) [62 grs.]; camphor, four grammes (4 Gm.) [62 grs.]; oil of anise, four cubic centimeters (4 Cc.) [65 ♏]; glycerin, forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Add nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of diluted alcohol to the other ingredients, contained in a suitable vessel, and macerate for 3 days, shaking frequently; then filter through paper, in a well-covered funnel, and pass enough diluted alcohol through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). This tincture has a brown-yellow color, a sweetish and somewhat bitter, sharply aromatic taste, and an odor resembling that of camphor and anise combined. In reaction it is acid, and, when added to water, renders the latter milky. It contains, in every 263 minims, 1 grain of opium. True benzoic acid should be preferred to that made from the urine of herbivorous animals.

Action, Medical Uses, and Dosage.—This is a very valuable and useful opiate, which is efficient in allaying troublesome *cough*, *nausea*, *whooping-cough*, slight *gastric and intestinal pains;* to cause sleep, and palliate *diarrhœa*. The dose for an adult is 1 to 2 fluid drachms; for an infant, 5 to 10 or 20 drops.

Related Preparations.—The liquids known by the names of *Godfrey's Cordial*, and *Bateman's Drops*, two very dangerous articles in the hands of nurses and many non-professional persons, are generally prepared as follows:

Godfrey's Cordial.—Dissolve carbonate of potassium, 6 drachms, in water, 6½ pints; add sugar-house molasses, 4 pints, and gently heat them to form a solution, removing any scum which floats upon the surface. Remove from the fire and add laudanum, 6 fluid ounces; alcohol, 8 fluid ounces, in which has been dissolved 1 fluid drachm of oil of sassafras. A fluid drachm of this cordial is equivalent to somewhat more than ¼ grain of opium.

Bateman's Pectoral Drops.—Take powdered opium, powdered catechu, camphor, red saunders, rasped, each, 2 drachms; oil of anise, ½ fluid drachm; diluted alcohol, 4 pints. Mix and macerate for 12 or 14 days. Two fluid drachms are equivalent to about ¼ grain of opium. The following is the modified formula of the *National Formulary:*

Tinctura Pectoralis (N. F.), *Pectoral tincture, Guttæ pectorales, Pectoral drops, Bateman's pectoral drops.*—"Tincture of opium (*U. S. P.*), forty-two cubic centimeters (42 Cc.) [1 fl℥, 202 ♏]; compound tincture of catechu (*U. S. P.*), thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; spirit of camphor (*U. S. P.*), forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏]; oil of anise, one cubic centimeter (1 Cc.) [16 ♏]; caramel, sixteen cubic centimeters (16 Cc.) [260 ♏]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the first 5 ingredients with enough diluted alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter. Each fluid drachm contains 2½ minims of tincture of opium"—(*Nat. Form.*).

Tinctura Opii Ammoniata, *Ammoniated tincture of opium.*—Take of "tincture of opium, 3 fluid ounces (Imp.), or 150 cubic centimeters (Metric); benzoic acid, 180 grains, or 20.6 grammes; oil of anise, 1 fluid drachm, or 6.25 cubic centimeters; solution of ammonia, 4 fluid ounces, or 200 cubic centimeters; alcohol (90 per cent), a sufficient quantity. Dissolve the oil of anise and the benzoic acid in 12 fluid ounces (or 600 cubic centimeters) of the alcohol; add the tincture of opium and the solution of ammonia; mix well; filter; add enough of the alcohol to form 1 pint (or 1000 cubic centimeters) of the tincture. Dose, ½ to 1 fluid drachm. This preparation contains the soluble matter of nearly 0.62 grain of opium (containing 10 per cent of morphine, reckoned as anhydrous) in 1 fluid drachm, or of nearly 5 grains of such opium in 1 fluid ounce"(—*Br. Pharm.*, 1898). This preparation is formulated after the old *Edinburgh Pharmacopœia* formula for *Elixir Paregoricum Scoticum*, or *Scotch Paregoric Elixir*, and was used to fulfil the same indications that our paregoric is designed to meet. The excess of ammonia employed and the alcohol hold the opium alkaloids in solution in a free condition. A weaker solution of ammonia would be apt to precipitate the morphine. It is an unsatisfactory preparation, and has once been discarded by the *British Pharmacopœia*. Being much used by the people of Great Britain, it has been reinstated. About 1 grain of opium is represented in every 90 minims.

TINCTURA PHYSOSTIGMATIS (U. S. P.)—TINCTURE OF PHYSOSTIGMA.

Preparation.—"Physostigma, in No. 40 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Physostigma*.) Dose, from 1 to 40 minims, beginning with the smaller doses.

TINCTURA PHYTOLACCÆ.—TINCTURE OF PHYTOLACCA.

Synonym: *Tincture of poke.*

Preparation.—Take of recently dried poke-root, in fine powder, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This tincture possesses the properties of the root (see *Phytolacca*), and may be used where that is indicated, as in *rheumatism*, *scrofula*, *syphilis*, etc. The dose is from 1 to 40 drops, which may be repeated as required.

TINCTURA PODOPHYLLI.—TINCTURE OF PODOPHYLLUM.

SYNONYM: *Tincture of mandrake.*

Preparation.—Take of mandrake root, in fine powder, 3 ounces; alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture. Or, "take of resin of podophyllum, 160 grains; rectified spirit, 1 pint (Imp.). Dissolve and filter. It contains 1 grain of the resin in 1 fluid drachm"—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—This tincture possesses the alterative, cholagogue, purgative, and other properties of the root. The tincture prepared from the root is to be preferred to that made by dissolving the resin. The dose is from 10 to 60 drops.

TINCTURA POLYGONI.—TINCTURE OF POLYGONUM.

SYNONYM: *Tincture of water-pepper.*

Preparation.—Take of water-pepper, the fresh herb, a sufficient quantity to fill a quart jar; then add Holland gin, or proof-spirit, as much as can be held in the jar. Macerate for 7 days; express and filter. This tincture may likewise be made from the dried herb, in powder, 6 ounces, to 1½ pints of proof-spirit, and macerating for 14 days; or by percolation, as explained under *Tincturæ.*

Action, Medical Uses, and Dosage.—This tincture has been used with efficacy in *amenorrhœa*, *dysmenorrhœa*, *suppressed lochial discharge*, and in moderate *menorrhagia.* The dose is a teaspoonful, 3 or 4 times a day.

TINCTURA PULSATILLÆ.—TINCTURE OF PULSATILLA.

Preparation.—Take of the recent herb pulsatilla, cut into small pieces, 8 ounces; absolute alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—(See *Pulsatilla.*) One fluid drachm of this tincture may be added to 4 fluid ounces of water, the dose of which is a teaspoonful, to be repeated several times a day.

TINCTURA PYRETHRI (U. S. P.)—TINCTURE OF PYRETHRUM.

SYNONYM: *Tincture of pellitory.*

Preparation.—"Pyrethrum, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This acrid tincture has a brown-yellow color, and, when in contact with water, becomes milky and opalescent.

Action and Medical Uses.—Used only in tooth and mouth washes; intended as local irritants in *toothache* and *paralytic states of the tongue and fauces.*

TINCTURA QUASSIÆ (U. S. P.)—TINCTURE OF QUASSIA.

Preparation.—"Quassia, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of alcohol to six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of water. Having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). An intensely bitter, pale brown-yellow tincture. It should not strike black with ferric compounds.

Action, Medical Uses, and Dosage.—(See *Quassia.*) Dose, ½ to 1 fluid drachm. In enema, it destroys *ascarides*.

TINCTURA QUILLAJÆ (U. S. P.)—TINCTURE OF QUILLAJA.

SYNONYM: *Tincture of soap bark.*

Preparation.—"Quillaja, coarsely ground, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Boil the quillaja, placed in a suitable vessel, with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of water for 15 minutes, strain, and wash the residue on the strainer with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water. Then boil the strained liquid down to six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏], allow it to cool, mix it with the alcohol, and, when the insoluble matter has subsided, filter the liquid portion through paper, and add enough water to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Uses.—(See *Quillaja.*) This preparation, aside from its therapeutic use, is chiefly employed as an emulsifying agent for oils, balsams, and resins.

TINCTURA QUININÆ COMPOSITA.—COMPOUND TINCTURE OF QUININE.

SYNONYM: *Ague bitters.*

Preparation.—Take of quinine, 30 grains; cream of tartar, 1 ounce; cloves, in powder, 1 ounce; diluted alcohol, 1 pint. Macerate for 24 hours, and filter.

Action, Medical Uses, and Dosage.—This tincture is febrifuge, antiperiodic, and tonic, and is used in *intermittent and remittent fevers*, and other diseases attended with symptoms of a periodical character. In *intermittent fever*, the dose for an adult is ½ fluid ounce every hour during the intermission, until 2 or 3 hours previous to the return of the next expected chill, when the dose should be given every ½ hour. The dose for children is 1 to 2 fluid drachms (T. V. Morrow, M. D.).

Related Tinctures.—TINCTURA QUININÆ, *Tincture of quinine*. "Take of hydrochlorate of quinine, 160 grains; tincture of orange peel, 1 pint (Imp.). Dissolve the hydrochlorate of quinine in the tincture with the aid of a little heat; then allow the solution to remain for 3 days in a closed vessel, shaking occasionally, and afterward filter"—(*Br. Pharm.*, 1885). Each fluid drachm contains 1¼ grains of the quinine salt. The preparation of the *British Pharmacopœia* (1898) contains 175 grains of the quinine salt to 1 pint of tincture of orange.

TINCTURA QUININÆ AMMONIATA, *Ammoniated tincture of quinine.*—"Take of sulphate of quinine, 160 grains; solution of ammonia, 2½ fluid ounces; proof-spirit, 17½ fluid ounces. Dissolve the sulphate of quinine in the spirit with the aid of a little heat, and add the solution of ammonia"—(*Br. Pharm.*, 1885). The preparation of the *British Pharmacopœia* (1898) is about $\frac{1}{11}$ stronger in alkaloid than that of 1885. Each fluid drachm contains 1 grain of the quinine salt. Used in *nervous debility* and *neuralgia*, and other troubles arising therefrom.

TINCTURA RHEI (U. S. P.)—TINCTURE OF RHUBARB.

Preparation.—"Rhubarb, one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]; cardamom, twenty grammes (20 Gm.) [309 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the rhubarb and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the glycerin with six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol, and three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of water. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour on more of a mixture of alcohol and water, made in the same proportions as before, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Tincture of rhubarb deposits upon standing yellow, granular, or crystalline matter, a mixture of *chrysophanic acid* and *emodin*, together with some other rhubarb constituents. The *U. S. P.* aims to prevent this precipitation by directing the use of glycerin and strong alcohol. This does not wholly prevent this phenomenon.

Action, Medical Uses, and Dosage.—This tincture is purgative, stomachic, and tonic. It is principally used in *flatulent colic*, *dyspepsia*, *constipation*, and rarely in *low forms of fever*. The dose, as a purgative, is from ½ to 1 fluid ounce; as a stomachic, 1, 2, or 3 fluid drachms.

Related Tinctures.—TINCTURA RHEI VINOSA (N. F.), *Vinous tincture of rhubarb.* "Fluid extract of rhubarb (*U. S. P.*), eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏]; fluid extract of bitter orange peel (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; tincture of cardamom (*U. S. P.*), eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏]; sugar, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the fluid extracts and the tinctures with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of sherry wine. In this dissolve the sugar by agitation, then add enough sherry wine to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter. *Note.*—This preparation corresponds, in strength, to that which is official in the *German Pharmacopœia*"—(*Nat. Form.*).

TINCTURA RHEI ET GENTIANÆ (N. F.), *Tincture of rhubarb and gentian.*—I. "Rhubarb, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; gentian, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the solids to a moderately coarse (No. 40) powder, and percolate it, in the usual manner, with diluted alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of percolate are obtained. Each fluid drachm represents 4 grains of rhubarb and 1 grain of gentian. *Note.*—When this preparation is required for immediate use, and it is not otherwise obtainable, it may be prepared in the following manner: II. Fluid extract of rhubarb (*U. S. P.*), seventy cubic centimeters (70 Cc.) [2 fl℥, 176 ♏]; fluid extract of gentian (*U. S. P.*), seventeen and one-half cubic centimeters (17.5 Cc.) [284 ♏]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the fluid extracts with enough diluted alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter"—(*Nat. Form.*).

TINCTURA RHEI AQUOSA (N. F.), *Aqueous tincture of rhubarb.*—I. "Rhubarb, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sodium borate, ten grammes (10 Gm.) [154 grs.]; potassium carbonate, ten grammes (10 Gm.) [154 grs.]; cinnamon water (*U. S. P.*), one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; alcohol, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium borate and the potassium carbonate in seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of water, and macerate in this solution, during 24 hours, the rhubarb, cut into thin slices and carefully freed from any adhering fine powder. Then strain it through muslin, heat the strained liquid to boiling, add the cinnamon water and alcohol, stir it well and filter, while warm, in a covered funnel. To the cold filtrate add enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 5⅔ grains of rhubarb. *Note.*—The product is practically identical with that obtained by the process of the *Ger. Pharm.*, in which this preparation is official. It is liable to deteriorate when kept too long, and should not be prepared in larger quantity than may be consumed within a short time. When this preparation is required for immediate use, and it is not otherwise obtainable, it may be prepared in the following manner: II. Fluid extract of rhubarb (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; sodium borate, ten grammes (10 Gm.) [154 grs.]; potassium carbonate, ten grammes (10 Gm.) [154 grs.]; cinnamon water (*U. S. P.*), one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; alcohol, seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium borate and the potassium carbonate in about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water. Add the cinnamon water, alcohol, and fluid extract of rhubarb, and lastly, enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Filter if necessary" (*Nat. Form.*).

TINCTURA RHEI COMPOSITA, *Compound tincture of rhubarb.*—Take of rhubarb, in fine powder, 4 ounces; bitter root, golden seal, gentian, prickly ash berries, each, in fine powder, 2 ounces; sassafras, cardamom seeds, each, in fine powder, 1 ounce; diluted alcohol, 5 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 5 pints of tincture. Compound tincture of rhubarb is laxative, tonic, and stomachic; it is especially useful in debilitated conditions of the digestive organs, *hepatic torpor*, *dyspepsia*, *constipation*, and to restore the tone of the bowels after the removal of *worms*, after *diarrhœas*, *dysenteries*, etc. The dose is from ½ to 1 fluid ounce, 2 or 3 times a day, in sweetened water, or sufficient to procure one, but not over two alvine evacuations daily (J. King).

TINCTURA RHEI AROMATICA (U. S. P.)—AROMATIC TINCTURE OF RHUBARB.

Preparation.—"Rhubarb, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; cassia cinnamon, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; cloves, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; nutmeg, twenty grammes (20 Gm.) [309 grs]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, water, diluted alcohol, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the rhubarb, cinnamon, cloves, and nutmeg, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the glycerin with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol and four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Uses and Dosage.—This tincture has a deep reddish-brown color, and precipitates when mixed with water. It is designed for the purpose of preparing an aromatic syrup of rhubarb. It is liable to precipitate substances like those forming in tincture of rhubarb. It may be added to many purgative tinctures. Dose, 1 to 4 fluid drachms.

TINCTURA RHEI DULCIS (U. S. P.)—SWEET TINCTURE OF RHUBARB.

Preparation.—"Rhubarb, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; glycyrrhiza, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; anise, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; cardamom, ten grammes (10 Gm.) [154 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, water, diluted alcohol, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the rhubarb, glycyrrhiza, anise, and cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the glycerin with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol and four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This preparation contains one-third less rhubarb than tincture of rhubarb, and is of a pleasanter taste than the latter.

Action, Medical Uses, and Dosage.—(See *Rheum.*) Dose, 1 to 3 fluid drachms.

TINCTURA SABINÆ.—TINCTURE OF SAVIN.

Preparation.—"Take of savin tops, dried and coarsely powdered, 2½ ounces (av.); proof-spirit, 1 pint (Imp.)"—(*Br. Pharm.*). Prepare as directed for *Tinctura Sennæ*. This tincture would more nearly represent savin if a stronger alcoholic menstruum were employed. It has a brownish-green color.

Action, Medical Uses, and Dosage.—(See *Sabina.*) Dose, 10 to 60 minims.

TINCTURA SANGUINARIÆ (U. S. P.)—TINCTURE OF SANGUINARIA.

SYNONYMS: *Tincture of bloodroot.*

Preparation.—"Sanguinaria, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; acetic acid, twenty cubic centimeters

(20 Cc.) [325 ♏]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of alcohol to four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the mixture to which the acetic acid had previously been added, and macerate for 24 hours; then pack it firmly in a cylindrical glass percolator, gradually pour on more of a mixture of alcohol and water, made in the same proportions as before, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). The acetic acid in this preparation very materially assists in the extraction of the virtues of the drug, and prevents, in a measure, the precipitation which is liable to occur. This tincture has the characteristic acidity of the drug and is of a deep brown-red color.

Action, Medical Uses, and Dosage.—In the dose of 2 to 4 fluid drachms, this tincture will prove emetic; and from 10 to 60 drops will act as a nauseant, expectorant, stimulant, and alterative (see *Sanguinaria*).

TINCTURA SANGUINARIÆ ACETATA COMPOSITA.—COMPOUND ACETATED TINCTURE OF SANGUINARIA.

SYNONYMS: *Compound acetated tincture of bloodroot, Acetous emetic tincture.*

Preparation.—Take of bloodroot, lobelia, skunk-cabbage root, each, in fine powder, 2 ounces; distilled vinegar, 2 pints, or a sufficient quantity; alcohol, 2 fluid ounces. Place the drugs in the vinegar, and form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 2 pints of tincture, to which add the alcohol.

Action, Medical Uses, and Dosage.—This preparation was formerly much used by physicians as an emetic and expectorant, in all cases where such agents were required. As an emetic, the dose is from 1 to 4 fluid drachms, in some sweetened aromatic infusion, to be repeated every 10 or 15 minutes until vomiting is produced; as an expectorant the dose is from 20 to 60 drops, every 1 or 2 hours. It also forms a useful external application to *erysipelas*, *tetter*, and other forms of *cutaneous disease*.

Related Tincture.—TINCTURA SANGUINARIÆ COMPOSITA, *Compound tincture of bloodroot, Emetic tincture.* Take of bloodroot, lobelia, skunk-cabbage root, each, in fine powder, 2 ounces; diluted alcohol, 2 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 2 pints of tincture. This tincture is used for the same purposes, in the same manner and dose, as the preceding.

TINCTURA SAPONIS VIRIDIS COMPOSITA (N. F.)—COMPOUND TINCTURE OF GREEN SOAP.

Preparation.—"Soft soap (*U. S. P.*), one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; oil of cade, twenty cubic centimeters (20 Cc.) [325 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Dissolve the soft soap in seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol, add the oil of cade, and then enough alcohol to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Employed as an external application in *itching* and *scaly skin diseases* (see *Oleum Cadinum*).

TINCTURA SCILLÆ (U. S. P.)—TINCTURE OF SQUILL.

Preparation.—"Squill, in No. 30 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol to two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of the menstruum, and macerate for 24 hours; then pack it moderately in a conical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This is a pale-yellow tincture, having the nauseant taste of the crude drug. Lustrous tufts of an acrid, bitter substance are precipitated in this tincture, according to Ménière.

Action, Medical Uses, and Dosage.—(See *Scilla.*) Dose, 10 to 20 minims.

TINCTURA SENEGÆ.—TINCTURE OF SENEGA.

Preparation.—Take of "senega root, in No. 40 powder, 4 ounces (Imp.), or 200 grammes (Metric); alcohol (60 per cent), a sufficient quantity. Moisten the powder with 4 fluid ounces (or 200 cubic centimeters) of the alcohol, and complete the percolation process. The resulting tincture should measure 1 pint (or 1000 cubic centimeters)"—(*Br. Pharm.*, 1898). This tincture possesses the acridity of senega, and has a yellow-brown color.

Action, Medical Uses, and Dosage.—(See *Senega.*) Dose, from ½ to 2 fluid drachms.

TINCTURA SENNÆ.—TINCTURE OF SENNA.

SYNONYMS: *Tinctura sennæ composita*, *Elixir salutis.*

Preparation.—"Take of senna, broken small, 2½ ounces (av.); raisins, freed from seeds, 2 ounces (av.); caraway fruit, bruised, ½ ounce (av.); coriander fruit, bruised, ½ ounce (av.); proof-spirit, 1 pint (Imp.). Macerate the solid ingredients for 48 hours in 15 fluid ounces of the spirit, in a closed vessel, agitating occasionally; then transfer to a percolator, and when the fluid ceases to pass, continue the percolation with the remaining 5 ounces of spirit. Afterward subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient proof-spirit to make 1 pint"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs the employment of a somewhat larger quantity of senna (4 ounces, Imp.).

Action, Medical Uses, and Dosage.—(See *Sennæ.*) Dose, from 1 to 4 fluid drachms.

Related Tincture.—TINCTURA SENNÆ COMPOSITA, *Compound tincture of senna, Elixir salutis.* Take of Alexandria senna, 2 ounces; jalap, in fine powder, 1 ounce; fennel or coriander seeds, ½ ounce; raisins, deprived of their seeds, 3 ounces; best French brandy, or diluted alcohol, 2 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 2 pints of tincture (*Ed.—Lond.*). This is an excellent purgative, especially for children, as it acts mildly and pleasantly. It is also useful in cases of *constipation* attended with *flatulence*. The dose for an adult is from ½ to 1 fluid ounce; for a child a year old, 1 fluid drachm. It may be given in a little sweetened water.

TINCTURA SERPENTARIÆ (U. S. P.)—TINCTURE OF SERPENTARIA.

Preparation.—"Serpentaria, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has the characteristic taste and odor of Virginia snakeroot, and a brown-yellow color.

Action, Medical Uses, and Dosage.—(See *Serpentaria.*) Dose, from 1 to 3 fluid drachms.

TINCTURA SERPENTARIÆ COMPOSITA.—COMPOUND TINCTURE OF SERPENTARIA.

SYNONYMS: *Compound tincture of Virginia snakeroot*, *Sudorific tincture.*

Preparation.—Take of Virginia snakeroot, ipecacuanha, each, in fine powder, saffron, camphor, and opium, each, in moderately coarse powder, 2 ounces; Holland gin, or diluted alcohol, 6 pints. Macerate for 14 days; express and filter through paper (Beach's *Amer. Prac.*). This tincture may also be prepared by percolation. The above is the original, and undoubtedly the best form of preparing this tincture, yet some physicians are opposed to the opium, and substitute in its place ladies'-slipper root, 8 ounces.

Action, Medical Uses, and Dosage.—This is a powerful sudorific, and is used in all cases where a copious perspiration is required, or where it is desired to lessen pain, allay nervous excitability, procure sleep, and keep up a determination to the skin. One teaspoonful in some warm herb tea, repeated every hour, aided by warm infusions and bathing the feet, will soon produce copious diaphoresis. In *pleurisy*, a much larger dose may be given. In other cases, it may be given in doses of from 10 to 60 drops. It will be found beneficial in *after-pains*, *painful dysmenorrhœa*, *amenorrhœa*, from recent exposure to cold, *cramp in the stomach*, *hysteria*, in *fevers* and *inflammatory diseases*, etc. Forty-eight minims of this tincture are equivalent to 1 grain of opium, as well as 1 grain of camphor, etc.

TINCTURA STAPHISAGRIÆ.—TINCTURE OF STAPHISAGRIA.

SYNONYM: *Tincture of stavesacre.*

Preparation.—Take of the seeds of stavesacre, in fine powder, 5 ounces; absolute alcohol, 8 fluid ounces, or a sufficient quantity. Form into a tincture by maceration or percolation, and make ½ pint of tincture.

Action, Medical Uses, and Dosage.—(See *Staphisagria.*) From 10 to 60 drops of this tincture may be added to 3 or 4 fluid ounces of water, the dose of which is a teaspoonful, to be repeated 3 or 4 times a day.

TINCTURA STILLINGIÆ.—TINCTURE OF STILLINGIA.

SYNONYM: *Tincture of queen's root.*

Preparation.—Take of the recent queen's root, cut into small pieces and bruised, 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity. Form into a tincture by maceration, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—This tincture possesses the virtues of the root, and may be used as a substitute for it in *scrofulous, syphilitic and rheumatic diseases.* It is likewise beneficial in *laryngeal*, *bronchial*, and *pulmonary affections.* The dose is from 10 to 30 or even 60 drops, to be administered in sweetened water. It may likewise be advantageously added to alterative syrups or tinctures.

TINCTURA STRAMONII SEMINIS (U. S. P.)—TINCTURE OF STRAMONIUM SEED.

SYNONYM: *Tinctura stramonii* (*U. S. P.*, 1880).

Preparation.—"Stramonium seed, in No. 40 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of diluted alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour diluted alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). The official tincture has a brown-yellow color, and, when dropped into, water renders it opalescent.

Action, Medical Uses, and Dosage.—This preparation may be administered wherever stramonium is indicated (see *Stramonium*). The dose is from 5 to 40 drops (employing the smaller doses at first), repeated every 3 or 4 hours, gradually increasing it, if necessary.

TINCTURA STROPHANTHI (U. S. P.)—TINCTURE OF STROPHANTHUS.

Preparation.—"Strophanthus, in No. 30 powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Digest the powder with seventy cubic centimeters (70 Cc.) [2 fl℥, 176 ♏] of the menstruum for 2 days, then transfer to a cylindrical percolator, gradually pour menstruum upon it, and continue the percolation very slowly, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained" (*U. S. P.*). Strophanthus seeds are not easily bruised, and, to facilitate their comminution, Dr. Squibb proposed to bruise them with fragments of glass in an iron mortar (*Ephemeris*, Vol. III, p. 15). An abundance of oil is contained in the seeds, for the removal of which no provision has been made in the official process. The process (see below) given by the *National Formulary* directs the use of ether in order to extract the oil. If made according to the *U. S. P.* official directions, the tincture has a brown-yellow or amber color; if according to the *National Formulary*, the color is green-yellow. It has a very bitter taste. The use of benzin to extract the oil has been suggested, but is not desirable, because it is difficult to remove from the tincture the benzin odor imparted to it. The tincture of strophanthus of the *British Pharmacopœia*, 1885 (*Additions*, 1890), likewise has the strength of 1 in 20, but directions are given to remove the oil with ether. The tincture of strophanthus of the *British Pharmacopœia* (1898) is prepared with half the proportion of strophanthus seeds used in the preceding Pharmacopœia; the previous extraction of oil by means of ether is omitted. Regarding the assay of tincture of strophanthus, see under *Strophanthus*.)

Action, Medical Uses, and Dosage.—(See *Strophanthus*.) Dose, from 1 to 10 minims.

Related Tincture.—TINCTURA STROPHANTHI (N. F.), *Tincture of strophanthus*. "Strophanthus seeds, freed from their comose appendage, reduced to No. 30 powder, and dried at 50° C. (122° F.), 1 troy ounce; stronger ether, a sufficient quantity; alcohol, enough to make 20 fluid ounces. Pack the strophanthus in a suitable percolator, pour on enough stronger ether to saturate the powder thoroughly, cover the percolator, and macerate during 24 hours. Then allow the percolation to proceed, gradually pouring on stronger ether, until the liquid passes through colorless. This ethereal percolate is to be rejected. Remove the marc from the percolator, and dry it, first by exposure to air, then at a temperature of 50° C. (122° F.). Again reduce it to powder, moisten it with alcohol, repack it in the percolator, and macerate during 48 hours. Then percolate it with alcohol, in the usual manner, until twenty (20) fluid ounces of tincture are obtained. Each fluid drachm represents 3 grains of strophanthus. The dose is about 2 to 10 minims. *Note.*—Strophanthus seeds are obtained from one or more species of *Strophanthus*, growing in eastern Africa, and are usually referred to *Strophanthus Kombé*, Oliver"—(*Nat. Form.*, 1st. ed.).

TINCTURA SUMBUL (U. S. P.)—TINCTURE OF SUMBUL.

Preparation.—"Sumbul, in No. 30 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Sumbul*.) Dose, 10 to 60 minims.

TINCTURA SYMPLOCARPI.—TINCTURE OF SYMPLOCARPUS.

SYNONYM: *Tincture of skunk-cabbage.*

Preparation.—Take of recently dried skunk-cabbage root, in fine powder 3 ounces; diluted alcohol, 1 pint, or a sufficient quantity (Beach's *Amer. Prac.*). Form into a tincture by maceration or percolation, and make 1 pint of tincture.

Action, Medical Uses, and Dosage.—Tincture of skunk-cabbage is antispasmodic, and will be found useful in *asthma*, *pertussis*, *hysteria*, and other *spasmodic affections*. It is also beneficial in *irritable or excitable conditions of the nervous system*. The dose is from 1 fluid drachm to ½ fluid ounce, repeated as often as required.

TINCTURA TOLUTANA (U. S. P.)—TINCTURE OF TOLU.

Preparation.—"Balsam of tolu, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Add the balsam of tolu to nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of alcohol, and macerate until it is dissolved; then filter through paper, adding through the filter, enough alcohol to make the tincture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). A yellow tincture, striking milky with water.

Action, Medical Uses, and Dosage.—This tincture possesses the properties of balsam of tolu, and may be used in *cough* and *chronic catarrhal diseases;* also as an adjunct to cough and expectorant compounds. The dose is from ½ to 1 or 2 fluid drachms.

Related Tincture.—TINCTURA TOLUTANA SOLUBILIS (N. F.), *Soluble tincture of tolu.* "Balsam of tolu, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; magnesium carbonate, ten grammes (10 Gm.) [154 grs.]; glycerin, four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏]; water, alcohol, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of alcohol with the glycerin, and dissolve the balsam of tolu in the mixture with the aid of heat, avoiding loss by evaporation. Next add four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water, and allow the mixture to become cold. Pour off the milky liquid from the resinous precipitate (which latter is to be rejected), mix it with the magnesium carbonate, by trituration, and filter. Lastly, pass enough of a mixture of one (1) volume of alcohol and two (2) volumes of water through the filter, to make the whole filtrate measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This preparation may be added to syrup or water without producing cloudiness. A mixture of 1 fluid ounce of this preparation with 15 fluid ounces of syrup yields a product which may be used as syrup of tolu in all cases where the official preparation is not required"—(*Nat. Form.*).

TINCTURA TOXICODENDRI.—TINCTURE OF POISON OAK.

SYNONYM: *Tincture of Rhus Toxicodendron.*

Preparation.—Take of fresh leaves of poison oak, 4 ounces; alcohol, 3 fluid ounces. Macerate for 14 days; express and filter under cover.

Action, Medical Uses, and Dosage.—This tincture may be used for all the purposes for which the poison oak is given, in the dose of from a fraction of a drop to 5 drops, in water. It should be kept in vials, well stoppered, as its active principle becomes dissipated on exposure.

TINCTURA VALERIANÆ (U. S. P.)—TINCTURE OF VALERIAN.

Preparation.—"Valerian, in No. 60 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol to two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Tincture of valerian depends, for its color, upon the condition of the valerian employed. Its color is either brown or red-brown, and, when added to water, it renders the latter turbid. The odor and taste of valerian is well preserved.

Action, Medical Uses, and Dosage.—(See *Valeriana.*) Dose, from ½ to 2 fluid drachms.

TINCTURA VALERIANÆ AMMONIATA (U. S. P.)—AMMONIATED TINCTURE OF VALERIAN.

Synonym: *Tinctura valerianæ composita.*

Preparation.—"Valerian, in No. 60 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; aromatic spirit of ammonia, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of aromatic spirit of ammonia, and macerate for 24 hours, in a closed vessel; then pack it firmly in a cylindrical glass percolator, and gradually pour aromatic spirit of ammonia upon it, keeping the percolator well covered, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture exhibits the sensible properties of ammonia and valerian. It has a brown color.

Action, Medical Uses, and Dosage.—This forms an excellent antispasmodic in *hysterical and nervous attacks*, especially when attended with *gastric acidity*. The dose is 1 or 2 fluid drachms, in mucilage, milk, or some sweetened fluid.

TINCTURA VANILLÆ (U. S. P.)—TINCTURE OF VANILLA.

Preparation.—"Vanilla, cut into small pieces and bruised, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sugar, in coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix alcohol and water in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water. Macerate the vanilla in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of this mixture for 12 hours, then drain off the liquid, and set it aside. Transfer the vanilla to a mortar, beat it with the sugar into a uniform powder, then pack it in a percolator, and pour upon it the reserved liquid. When this has disappeared from the surface, gradually pour on menstruum, and continue the percolation, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture represents what was known as *Fluid extract* or *Essence of vanilla.* It is, however, much stronger than commercial extract of vanilla (1 ounce to 1 pint). When added to syrup in the proportion of ounce to pint, it yields a good *Syrup of vanilla.*

Uses.—Tincture of vanilla is used exclusively as a flavoring substance.

Related Tincture.—Tinctura Vanillini Composita (N. F.), *Compound tincture of vanillin, Compound essence of vanillin.* "Vanillin, six and one-half grammes (6.5 Gm.) [100 grs.]; cumarin, four decigrammes (0.4 Gm.) [6 grs.]; alcohol, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; syrup (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; compound tincture of cudbear (F. 419), sixteen cubic centimeters (16 Cc.) [260 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the vanillin and cumarin in the alcohol, add the glycerin and syrup, and compound tincture of cudbear, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form*).

TINCTURA VERATRI VIRIDIS (U. S. P.)—TINCTURE OF VERATRUM VIRIDE.

Synonyms: *Tincture of American hellebore, Tincture of green hellebore.*

Preparation.—"Veratrum viride, in No. 60 powder, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). This tincture has a dark reddish-brown color. When dropped into water it produces an opalescence and renders the mixture turbid. Its taste is acrid and bitter. It should not be confused with *Tincture of Helleborus viridis*, a European drug.

Action, Medical Uses, and Dosage.—(See *Veratrum.*) The dose is from 1 to 5 minims.

TINCTURA VIBURNI COMPOSITA.—COMPOUND TINCTURE OF VIBURNUM.

SYNONYM: *Compound tincture of high-cranberry bark.*

Preparation.—Take of high-cranberry bark, in fine powder, 2 ounces; lobelia seed, skunk-cabbage seed, each, in fine powder, 1 ounce; stramonium seed, bruised, capsicum, bloodroot, each, in fine powder, ½ ounce; alcohol, 4 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 4 pints of tincture.

Action, Medical Uses, and Dosage.—This old Eclectic tincture is a stimulant and antispasmodic, and will be found efficacious in *asthma*, *hysteria*, and *nervous and spasmodic diseases.* I have effected many cures of asthma (uncomplicated) with this remedy. The dose is from 20 to 60 drops, 3 times a day; or, during a paroxysm, as often as required (J. King).

TINCTURA VIBURNI OPULI COMPOSITA (N. F.), *Compound tincture of viburnum.*—"Viburnum opulus, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; dioscorea, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; scullcap, ten grammes (10 Gm.) [154 grs.]; cloves, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; cinnamon, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the drugs to a moderately coarse (No. 40) powder. Mix the glycerin with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol and moisten the powder with one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of this mixture, and macerate for 48 hours in a percolator. Then percolate with the remainder of this menstruum, followed by a mixture of five (5) volumes of alcohol and one (1) volume of water, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*Nat. Form.*).

TINCTURA XANTHOXYLI.—TINCTURE OF XANTHOXYLUM.

SYNONYM: *Tincture of prickly ash berries.*

Preparation.—Take of prickly ash berries, in fine powder, 8 ounces; diluted alcohol, 2 pints, or a sufficient quantity. Form into a tincture by maceration or percolation, as explained under *Tincturæ*, and make 2 pints of tincture.

Action, Medical Uses, and Dosage.—This tincture possesses all the virtues of the berries (see *Prickly Ash Berries*). In *cholera*, the dose is from ½ to 1 fluid ounce, repeated as often as required; in ordinary cases, from 1 to 4 fluid drachms, given in water. Probably a tincture of the oil of the berries will effect the same results (J. King).

TINCTURA ZEDOARIÆ AMARA (N. F.)—BITTER TINCTURE OF ZEDOARY.

SYNONYM: *Compound tincture of zedoary.*

Preparation.—"Zedoary, root, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; aloes, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; rhubarb, sixty-two grammes (62 Gm.) [2 ozs. av., 82 grs.]; gentian, sixty-two grammes (62 Gm.) [2 ozs. av., 82 grs.]; white agaric, sixty-two grammes (62 Gm.) [2 ozs. av., 82 grs.]; saffron, sixty-two grammes (62 Gm.) [2 ozs. av., 82 grs.]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; alcohol, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the solids to a moderately coarse (No. 40) powder, moisten this with a sufficient quantity of a mixture of two (2) volumes of alcohol and one (1) volume of water, and percolate it in the usual manner, with this menstruum, until seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of percolate are obtained. Add to this the glycerin, and set it aside. Then continue the percolation until the drugs are practically exhausted. Evaporate the new percolate to one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏], and add it to the reserved portion. Each fluid drachm represents 15 grains of zedoary, 7½ grains of aloes, and 3¾ grains, each, of the other drugs. *Note.*—The above preparation is not identical with the *Tinctura Zedoariæ Composita* (also known as *Tinctura Carminativa*, *Tinctura Wedelii*), which was formerly official in some continental pharmacopœias"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Zedoary.*)

TINCTURA ZINGIBERIS (U. S. P.)—TINCTURE OF GINGER.

Preparation.—"Ginger, in No. 40 powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the ginger with fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏] of alcohol, and macerate for 24 hours; then pack it firmly in a cylindrical percolator, and gradually pour alcohol upon it, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of tincture are obtained"—(*U. S. P.*). Good Jamaica ginger is required in preparing this tincture. A turbid tincture results if dilute alcohol be employed. The preparation has a brown-yellow or reddish color, and has the characteristic pungent taste and aroma of ginger. When added to water, it renders the latter milky.

Action, Medical Uses, and Dosage.—(See *Zingiber.*) Tincture of ginger is an aromatic carminative, and may be added to tonic, purgative, and aromatic preparations with advantage. It may be used in *flatulency*, *torpor of the digestive organs*, and in *debilitated conditions of the alimentary canal*. The dose is from 10 to 60 drops, in sweetened water, milk, wine, or mucilage, as the indications will allow. Its chief use is in the preparation of syrup of ginger.

Related Tincture.—TINCTURA ZINGIBERIS FORTIOR, *Strong tincture of ginger*, *Essence of ginger*. "Take of ginger, in fine powder, 10 ounces (av.); rectified spirit, a sufficiency. Pack the ginger tightly in a percolator, and pour over it carefully ½ pint of the spirit, at the expiration of 2 hours add more spirit, and let it percolate slowly until 1 pint of tincture has been collected"—(*Br. Pharm.*, 1885). Dose, 15 to 60 minims.

TORMENTILLA.—TORMENTIL.

The root of *Potentilla Tormentilla*, Schrank (*Tormentilla erecta*, Willdenow; *Tormentilla officinalis*, Smith).

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Tormentil*, *Septfoil*.

Botanical Source.—Tormentil has a perennial, tough, woody rhizome, about the thickness and length of the upper joint of the forefinger, with numerous radicles. The stems are slender, weak, erect, often procumbent, branching at the summit, and 5 or 10 inches high. The leaves are almost sessile, and consist of 3 oblong, acute, deeply serrated, somewhat hairy leaflets; the stipules are smaller than the leaflets, and deeply cut. The flowers are small, bright-yellow, with the parts of the calyx and corolla in fours, and borne on slender, axillary, hairy stalks much longer than the leaves. Carpels corrugated when ripe (L.).

History and Description.—Tormentil, or septfoil, is a plant common to Europe. All parts of it are astringent, but the rhizome is the part usually employed. It has a very irregular external form, being sometimes cylindrical, at others, tuberculated. Externally, it is of a dark red-brown color; internally, flesh-red or brownish. Its taste is strongly astringent, and its odor faintly aromatic. Water takes up its astringent principle; the infusion forms a black-greenish precipitate of tannate of iron with ferric chloride, and a grayish, curdy one of tannate of gelatin with a solution of gelatin. In the Faroe and Orkney islands it is used in tanning leather; in Lapland it is used as a red dye. It is equally applicable in medicine with catechu, kino, and other foreign astringents.

Chemical Composition.—According to Rembold (1867), tormentilla root contains *tormentilla-tannic acid* ($C_{26}H_{22}O_{11}$; 24 to 30 per cent, Bowman, 1869), with *quinovic* ($C_{24}H_{38}O_4$, Hlasiwetz) and some *ellagic acid* ($C_{14}H_6O_8$). When the tannic acid is heated with diluted sulphuric acid, insoluble *tormentilla-red*, a phlobaphene, but no sugar, is formed. Rembold believes it identical with rhatany-red and hippocastanum-red. Fused with caustic potash, it forms *phloroglucin* and *protocatechuic acid*. Calcium oxalate is also a constituent of the root.

Action, Medical Uses, and Dosage.—Tormentil is astringent and tonic, and may be used in *chronic diarrhœa* and *dysentery*, *passive hemorrhages*, etc., in decoction; also as an astringent injection, and as a local application to flabby *ulcers*. Dose of the decoction, 1 or 2 fluid ounces; of the extract, 10 or 15 grains; of the powdered root, from 30 to 60 grains, 3 or 4 times a day. The extract may be made by boiling 1 part of the coarsely-bruised root with 8 parts of water; straining; repeating the boiling with another equal quantity of water; mixing the two strained decoctions; and evaporating to the consistence of an extract. Alum or tannic acid may be added to this, as required.

Related Species.—*Potentilla canadensis*, Linné, *Five-finger.*—This is a perennial, villose-pubescent plant, frequently known by the name of *Cinque-foil.* It has a sarmentose, procumbent and ascending stem, 2 to 18 inches in length. Leaves palmately 5-foliate; leaflets obovate, silky beneath, cut-dentate toward the apex, entire and attenuate toward the base. Stipules ovate, hairy, deeply 2 or 3-cleft, or entire. Flowers yellow, on long, axillary, solitary pedicels. Calyx segments lanceolate or linear; bracteoles of the calyx longer than the segments, nearly as long as the petals; petals obcordate, longer than the calyx. There are two varieties of this plant, the *Potentilla canadensis*, var. *pumila*, which is very small and delicate, flowering in April and May, growing in dry, sandy soils, and the stem rising about 3 or 4 inches. The other is the *Potentilla canadensis*, var. *simplex*, which is less hirsute, with a simple stem, erect or ascending at base, and oval-cuneiform leaflets. It grows in richer soils to 12 and 16 inches high, and flowers from June to August (W.—G.). Five-finger is common to the United States, growing by roadsides, on meadow banks and waste grounds, and flowering from April to October. It is the *Potentilla sarmentosa* of some botanists. The root is the part used. It has a bitterish, styptic taste, and yields its virtues to water. This plant is a tonic and astringent. A decoction has been found useful in *fevers*, *bowel complaints*, *night-sweats*, *menorrhagia*, and other *hemorrhages*; also, it is an excellent local application in form of gargle, for *spongy*, *bleeding gums*, and *ulcerated mouth and throat.* The European herb, *Potentilla reptans*, possesses similar properties.

The following species contain a bitter body, mucilage, tannin, etc.: *Potentilla reptans*, Linné, *Creeping cinque-foil; P. fruticosa*, Linné, *Shrubby cinque-foil; P. palustris*, Scopoli. *Marsh cinque-foil; P. anserina*, Linné, *Silverweed*, *Goose-grass;* and *P. argentea*, Linné, *Silvery cinque-foil.*

TRAGACANTHA (U. S. P.)—TRAGACANTH.

"A gummy exudation from *Astragalus gummifer*, Labillardière, and from other species of *Astragalus*"—(*U. S. P.*).

Nat. Ord.—Leguminosæ.

Common Names and Synonym: *Tragacanth*, *Gum tragacanth; Gummi tragacantha.*

Botanical Source and History.—"Tragacanth is the gummy exudation from the stems of several species of *Astragalus*, belonging to the subgenus *Tragacantha.* The plants of this group are low perennial shrubs, remarkable for their leaves having a strong, persistent, spiny petiole. As the leaves and shoots are very numerous and regular, many of the species have the singular aspect of thorny, hemispherical cushions, lying close to the ground, while others, which are those furnishing the gum, grow erect with a naked, woody stem, and somewhat resemble furze bushes. A few species occur in southwestern Europe, others are found in Greece and Turkey; but the largest number are inhabitants of the mountainous regions of Asia Minor, Syria, Armenia, Kurdistan, and Persia. The tragacanth of commerce is produced in the last-named countries" (*Pharmacographia*). The same authority enumerates, among others, the following species, the list being based upon Boissier's *Flora Orientalis* (1872), and revised by Haussknecht, who studied the gum-yielding shrubs in their native habitat:

I. *Astragalus adscendens*, Boissier and Haussknecht.—Mountains of southwest Persia. Yields an abundance of gum.

II. *Astragalus leioclados*, Boissier.

III. *Astragalus brachycalyx*, Fischer.—Mountains of Persian Kurdistan.

IV. *Astragalus gummifer*, Labillardière. A small shrub of wide distribution, occurring on the Lebanon and Mount Hermon, in Syria; the Beryt Dagh, in Cataonia; the Arjish Dagh (Mount Argæus), near Kaisariyeh, in central Asia Minor; and in Armenia and northern Kurdistan.

V. *Astragalus microcephalus*, Willdenow. From the southwest of Asia Minor to the northeast coast, and to Turkish and Russian Armenia.

VI. *Astragalus pycnocladus*, Boissier and Haussknecht. Closely related to the preceding. High mountains of Persia. Yields gum in abundance.

VII. *Astragalus stromatodes*, Bunge.—Northern Syria. This and the next species are the chief source of so-called *Aintab tragacanth*.

VIII. *Astragalus kurdicus*, Boissier.—Mountains of Cilicia and Cappadocia, extending to Kurdistan.

IX. *Astragalus Parnassi*, Boissier, var. *cyllenea*.—Northern mountains of Morea. Yields the tragacanth of Greece.

X. *Astragalus verus*, Olivier.—Northwest Persia and Asia Minor. Probably yields some tragacanth.

Collection, Description, and Tests.—Tragacanth exudes naturally from July to September, either from wounds cut into the shrub, or from spontaneous fissures. It usually assumes the form of tortuous bands of a parchment-like appearance. Sometimes it exudes in large tears, which have more or less the vermicular form, it then has a reddish color, and is less pure. As officially described, tragacanth occurs in "narrow or broad bands, more or less curved or contorted, marked by parallel lines or ridges, white or faintly yellowish, translucent, horn-like, tough, and rendered more easily pulverizable by a heat of 50° C. (122° F.). On treating tragacanth with water, it swells, and gradually forms a gelatinous mass, which is tinged blue by iodine T.S., and the fluid portion of which is precipitated on the addition of alcohol, but is not colored blue by iodine T.S."—(*U. S. P.*). Solution of gum tragacanth, when dry, is more adhesive than gum Arabic.

According to Sidney H. Maltass (*Amer. Jour. Pharm.*, 1855, p. 423), tragacanth is collected principally in Caissar, Yalavatz, Isbarta, Bourdur, and Angora. In July and August the natives clear away the earth from the lower part of the stem of the shrub, and make several longitudinal incisions in the bark with a knife. The gum exudes the whole length of the incision, and dries in flakes, and in 3 or 4 days is collected. If the weather be hot and dry, the gum is white and clean; if it be damp, with but moderate heat, the gum requires a longer time to dry, and assumes a brown or yellow tinge. When packed for exportation, the large, white, flaky or *leaf gum* is picked out, and the residue is sifted through a coarse sieve; what remains upon the sieve is *common* or *sorts gum*. The gum which passed through the first sieve is now resifted in a finer sieve, that which passes through being termed *Sesame seed*, and that remaining on the sieve, *Vermicelli*. All these latter varieties are carefully picked by women, who reject the impurities, and place the purer pieces with the first two qualities. Tragacanth is very liable to adulteration with Moussul gum and Caramania gum (an exudation from plum and almond trees, sometimes known as *Bassora gum*, *Hog gum tragacanth*, or *Kutera gum*), two inferior articles, of a dark color, and which do not occur in flaky pieces, but which are pounded into small, angular pieces after having been whitened with white lead. In English commerce, the best tragacanth is known as *Syrian tragacanth*. In this country, distinction is made between *Aleppo* and *Turkey tragacanth*, the latter commanding a somewhat higher price.

Chemical Composition.—Gum tragacanth, according to Giraud (*Amer. Jour. Pharm.*, 1875, p. 329, and 1878, p. 127), consists of water (20 per cent), pectic compounds (*bassorin*, perhaps Frémy's *pectose*, 60 per cent; it is insoluble in water, but swells up when in contact with it; also called *tragacanthin*, *adraganthin*), soluble gum (*pectin*, not arabin [see *Acacia*], 8 to 10 per cent), cellulose (3 per cent), starch (2 to 3 per cent), mineral matters (3 per cent), nitrogenous matters (traces). John Ogle's results (*ibid.*, 1889, p. 427, from *Pharm. Jour. Trans.*) show moisture (18.92 per cent), soluble gum (35.94 per cent), ash (2.75 per cent), and insoluble gum (42.39 per cent). No starch was found, although its non occurrence is very rare (see Prof. Maisch, *ibid.*, foot-note; and E. Masing, *Archiv der Pharm.*, Vol. CXVII, 1880, p. 41). The insoluble part can be converted into water-soluble pectin by boiling the gum for 3 hours with a 1 per cent acid solution; also by long-continued boiling with water alone (Giraud). The resulting pectin is insoluble in alcohol. Non-fermentable sugar is likewise formed in this reaction. The insoluble part of gum tragacanth is dissolved with yellow color by strong alkalies. The soluble portion presents the following differences from arabin (see *Acacia*). It does not exhibit an acid reaction (Flückiger, 1891), does not precipitate with solution of borax, nor of ferric chloride. It is precipitated both by neutral and basic lead acetate, while acacia is precipitated by the basic lead salt only. E. Masing (*loc. cit.*) found the ash in 24 specimens to vary from 1.8 to 4.5 per cent; in exceptional cases (*Sterculia gums*, etc.) it was 6.4 to 8 per cent. (For a chemical comparison of the Australian sterculia gums with tragacanth, see J. H. Maiden, *Amer. Jour. Pharm.*, 1890, p. 26.)

Action and Medical Uses—Tragacanth can only act as a demulcent; but on account of its insolubility, it is rarely given internally. In powder, it is used as a vehicle for active and heavy medicines, for the purpose of giving cohesion and firmness to lozenges, and to form paste, which druggists use to label their prescriptions. Tragacanth, 1 ounce; gum Arabic, white sugar, each, 2 ounces, mixed together, in very fine powder, forms an excellent paste for covering microscopic slides with paper, as it dries quickly before it can become sour or moldy. It should be made into paste only as required for use, though a paste for labelling purposes may be preserved for a considerable time by the addition of a few drops of oil of cloves, adding water, when necessary, to thin the product.

Related Gums.—(See *Hog Gum.*) SARCOCOLLA. The gum-resinous exudate from *Penæa Sarcocolla*, Linné; *Penæa mucronata*, Linné, and other species of *Penææ* (*Nat. Ord.*—Penæaceæ). Shrubs of central and south Africa. The exudation, according to Dymock (1879), also comes from Bushire. The latter product is usually accompanied by fragments and seeds of a leguminous plant, probably an *Astragalus*. Sarcocolla consists of small, rounded, yellowish, reddish or brownish, sponge-like grains, quite friable, and often in agglutinated masses. Fine hairs are often found intermixed with it. It has no odor, except, when heated, it evolves the odor of burning sugar, but has an insipid and sweetish taste, followed by bitterish acridity; the taste has been compared to that of liquorice root. Water dissolves the gum; in alcohol it is nearly wholly soluble, the residue consisting of impurities. According to Pelletier (1834), ether separates from it a resin; from the residue, alcohol extracts a peculiar body (*sarcocollin*), white gummy material remaining. *Sarcocollin* ($C_{13}H_{23}O_6$), or pure sarcocolla, constitutes about 65 per cent of the drug. It is amorphous, both bitter and sweet to the taste, and soluble in water and alcohol. It was regarded by Dr. Thompson as holding a position intermediate between gum and sugar. Sarcocolla is not now employed in medicine, but was formerly used to heal *wounds*, check *otorrhœa*, and as an application to *scrofulous enlargements* and *chronic articular inflammations*.

SASSA GUM.—A gum introduced from the Orient, forming mammillated masses, or convoluted, translucent segments, of a reddish hue, and somewhat shiny surface. It resembles tragacanth in taste, except that it is also subacrid. It softens in water, swelling to 3 or 4 times its bulk, and becomes white. It does not, however, form a mucilage. Iodine colors it blue.

CASHEW GUM.—A brownish-yellow gum, which is translucent, feebly iridescent, and partially dissolved by water, is obtained from the *Anacardium occidentale*, Linné. It is also known as *Gomme acajou*.

CHERRY GUM.—Irregular and nodular masses exuded from various species of plum and cherry. It is translucent, imperfectly soluble in water, and has a brownish or amber color.

Related Species.—*Astragalus bœoticus*, Linné. Mediterranean basin. Seeds have been substituted for coffee.

Astragalus glycyphyllos, Linné.—Leaves and seeds diuretic.

Astragalus escapus, Linné.—Root is bitter, astringent, and mucilaginous; diuretic.

LOCO OR CRAZY WEEDS.—Under these common names several western weeds have been known, and poisonous effects upon horses and cattle have been attributed to them. A small amount of an alkaloid was isolated from one of the plants, but no toxic effects were produced. Prof. J. U. Lloyd, who has studied the subject, suggests that, possibly, the poisonous effects may be due to a ferment, such as gives jequirity its virulence. The subject has not yet been settled. These plants are the *Astragalus mollissimus*, Torrey, west of the Mississippi, from Nebraska south to Texas, *Oxytropis Lamberti*, *Crotalaria sagittalis*, and other plants. From Lloyd's papers on *Loco* (*Ec. Med. Jour.*), we abstract the following:

"Loco yields the usual constituents of herbs. It may be safely said that, if a specimen of the plant were to be examined, in the ordinary manner, by a chemist who had no idea of its importance, he would report that it did not contain a characteristic proximate constituent. Gum, chlorophyll, fat, resin, coloring matter, mineral salts abound, and, as is usual with most plants, alkaloidal reactions. No alkaloids in abundance, none toxic at least, no toxic glucosid. Such were my experiences. The physiological investigations were, in turn, as barren of results. Neither any constituent, nor the tincture or extract of the herb, seemed to be dominated by any physiologically active agent. I became skeptical concerning even the reputed virulence of loco, and would chew the plant, and swallow the spittle. Whether it be that conditions were not favorable to my research, or that my methods were at fault, remained undetermined; loco products would not 'loco.'"

"Preparations of the loco plant and the plant in substance have no physiological effect on men, rabbits, cats, or dogs. Cattle, horses, and sheep are the animals subject to the disease, 'locoed.' Horses are the most easily affected, cattle being less subject than either horses or sheep. The principal symptoms, as manifested in the horse, are hallucination, followed by dangerous and uncontrollable mania. The muscular system is seriously impaired, the movements of the beast being uncertain and staggering, not unlike those of intoxicated beings. The animal loses the power to back. A characteristic feature in this disease is the peculiar high step taken by the animal, which often, when urged over a very small obstacle, leaps as if making an effort to get over a very high object. A prominent characteristic is the great emaciation, the body soon becoming totally devoid of fat. In the more advanced stage, the animal becomes stupid, prefers to be alone, wanders around listlessly and aimlessly, and will eat no other food but the loco, wandering from the loco to water, and from water back to loco. Any excitement brings on fits, more especially if the animal be driven through water, when it frequently becomes so exhausted as to fall helplessly into the stream, and is drowned; even a depth of 1 or 2 feet is sufficient. The mucous tissues are extremely pallid, the bowels constipated, the hair becomes rough and lusterless. The principal post-mortem changes seem to be a softening of the intestinal tract, which is infested with an enormous amount of parasites of various kinds. The intestines are, in some places, perforated, or at least so friable as to prevent handling without breaking apart in places. A constant feature in horses is a hemorrhagic floating clot in the fourth ventricle, and at the base of the brain, suspended in an abnormally large quantity of serum. All the serous cavities are filled with an excessive secretion of serum. The animal appears to perish from starvation, with constant excitement of the nervous system, but sometimes appears to suffer acute pain, causing him to expend his strength in running wildly from place to place, pawing and rolling until he falls and dies in a few minutes. Cattle, in addition to appearing wasted, seem to be stunted in their growth, so that a 4-year-old animal, affected with loco during its growth, becomes no larger than it should be at 2 years. This briefly gives the results of the disease as condensed from *Bulletin No.* 25 of the *Colorado State Agricultural College*, the subject being admirably treated by the author, David O'Brine." For full information on this subject, consult the papers referred to.)

Baccharis cordifolia.—The South American composite, *Mio Mio*, exerts a deadly force upon sheep and cattle. It contains an alkaloid, *baccharine*, isolated by P. N. Arata (*Pharm. Jour. Trans.*, Vol. X, 1879, p. 6[illegible]).

TRIFOLIUM.—RED CLOVER.

The blossoms of *Trifolium pratense*, Linné.

Nat. Ord.—Leguminosæ.

Botanical Source.—Red clover is a biennial plant with several stems arising from the same root, ascending, somewhat hairy, and varying much in its height. The leaves are ternate; the leaflets oval or obovate, entire, nearly smooth, often notched at the end, and lighter colored in the center. Stipules ovate and mucronate. Flowers red, fragrant, in short, dense, ovate, sessile spikes or heads. Corollas unequal, monopetalous; lower tooth of the calyx longer than the four others, which are equal, and all shorter than the rose-red corolla (W.—G.).

History.—This plant is common to the United States, being extensively cultivated in grass lands, with herds-grass (*Phleum pratense*) and other grasses, and often alone: it flowers throughout the summer. The blossoms or flowers, are the parts used. A strong decoction is made of them, which is evaporated to the consistence of an extract. A tincture is also prepared. Frederick Graser obtained from the flower-heads two resins, fat, chlorophyll, tannin, ash (7½ per cent), etc. The ether-soluble resin dissolves green in ammonia, and yellow in potassa (*Amer. Jour. Pharm.*, 1883, p. 194).

Action, Medical Uses, and Dosage.—Red clover is an excellent alterative, and one of the few remedies which favorably influences *pertussis*. In earlier editions of this work it was stated that "a strong infusion of the plant is said to afford prompt relief in *whooping-cough*, suspending the spasmodic cough entirely in 2 or 3 days; it is to be given in ½ fluid ounce, every 1 or 2 hours, throughout the day." Since then the remedy has come into extensive use, but the statement should be modified, as it does not reach all classes of cases. When the proper case is found it acts promptly, but as yet the specific indications in this complaint have not been discovered. It is also a remedy in other *spasmodic coughs*, as those of *measles*, *bronchitis*, *laryngitis*, *phthisis*, etc. It is an excellent internal agent for those individuals disposed to tibial and other forms of *ulcers*, and it unquestionably retards the growth of *carcinomata*, and may be freely administered to those of a *cancerous diathesis*. The extract, spread on linen or soft leather, has long been said to be an excellent remedy for cancerous ulcers. This assertion, however, has not been so well verified as its action in retarding the growths when administered internally for a prolonged period. It is also highly recommended in ill-conditioned *ulcers* of every kind, and deep, ragged-edged, and otherwise badly-conditioned *burns*. It possesses a peculiar soothing property, proves an efficient detergent, and promotes a healthful granulation. The infusion (℥i to water Oj) may be used freely; a strong tincture may be prepared from the recently dried flowers (℥viii) in 50 per cent alcohol (Oj). The dose of this will range from 1 to 60 drops; specific trifolium, 1 to 60 drops.

Specific Indications and Uses.—Some forms of whooping-cough; irritation of the larnygo-pulmonic passages; provoking spasmodic cough; cough of measles; cancerous diathesis.

Pharmaceutical Preparation of Clover.—Extract of Trifolium Compound. This preparation is a specialty of the Wm. S. Merrell Chemical Co., of Cincinnati, Ohio. It is a combination of the alterative, tonic, and eliminative properties of the recently expressed juices or extracts from fresh or green plants with potassium iodide. The compound contains the extracts of Trifolium pratense, Stillingia sylvatica, Lappa minor, Phytolacca decandra. Cascara amarga, Berberis aquifolium, Podophyllum peltatum, tincture of Xanthoxylum carolinianum and potassium iodide. It is designed for administration in *syphilis, scrofula, chronic rheumatism, glandular and various skin affections.*

TRIGLOCHIN.—ARROW-GRASS.

The herb of *Triglochin maritimum*, Linné.

Nat. Ord.—Juncaginaceæ.

Common Name: *Arrow-grass.*

Botanical Source.—This is an herbaceous plant, found in marshes and other damp situations throughout the United States, especially near the sea coast. It has numerous narrow, grass-like, but fleshy leaves, all radical and sheathed at the base. The flowers are very small, greenish, and borne in slender, spicate racemes on erect scapes, which are from 1 to 2 feet high. The sepals are 3, ovate; the petals are also 3, and colored green like the sepals. The pistil consists of 6 united ovaries, which divides, in fruit, into 6 dry, linear, 1-seeded carpels.

Triglochin palustre, a smaller species, with only 3 carpels, is found in similar situations. Both species grow in Europe. Their constituents have probably never been examined chemically.

Action and Medical Uses.—Triglochin maritimum is said to be much sought after by cattle, especially subsequent to frost; they thrive upon it, and grow fat; while, with cows giving suck, it greatly increases the quantity and richness of their milk. Dr. E. F. Jones, of Colorado, reports it to be an active diuretic, of considerable value in *kidney and bladder affections*. To be employed in infusions.

TRILLIUM.—BETHROOT.

The root of *Trillium erectum*, Linné, var. *album* (*Trillium pendulum*, Muhlenberg), and other species of *Trillium*.

Nat. Ord.—Liliaceæ.

Common Names: (See below.)

Botanical Source, History, and Description.—This is one of an extensive genus of North American, herbaceous, perennial plants, which are variously known under the names of *Wake-robin*, *Birth-root*, *Indian-balm*, *Lamb's quarter*, *Ground lily*, etc. It has an oblong, tuberous root, from which arises a slender stem, 10 to 15 inches in height. Leaves, 3 in number, are whorled at the top of the stem, suborbicular-rhomboidal, abruptly acuminate, 3 to 5 inches in diameter, and borne on petioles about a line in length. The flowers are white, solitary, terminal, cernuous, on a recurved peduncle from 1 to 2½ inches long. Sepals green, oblong-lanceolate, acuminate, and 1 inch long; petals oblong-ovate, acute, and 1¼ inches in length by ½ an inch broad. Styles 3, erect, with recurved stigmas (B. — W.).

This plant is common to the middle and western states, growing in rich soils, in damp, rocky, and shady woods, and flowering in May and June. Nearly all the species of the genus Trillium are medicinal, and possess analogous properties; and among them the most common, and consequently the most frequently collected and employed are those given below, under the heading *Related Species.*

Fig. 248.

Trillium erectum.

These plants may be generally known by their 3 verticillate, net-veined leaves, and their solitary, terminal flower, which varies in color in the different species, being white, red, purple, whitish-yellow, or reddish-white; the peduncle will also be found erect in some species, and recurved in others. The roots of these plants are oblong or terete, somewhat tuberous, dark or brownish externally, white internally, from 1 to 5 inches in length, and from ½ to 1½ inches in diameter, beset with a few branching fibers laterally. They have a faint, slightly terebinthinate odor, and a peculiar aromatic and sweetish taste; when chewed they impart an acrid astringent impression in the mouth, causing a flow of saliva, and a sensation of heat in the throat and fauces. The rootlets have but little of the acrimony of the root. The latter yields its active principles to water, and its tonic and stimulant virtues to diluted alcohol.

Chemical Composition.—The acrid principle of this root, *trilline*, was obtained by Prof. Wayne in 1856. (For its preparation, see this *Dispensatory*, preceding edition.) This principle is probably identical with *saponin*, of which V. J. Reid (*Amer. Jour. Pharm.*, 1892, p. 67) obtained 4.86 per cent; other constituents of the root are fixed oil (about 8 per cent), starch, tannin, and an acid crystalline principle, probably a decomposition product of saponin. No volatile oil is present (D. J. Prendergast, *Amer. Drug.*, 1887, p. 206).

Action, Medical Uses, and Dosage.—Bethroot is astringent, tonic, and antiseptic; it has been employed successfully in *hemoptysis*, *hematuria*, *menorrhagia*, *uterine hemorrhage*, *metrorrhagia*, *leucorrhœa*, *cough*, *asthma*, and *difficult breathing*, and is said to have been much used by the Indian women to promote parturition. The astringent varieties of Trillium have been found useful in *hemorrhages;* the acrid species in *chronic affections* of the *respiratory organs*, *phthisis*, *hectic fever*, etc. All the varieties have been found efficient, either internally or externally, in *chronic mucous discharges*, *bronchorrhœa*, *leucorrhœa*, *menorrhagia*, etc. Boiled in milk, it has been administered with benefit in *diarrhœa* and *dysentery;* and an infusion of equal parts of Trillium and Lycopus virginicus, has been highly recommended for the cure of *diabetes*. It does not diminish the amount of sugar excreted in the saccharine form, but restrains the secretion of the renal discharges in both forms. Externally, the root, made into a poultice, is very useful in *tumors*, *indolent* or *offensive ulcers*, *anthrax*, *buboes*, *stings of insects*, and to restrain *gangrene*. In some instances its efficacy has been increased by combination with bloodroot. The red bethroots will, it is said, check ordinary *epistaxis*, by merely smelling the freshly-exposed surface of the recent root, and it is therefore probable that they contain an astringent principle of a volatile nature. The leaves of the beth plants, boiled in lard, have been much used, in some sections of the country, as an application to *ulcers*, *tumors*, etc. Dose, of powdered bethroot, 1 drachm, to be given in hot water; of the strong infusion, which is the most common form of administration, from 2 to 4 fluid ounces. A strong tincture of the fresh root (℥viii in alcohol, 76 per cent, Oj) may be given in doses of from 1 to 20 drops. These plants undoubtedly possess active properties, and deserve further investigation. *Trilline*, as prepared by Prof. Wayne, has not been used in medicine; but a less-active agent, of no therapeutical value, has been sold under the same name.

Specific Indications and Uses.—Relaxation of tissues, with mucous discharges or passive hemorrhage.

Related Species.—*Trillium sessile*, Linné. Leaves sessile, mottled, a deep-purple; flower sessile and dull-purple; petals erect, some spreading.

Trillium recurvatum, Beck.—Leaves petioled; sepals green and reflexed; petals erect or recurved; flower dull-purple.

Trillium nivale Riddell.—Leaves petiolate; flower erect on peduncles, and white; petals half longer than the sepals.

Trillium erythyrocarpum, Michaux, *Smiling wake-robin.*—Flower erect and peduncled; petals recurved, longer by twice than sepals, wavy, and penciled at base, a beautiful purple.

Trillium grandiflorum, Salisbury.—Leaves sessile, sharply acuminate; petals much longer than sepals; white, or shading to rose; flower suberect.

Trillium erectum, Linné, *Bath flowers.*—Leaves almost petiolate, broad as long; scarcely erect peduncle; nodding, dark-purple flower; ill-scented.

Trillium cernuum, Linné.—Peduncle long, twice the length of flower, and half as long as and deflexed under the leaves; flower white or rose; petals flat, and stigmas the length of the anthers.

Trillium stylosum, Nuttall.—Peduncle no longer than the flower, and decurved; petals larger than sepals, and recurved; flower white or rose; styles united.

TRIMETHYLAMINA.—TRIMETHYLAMINE.

FORMULA: $N(CH_3)_3$. MOLECULAR WEIGHT: 58.92.

History and Description.—Trimethylamine is isomeric with propylamine, under which name it was described by the older works. It was discovered by Wertheim (1850), and first employed in medicine by Avenarius, a physician of St. Petersburg (1854). It is a constituent of the three closely-related substances—*choline* (*neurine*), *muscarine*, and *betaïne* (see *Related Substances*, below), and, when found in nature, it is probably a decomposition product of one of these. It occurs in herring-brine, wherein it was first discovered; in *Chenopodium vulvaria*, Linné, or Stinking goosefoot; in ergot (*secaline*, of Winckler; see *Ergota*), and the rust of wheat; in the flowers of some species of Rosaceæ, *e. g.*, *Cratægus Oxyacantha*, Linné, *Pyrus communis*, Linné; in *Arnica montana;* in the leaf of the sugar-beet (*Beta vulgaris*, Linné); in the seeds of the beech; in putrefactive processes, *e. g.*, when urine, calves' blood, brains, bile, cod-liver oil, yeast, etc., undergo decomposition. It is among the early decomposition products in the cadaver. Trimethylamine was obtained synthetically by Prof. A. W. Hofmann in 1851. It was formerly prepared almost exclusively from fish-brine, by mixing the brine with excess of slaked lime, distilling, and saturating the distillate with hydrochloric acid, and evaporating. Exhaust the residue with alcohol, filter, evaporate the filtrate to dryness, and distill carefully from an excess of slaked lime made into a paste with water. At present the beet-sugar industry yields large quantities of trimethylamine, from the spent beet-molasses. The product, however, is liable to be mixed with dimethylamine ($NH[CH_3]_2$) (as much as 50 per cent), and monomethylamine (NH_2CH_3), propylamine and butylamine. (For their detection, see Duvillier and Buisine, *Amer. Jour. Pharm.*, 1880, p. 33.)

Trimethylamine ($N[CH_3]_3$) at low temperatures, is a colorless fluid of a strongly alkaline character, at ordinary temperature, a gas; has an odor similar to that of herring-brine, boils at less than 9° C. (48.2°F.), is soluble with avidity in alcohol, water, and ether, is inflammable, and forms soluble salts with bases.

Hydrochlorate of Trimethylamine (*Trimethylamine hydrochloride*) is chiefly used in medicine, and is often known under the improper name "*Chloride of Propylamin.*" It is made by decomposing the crude hydrochlorate, obtained from brine, with caustic lime or potash, passing the vapor of trimethylamine, that is given off, into dilute hydrochloric acid, evaporating the solution thus obtained, and recrystallizing the residue from stronger alcohol. It is a white, deliquescent salt, of a slight odor, a saline taste, and soluble in alcohol and water. An aqueous solution of trimethylamine has been largely sold as *propylamine.*

Action, Medical Uses, and Dosage.—Trimethylamine has a depressive action upon the pulse and the temperature, reducing the former from 2 to 18 beats per hour, and the latter from 1 to 3 degrees; depending upon the dose administered, and the condition of the person experimented upon. It appears to exert no action upon the surface of the body unless applied with friction, when it occasions rubefaction. Upon mucous membranes it has an irritating and caustic action, on which account it is necessary in administering it to employ it in mixtures. It appears to possess no diaphoretic or diuretic effect, and, properly given, occasions no derangement of the digestive organs. According to M. Peltier, the physiological action of trimethylamine is, a gentle excitant of the skin, a caustic to the mucuos membrane, a sedative to the nervous system, a hyposthenizant to the arterial system, and a modifier of urea in the urine, diminishing its amount considerably; therapeutically, it calms the pains in *rheumatism*, diminishes the articular congestion, at the same time rapidly reducing the fever. The hydrochlorate of trimethylamine occasions the same effects, and is generally preferred for therapeutical use, on account of its taste and odor being more agreeable. These agents have been highly recommended in *acute articular rheumatism*, in which they promptly allay the pain, and are said to cure in a very short time, from 4 to 12 days. They have likewise been found promptly efficient in the treatment of *chorea*. The method pursued by Avenarius, probably the best for the administration of trimethylamine, is as follows: To 6 fluid ounces of peppermint water add 2 drachms of white sugar, and 24 drops of trimethylamine. The dose of this is ½ fluid ounce, to be repeated, according to the urgency of the case, every 2, 3, or 4 hours. The dose of the hydrochlorate of trimethylamine is from 5 to 15 grains, in the course of 24 hours. It may be prepared for administration, in a very agreeable form as follows: Mix together, hydrochlorate of trimethylamine, 154 grains; tincture of the yellow rind of orange, 1 fluid ounce; syrup, 2 pints. The dose of this is from ½ to 1½ fluid ounces (J. King). Dr. Scudder cautioned regarding the employment of trimethylamine, stating, that in one instance under its use, he had developed a typical case of typhoid fever; nevertheless he believed that in small doses it would be useful "to strengthen the circulation, improve nutrition, and stimulate waste and repair." In rheumatic complaints, he regarded it a safe remedy only after the circulation had been brought under the control of the special sedatives, and the secretions were well established. The remedy, although evidently of much value, has now been displaced by other agents, and is at present seldom employed. The dose of trimethylamine is from 1 to 5 drops, every 4 hours; of the hydrochlorate, from 1 to 8 grains. For its influence on waste and nutrition, Prof. Scudder suggested: R Trimethylamine hydrochlorate, grs. x; sugar of milk, grs. 1000; triturate thoroughly. Dose, 1 to 5 grains.

Related Substances.—PROPYLAMINE (normal, C_3H_9N) is obtained by hydrogenation of proprionitril ($C_2H_5.CN$) (cyanide of ethyl), as follows: $C_2H_5.CN+2H_2=C_2H_5CH_2.NH_2$, and may also be prepared by other chemical processes. It is a strongly alkaline liquid, boils at 50° C. (122° F.), has the specific gravity 0.7283 at 0° C. (32° F.), and forms a platino-chloride which crystallizes in orange-yellow monoclinic prisms (Fowne). It is not used in medicine, though it agrees with trimethylamine hydrochlorate in effects. Other related bodies are:

AMYLAMINE ($NH_2C_5H_{11}$), a colorless fluid.

AMYLAMINE HYDROCHLORATE, or *Amylamine chloride* ($C_5H_{13}N.HCl$) forms 4-sided, efflorescent octohedra or scales, freely soluble in alcohol or water. In doses of from 7 to 15 grains, it slows the pulse and diminishes the temperature in man.

METHYLAMINE (NH_2CH_3) and DIMETHYLAMINE ($NH[CH_3]_2$) are both colorless and inflammable gases.

CHOLINE, or *Neurine* ($C_5H_{15}NO_2$), an alkaline fluid, is a constituent of the complex substance *lecithine*, which is found in bile, eggs, brains, milk, yeast, etc.; choline also occurs in white mustard (*sinkaline*), in cotton-seeds, herring-brine, in the seeds of fenugreek, in the fly-agaric (*Agaricus muscarius*), and is an early decomposition product of the human cadaver (Brieger).

MUSCARINE ($C_5H_{13}NO_2$) is a deliquescent, crystallizable and poisonous alkaloid, occuring in the fly-agaric, together with choline, and is obtainable by oxidation of choline.

BETAINE ($C_5H_{11}NO_2$), forming neutral deliquescent crystals, is the inner anhydride of an acid obtainable by oxidation of muscarine, and hence of choline; also by way of several other chemical processes. Its chief occurrence is in the juice of the beet-root, and of the beet-root molasses. *Choline*, *muscarine*, and *betaine*, respectively, stand in the relation of alcohol to aldehyde and acid. All three contain the trimethylamine group.

TRIOSTEUM.—FEVER-ROOT.

The bark of the root of *Triosteum perfoliatum*, Linné.

Nat. Ord.—Caprifoliaceæ.

COMMON NAMES: *Fever-wort*, *Wild ipecac*, *Bastard ipecac*, *Horse-gentian*, *Wild coffee*, *Dr. Tinker's weed*.

Botanical Source.—This plant is indigenous, with a perennial, thick, and fleshy root, subdivided into numerous horizontal branches. The stems are several from same root, simple, stout, erect, round, hollow, soft, pubescent, and from 2 to 4 feet high. The leaves are opposite, oval-acuminate, mostly connate, entire, abruptly contracted at base, nearly smooth above, pubescent beneath, prominently veined, 6 inches long by 3 broad; in some plants the upper leaves are almost amplexicaul. Flowers dull-purple, axillary, sessile, mostly in clusters of 3 or 5, in the form of whorls, rarely solitary. Calyx-tube ovoid; limb 5-parted; segments linear-lanceolate, leaf-like, and persistent, having a solitary bract; corolla tubular, gibbous at the base, somewhat equally 5-lobed, and scarcely longer than the calyx. Stamens 5, included; filaments hairy. Ovary inferior; style long and slender; stigma capitate and lobed. The fruit is an oval berry, about 9 lines long and 6 thick, of an orange-red or purple color when ripe, hairy, somewhat 3-sided, crowned with the persistent calyx, 3-celled, each cell containing a hard, bony, furrowed seed (W.—G.—B.).

History and Description.—Fever-root is found throughout the United States, in lime-stone and rich soils, in shady locations, and among rocks, flowering from May to August. The root is the medicinal part. It is of a dirty yellowish-brown color externally, about 1½ feet long, and about 9 lines in diameter, whitish internally, sends out fibers, has a nauseous smell, and a disagreeable amarous taste. When dried, it is readily reduced to powder. Its virtues are imparted to water, alcohol, or ether. The root has been used as, perhaps, an unintentional substitute for ipecac root and senega root. C. Hartwich (*Pharm. Rundschau*, 1895, p. 104) found it to contain starch, and an alkaloid differing from emetine; he named it *triosteine*. Schlotterbeck and Teeters (*ibid*, p. 180) made a complete analysis of the root, and confirmed the presence of alkaloid.

Action, Medical Uses, and Dosage.—The bark of the root is emetic when recent, or when administered in large doses of the powder. In doses of from 20 grains to 1 drachm, the powder is a mild, but slow, cathartic, with a tonic influence. It is feebly sedative, and the secretions are augmented by it. Its action upon the skin is similar to, but less decided, than that of asclepias. Small doses may be given to lessen the frequency of the heart-action, and reduce the temperature in *febriculæ* and *mild inflammatory complaints*. In the early stages of *fever*, it may be given in all cases where a gentle action on the bowels is desired. It has been recommended as a laxative tonic in *dyspepsia* and *autumnal fevers*, also in *hysteria*, *hypochondria*, and convalescence after febrile diseases. Some have stated it to possess diuretic properties, and have employed it in *chronic rheumatism* with success. Rafinesque considered the leaves to be diaphoretic. The hard seeds are said to be very similar in flavor to coffee, when roasted and ground. Dose of the tincture, from 1 to 4 fluid drachms; of a strong tincture of the recent root for its sedative effects, 1 to 10 drops; of the extract, which is one of the best forms of administration, from 5 to 15 grains.

Specific Indications and Uses.—Headache; colic; bilious vomiting and diarrhœa.

Related Species.—*Triosteum angustifolium*, Linné, smaller than the above, with a bristly, hairy stem; lanceolate and subconnate leaves, tapering to the base; peduncles opposite; 1-flowered, and flower of a greenish-cream color, possesses analogous properties, and may be substituted as an equivalent for the above (W.).

TRITICUM (U. S. P.)—TRITICUM.

"The rhizome of *Agropyrum repens* (Linné), Beauvois, gathered in the spring and deprived of the roots"—(*U. S. P.*) (*Triticum repens*, Linné).

Nat. Ord.—Gramineæ.

Common Names: *Couch-grass*, *Quick-grass*, *Quitch*, *Quitch-grass*, *Quickens*, *Dog-grass*.

Botanical Source and History.—This perennial plant has a jointed, long, whitish rhizome, each joint giving off a tuft of fibrous radicles. The flowering spikes surmount the culm, which grows from 2 to 4 feet high. The spikes are from 4 to 8-flowered, and are 3 to 4 inches long. The florets are pointed or obtuse, variable, and generally awnless. It has flat, rough leaves. The plant grows on cultivated grounds and along roadsides, usually in rich soils, and has become a nuisance in some situations. It is a native of Europe, but has become naturalized in this country.

Description and Chemical Composition.—"Very long and creeping; about 2 Mm. (½ inch) thick; as met with in the shops, cut into sections about 1 Cm. (⅖ inch) long; smooth, but wrinkled; hollow in the center, straw-yellow; inodorous; taste sweetish"—(*U. S. P.*) The rhizome of couch-grass, according to Ludwig and Muller (*Jahresb. der Pharm.*, 1872, p. 22, and 1873, p. 25), contains *lævulose* (from 2.5 to 3.3 per cent); *triticin*, a very hygroscopic, lævo-rotatory substance allied to inulin, soluble in diluted alcohol and water, insoluble in ether, little soluble in strong alcohol. Upon hydrolysis with water or diluted acids, it yields lævulose. Other constituents of the rhizome are *acid malates*, and about 11 per cent of a nitrogenous gummy substance forming insoluble compounds with neutral and with basic lead acetate. The dried rhizome yields 4.5 per cent of ash, containing much silicic acid. (For some possible economic uses of the rhizome, see Plauchud, *Jour. Pharm. Chim.*, 1877, p. 389.

Action, Medical Uses, and Dosage.—Couch-grass is diuretic and slightly aperient. It is an excellent agent in cases of excessive *irritability of the bladder* from any cause, lessening the frequency and pain of urination. It is a very efficient agent in *cystitis*, and those forms of *dysuria* due to *chronic cystic irritability*. It is highly praised as a remedy for *incipient nephritis*, allaying irritation, congestion and inflammation. Triticum is valued in *pyelitis* and other *catarrhal and purulent urinary affections*. It has been advised in *gonorrhœa*, *chronic prostatitis with enlarged prostate*, *hematuria*, and *strangury*. It is also recommended for its effects upon the renal secretion in *gout*, *rheumatism*, and *jaundice*. Infusion of triticum has long been used as a *fever* drink, and it has the well-merited reputation of preventing gravelly conditions. As a "spring medicine," for which it has been used by some, it is undoubtedly effectual in removing the broken-down material by way of the kidneys. The infusion is the best form of administration. To prepare the infusion: 1 ounce of the underground stem (or so-called root) is infused for 1 hour in a pint of boiling water. When strained, and cool, it may be given in wineglassful doses several times a day. It may likewise be used in the form of syrup. Specific triticum is a reliable alcoholic preparation, the dose being from 1 to 20 drops, in water.

Specific Indications and Uses.—Irritation of the urinary apparatus; pain in the back; frequent and difficult or painful urination; gravelly deposits in the urine; catarrhal and purulent discharges from urethra.

Pharmaceutical Preparation.—TRITIPALM. This is a specialty of Frederick Stearns & Co., of Detroit, Mich. It represents a combination of 60 grains of the fresh root of triticum and 30 grains of the fresh fruit of saw palmetto (*Serenoa serrulata*), in each fluid drachm. It is a palatable compound fluid extract, and is designed as a general nutrient tonic and sedative to *irritated and inflamed states of the mucous membranes of nose*, *throat*, and *bronchiæ*, especially arresting purulent discharges; it also acts upon the glandular appendages of the reproductive tract. It is specially recommended in *nephritis*, *simple and gonorrhœal urethritis*, *cystitis*, *vesical irritability*, *strangury*, *dysuria*, and *atrophy of the mammæ*, *testes*, *ovaries*, *uterus*, and especially of the *prostate gland*. The dose is 1 fluid drachm, followed by a draught of water, 4 times a day.

Related Species. *Cynodon Dactylon*, Persoon, *Scotch grass*, *Bermuda grass*. The rhizome is used like couch-grass by the Mexicans and Spaniards.

Sorghum vulgare, *Broom-corn*.—The seeds of this plant are employed by the negroes of the southern states as a remedy for *bladder troubles*, such as *cystitis*. They make a decoction of the seeds (2 ounces) in 1 quart of water, and boil it down to 1 pint.

TRITURATIONES (U. S. P.)—TRITURATIONS.

Preparation.—"Unless otherwise directed, triturations are to be prepared by the following formula: Take of the substance, ten grammes (10 Gm.) [154 grs.]; sugar of milk, in moderately fine powder, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Weigh the substance and the sugar of milk, separately; then place the substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal measure of sugar of milk, mix well by means of a spatula, and triturate them thoroughly together. Then add fresh portions of the sugar of milk, from time to time, until the whole is added, and continue the trituration until the substance is intimately mixed with the sugar of milk and reduced to a fine powder"—(*U. S. P.*).

History.—The official triturations are prepared according to the Homœopathic method. While only a definite proportion is aimed at by the Pharmacopœia, in Homœopathic pharmacy triturations not only are considered in the light of definite quantities, but are believed to assume increased medicinal power.

The drug is, from their view, "potentiated." Homœopathic triturations are denominated decimal or centesimal, according to the amount of active ingredient contained therein. If 1 part of the medicine be triturated with 9 parts of sugar of milk, gradually added, the first decimal trituration (1 x) is formed; if, however, 1 part of the medicine be triturated with 99 parts of milk-sugar, gradually added, the resulting preparation is the first centesimal trituration (1). By adding 1 part of the first decimal trituration to 9 parts of sugar of milk, or 1 part of the centesimal trituration to 99 parts of sugar of milk, gradually added, we obtain respectively the second decimal (2 x) or second centesimal trituration (2), and so on up the scale. Great care is to be observed that the mortar is perfectly clean, it being first washed with cold, then with hot water, and finally a little alcohol is burned in it. Moreover, each substance is triturated for a definite length of time. Similar preparations to the Homœopathic and official forms are what were introduced under the following term, and were described in previous editions of this *Dispensatory*, as

LACTINATED PREPARATIONS.—"These are forms, in which active and powerful medicines are presented to the profession by the manufacturers. The medicinal lactinated preparations are composed of alcoholic extracts, essential or inspissated tinctures, and juices, resinoids, etc., thoroughly triturated with lactin or sugar of milk. They are said to be best formed in the process of mixture, by mixing the lactin with the medicine before it is dried, and then carefully drying and powdering them together. This combination of medicines with lactin has the advantage: (1) of presenting many of the soft resinoids and inspissated tinctures, in the dry powdered form, without changing their chemical character, as is liable to be done by mixing them with alkalies or mineral substances; (2) of rendering them soluble, or at least readily miscible in water, and thus more easily administered, and more readily diffused in the stomach; (3) of greatly increasing the activity of all the resinoids, and such other preparations as are but partially soluble in water. Four grains of such a mixture, although it contains only 1 grain of the medicine, will generally be found as active as 2 grains of the same medicine given in its isolated state, while at the same time it produces less irritation and other unpleasant effects. Many concentrated agents are much improved by this mode of combination, and are kept prepared in this way, as in their pure state they are so concentrated and insoluble as to act as irritants on the stomach before they can be sufficiently diffused and absorbed to produce their therapeutical effects.

"The lactinated medicines should be kept in 1 ounce or 2 ounce vials, with as little exposure to air and light as possible. All articles containing volatile principles, as the essential oils, soft resinoids, and oleoresins, should be kept in ½ ounce or 1 ounce vials, as by frequently exposing them to the air they become inert. Those articles which absorb moisture from the air, and thus render the combination hard, or which require very large proportions of lactin to form a dry mixture, should not be lactinated.

"Lactinated preparations are made of various proportions of lactin, and which are expressed on the label of the vials containing them; thus, there may be equal parts, each, of the medicine and the sugar of milk; or to 1 part of the former, there may be added 2, 5, or 10 parts of the latter.

"Ordinary cane-sugar, saturated with concentrated alcohol, or ethereal tinctures of various medicines, and then dried, has been used by medical men, and found very useful; but it will be found inferior to, and less permanent than, a lactinated medicine properly prepared" (J. King).

It will be observed that these preparations preceded the "Abstracts" of the *U. S. P.*, 1880.

TRITURATIO CALCII SULPHIDUM.—TRITURATION OF CALCIUM SULPHIDE.

Preparation.—Take of calcium sulphide, 1 part; sugar of milk, 99 parts; to make 100 parts. Mix thoroughly by trituration. This forms the first centesimal trituration (1). To prepare the first decimal (1 x): Take calcium sulphide, 10 parts; sugar of milk, 90 parts; to make 100 parts. Mix thoroughly by trituration.

Action, Medical Uses, and Dosage.—(See *Calcii Sulphidum.*) These preparations usually pass under the names of triturations of *Hepar Sulphuris*, a misnomer, as true *hepar sulphur* is potassium sulphide. The dose of the first centesimal (1) is from 5 to 20 grains; of the first decimal (1 x), ½ to 2 grains.

TRITURATIO CARBO LIGNI.—TRITURATION OF WOOD CHARCOAL.

SYNONYMS: *Trituration of carbo vegetabilis, Trituration of vegetable charcoal.*

Preparation.—Take of carbo ligni, 1 part; sugar of milk, 99 parts. Mix thoroughly by trituration. This forms the first centesimal trituration (1). To prepare the first decimal (1 x): Take of carbo ligni, 10 parts; sugar of milk, 90 parts; to make 100 parts. Mix thoroughly by trituration.

Action, Medical Uses, and Dosage.—(See *Carbo Ligni.*) Dose, 1 to 10 grains.

TRITURATIO ELATERINI (U. S. P.)—TRITURATION OF ELATERIN.

Preparation.—"Elaterin, ten grammes (10 Gm.) [154 grs.]; sugar of milk, in moderately fine powder, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix them thoroughly by trituration"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Elaterinum.*) Dose, ¼ to ¾ grain.

TRITURATIO PODOPHYLLI.—TRITURATION OF PODOPHYLLIN.

Preparation.—Take of resin of podophyllum, 1 part; sugar of milk, 99 parts; to make, 100 parts. Mix thoroughly by trituration. This forms the first centesimal trituration (1). To prepare the first decimal (1 x): Take of resin of podophyllum, 10 parts; sugar of milk, 90 parts; to make 100 parts. Mix thoroughly by trituration.

Action, Medical Uses, and Dosage.—(See *Resina Podophylli.*) These preparations are extensively used in Eclectic practice. The dose of the first centesimal (1) is from 1 to 10 grains; of the first decimal (1 x), 1 to 3 grains.

TRITURATIO SANTONINI ET PODOPHYLLI.—TRITURATION OF SANTONIN AND PODOPHYLLIN.

Preparation.—Take of santonin, 10 grains; resin of podophyllum, 2 grains; white sugar (or milk sugar), 2 drachms. Mix thoroughly by trituration. Divide into 20 powders (see Scudder's *Prac. of Med.*).

Action, Medical Uses, and Dosage.—This trituration is an admirable form for administering santonin, with a laxative, for the removal of *intestinal worms*. The dose is 1 powder, night and morning. Each powder contains about 6½ grains of the trituration, representing ½ grain of santonin and $\frac{1}{10}$ grain of resin of podophyllum.

TROCHISCI.—TROCHES.

Troches, or lozenges, are medicinal substances in powder, which are formed into solid cakes, by the aid of sugar and gum. These cakes are circular, flat, a line or so in thickness, and about ½ inch in diameter. They are usually intended for gradual solution while retained in the mouth, and form a very pleasant mode of exhibiting many useful remedies. Gum Arabic and tragacanth are both employed, but the latter is preferred on account of the greater cohesiveness of its gum. In preparing troches, the best tragacanth should be selected, and placed in sufficient cold water to form a mucilage of the consistence of paste; this must be strained previous to using it. The medicinal powders having been well incorporated with the sugar, are by means of a sufficient quantity of the mucilage of tragacanth, worked into a soft dough, upon a plate of marble or porcelain. After all have been duly incorporated, the thick paste or dough is rolled out on the marble plate, its adhesion to the roller being prevented by sprinkling over it, from time to time, some powdered starch, or a powder of starch and sugar. Uniformity of thickness is effected by the use of a frame of wood or iron, which is placed upon the marble plate, and upon which the extremities of the roller move during the process of rolling. The rolled-out or extended layer of dough is now sprinkled with some of the powdered starch, and the troches are cut of the required shape and size by means of a tin-plate punch. The troches are then placed on a sieve, and dried in a drying-room or closet, after which the superfluous powder is removed by means of the sieve, and the troches placed in well-covered bottles (Mohr and Redwood).

"Lozenges are frequently composed of extract of liquorice and gum Arabic with sugar, which renders them quite tough, so as to become unmanageable by long standing. In such cases, the best mode is to thoroughly mix the articles together, and then add the sugar, in the form of a dense syrup, made with but two-thirds of the usual quantity of water required for simple syrup, mix it quickly, and, while yet warm, roll the mass into long cylinders, and, when nearly dry, cut them of the required size" (W. Procter, Jr.). It may be added that troches are not now used as freely as they were when the foregoing was written. Sugar and gelatin-coated pills, triturations, and tablets have largely superseded them.

TROCHISCI ACIDI TANNICI (U. S. P.)—TROCHES OF TANNIC ACID.

Preparation.—"Tannic acid, six grammes (6 Gm.) [93 grs.]; sugar, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; tragacanth, in fine powder, two grammes (2 Gm.) [31 grs.]; stronger orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with stronger orange-flower water, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly 1 grain of the acid is contained in each troche.

Action and Medical Uses.—(See *Acidum Tannicum.*)

TROCHISCI AMMONII CHLORIDI (U. S. P.)—TROCHES OF AMMONIUM CHLORIDE.

Preparation.—"Ammonium chloride, in fine powder, ten grammes (10 Gm.) [154 grs.]; extract of glycyrrhiza, in fine powder, twenty-five grammes (25 Gm.) [386 grs.]; tragacanth, in fine powder, two grammes (2 Gm.) [31 grs.]; sugar, in fine powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; syrup of tolu, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with syrup of tolu, form a mass, to be divided into 100 troches"—(*U. S. P.*). A little over 1½ grains of the salt are contained in each troche (see also *Trochisci Glycyrrhiza Composita*).

Action and Medical Uses.—(See *Ammonii Chloridum.*)

TROCHISCI CAPSICI.—TROCHES OF CAPSICUM.

Preparation.—Take of capsicum, in powder, ½ ounce; sugar, 6 ounces; mucilage of gum tragacanth, a sufficient quantity. Mix the sugar and capsicum thoroughly together, and, with the mucilage, beat them into a proper mass for making 240 lozenges.

Action and Medical Uses.—These troches will be found useful in *dryness and irritation of the throat, relaxed uvula*, and in all cases where capsicum is indicated. Each troche contains 1 grain of capsicum.

TROCHISCI CAPSICI ET LOBELIÆ.—TROCHES OF CAPSICUM AND LOBELIA.

Preparation.—Take of capsicum, in powder, ½ ounce; oil of lobelia, 24 minims; sugar, 6 ounces; mucilage of tragacanth, a sufficient quantity. Mix the sugar and capsicum thoroughly together, add the oil, and, with the mucilage, beat them into a proper mass for making 240 lozenges.

Action and Medical Uses.—These troches are stimulant and expectorant, and may be employed wherever such a combination is desired. Each troche contains 1 grain of capsicum, and $\frac{1}{10}$ minim of oil of lobelia.

TROCHISCI CATECHU (U. S. P.)—TROCHES OF CATECHU.

SYNONYM: *Catechu lozenge.*

Preparation.—"Catechu, in fine powder, six grammes (6 Gm.) [93 grs.]; sugar, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; tragacanth, in fine powder, two grammes (2 Gm.) [31 grs.]; stronger orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with stronger orange-flower water, form a mass, to be divided into 100 troches"—(*U. S. P.*). About 1 grain of catechu is contained in each troche.

Action, Medical Uses, and Dosage.—May be used for the same purposes and in the same doses as troches of krameria. They are commonly employed in *hoarseness* due to *catarrhal states of the pharynx and larynx.*

TROCHISCI CRETÆ (U. S. P.)—TROCHES OF CHALK.

Preparation.—"Prepared chalk, twenty-five grammes (25 Gm.) [386 grs.]; acacia, in fine powder, seven grammes (7 Gm.) [108 grs.]; spirit of nutmeg, three cubic centimeters (3 Cc.) [49 ♏]; sugar, in fine powder, forty grammes (40 Gm.) [1 oz., 180 grs.]; water, a sufficient quantity to make 100 troches. Rub the powders with the spirit of nutmeg until they are thoroughly mixed; then, with water, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly 4 grains of chalk are contained in each troche.

Action and Medical Uses.—Troches of chalk are antacid, and are sometimes employed to check slight *diarrhœa*, with acidity.

TROCHISCI CUBEBÆ (U. S. P.)—TROCHES OF CUBEB.

Preparation.—"Oleoresin of cubeb, four grammes (4 Gm.) [62 grs.]; oil of sassafras, one cubic centimeter (1 Cc.) [16 ♏]; extract of glycyrrhiza, in fine powder, twenty-five grammes (25 Gm.) [386 grs.]; acacia, in fine powder, twelve grammes (12 Gm.) [185 grs.]; syrup of tolu, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oleoresin and the oil, and incorporate them with the mixture. Lastly, with syrup of tolu, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly ⅔ grain of oleoresin of cubeb is contained in each troche.

Action and Medical Uses.—These troches are employed in *pharyngeal and laryngeal inflammations* of subacute or chronic type, where there is tenacious catarrhal secretion.

TROCHISCI DIOSCOREÆ.—TROCHES OF DIOSCOREA.

Preparation.—Take of extract of dioscorea, 1 ounce; ginger, ½ ounce; oil of peppermint, 24 minims; sugar, 6 ounces; mucilage of tragacanth, a sufficient quantity. Mix the sugar, extract of dioscorea, and ginger thoroughly together, add the oil, and, with the mucilage, beat them into a proper mass for making 240 lozenges.

Action and Medical Uses.—These troches are useful in cases of *colic*, *flatulency*, *borborygmi*, and to cure as well as prevent a return of *bilious colic.* Each troche contains 2 grains of extract of dioscorea (J. King).

TROCHISCI FERRI (U. S. P.)—TROCHES OF IRON.

Preparation.—"Ferric hydrate, dried at a temperature not exceeding 80° C. (176° F.) thirty grammes (30 Gm.) [463 grs.]; vanilla, cut into slices, one gramme (1 Gm.) [15 grs.]; sugar, in fine powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; mucilage of tragacanth, a sufficient quantity to make 100 troches. Rub the vanilla, first, with a portion of the sugar to a uniform powder, and afterwards with the ferric hydrate and the remainder of the sugar, until they are thoroughly mixed; then, with mucilage of tragacanth, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly 5 grains of ferric hydroxide are contained in each troche.

Action, Medical Uses, and Dosage.—An unnecessary preparation, intended as a convenient method of administering iron. Dose, 1 to 3 troches.

TROCHISCI GLYCYRRHIZÆ COMPOSITA.—COMPOUND TROCHES OF LIQUORICE.

Preparation.—Take of ammonium chloride, in powder, 1½ drachms; hydrochlorate of morphine, 6 grains; gum Arabic, sugar, extract of liquorice, each, in powder, 7 drachms; oil of sassafras, 30 minims; oil of stillingia, 20 minims; tincture of balsam of tolu, 3 fluid drachms. Mix the powders thoroughly together, then add the oils and tincture, and with water form them into a mass, to be divided into 180 troches.

Action, Medical Uses, and Dosage.—These troches are very valuable in *cough*, *irritation* or *tickling of the throat*, *laryngitis* and *bronchitis*, in which affections they are unrivaled. Each troche contains $\frac{1}{30}$ grain of morphine hydrochlorate (J. King). (See also *Trochisci Ammonii Chloridi*, *U. S. P.*)

TROCHISCI GLYCYRRHIZÆ ET OPII (U. S. P.)—TROCHES OF GLYCYRRHIZA AND OPIUM.

SYNONYM: *Opium lozenge.*

Preparation.—"Extract of glycyrrhiza, in fine powder, fifteen grammes (15 Gm.) [232 grs.]; powdered opium, one-half gramme (0.5 Gm.) [8 grs.]; acacia, in fine powder, twelve grammes (12 Gm.) [185 grs.]; sugar, in fine powder, twenty grammes (20 Gm.) [309 grs.]; oil of anise, two-tenths of a cubic centimeter (0.2 Cc.) [3 ♏]; water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oil of anise (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with water, form a mass, to be divided into 100 troches"—(*U. S. P.*). About $\frac{1}{12}$ grain of opium is contained in each troche. A similar troche, bearing same title as the official preparation, was very popular under the name of *Wistar's Cough Lozenge.* (The official troche is also known by this common name.) Wistar's cough lozenges are prepared as follows: Take of powdered opium, 1 drachm; powdered liquorice, 3 ounces; powdered gum Arabic, 2½ ounces; powdered white sugar, 2 ounces. Triturate these thoroughly together, with oil of anise 20 minims, and finally add a sufficient quantity of water to form a mass of the proper consistence. Divide into troches of 5 or 6 grains each. Ten lozenges contain 1 grain of opium.

Action and Medical Uses.—These lozenges are a soothing and lenitive preparation for *catarrhs* and *tickling coughs*, in cases where opium is not contraindicated.

TROCHISCI IPECACUANHÆ (U. S. P.)—TROCHES OF IPECAC.

SYNONYM: *Ipecacuanha lozenge.*

Preparation.—"Ipecac, in No. 60 powder, two grammes (2 Gm.) [31 grs.]; tragacanth, in fine powder, two grammes (2 Gm.) [31 grs.]; sugar, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; syrup of orange, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with syrup of orange, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly $\frac{1}{3}$ grain of ipecac is contained in each lozenge.

Action and Medical Uses.—These troches are expectorant, and will be found valuable in *coughs*, *catarrhs*, etc.

TROCHISCI KRAMERIÆ (U. S. P.)—TROCHES OF KRAMERIA.

Preparation.—"Extract of krameria, six grammes (6 Gm. [93 grs.]; sugar, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; tragacanth, in fine powder, two grammes (2 Gm.) [31 grs.]; stronger orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with stronger orange-flower water, form a mass, to be divided into 100 troches"—(*U. S. P.*). Nearly 1 grain of krameria is contained in each troche.

Action, Medical Uses, and Dosage.—(See *Krameria.*) Troches of krameria are used in relaxed condition of the mucous surfaces of the throat and alimentary canal. Dose, 1 to 10 or more troches.

TROCHISCI MAGNESIÆ (N. F.)—TROCHES OF MAGNESIA.

Preparation.—"Magnesia, nineteen and one-half grammes (19.5 Gm.) [301 grs.]; nutmeg, in fine powder, one gramme (1 Gm.) [15 grs.]; sugar, in fine powder, fifty-eight and one-half grammes (58.5 Gm.) [2 ozs. av., 28 grs.]; mucilage of tragacanth (*U. S. P.*), a sufficient quantity to make 100 troches. Rub the magnesia and the powders together until they are thoroughly mixed; then, with mucilage of tragacanth, form a mass, to be divided into 100 troches"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—These are antacid and laxative, and may be used in cases of *gastric acidity* and *costiveness*. Dose, 1 to 3 troches.

TROCHISCI MENTHÆ PIPERITÆ (U. S. P.)—TROCHES OF PEPPERMINT.

Preparation.—"Oil of peppermint, one cubic centimeter (1 Cc.) [16 ♏]; sugar, in fine powder, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; mucilage of tragacanth, a sufficient quantity to make 100 troches. Rub the oil of peppermint and the sugar together until they are thoroughly mixed; then, with mucilage of tragacanth, form a mass, to be divided into 100 troches"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—These are carminative and antispasmodic, and will be found useful in *sick stomach*, *slight pains in the stomach or bowels*, *flatulency*, and griping from purgative medicines. If eaten too freely, they cause derangement of the stomach. Dose, 1 to 5 or more troches.

TROCHISCI MORPHINÆ.—MORPHINE LOZENGES.

Preparation.—"Take of hydrochlorate of morphine, 20 grains; tincture of tolu, $\frac{1}{2}$ fluid ounce; refined sugar, in powder, 24 ounces (av.); gum acacia, in powder, 1 ounce (av.); mucilage of gum acacia, a sufficiency; distilled water, $\frac{1}{2}$ fluid ounce. Dissolve the hydrochlorate of morphine in the water; add this solution to the tincture of tolu, previously mixed with 2 fluid ounces of the mucilage; then add the gum and sugar, previously mixed, and more mucilage, if necessary, to form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber at a moderate temperature. Each lozenge contains $\frac{1}{36}$ grain of hydrochlorate of morphine"—(*Br. Pharm.*, 1885). The present *British Pharmacopœia* (1898) directs *Trochiscus Morphinæ* of the same strength; it is made by incorporating morphine hydrochloride with the tolu basis.

Action, Medical Uses, and Dosage.—(See *Morphinæ.*)

TROCHISCI MORPHINÆ ET IPECACUANHÆ (U. S. P.)—TROCHES OF MORPHINE AND IPECAC.

SYNONYM: *Morphine and ipecacuanha lozenge.*

Preparation.—"Morphine sulphate, sixteen centigrammes (0.16 Gm.) [2.5 grs.]; ipecac, in No. 60 powder, fifty centigrammes (0.50 Gm.) [8 grs.]; sugar, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; oil of gaultheria, two-tenths cubic centimeter (0.2 Cc.) [3 ♏]; mucilage of tragacanth, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then add the oil of gaultheria (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with mucilage of tragacanth, form a mass, to be divided into 100 troches"—(*U. S. P.*). About $\frac{1}{40}$ grain of morphine sulphate and $\frac{1}{12}$ grain of ipecacuanha are contained in each troche.

Action, Medical Uses, and Dosage.—These troches are employed to relieve *cough*. Dose, 1 to 2 troches.

TROCHISCI OLEI CROTONIS.—TROCHES OF CROTON OIL.

Preparation.—Take of croton oil, 5 minims; starch, 20 grains; sugar, 1 drachm; chocolate, 2 drachms. Mix the oil with the solid ingredients in powder, and add a sufficient quantity of water to form a mass of proper consistence for 30 lozenges.

Action and Medical Uses.—These lozenges are cathartic. Each lozenge contains $\frac{1}{6}$ minim of croton oil.

TROCHISCI POTASSII CHLORATIS (U. S. P.)—TROCHES OF POTASSIUM CHLORATE.

SYNONYM: *Chlorate of potash lozenge.*

Preparation.—"Potassium chlorate, in fine powder, thirty grammes (30 Gm.) [463 grs.]; sugar, in fine powder, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; tragacanth, in fine powder, six grammes (6 Gm.) [93 grs.]; spirit of lemon, one cubic centimeter (1 Cc.) [16 ♏]; water, a sufficient quantity to make 100 troches. Mix the sugar with the tragacanth and the spirit of lemon, by trituration, in a mortar; then transfer the mixture to a sheet of paper, and, by means of a bone spatula, mix it with the potassium chlorate, being careful, by avoiding trituration or pressure, to prevent the mixture from igniting or exploding. Lastly, with water, form a mass, to be divided into 100 troches"—(*U. S. P.*). On account of the explosiveness of potassium chlorate, when rubbed with organic matter, great care must be exercised in preparing this lozenge. The official directions should be exactly followed.

Action and Medical Uses.—These lozenges are useful in *sore mouth* and *throat*, *laryngitis*, *chronic gastritis*, *mercurial sore mouth*, *nurse's sore mouth*, etc. Solutions of the salt are far preferable.

TROCHISCI RESINÆ PODOPHYLLI.—TROCHES OF RESIN OF PODOPHYLLUM.

Preparation.—Take of resin of podophyllum, 20 grains; extract of leptandra, 80 grains; oil of sassafras, 1 fluid drachm; sugar, 6 ounces; mucilage of tragacanth, a sufficient quantity. Rub the sugar, resin of podophyllum, and extract of leptandra together until they are thoroughly mixed; then add the oil, and, with the mucilage, beat them into a proper mass for 480 lozenges.

Action, Medical Uses, and Dosage. Cholagogue, alterative, and purgative, Patients laboring under *constipation*, *hepatic torpor*, *dysentery*, or other diseases in which the above combination is desired or indicated, may use several of these troches a day, according to the effects which they produce. Each troche contains $\frac{1}{24}$ grain of resin of podophyllum, and $\frac{1}{5}$ grain of extract of leptandra; in ordinary cases, 12 troches used per day will maintain regularity of the bowels. If it be desired to have these lozenges more active, 40 or 60 grains of resin of podophyllum may be added for the same number.

TROCHISCI RHEI ET POTASSÆ.—TROCHES OF RHUBARB AND POTASSA.

Preparation.—Take of rhubarb, in powder, 2 ounces; bicarbonate of potassium, 1 ounce; oil of peppermint, 1 fluid drachm; sugar, 12 ounces; mucilage of tragacanth, a sufficient quantity. Rub the rhubarb, sugar, and potassium salt thoroughly together; then add the oil, and, with the mucilage, beat them into a proper mass for 500 lozenges.

Action, Medical Uses, and Dosage.—These troches may be used by persons subject to or laboring under *diarrhœa, dysentery, cholera morbus, acidity of stomach, heartburn*, etc. They will also prove tonic in small quantity. From 6 to 12 may be used daily. Each troche contains 2 grains of rhubarb.

TROCHISCI SANTONINI (U. S. P.)—TROCHES OF SANTONIN.

SYNONYM: *Santonin lozenge.*

Preparation.—"Santonin, in fine powder, three grammes (3 Gm.) [46 grs.]; sugar, in fine powder, one hundred and ten grammes (110 Gm.) [3 ozs. av., 385 grs.]; tragacanth, in fine powder, three grammes (3 Gm.) [46 grs.]; stronger orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with stronger orange-flower water, form a mass, to be divided into 100 troches. Troches of santonin should be kept in dark, amber-colored vials"—(*U. S. P.*). Nearly ½ grain of santonin is contained in each troche.

Action, Medical Uses, and Dosage.—To expel intestinal *worms*, 1 troche, night and morning.

Related Preparation.—TROCHISCI SODII SANTONINATIS (N. F.), *Troches of sodium santoninate.* "Sodium santoninate, in fine powder, six and one-half grammes (6.5 Gm.) [100 grs.]; sugar, in fine powder, one hundred and thirty grammes (130 Gm.) [4 ozs. av., 256 grs.]; tragacanth, in fine powder, three and three-fourths grammes (3.75 Gm.) [58 grs.]; orange-flower water, a sufficient quantity to make 100 troches. Rub the powders together until they are thoroughly mixed; then, with orange-flower water, form a mass, to be divided into 100 troches. Troches of sodium santoninate should be kept in dark amber-colored vials"—(*Nat. Form.*). This troche contains 1 grain of sodium santoninate.

TROCHISCI SANTONINI COMPOSITA.—COMPOUND TROCHES OF SANTONIN.

Preparation.—Take of santonin 25 grains; resin of jalap, 10 grains; gum Arabic, in powder, 30 grains; pure chocolate, 60 grains; white sugar, 160 grains; water, a sufficient quantity (about 15 minims). Rub the santonin, resin of jalap, gum Arabic, chocolate, and sugar together until they are thoroughly mixed; then add enough water to form a mass of proper consistence. Divide into 64 pills or troches, and coat with sugar. Gamboge or resin of podophyllum may be substituted for the resin of jalap.

Action, Medical Uses, and Dosage.—These are useful as a vermifuge. For a child from 3 to 6 years of age, from 2 to 4 may be used daily, as long as required. Said to be similar to the formula of Fougera, of New York. (See also *Trituratio Santonini et Podophylli.*)

TROCHISCI SODII BICARBONATIS (U. S. P.)—TROCHES OF SODIUM BICARBONATE.

SYNONYM: *Bicarbonate of soda lozenge.*

Preparation.—"Sodium bicarbonate, twenty grammes (20 Gm.) [309 grs.]; sugar, in fine powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; nutmeg, bruised, one gramme (1 Gm.) [15 grs.]; mucilage of tragacanth, a sufficient quantity to make 100 troches. Triturate the nutmeg with the sugar, gradually added, until they are reduced to a fine powder, and mix this intimately with the sodium bicarbonate; then, with mucilage of tragacanth, form a mass, to be divided into 100 troches"—(*U. S. P.*). About 3 grains of sodium bicarbonate are contained in each lozenge.

Action and Medical Uses.—These are antacid, and will be found useful in *heartburn*, especially during pregnancy, in *acid stomach*, and in urine containing *excess of uric acid*.

TROCHISCI STILLINGIÆ COMPOSITA.—COMPOUND TROCHES OF STILLINGIA.

Preparation.—Take of oil of stillingia, 1 fluid drachm; oil of prickly ash berries, oil of sassafras, each, 4 fluid drachms; sugar, 10 ounces; mucilage of gum tragacanth, a sufficient quantity. Rub the oils with the sugar until they are thoroughly mixed; then, with the mucilage, form a mass, to be divided into 480 lozenges.

Action and Medical Uses.—These troches form a very agreeable remedy for *rheumatic*, *syphilitic*, *scrofulous*, *bronchial and laryngeal affections*, and may be used somewhat freely by patients thus afflicted. Eight lozenges contain 1 minim of oil of stillingia, and the quantity used per day must be regulated according to their influence on the stomach and bowels. They will likewise be found beneficial in *chronic affections of the mucous membranes* (J. King).

TROCHISCI SULPHURIS.—SULPHUR LOZENGES.

Preparation.—"Take of precipitated sulphur, 3600 grains; acid tartrate of potassium, 720 grains; refined sugar, in powder, 5760 grains; gum acacia, in powder, 720 grains; tincture of orange peel, 720 minims; mucilage of acacia, 720 minims. Mix the tincture of orange with the powders, and add the mucilage to form a suitable mass. Divide into 720 lozenges, and dry these in a hot-air chamber at a moderate temperature. Each lozenge contains 5 grains of sulphur"—(*Br. Pharm.*, 1885). The process of the *British Pharmacopœia* (1898) agrees with this. Each troche also contains 1 grain of cream of tartar.

Action and Medical Uses.—(See *Sulphur*.)

TROCHISCI ZINGIBERIS (U. S. P.)—TROCHES OF GINGER.

Preparation.—"Tincture of ginger, twenty cubic centimeters (20 Cc.) [325 ♏]; tragacanth, in fine powder, four grammes (4 Gm.) [62 grs.]; sugar, in fine powder, one hundred and thirty grammes (130 Gm.) [4 ozs. av., 256 grs.]; syrup of ginger, a sufficient quantity to make 100 troches. Mix the tincture of ginger with the sugar, and, having exposed the mixture to the air until dry, reduce it to a fine powder. To this add the tragacanth, and mix thoroughly. Lastly, with syrup of ginger, form a mass, to be divided into 100 troches"—(*U. S. P.*). About 3 minims of tincture of ginger are contained in each troche.

Action and Medical Uses.—These form a grateful cordial stimulant, and may be used in all cases of *flatulence*, *debility of the stomach*, etc.

TUSSILAGO.—COLTSFOOT.

The leaves and flowers of *Tussilago Farfara*, Linné.

Nat. Ord.—Compositæ.

COMMON NAME: *Coltsfoot*.

Botanical Source.—Coltsfoot has a long, perennial, creeping, horizontal rhizome, with many fibers. The leaves are radical, erect, on furrowed, channelled foot-stalks, heart-shaped, slightly lobed, copiously and sharply toothed, very smooth, of a slightly glaucous-green above, pure white and densely cottony, with prominent veins beneath; when young, they are revolute, and thickly enveloped in cottony down. They do not appear until after the flowers are withered; they are 5 to 8 inches long by 3 to 6 broad. The flowers are large, bright-yellow, and compound; the heads drooping in the bud, and about 1 inch broad; the rays are spreading, copious, and very narrow. Each flower-head is borne on a simple, round, woolly scape, about 5 inches high, scaly, with numerous, reddish, smooth, scattered bracts, and crowded under the head like an exterior involucre. Receptacle naked. Anthers scarcely tailed; styles of the disk inclosed and abortive; of the ray bifid, with taper arms. Achenium of the ray oblong-cylindrical; of the disk abortive. Pappus of the ray in many rows; of the disk in 1 row, consisting of very fine setæ (L.).

History and Description.—This plant grows in Europe, the Crimea, Persia, Siberia, and the East Indies, from the seashore to elevations of nearly 8000 feet; it also grows in this country in wet places, on the sides of brooks, flowering in March and April. Its presence is a certain indication of a clayey soil (W.). The flowers are rather fragrant, and continue so after having been carefully dried. The leaves are the parts used, though all parts of the plant are active, and should always be employed, especially the leaves, flowers, and root. The leaves should be collected at about the period they have nearly reached their full size; the flowers as soon as they commence opening; and the root immediately after the maturity of the leaves. When dried, all parts have a bitter, mucilaginous taste, and yield their properties to water or diluted alcohol.

Chemical Composition.—According to analysis by C. S. Bondurant (*Amer. Jour. Pharm.*, 1887, p. 340), the leaves contain a small quantity of an acrid volatile oil, wax, caoutchouc, a bitter glucosid, soluble in ether and water, resin, tannin, *saponin*, albuminous matter, mucilage (3.4 per cent), etc. The dried leaves yielded 17 per cent of ash.

Action, Medical Uses, and Dosage.—Coltsfoot may be regarded as emollient, demulcent, and slightly tonic (P.). It relieves irritation of the mucous tissues. The decoction is usually administered in doses of from 1 to 3 or 4 fluid ounces, and has been found useful in *coughs*, *asthma*, *whooping-cough*, *laryngitis*, *pharyngitis*, *bronchitis*, and other *pulmonary affections;* in *gastric and intestinal catarrh;* and is said to have been useful in *scrofula*. The powdered leaves form a good errhine for *giddiness*, *headache*, *nasal obstructions*, etc. Used externally, in form of poultice, to *scrofulous tumors*. A strong tincture of the leaves and the flowers, using strong alcohol, may be given in doses of 1 to 10 drops.

Related Species.—*Aplopappus laricifolius* (*Nat. Ord.*—Compositæ), *Yerba del Pasmo*. Southwestern United States. This plant is mentioned by Prof. H. T. Webster, M.D. (*Dynam. Therap.*, p. 120), as a remedy worthy of investigation, reports having been made of its efficacy in "*tetanus*, *eclampsia*, *chorea*, and other *spasmodic affections*." A tea of the herb is made use of in small and oft-repeated doses, and, in *traumatic tetanus*, the parts are also bathed with the infusion.

Cineraria maritima (*Nat. Ord.*—Compositæ). South America. The fresh juice of this plant is accredited with curative properties in ocular disorders, especially in *ophthalmia*. It has been lauded as a remedy to cure *cataract* by absorption (see *Pharm. Jour. Trans.*, Vol. XVIII, 1887–88, p. 985). Two drops of the milky juice are to be dropped into the palpebral fissure, and the tissues subjected to gentle massage.

Mutisia viciæfolia, Cavanilles (*Nat. Ord.*—Compositæ), *Scale-flowers*, *Span*, *Chinchircoma*.—Western South America (see illustration and description, by Dr. Rusby, in *Drug. Bull.*, 1888, p. 369). Flowers reputed antispasmodic and cardiac tonic. Employed in *respiratory affections*, particularly for *cough and croup disorders*. It has also been used for *hysteria* and *cardiac weakness*, brought on by high altitudes. The dose of the fluid extract has been given as 10 to 60 minims.

Siegesbeckia orientalis, Linné. Mauritius Islands. Contains a white crystalline body, *darutyne*, resembling salicylic acid. Plant used in *leprosy*, *syphilis*, and various *skin diseases*.

TYPHA.—CATTAIL FLAG.

The root of *Typha latifolia*, Linné.

Nat. Ord.—Typhaceæ.

COMMON NAMES: *Cattail*, *Cattail flag*, *Cattail rush*, *Reed mace*.

Botanical Source.—Cattail flag is a perennial plant, with a smooth, round stem, 3 to 5 feet high, leafy below, and terminated by large cylindric spikes. The leaves are flat, erect, ensiform, slightly concave within near the base, 2 to 4 feet long, and nearly 1 inch wide. Flowers very numerous. Spikes of a brownish color, 6 to 10 inches in length, and about 1 inch in diameter, composed of slender, downy flowers, so compact, particularly the fertile ones, as to be of considerable hardness. The upper portion is smaller, and composed of the sterile flowers, so that the staminate and pistillate parts of the spike approximate, or, are almost continuous (W.—G.).

History.—This plant is common to all parts of the United States, and is found growing in ditches, muddy pools, borders of ponds, and other wet places, flowering in July. The leaves are called flags, and are used for weaving the seats of chairs. The flowers have been used for making beds. The root is the part used. It yields its properties to water. The Pah-Ute Indians used the flowering ends of the plant as a food, either raw, or boiled in water (Edward Palmer, *Amer. Jour. Pharm.*, 1878, p. 547).

Action, Medical Uses, and Dosage.—Astringent and emollient. Boiled with milk, it has been found useful in *dysentery*, *diarrhœa*, and *infantile summer complaint*, and a decoction of it has been beneficial in *gonorrhœa*. Externally, the root, in combination with elm and aromatics, forms an excellent poultice for *white swellings*, *tumors*, and *ulcers*. The root, bruised until it becomes like a jelly, forms an excellent application for *burns* and *scalds*, *erysipelas*, *ophthalmia*, and all *local inflammations*.

ULMUS (U. S. P.)—ELM.

"The inner bark of *Ulmus fulva*, Michaux"—(*U. S. P.*) (*Ulmus rubra*, F. A. Michaux).

Nat. Ord.—Urticaceæ.

Common Names and Synonyms: *Slippery-elm*, *Elm bark*; *Ulmi cortex*, *Cortex ulmi interior*.

Illustration: Bentley and Trimen, *Med. Plants*, 233.

Botanical Source.—Slippery-elm, also called *Red elm* and *Moose-elm*, is a tree from 20 to 60 feet in height, and 1 to 2 feet in diameter. The bark is brownish, that of the branches whitish and scabrous. The leaves are 4 to 6 inches long, 2 to 3 inches broad, lanceolate-oval, or obovate-oblong, conspicuously acuminate, doubly serrate, the upper surface scabrous, beneath tomentose-pubescent, and standing on downy foot-stalks about 4 lines long. Buds rusty-woolly. Flowers sessile, in dense, lateral clusters, and appear before the leaves. Calyx about 7-lobed, campanulate and downy; corolla none; stamens 5 or 7, short and reddish. The fruit is an orbicular samara, compressed, with a broad, membranaceous border, not fringed, and about 6 lines in diameter; seed 1, and round (W.—G.—Darlington).

History and Description.—The slippery-elm is a large tree, common to this country, especially in the western states. It grows in woods and low grounds, along fences, and in rich, dry, or moist soils, flowering in April. The official part is the inner bark, which is generally separated from the tree in long strips. The *U. S. P.* describes it as "in flat pieces, varying in length and width about 3 Mm. (⅛ inch) thick, tough, pale brownish-white, the inner surface finely ridged; fracture fibrous and mealy; the transverse section delicately checkered; odor slight, peculiar; taste mucilaginous, insipid"—(*U. S. P.*). It is also met with in the form of a ragged, fibrous mass, and in very fine powder, of a whitish-yellow or pale-fawn color, which is obtained by grinding the bark. The ground bark is often adulterated with starch.

Chemical Composition.—Slippery-elm bark consists principally of mucilage and woody fiber. Water takes up its mucilage, from which it is precipitated by the acetates of lead. The presence of starch has been demonstrated by J. U. Lloyd; at the same time it was shown that the mucilage contains a principle which decolorizes iodide of starch, the color being partly restored by diluted sulphuric acid (see *Amer. Jour. Pharm.*, 1895, p. 459). Dr. C. W. Wright states that, when fatty substances are heated for several minutes with slippery-elm bark, in the proportion of 1 part of the bark to 128 parts of the fat, and then the fat be removed by straining, this has acquired the property of not undergoing rancidity (*Amer. Jour. Pharm.*, 1852, p. 180).

Action, Medical Uses, and Dosage.—Elm bark is nutritive, expectorant, diuretic, demulcent, and emollient, and is a very valuable remedial agent. In *mucous inflammations of the lungs, bowels, stomach, bladder*, or *kidneys*, used freely in the form of a mucilaginous drink (1 ounce of the powdered bark to 1 pint of water), it is highly beneficial, as well as in *diarrhœa, dysentery, coughs, pleurisy, strangury*, and *sore throat*, in all of which it tends powerfully to allay the inflammation. A tablespoonful of the powder boiled in a pint of new milk, affords a nourishing diet for infants weaned from the breast, preventing the bowel complaints to which they are subject, and rendering them fat and healthy. Some physicians consider the constant use of it, during and after the seventh month of gestation, as advantageous in facilitating and causing an easy delivery; ½ pint of the infusion to be drank daily. Elm bark has likewise been successfully employed externally in *cutaneous diseases*, especially in obstinate cases of *herpetic and syphilitic eruptions*, and certainly possesses more efficient virtues than are commonly supposed. As an emollient poultice, the bark has been found very serviceable when applied to *inflamed parts, suppurating tumors, fresh wounds, burns, scalds, bruises*, and *ulcers;* and in the excruciating *pains of the testes*, which accompany the *metastasis of mumps*, whether of recent or long standing, the constant use of an elm poultice, regularly changed every 4 hours, will be found a superior remedy. Notwithstanding its general value as an application to *ulcers*, it will often be found injurious, especially when used as a cataplasm to *ulcers of the limbs*, rendering the ulcer more irritable and difficult to heal, and frequently converting a simple sore, which might be cured by astringent or other washes, into an almost intractable ulcer; much care is, therefore, required in the application of this bark externally. As an injection, the infusion will prove useful in *diarrhœa, dysentery. tenesmus*, and *hemorrhoids*, also in *gonorrhœa* and *gleet*. The powder, sprinkled on the surface of the body, will prevent and heal *excoriations* and *chafings*, and allay the itching and heat of *erysipelas*. As the bark increases in bulk by imbibing moisture, it has been recommended to form bougies and tents of it for the dilatation of *strictures, fistulas*, etc., but in urethral strictures it has proved troublesome, from the liability of the part behind the stricture breaking off in the attempt to withdraw it, and passing into the bladder. The infusion of the bark is the common form of administration, and may be drank *ad libitum* (J. King). (See *Mucilago Ulmi.*)

Related Species.—*Ulmus campestris*, Linné, or *European elm*, is official in the *French Codex*, being used, like our slippery-elm, for the production of a mucilage, and, being astringent, has been used against *tapeworms*, and in *chronic skin affections*, syphilitic or otherwise. Its mucilage resembles that of flaxseed (Braconnot, 1846). A bitter glucosid, not yet isolated, much mucilage, some resin, and iron-greening tannin (Johnson, 1875) are contained in it. The bark is thinner than slippery-elm bark, cinnamon-colored on both sides, and has but little odor, and a bitterish, astringent and mucilaginous taste. The tree has been introduced into New England.

Ulmus effusa, Willdenow, *European black elm*, also yields some elm bark.

Ulmus americana, Linné, *White elm.*—America. A magnificent shade tree. Its inner bark is collected in Michigan.

Ulmus alata, Michaux, or *Winged elm*, of the southern United States, yields a bark, which is used in making cordage.

Celtis reticulosa.—An East Indian tree, from which Prof. Dunstan has isolated *skatole*, the characteristic odorous principle of human fæces (*Pharm. Jour. Trans.*, 1889).

UNGUENTA.—OINTMENTS.

Ointments are fatty substances, designed for external use, in which are incorporated certain medicines; their consistence is somewhat like that of good lard, being sufficiently soft to admit of being rubbed into the skin. They are most commonly prepared with benzoinated lard as a vehicle, which should be entirely free from salt or rancidity; soft and hard petrolatum are directed by the *British Pharmacopœia* in many instances under the name of hard and soft paraffins; occasionally wax, combined with olive or almond oils, is employed. About one-fifth part of yellow wax is added to the lard in the preparation of many ointments. Glycerite of starch and hydrous wool fat (*Adeps Lanæ Hydrosus*) are also convenient ointment vehicles; they readily mix with water. Sometimes fresh butter is used. Lard may be prepared for this purpose by melting it in twice its quantity of boiling water, stirring the mixture constantly; then setting it aside to cool, and separating the lard when it has solidified. This forms a fair prepared lard (*Adeps Suillus Præparatus*), or the benzoinated lard of the Pharmacopœia may be used. Substances entering into the formation of ointments, and which are not soluble in the fatty matter, should be reduced to a very fine powder previous to incorporation with it; or, if they are dissolved in alcohol or water as hard extracts, etc., they may be first softened by trituration with a small quantity of one of these solvents. Alcoholic fluids are more difficult to incorporate than concentrated aqueous preparations, and the latter should be employed slightly warmed. When ointments prepared of animal fats are long kept they are very apt to become rancid, hence it is usually preferable to make up only small portions at a time, or whenever required for use. Either benzoic acid, or poplar buds, if not objectionable, or incompatible with the ointment, will, when added to it, prevent in a great degree the disposition to rancidity. About 1 drachm of tincture of benzoin to each pound of lard has been found to answer the purpose much better than benzoic acid in the preservation of this fat from rancidity. This, however, is unnecessary where benzoinated lard has been employed. The greasy odor of ointments may be removed by triturating each ounce of ointment with 10 drops of sweet spirit of niter. According to Dr. C. W. Wright, fats and fixed oils may be preserved free from rancidity and disagreeable odor, for a long time, by melting them with powdered slippery-elm, in the proportion of 1 drachm of the bark to 1 pound of the fat; after 10 or 15 minutes' application of heat, the fat must be strained off. The elm bark communicates an odor to the fat that is scarcely distinguishable from that of the kernel of the hickory nut. Prof. E. S. Wayne long ago recommended paraffin as a substitute for lard; it might be added to lard if some third body could be found which would prevent separation on cooling, or it can be used alone, as is now commended in the British preparations. In European pharmacy the term *unguenta* includes both ointments and cerates. *Onguent*, in French pharmacy, has reference only to ointments containing resinous matter; *cerates*, to mixtures of fatty bodies and wax; and *pommades*, to those containing fats only.

Oleic Ointments.—Ointments of the Oleates. M. L'Hermite proposed as a substitute for the oleaginous and glycerinic solution of the alkaloids, solutions of these bases in *oleic acid*. He objected to the oils from their incapability of dissolving the alkaloids, and to the glycerin from its not possessing unctuous properties. Oleic acid triturated with the alkaloids, dissolves them and their salts perfectly, and may then be perfumed. Oleate of Morphine.—A grain and a half of powdered morphine, 1 ounce of pure oleic acid, and 6 drops of essence of bergamot. Oleate of Quinine.—A drachm of powdered sulphate of quinine to 10 drachms of aromatized oleic acid; dissolved by the aid of a gentle heat. Oleate of Veratrine.—Six grains of powdered veratrine dissolved in an ounce of oleic acid. Oleate of Atropine, or of Strychnine.—Three to 15 grains of atropine, or strychnine, dissolved in 10 drachms of oleic acid. These oleates will serve for the preparation of ointments, and may be hardened by the addition of stearic acid or a mixture of stearic and palmitic acids, which acids will also dissolve the vegetable bases when heated. Thus: Oleic Ointment of Quinine.—Take of sulphate of quinine, 1 drachm; oleic acid, 7½ drachms; stearic acid (of candles), 2¼ drachms; fuse and dissolve. Oleic Ointment of Veratrine.—Take of veratrine, 6 grains; oleic acid, 6 drachms; stearic acid, 2 drachms; mix and dissolve, etc. Oleic acid is also a good solvent for resinous matters and the volatile oils (*Amer. Jour. Pharm.*, Vol. XXVII, p. 72). (See also *Unguentum Zinci Oleati.*)

UNGUENTUM (U. S. P.)—OINTMENT.

Synonyms: *Unguentum simplex, Unguentum adipis, Simple ointment.*

Preparation.—"Lard, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; yellow wax, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the yellow wax, and gradually add to it the lard; then stir the mixture constantly until it is cool"—(*U. S. P.*).

Action and Medical Uses.—This is an emollient ointment, employed as a mild and cooling dressing to *ulcers*, *excoriations*, *blisters*, etc. It enters into the formation of several ointments.

Related Preparation.—Unguentum Paraffini, *Paraffin ointment*. "Take of hard paraffin, 3 ounces (Imp.) or 90 grammes (Metric); soft paraffin, 7 ounces (Imp.) or 210 grammes. Melt together in a shallow evaporating dish; as the liquid cools triturate constantly, until, when cold, a uniform plastic ointment is produced. When paraffin ointment is used as the basis of white ointments, it should be prepared with the white variety of soft paraffin; and when used in colored ointments, it should be prepared with the yellow variety of soft paraffin. The proportions of hard and soft paraffins in paraffin ointment may be modified to meet the exigencies of climate and prevailing temperature"—(*Br. Pharm.*, 1898). This ointment enters into the composition of several ointments of the *British Pharmacopœia*, 1898. It is used in the manner of simple ointments.

UNGUENTUM ACIDI BORICI.—OINTMENT OF BORIC ACID.

SYNONYM: *Ointment of boracic acid.*

Preparation.—"Take of boric acid, in fine powder, 2½ ounces (av.); soft paraffin, 10 ounces (av.); hard paraffin, 5 ounces (av.). Melt the hard and soft paraffins together, and add the boric acid distributed over the surface of the liquid by passing it through a sieve, then stir together constantly until cold"—(*Br. Pharm.*, 1885).

Action and Medical Uses.—(See *Acidum Boricum.*)

UNGUENTUM ACIDI CARBOLICI (U. S. P.)—OINTMENT OF CARBOLIC ACID.

Preparation.—"Carbolic acid, five grammes (5 Gm.) [77 grs.]; ointment, ninety-five grammes (95 Gm.) [3 ozs. av., 154 grs.]; to make one hundred grammes 100 Gm.) [3 ozs. av., 231 grs.]. Mix thoroughly"—(*U. S. P.*). This is a sufficiently strong ointment, and contains 5 per cent of carbolic acid. The *U. S. P.* (1880) preparation contained double that amount.

Action and Medical Uses.—(See *Acidum Carbolicum.*) Used in the treatment of various *skin affections.*

UNGUENTUM ACIDI HYDROCHLORICI.—OINTMENT OF HYDROCHLORIC ACID.

Preparation.—Take of hydrochloric acid, 1 fluid drachm; spermaceti ointment, 1 ounce. Mix together in a glass or porcelain mortar.

Action and Medical Uses.—This ointment is used in *scald-head*, to be applied night and morning, after the scabs have been removed by a poultice (Corrigan). Prof. Bloyer prefers a lotion made of carbolic acid, 1½ drachms; glycerin, 4 drachms; water, 1 pint. To be applied to the affected parts freely whenever the scalp itches or becomes dry.

UNGUENTUM ACIDI SALICYLICI.—OINTMENT OF SALICYLIC ACID.

Preparation.—"Take of salicylic acid, 60 grains; soft paraffin, 1080 grains; hard paraffin, 540 grains. Melt the hard and soft paraffins together, add the salicylic acid, and stir the whole constantly until cold"—(*Br. Pharm.*, 1885). The salicylic acid strength is here 1 in 28. The *British Pharmacopœia* (1898) directs a strength of but 1 in 50.

UNGUENTUM ACIDI SULPHURICI.—OINTMENT OF SULPHURIC ACID.

Preparation.—Take of sulphuric acid, 1 fluid drachm; prepared lard, 1 ounce. Mix together in a glass or porcelain mortar.

Action and Medical Uses.—Used in *ringworm*, *itch*, and other *cutaneous diseases;* also in *rheumatism* and *neuralgia* (Brugnatelli).

UNGUENTUM ACIDI TANNICI (U. S. P.)—OINTMENT OF TANNIC ACID.

Preparation.—"Tannic acid, in fine powder, twenty grammes (20 Gm.) [309 grs.]; benzoinated lard, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the tannic acid with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of iron utensils"—(*U. S. P.*).

Action and Medical Uses.—Astringent and antiseptic. Useful in *piles, ulcers,* some forms of *cutaneous disease,* and where such indications are required.

UNGUENTUM ACONITI.—OINTMENT OF ACONITE.

Preparation.—Take of alcoholic extract of aconite, 1 drachm; lard, 2 drachms. Soften the extract with a small quantity of alcohol, if necessary, and mix with the lard (see *Stramonium Ointment*).

Action and Medical Uses.—This ointment is used in violent *neuralgic and rheumatic pains* (Turnbull).

Related Ointment.—UNGUENTUM ACONITINÆ. The *British Pharmacopœia* (1898) gives an *Unguentum Aconitinæ* (*Aconitine ointment*), made by rubbing 10 grains (Imp.), or 0.5 gramme, of aconite with 80 grains, or 4 grammes, of oleic acid, and gently warming the mixture until dissolved; add 410 grains, or 20.5 grammes, of lard. Mix. These ointments must not be applied to wounds, ulcers, cuts, or abrasions, etc.

UNGUENTUM ALKALINUM.—ALKALINE OINTMENT.

Preparation.—Take of carbonate of sodium, 2 drachms; tincture of opium, 1 fluid drachm; lard, 1 ounce. Rub together in a porcelain or Wedgewood mortar.

Action and Medical Uses.—This is used in several forms of cutaneous diseases, as *lichen, lepra, psoriasis, ichthyosis, porrigo, favosa,* etc. (Soubeiran).

UNGUENTUM ALKALINUM CAMPHORATUM.—CAMPHORATED ALKALINE OINTMENT.

Preparation.—Take of carbonate of potassium, 20 grains; camphor, 6 grains; lard, 7 drachms. Rub together in a mortar.

Action and Medical Uses.—This ointment is used in *sycosis,* and several forms of *cutaneous diseases* (Cazenave).

UNGUENTUM AMMONIACALE.—AMMONIACAL OINTMENT.

SYNONYM: *Gondret's pomade.*

Preparation.—Take of lard, 6 drachms; suet, 4 drachms; almond oil, 2 drachms; stronger solution of ammonia, 12 fluid drachms. Melt the lard, suet, and oil together, then add the ammonia, and shake the whole together in a closed bottle.

Action and Medical Uses.—This preparation is rubefacient and vesicant. To produce its vesicating influence, it must be covered with a compress after inunction.

UNGUENTUM ANTIMONII TARTARATI.—OINTMENT OF TARTARATED ANTIMONY.

SYNONYMS: *Tartar emetic ointment, Antimonial ointment, Unguentum antimonii, Unguentum stibiatum, Unguentum stibio-kali tartarici.*

Preparation.—"Take of tartarated antimony, in fine powder, ¼ ounce (av.); simple ointment, 1 ounce (av.). Mix thoroughly"—(*Br. Pharm.,* 1885).

Action and Medical Uses.—This agent was formerly in common use to produce its peculiar pustular eruption, as a means of counter-irritation. Unless very carefully used, painful inflammation and ulceration—occasionally gangrene may result from its application. The scars left thereafter are permanent. This ointment was not used by Eclectic doctors, and has been practically abandoned in other schools.

UNGUENTUM AQUÆ ROSÆ (U. S. P.)—OINTMENT OF ROSE WATER.

Synonym: *Cold cream.*

Preparation.—"Spermaceti, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; white wax, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 120 grs.]; expressed oil of almond, six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏]; stronger rose water, one hundred and ninety cubic centimeters (190 Cc.) [6 fl℥, 204 ♏]; sodium borate, in fine powder, five grammes (5 Gm.) [77 grs.]. Reduce the spermaceti and the white wax to fine shavings, and melt them at a moderate heat; then add the expressed oil of almond, pour the mixture into a warmed, shallow Wedgwood mortar, carefully add, without stirring, the whole of the stronger rose water, in which the sodium borate had previously been dissolved, and stir rapidly and continuously, until the mixture becomes uniformly soft and creamy"—(*U. S. P.*). An egg-beater provides an excellent means for stirring the mixture.

Description.—This ointment should be very soft and pure white, and a perfectly homogeneous mass. It gradually becomes rancid. Ointment of rose water contains 20 per cent of rose water. A little glycerin or benzoic acid tends to prevent rancidity.

Action and Medical Uses.—This is a delightful cooling ointment, much employed as an application to *irritated, chapped and abraded surfaces*, as *chapped lips, hands*, etc. It was formerly made of white wax, 1 part; spermaceti, 4 parts; rose water, 8 parts; oil of almond, 16 parts; but, on account of its tendency to decomposition and rancidity, the preceding formula is preferred.

UNGUENTUM BAPTISIÆ.—OINTMENT OF WILD INDIGO.

Preparation.—Take of wild indigo root, in coarse powder, 20 pounds; fresh butter, 10 pounds; beeswax, 3 pounds; tallow, 1½ pounds; diluted alcohol, a sufficient quantity. Macerate the root in diluted alcohol for 48 hours; then transfer it to a percolator, and gradually pour upon it diluted alcohol, until the liquid passes nearly tasteless. Add the filtered liquor to the other ingredients, and carefully digest with heat, until the alcohol and water have evaporated; then strain the mixture (Beach's *Amer. Prac.*).

Action and Medical Uses.—This ointment is cleansing, detergent, discutient, antiseptic, etc. It is useful in many *cutaneous affections, erysipelas, scrofulous, gangrenous*, and all other forms of *ulcers, piles*, etc.

UNGUENTUM BELLADONNÆ (U. S. P.)—BELLADONNA OINTMENT.

Preparation.—"Alcoholic extract of belladonna leaves, ten grammes (10 Gm.) [154 grs.]; diluted alcohol, five grammes (5 Gm.) [77 grs.]; benzoinated lard, eighty-five grammes (85 Gm.) [3 ozs. av.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the extract with the diluted alcohol until it is uniformly soft, then gradually add the lard, and mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—This forms an anodyne application for the relief of *pain* and *spasm*, and may be advantageously applied to *local neuralgia*, to *painful joints*, to dilate the pupil, and also the os uteri, and to the denuded spine in violent *tetanus, delirium tremens*, and *puerperal convulsions*. It is to be preferred to atropine ointment as an application to the uterus and vagina.

Related Ointment.—Unguentum Atropinæ (*Br. Pharm.*, 1898), for similar purposes, is made by triturating atropine, 10 grains (Imp.), or 0.5 gramme, with oleic acid, 40 grains (Imp.), or 2 grammes, and gently warming the mixture until dissolved; then add lard, 450 grains (Imp.), or 22.5 grammes, and mix. It must be used with caution, and not be applied on abraded surfaces. It is used to allay *irritation*, particularly of the urethra and rectum, and to control *pain* and *spasm*. It is most largely employed as a local anodyne in *superficial neuralgias*.

UNGUENTUM BENZOINI.—OINTMENT OF BENZOIN.

SYNONYMS: *Benzoated lard*, *Benzoinated lard.*

Preparation and History.—(See *Adeps Benzoinatus.*)

Action and Medical Uses.—This forms an excellent vehicle for ointments, as benzoin enables the lard to resist rancidity. Poplar buds have the same effect.

UNGUENTUM CAMPHORÆ (N. F.)—CAMPHOR OINTMENT.

SYNONYM: *Unguentum camphoratum.*

Preparation.—"Camphor, in coarse powder, twenty-two grammes (22 Gm.) [339 grs.]; white wax, eleven grammes (11 Gm.) [170 grs.]; lard, sixty-seven grammes (67 Gm.) [2 ozs. av., 159 grs.]. Melt the white wax and lard with a gentle heat, then add the camphor, and stir the ointment until it is cold"—(*Nat. Form*).

Action and Medical Uses.—This ointment is a convenient form for the local application of camphor, for the uses of which see *Camphora.*

UNGUENTUM CANTHARIDIS.—OINTMENT OF CANTHARIDES.

SYNONYMS: *Ointment of Spanish flies*, *Unguentum irritans.*

Preparation.—"Take of cantharides, yellow wax, of each, 1 ounce (av.); olive oil, 6 fluid ounces. Infuse the cantharides in the oil, in a covered vessel, for 12 hours; then place the vessel in boiling water for 15 minutes, strain through muslin with strong pressure, add the product to the wax previously melted, and stir constantly while the mixture cools"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs cantharides 1 part, and benzoated lard 10 parts. Another formula is as follows:

Take of finely powdered Spanish flies, olive oil, each, 3 ounces; oil of turpentine, 1½ fluid ounces; yellow wax, resin, each, 2 ounces. Mix the flies, olive oil, and turpentine, place them in a vessel on a water-bath, and continue the heat until the turpentine has nearly evaporated, stirring the mixture occasionally. Then add the wax and resin previously melted together, and heat till the articles are thoroughly incorporated; remove from the bath and stir till cold (W. Procter, Jr.).

Action and Medical Uses.—This is used not for the purpose of causing vesication, but as a rubefacient stimulating dressing to blisters, to induce a continuation of the discharge, whenever such is desirable. It has also been applied in *alopecia* and *muscular rheumatism.*

UNGUENTUM CETACEI.—OINTMENT OF SPERMACETI.

Preparation.—"Take of spermaceti, 200 parts by weight; white beeswax, 80 parts; almond oil, 720 parts; benzoin, in coarse powder, 20 parts. Melt together the spermaceti, beeswax and almond oil; add the benzoin, and, frequently stirring the mixture, continue the application of heat for 2 hours; remove from the source of heat, strain, and stir the ointment constantly until cold"—(*Br. Pharm.*, 1898).

Action and Medical Uses.—This is a mild emollient ointment, employed as a dressing for *excoriations*, *wounds*, *vesicated surfaces*, etc. Owing to its disposition to rancidity, but a small quantity should be prepared at a time. This change is retarded somewhat by the benzoin.

UNGUENTUM CHRYSAROBINI (U. S. P.)—CHRYSAROBIN OINTMENT.

Preparation.—"Chrysarobin, five grammes (5 Gm.) [77 grs.]; benzoinated lard, ninety-five grammes (95 Gm.) [3 ozs. av., 154 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the chrysarobin with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*). This ointment should be perfectly smooth, and of a yellow color. It will stain garments.

Action and Medical Uses.—(See *Chrysarobinum.*)

UNGUENTUM COCCULI.—OINTMENT OF COCCULUS INDICUS.

Preparation.—"Take of the kernels of Cocculus Indicus, 1 ounce; prepared lard, 5 ounces. Beat the kernels well in a mortar, first alone, and then with a little of the prepared lard; and then gradually add the rest of the lard" (*Ed.*).

Action and Medical Uses.—This ointment is employed in the treatment of *itch* and *porrigo scutulata*, as well as an application to destroy *lice*. An ointment composed of picrotoxin 1 grain, lard 48 grains, is used for similar purposes.

UNGUENTUM CREASOTI.—OINTMENT OF CREASOTE.

Preparation.—"Take of creasote, 1 fluid drachm; simple ointment, 1 ounce (av.). Mix thoroughly"—(*Br. Pharm.*, 1885).

Action and Medical Uses.—This ointment is used in some cutaneous diseases, *porrigo of the scalp*, and as an antiseptic and stimulant to *indolent* or *gangrenous ulcers*, or flabby, fungoid tissues with unhealthy discharges, and is an invaluable application to *burns*, when diluted by the addition of lard, 2 ounces. Its further uses are those of creasote, externally applied (see *Creosotum*).

UNGUENTUM CUCUMIS.—OINTMENT OF CUCUMBER.

Preparation.—Take of green cucumbers (suitable for table use), 7 pounds pure white lard, 24 ounces; selected veal suet, cut in pieces, 15 ounces. The unpared cucumbers, after being washed, are to be reduced to a pulp by grating, and the juice expressed and strained. The suet is to be heated over a salt water-bath until the fat is fused out from the membranes; then add the lard, and, when liquefied, strain the mixture through muslin into a wide-mouthed earthen vessel capable of holding a gallon, and stir it until it commences to thicken, when one-third of the cucumber juice is to be added and beaten with the ointment, by means of a wooden spatula, until its odor has been almost wholly extracted. Then allow it to stand until the fluid separates, which must be removed by decantation, and add another third of the juice. This must be beaten in like manner until exhausted, then decanted, and finally the last third added and similarly treated. The jar is then to be closely covered and placed in a water-bath, where it must remain an hour, or until the fatty matter entirely separates from the enveloped juice. The green albuminous coagulum which floats upon the surface is then to be skimmed off, and the jar put aside in a cool place, that the ointment may solidify. The crude ointment is then to be carefully separated from the watery liquid on which it floats, melted by a gentle heat, and strained—part in a jar, and closely sealed for keeping—the remainder into a mortar, and triturated with a little rose water, until it is very white and creamy, for present use. It is usual to keep this ointment in nearly-filled glass jars, and to cover it with rose water to prevent the access of air. Thus prepared, cucumber ointment readily keeps from season to season (W. Procter, Jr.).

Action and Medical Uses.—This forms an emollient application, very useful for *chapped lips and hands*, *irritated* or *excoriated surfaces*, etc.

UNGUENTUM DIACHYLON (U. S. P.)—DIACHYLON OINTMENT.

SYNONYMS: *Unguentum plumbi Hebræ*, *Hebra's lead ointment.*

Preparation.—"Lead plaster, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; olive oil, four hundred and ninety grammes (490 Gm.) [1 lb. av., 1 oz., 124 grs.]; oil of lavender flowers, ten cubic centimeters (10 Cc.) [16 ♏]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt together the lead plaster and the olive oil on a water-bath; then, having allowed the mixture to become partly cool, add the oil of lavender flowers, and stir constantly, until the ointment is cold"—(*U. S. P.*).

Action and Medical Uses.—This ointment is a favorite with many dermatologists as an application in numerous *skin diseases*, particularly those of an *eczematous type*, and in *sycosis menti*. *Offensive sweating of the feet* is said to be checked by it.

UNGUENTUM EUCALYPTI.—OINTMENT OF EUCALYPTUS.

Preparation.—"Take oil of eucalyptus, by weight, 1 ounce (av.); soft paraffin, hard paraffin, of each, 2 ounces (av.). Melt the hard and soft paraffins together add the oil, and stir until cold"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs an ointment of half the above strength in oil of eucalyptus.

Action and Medical Uses.—(See *Eucalyptus*.) This ointment is used chiefly in *skin diseases*, and as an antiseptic and stimulant dressing for *old ulcers*.

UNGUENTUM FULIGINIS.—OINTMENT OF WOOD-SOOT.

Preparation.—Take of wood-soot, in very fine powder, ½ ounce; lard, 2 ounces Triturate them together (Soubeiran).

Action and Medical Uses.—Applied on cotton batting, this ointment is very useful in *burns* and *erysipelatous inflammations;* and is also beneficial in *tinea capitis* and several *cutaneous diseases*.

UNGUENTUM GALLÆ (U. S. P.)—NUTGALL OINTMENT.

SYNONYM: *Ointment of galls.*

Preparation.—"Nutgall, in No. 80 powder, twenty grammes (20 Gm.) [309 grs.]; benzoinated lard, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the nutgall with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*).

Action and Medical Uses.—This ointment is useful in *falling of the bowels*, *external hemorrhoidal swellings*, and *foul, obstinate ulcers*. When the piles are irritable, half a drachm of pulverized opium may be advantageously added.

Related Ointment.—UNGUENTUM ACIDI GALLICI (N. F.), *Ointment of gallic acid*. "Gallic acid, ten grammes (10 Gm.) [154 grs.]; benzoinated lard (*U. S. P.*), ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]. Rub the gallic acid with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of an iron spatula"—(*Nat. Form.*).

UNGUENTUM GALLÆ CUM OPIO.—OINTMENT OF GALLS AND OPIUM.

Preparation.—"Take of gall ointment, 925 grains (Imp.), or 92.5 grammes; opium, in very fine powder, 75 grains (Imp.), or 7.5 grammes. Mix by trituration; 100 parts of this ointment contain 7½ parts of opium"—(*Br. Pharm.*, 1898).

Action and Medical Uses.—This ointment is of value in *piles* and *rectal prolapse;* it is also of service in *vaginal relaxation*. Owing to the large amount of opium present, care should be exercised in its employment on mucous surfaces.

UNGUENTUM HYDRARGYRI NITRATIS (U. S. P.)—OINTMENT OF MERCURIC NITRATE.

SYNONYMS: *Citrine ointment*, *Unguentum citrinum*, *Unguentum hydrargyri citrinum*, *Ointment of nitrate of mercury*, *Mercurial balsam*, *Yellow citrine ointment*.

Preparation.—"Mercury, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]. nitric acid, one hundred and seventy-five grammes (175 Gm.) [6 ozs. av., 76 grs.]; lard oil, seven hundred and sixty grammes (760 Gm.) [1 lb. av., 10 ozs., 353 grs.].

Heat the lard oil, in a glass or porcelain vessel, to a temperature of 100° C. (212° F.); then withdraw the heat, gradually add seventy grammes (70 Gm.) [2 ozs. av., 205 grs.] of nitric acid, and when the reaction moderates reapply the heat, until effervescence ceases. Then allow the mixture to cool to about 40° C. (104° F.). Having dissolved the mercury in the remainder of the nitric acid with the aid of sufficient heat to prevent the solution from crystallizing, add this solution to the mixture. When the mass has become entirely cold mix it thoroughly by trituration, avoiding the use of a metallic spatula"—(*U. S. P.*). The official process is based upon that of Mr. Rother.

Action and Medical Uses.—This ointment has been used in *herpes*, *porrigo*, *eczema*, *psoriasis*, and similar obstinate cutaneous affections, in *ophthalmia tarsi*, and those slight excoriations of the tarsi attended with extreme itching, and in all the inflammations of the eyes attended by eruptive disorders of the hairy scalp or face; it may be applied by means of a camel's-hair pencil. It is also used as a dressing to stimulate *syphilitic*, *phagedenic*, and *obstinate ulcers*, and particularly for the *squamous* and *tubercular syphilitic skin affections*. It is also employed to destroy *pediculi* and various *parasites* giving rise to *parasitic skin affections*. In ophthalmic affections it is frequently applied mixed with an equal weight of almond oil. A milder ointment of nitrate of mercury is made by rubbing together 1 part of ointment of nitrate of mercury with 7 parts of lard. It should be prepared only as required (see also below). Occasionally employed by Eclectic physicians. Brown citrine ointment has been used by Prof. J. M. Scudder and others in *chronic eczema*, *sycosis*, *barbers' itch*, and in some cases of *pruritis* (*Spec. Med.*).

Related Ointments.—UNGUENTUM HYDRARGYRI NITRATIS DILUTUM, *Diluted ointment of nitrate of mercury*. "Take of nitrate of mercury ointment, 1 ounce (av.); soft paraffin, 2 ounces (av.). Mix"—(*Br. Pharm.*, 1885). The latest *British Pharmacopœia* directs double the amount of soft yellow paraffin.

BROWN CITRINE OINTMENT.—Cod-liver oil, 75 ounces; red oxide of mercury, 2 ounces; nitric acid, 4½ ounces. Dissolve the red oxide of mercury in the nitric acid, and then slowly add the solution, with constant stirring, to the cod-liver oil, previously heated to a temperature of 212° F. This preparation is a favorite in Cincinnati with oculists, and has been used for over thirty years. It was once made twice the strength of the above, but it was found preferable to double the proportion of oil. The preparation is in the form of a deep-brown liquid or paste, and should be kept, as well as dispensed, in a wide-mouthed bottle instead of a jar.

UNGUENTUM HYDRARGYRI AMMONIATI (*U. S. P.*), *Ointment of ammoniated mercury*, *Ointment of white precipitate*, *Unguentum præcipitati albi*.—"Ammoniated mercury, in very fine powder, ten grammes (10 Gm.) [154 grs.]; benzoinated lard, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the ammoniated mercury with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*). The *British Pharmacopœia* (1898) directs ammoniated mercury, 1 part; paraffin ointment, white, 9 parts. Mix thoroughly. Uses similar to those of *Unguentum Hydrargyri Nitratis* (which see).

UNGUENTUM HYDRARGYRI OXIDI FLAVÆ (U. S. P.)

OINTMENT OF YELLOW MERCURIC OXIDE.

Preparation.—"Yellow mercuric oxide, in very fine powder, ten grammes (10 Gm.) [154 grs.]; ointment, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the yellow mercuric oxide with the ointment, gradually added, until they are thoroughly mixed"—(*U. S. P.*). This ointment should be prepared in small amounts on account of its liability to become rancid. (For uses, see *Hydrargyri Oxidum Flavum.*)

Related Ointments.—UNGUENTUM HYDRARGYRI OXIDI RUBRI (*U. S. P.*), *Ointment of red mercuric oxide*, *Unguentum præcipitatum rubrum*, *Ointment of red precipitate*. "Red mercuric oxide, in very fine powder, ten grammes (10 Gm.) [154 grs.]; castor oil, five grammes (5 Gm.) [77 grs.]; ointment, eighty-five grammes (85 Gm.) [3 ozs. av.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Triturate the red mercuric oxide with the castor oil, until a perfectly smooth mixture results; then gradually incorporate the ointment, and mix thoroughly"—*U. S. P.*). The British preparation (*Br. Pharm.*, 1898) is composed of red oxide of mercury, ¼ ounce (Imp.), or 10 grammes; and paraffin ointment (yellow), 2¼ ounces (Imp.), or 90 grammes. As the ointment ages it becomes discolored and rancid, a condition sought to be retarded by the use of the castor oil. This ointment is used similarly to ointment of the yellow oxide in *blepharitis ciliaris*, though less eligible; also employed in the treatment of *indolent syphilitic ulcers*, *acne*, and to abort *boils*. Rarely used in Eclectic practice.

Unguentum Hydrargyri (*U. S. P.*), *Mercurial ointment*, *Blue ointment*, *Unguentum mercuriale*, *Unguentum neapolitanicum*, *Ointment of mercury.*—"Mercury, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; lard, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; suet, two hundred and thirty grammes (230 Gm.) [8 ozs. av., 49 grs.]; oleate of mercury, twenty grammes (20 Gm.) [309 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Triturate the oleate of mercury with the mercury, gradually added, in a mortar, until globules of the metal are no longer visible. Then add the lard and suet, previously melted together and partially cooled, and continue the trituration until globules of mercury are no longer visible under a lens magnifying 10 diameters"—(*U. S. P.*). The oleate of mercury is employed to "extinguish" the mercury, which is difficult to accomplish with sweet fats. Formerly a small amount of rancid ointment was used for the same purpose. This ointment is no longer made by the apothecary, but is purchased from the manufacturer, and detailed remarks concerning its manipulation are superfluous. The official ointment contains one-half its weight of mercury, but much of the commercial drug is but one-third mercury. It must be kept in a cool place. Mercurial ointment, to be of any service, must be applied by gentle friction, continued for some time, at each application, in order to promote its absorption. When it is intended to produce the constitutional effects of the mercury, as in *syphilitic diseases*, those parts of the body are selected in which the cuticle is thinnest, as the inside of the thighs and legs, and under the arms. In *liver complaints* the inunctions are made over the region of that organ; and in *buboes*, *swellings of the glands*, etc., it is usually applied immediately over the affected parts. About ½ or 1 drachm, rubbed in night and morning, will be sufficient; and the person who applies the ointment should protect his hands by enveloping them in some article through which the ointment will not pass, as a soft, oiled pig's bladder, turned inside out, India rubber gloves, etc. Or, a strip of muslin 2 or 3 inches wide may be formed into a roll about 1 inch in diameter, one extremity of which may be used to rub over the skin as a substitute for the hand. During the whole course of the inunction the patient should wear the same drawers night and day. The ointment is sometimes used internally, in addition to its external application, and is said to promptly excite salivation. It is often used in a milder form as a dressing to *ulcers*, and in *cutaneous diseases;* being, in such instances, diluted with 2, 3, or 4 times its weight of lard, as may be desired. Not employed in Eclectic practice.

Unguentum Hydrargyri Compositum, *Compound ointment of mercury.*—"Take of ointment of mercury, 6 ounces (av.); yellow wax, olive oil, of each, 3 ounces (av.); camphor, 1½ ounces (av.). Mix the wax and oil by the aid of heat, then incorporate the ointment of mercury, and when the mixture is nearly cold, add the camphor in powder; stir the whole thoroughly together"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) employs mercury ointment, 10 parts; yellow beeswax, olive oil, of each, 6 parts; and camphor, in flowers, 3 parts.

Unguentum Hydrargyri Iodidi Rubri, *Ointment of red iodide of mercury.*—"Take of iodide of mercury, in fine powder, 16 grains; simple ointment, 1 ounce (av.). Mix thoroughly"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs mercuric iodide, 2 parts; and benzoinated lard, 48 parts. Employed by physicians of the regular school in *syphilitic and scrofulous ulcers*, and *glandular enlargements*, *goitre*, and *hepatic and splenic enlargements.*

Unguentum Hydrargyri Subchloridi, *Ointment of subchloride of mercury*, *Unguentum calomelanos*, *Ointment of calomel.*—"Take of subchloride of mercury, 80 grains; benzoated lard, 1 ounce (av.). Mix thoroughly"—(*Br. Pharm.*, 1885). The proportions of the *British Pharmacopœia* (1898) are mercurous chloride, 1 part; benzoated lard, 9 parts. Employed upon *syphilitic skin eruptions* when of limited extent.

UNGUENTUM IODI (U. S. P.)—IODINE OINTMENT.

Synonym: *Unguentum iodinum.*

Preparation.—"Iodine, four grammes (4 Gm.) [62 grs.]; potassium iodide, one gramme (1 Gm.) [15 grs.]; water, two cubic centimeters (2 Cc.) [32 ♏]; benzoinated lard, ninety-three grammes (93 Gm.) [3 ozs. av., 123 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the iodine and the iodide of potassium, first with the water, and then with the benzoinated lard, gradually added, until they are thoroughly mixed, avoiding the use of a metallic spatula. This preparation should be freshly made when required"—(*U. S. P.*). The presence of the potassium iodide is to insure the divisibility of the iodine. The lard must be gradually added, and the mixture thoroughly rubbed until no longer gritty. The ointment should be of a uniform color. It imparts an orange stain to the skin.

Action and Medical Uses.—This preparation is used as a local application in *bronchocele*, *scrofulous*, and other *chronic glandular enlargements*, and in *opacities of the cornea;* it is undoubtedly absorbed, and thus effects its influence; the discoloration of the skin occasioned by its use gradually disappears. Applied twice a day to *enlarged tonsils*, by means of a camel's-hair pencil, it has caused the enlargement to disappear in the course of 2 months. It is likewise used to promote absorption after *inflammations*, *pleurisy*, and *pericarditis*, and to prevent inflammatory effects in *chilblains.* It is better to prepare it only as it is required for use.

UNGUENTUM IODOFORMI (U. S. P.)—IODOFORM OINTMENT.

Preparation.—"Iodoform, in very fine powder, ten grammes (10 Gm.) [154 grs.]; benzoinated lard, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the iodoform with the benzoinated lard, gradually added, until they are thoroughly mixed. This preparation should be freshly made, when required"—(*U. S. P.*).

Action and Medical Uses.—This forms a stimulating, antiseptic, and anæsthetic ointment, used for the general purposes for which iodoform is locally applied (see *Iodoformum*).

UNGUENTUM IPECACUANHÆ.—OINTMENT OF IPECACUANHA.

Preparation.—Take of ipecacuanha, in powder, 2 drachms; olive oil, 2 fluid drachms; lard, ½ ounce. Mix together.

Action and Medical Uses.—Rubbed on the skin for a few minutes, once or twice a day, this ointment produces an eruption. It is used as a counter-irritant in *diseases of the throat*, and in pulmonary affections is applied to the chest. When it is desired to make it more active, 1½ fluid drachms of croton oil may be added to the formula. If rubbed on the surface for 20 or 30 minutes at a time, repeated 3 or 4 times a day, and covered with flannel after each application, it will produce vesicles in 36 hours.

Related Preparation.—UNGUENTUM MEZEREI (N. F.), *Mezereum ointment.* "Fluid extract of mezereum (F. 170), twenty-five cubic centimeters (25 Cc.) [406 ♏]; lard, eighty grammes (80 Gm. [2 ozs. av., 360 grs.]; yellow wax, twelve grammes (12 Gm. [185 grs.]. Melt together with lard and wax with a moderate heat, add the fluid extract, and stir the mixture constantly until the alcohol has evaporated. Then continue to stir until cool"—(*Nat. Form.*). This is an irritant, and is applied to *obstinate ulcers, wounds*, etc., to excite suppuration; sometimes it is used to keep up the discharge from vesicated surfaces.

UNGUENTUM MYRICÆ.—OINTMENT OF BAYBERRY.

Preparation.—Take of bayberry-tallow, white turpentine, each, 2 ounces; olive oil, 1 ounce. Melt together, and strain"—(Beach's *Amer. Prac.*).

Action and Medical Uses.—This forms an excellent application to *scrofulous ulcers* and *indolent ulcers* generally.

UNGUENTUM MYRICÆ COMPOSITUM.—COMPOUND OINTMENT OF BAYBERRY.

Preparation.—Take of bayberry-tallow, sweet gum, each, 1 ounce; suet, 2 ounces. Melt together, and strain.

Action and Medical Uses.—This ointment is very advantageous in *scrofulous ulcers, tinea capitis, porrigo scutulata, itch, salt-rheum*, and several other forms of *cutaneous diseases;* also in *piles* and *fistulous ulcers*. In *fistula* and some cutaneous diseases, the addition of 3 or 4 drachms of zinc sulphate, in powder, will be found beneficial (J. King).

UNGUENTUM PHYTOLACCÆ.—OINTMENT OF POKE.

Preparation.—Take of the leaves of poke, collected just before the ripening of the berries, 4 pounds; lard, 1 pound; spirit, 1 pint; wax, 2 ounces. Mix, and slowly simmer together until the leaves are crisp, and then express through linen. An ointment is sometimes made by mixing 1½ drachms of powdered poke leaves or root, or of the extract of poke, with 1 ounce of lard (see *Stramonium Ointment*).

Action and Medical Uses.—This is used as an application to *ulcers, porrigo, tinea capitis*, and other *cutaneous affections*, and as a discutient to various *tumors* (J. King).

UNGUENTUM PICIS LIQUIDÆ (U. S. P.)—TAR OINTMENT.

Preparation.—"Tar, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; yellow wax, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; lard, three hundred and seventy-five grammes (375 Gm.) [13 ozs. av., 100 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt together the yellow wax and the lard at a moderate heat; then incorporate the tar, strain the mixture through muslin, and stir the ointment constantly until it is cool"—(*U. S. P.*).

Action and Medical Uses.—This is a stimulating ointment. It is used principally in *tinea capitis* and *ringworm of the scalp*, being kept constantly applied to the part by means of a cap. It has also been efficient in some other *cutaneous diseases*, particularly the dry stage of *eczema*. It may be applied to unhealthy *ulcers*.

Related Ointments.—Unguentum Picis Compositum (N. F.), *Compound tar ointment.* "Oil of tar, four grammes (4 Gm.) [62 grs.]; tincture of benzoin (*U. S. P.*), two cubic centimeters (2 Cc.) [32 ♏︎]; oxide of zinc, three grammes (3 Gm.) [46 grs.]; yellow wax, twenty-six grammes (26 Gm.) [401 grs.]; lard, thirty-two grammes (32 Gm.) [1 oz. av., 56 grs.]; cotton-seed oil, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]. Melt the yellow wax and lard with the cotton-seed oil at a gentle heat. Add the tincture of benzoin, and continue heating until all the alcohol has evaporated. Then withdraw the heat, add the oil of tar, and finally the oxide of zinc, incorporating the latter thoroughly, so that on cooling a smooth homogeneous ointment may result"—(*Nat. Form*).

Unguentum Picis Betulæ, *Unguentum rusci, Wolff's tar ointment.*—Birch tar, 4 parts; unguentum, 21 parts. Mix.

UNGUENTUM PIPERIS NIGRI.—OINTMENT OF BLACK PEPPER.

Preparation.—Take of prepared lard, 1 pound; suet, 4 ounces; tar, 1 pint; black pepper, in powder, 4 ounces. Melt the lard and tar together, then add the suet and pepper.

Action and Medical Uses.—This is used in *tinea capitis*, in the same manner as the ointment of tar.

UNGUENTUM PLUMBI ACETATIS.—OINTMENT OF ACETATE OF LEAD.

Preparation.—"Take of lead, in fine powder, 12 grains; benzoated lard, 1 ounce (av.). Mix thoroughly"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) employs lead acetate, 1 part; and paraffin ointment, white, 24 parts.

Action and Medical Uses.—This forms an application for *cuts, abrasions, acute local inflammations*, and *excoriations*.

UNGUENTUM PLUMBI CARBONATIS (U. S. P.)—OINTMENT OF LEAD CARBONATE.

Preparation.—"Lead carbonate, in very fine powder, ten grammes (10 Gm.) [154 grs.]; benzoinated lard, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the lead carbonate with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*).

Action and Medical Uses.—This ointment is used as a dressing for *abrasions, blistered and inflamed surfaces, burns*, etc.

UNGUENTUM PLUMBI COMPOSITUM.—COMPOUND LEAD OINTMENT.

Synonym: *Mayer's ointment.*

Preparation.—Take of olive oil, 2½ pounds; white turpentine, ½ pound; beeswax, unsalted butter, each, 4 ounces; red lead, 1 pound; honey, 12 ounces; powdered camphor, ½ pound. Melt the olive oil, white turpentine, beeswax, and butter together, and strain; then heat them to nearly the boiling point, and gradually add the red lead, stirring the mixture constantly until it becomes black or brown. Then remove from the fire, and, when it becomes somewhat cool, add to it the honey and camphor, previously mixed together.

Action and Medical Uses.—This forms a very beneficial ointment for all kinds of *ulcers, cuts, wounds*, and several *cutaneous diseases*. It is of a more solid consistence than ointments are generally. It is highly prized by the German population, who have held it for a long time as a secret among themselves. The profession are indebted to Mr. Joseph P. Mayer, of Cincinnati, for a knowledge of it. This ointment was extensively used by the earlier Eclectics, and is still quite popular.

UNGUENTUM PLUMBI IODIDI (U. S. P.)—OINTMENT OF LEAD IODIDE.

Preparation.—"Lead iodide, in very fine powder, ten grammes (10 Gm.) [154 grs.]; benzoinated lard, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the lead iodide with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*).

Action and Medical Uses.—(See *Plumbi Iodidum*.) This ointment is employed chiefly to discuss *glandular enlargements; testicular hypertrophy*, following *gonorrhœa*, is said to be markedly reduced by it.

UNGUENTUM POTASSII CYANIDI.—OINTMENT OF CYANIDE OF POTASSIUM.

Preparation.—Take of cyanide of potassium, 12 grains; oil of almond, 2 drachms; cold cream, 2 ounces. Triturate together.

Action and Medical Uses.—This is used as an application to the sound skin in *neuralgia* (Cazenave).

UNGUENTUM POTASSII IODIDI (U. S. P.)—OINTMENT OF POTASSIUM IODIDE.

Preparation.—"Potassium iodide, twelve grammes (12 Gm.) [185 grs.]; sodium hyposulphite, 1 gramme (1 Gm.) [15 grs.]; water, hot, ten cubic centimeters (10 Cc.) [162 ♏]; benzoinated lard, seventy-seven grammes (77 Gm.) [2 ozs. av., 313 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the potassium iodide and the sodium hyposulphite in the hot water, then mix the solution with the benzoinated lard"—(*U. S. P.*). The sodium hyposulphite is added to counteract, or rather to prevent, the liberation of iodine which is likely to take place through changes in the fat, such as were experienced in the earlier official ointment.

Action and Medical Uses.—This ointment is employed as a discutient for *swellings* and *tumors* of a scrofulous character, and for *goitre*. It is less effective than iodine, but has the advantage of not staining the parts and garments.

UNGUENTUM POTASSÆ SULPHURATÆ.—OINTMENT OF SULPHURATED POTASH.

Preparation.—"Take of sulphurated potash, 30 grains; hard paraffin, ¼ ounce (av.); soft paraffin, ¾ ounce (av.). Triturate the sulphurated potash in a glass or porcelain mortar, and gradually add the melted mixture of the hard and soft paraffins, rubbing them together until the ointment is perfectly smooth and free from grittiness. This ointment should be recently prepared"—(*Br. Pharm.*, 1885).

Action and Medical Uses.—This ointment is useful in *ringworm, itch*, and other forms of *cutaneous diseases*. It is, however, unstable, and should be prepared only as needed.

UNGUENTUM SABINÆ.—OINTMENT OF SAVIN.

SYNONYMS: *Ceratum sabinæ*, *Savine cerate*.

Preparation.—"Take of fresh savin tops, bruised, 8 ounces (av.); yellow wax, 3 ounces (av.); benzoated lard, 16 ounces (av.). Melt the lard and wax together on a water-bath, add the savin, and digest for 20 minutes. Then remove the mixture, and express through calico"—(*Br. Pharm.*, 1885). As savin, in fresh condition, is not likely to be obtained in this country, the following formula of the *U. S. P.* (1880) may be employed, though the preparation is unsatisfactory as compared with the above-directed ointment:

CERATUM SABINÆ.—"Fluid extract of savine, 25 parts; resin cerate, 90 parts. Melt the resin cerate by means of a water-bath, add the fluid extract of savine, and continue the heat until the alcohol has evaporated, then remove the heat, and stir constantly until cool"—(*U. S. P.*, 1880).

Action and Medical Uses.—Like ointment of cantharides, this preparation may be employed to maintain a discharge from vesicated surfaces, being preferred over the former on account of its freedom from the liability of producing strangury. It is occasionally used in the same manner upon setons.

UNGUENTUM SCROPHULARIÆ.—OINTMENT OF FIGWORT.

Preparation.—Take of fresh figwort leaves, 2 pounds; lard, 1 pound; tallow, ½ pound. Boil together until the leaves are crisp, and then strain with expression; or, it may be made from the extract, the same as explained under *Unguentum Stramonii.*

Action and Medical Uses.—This ointment is useful in *piles*, *painful tumors*, *ulcers*, and *cutaneous diseases*. Dr. W. Stokes considered it a specific in *gangrenous pemphigus*.

UNGUENTUM STAPHISAGRIÆ.—OINTMENT OF STAVESACRE.

Preparation.—"Take of stavesacre seeds, 4 ounces (av.); benzoinated lard, 8 ounces (av.). Crush the seeds, and macerate them in the lard, kept melted over a water-bath for 2 hours. Strain through calico, and set aside to cool. This ointment contains about 10 per cent of the oil of stavesacre"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) uses stavesacre seeds, 4 parts; benzoated lard, 17 parts; and yellow beeswax, 2 parts.

Action and Medical Uses.—This ointment is said to be extensively employed in England in *itch*, *prurigo*, and certain other *skin diseases*. Its chief use, however, is to destroy *pediculi*, both of the head and body.

UNGUENTUM STRAMONII (U. S. P.)—STRAMONIUM OINTMENT.

Preparation.—"Extract of stramonium seed, ten grammes (10 Gm.) [154 grs.]; diluted alcohol, five grammes (5 Gm.) [77 grs.]; benzoinated lard, eighty-five grammes (85 Gm.) [3 ozs. av.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the extract with the diluted alcohol until it is uniformly soft, then gradually add the benzoinated lard, and mix thoroughly"—(*U. S. P.*). Or, take of extract of stramonium, 1 drachm; alcohol, 1 fluid ounce; white wax, ½ ounce; lard, 4½ ounces. Dissolve the extract in the alcohol, then add the wax and lard, previously melted together, and continue the heat to evaporate the alcohol; strain while hot, and keep stirring till cold. This ointment may likewise be made as follows: Take of fresh stramonium leaves, cut in pieces, 1 pound; lard, 1 pound; yellow wax, 3 ounces. Boil together until the leaves become crisp, and then strain with expression. Prof. A. J. Howe preferred an ointment of stramonium made like the last mentioned. He used it in cases of hemorrhoids.

Action and Medical Uses.—This forms an anodyne ointment which will be found serviceable in *irritable ulcers, burns, mammary cancer, scalds, irritable cutaneous diseases, painful hemorrhoids*, and as a discutient to *indolent ulcers*. Like belladonna, though in a lesser degree, it relieves *spasm* and *pain*.

UNGUENTUM STRAMONII COMPOSITUM.—COMPOUND OINTMENT OF STRAMONIUM.

Synonym: *Discutient ointment.*

Preparation. Take of the bark of the root of bittersweet, stramonium leaves, cicuta leaves, deadly nightshade, yellow-dock root, each, 2 ounces; lard, 1 pound; Venice turpentine, 2 ounces; spirit, a sufficient quantity. Bruise the roots and leaves, cover them with spirit, and allow them to digest with a moderate heat for 4 hours; then add the lard, and continue the heat until the leaves are crisped. Lastly, strain and express through linen, add the turpentine, and stir constantly till cold (Beach's *Amer. Prac.*).

Action and Medical Uses.—This ointment is useful to discuss *tumors* of various kinds; it must be well rubbed on the parts, 2 or 3 times a day, covering them with cotton held in place by a bandage, after each inunction.

UNGUENTUM STRYCHNINÆ.—OINTMENT OF STRYCHNINE.

Preparation.—"Take of strychnine, 20 grains; oleic acid, 2 drachms (or a sufficient quantity to dissolve the strychnine); simple ointment, 6 drachms. Triturate the strychnine with the oleic acid, and then add the lard.

Action and Medical Uses.—This forms a powerful local application, which may be employed whenever the external use of strychnine is indicated. A small portion to be applied upon the desired part, with friction, 2 or 3 times a day. It must be employed with care, not permitting it to come in contact with abraded or ulcerated surfaces, wounds, etc.

UNGUENTUM SULPHURIS (U. S. P.)—SULPHUR OINTMENT.

Preparation.—"Washed sulphur, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; benzoinated lard, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Rub the washed sulphur with the benzoinated lard, gradually added, until they are thoroughly mixed"—(*U. S. P.*).

Action and Medical Uses.—Sulphur ointment is considered a certain cure for the *itch*. It must be applied over the whole surface of the body every night, until cured; it usually cures in 4 or 5 days; after which the body should be thoroughly washed with soap and water. It will also be found useful in *tinea capitis, crusta lactea*, and several other *cutaneous diseases*. The last Pharmacopœia has replaced sublimed sulphur with washed sulphur, but it is doubtful if such a change is an improvement; possibly it is a detriment. The antiparasitic virtues of the ointment are undoubtedly due to the presence of certain impurities in the sulphur, especially sulphur dioxide, and these free acids, etc., are lost in the substitution of washed sulphur.

Related Ointments.—Unguentum Sulphuris Alkalinum (N. F.), *Alkaline sulphur ointment* (*U. S. P.*, 1880): "Washed sulphur, twenty grammes (20 Gm.) [309 grs.]; potassium carbonate, ten grammes (10 Gm.) [154 grs.]; water, five cubic centimeters (5 Cc.) [81 ♏]; benzoinated lard (*U. S. P.*), sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]. Rub the sulphur with the potassium carbonate and the water, gradually add the benzoinated lard, and mix thoroughly"—*Nat. Form.*).

Unguentum Sulphuris Compositum (N. F.), *Compound sulphur ointment, Wilkinson's ointment, Hebra's itch ointment.*—"Precipitated calcium carbonate, ten grammes (10 Gm.) [154 grs.]; sublimed sulphur, fifteen grammes (15 Gm.) [231 grs.]; oil of cade, fifteen grammes (15 Gm.) [231 grs.]; soft soap (*U. S. P.*), thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; lard, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]. Mix the lard with the soft soap and oil of cade. Then gradually incorporate the sublimed sulphur and precipitated calcium carbonate"—*Nat. Form.*). Efficient in treatment of *itch*, especially when it proves very obstinate and unyielding to the milder treatment.

UNGUENTUM SULPHURIS IODIDI.—OINTMENT OF IODIDE OF SULPHUR.

Preparation.—"Take of iodide of sulphur, 30 grains; hard paraffin, ¼ ounce (av.); soft paraffin, ¾ ounce (av.). Triturate the iodide of sulphur in a glass or porcelain mortar, and gradually add the melted mixture of the hard and soft paraffins, rubbing them together until the ointment is perfectly cold and free from grittiness"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) directs to take of sulphur iodide, 2 parts; glycerin, 2 parts; benzoated lard, 46 parts. Triturate the sulphur iodide and glycerin in a slightly warmed mortar until a smooth paste results; gradually add the benzoated lard; stir until cold"—(*Br. Pharm.*, 1898).

Action and Medical Uses.—This ointment, when fresh, is of considerable value in *chronic, non-inflammatory skin diseases*, particularly in dry forms of *eczema* and *impetigo;* also used in *acne, lupus, porrigo, lepra*, and *psoriasis.* It is a very unstable product, and should not be employed when decomposition has set in.

UNGUENTUM TABACI.—OINTMENT OF TOBACCO.

Preparation.—Take of extract of tobacco, 1 drachm; alcohol, 1 fluid ounce; yellow wax, ½ ounce; lard, 4½ ounces. Dissolve the extract in the alcohol, then add the wax and lard, previously melted together, and continue the heat to evaporate the alcohol; strain while hot, and keep stirring until cold. The extract of tobacco must be prepared in the same manner as the extract of belladonna; or the ointment may be prepared by taking the fresh leaves of tobacco, 2 pounds; lard, ½ pound; spirit, ½ pint; and wax, 1 ounce; and proceeding in the same manner as explained for ointment of poke (*Unguentum Phytolaccæ*).

Action and Medical Uses.—Tobacco ointment forms an anodyne application, useful in various *affections of the skin, piles, scald-head, irritable swellings, painful ulcers*, etc. Some caution is necessary not to use it too freely, lest it produce its constitutional narcotic effects. An ointment made from the dried leaves is of but little value; one made by rubbing 20 drops of the empyreumatic oil of tobacco with 1 ounce of simple ointment, forms an active preparation.

UNGUENTUM TEREBINTHINÆ.—OINTMENT OF TURPENTINE.

Preparation.—"Take of oil of turpentine, 1 fluid ounce; resin, in coarse powder, 54 grains; yellow wax, ½ ounce (av.); prepared lard, ½ ounce (av.). Melt the ingredients together by the heat of a steam or water-bath. Remove the vessel, and stir the mixture constantly while it cools"—(*Br. Pharm.*, 1885).

Action and Medical Uses.—This ointment forms a good application to *recent inflammations* of the surface, and in *erythema, erysipelas*, and *burns.*

UNGUENTUM VERATRI ALBI.—OINTMENT OF WHITE HELLEBORE.

Preparation.—"Take of veratrum album (the root) in powder, 2 ounces; lard, 8 ounces; oil of lemon, 20 minims. Mix them together—(*Lond.*).

Action and Medical Uses.—This ointment, being more agreeable than sulphur ointment, is sometimes employed in *itch* with benefit; but it should be cautiously applied to children. The substitution of poke ointment for the lard will render it still more certain and effective.

UNGUENTUM VERATRINÆ (U. S. P.)—VERATRINE OINTMENT.

SYNONYMS: *Unguentum veratriæ*, *Veratria ointment.*

Preparation.—"Veratrine, four grammes (4 Gm.) [62 grs.]; olive oil, six grammes (6 Gm.) [93 grs.]; benzoinated lard, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the veratrine with the olive oil in a mortar, then gradually add the benzoinated lard and mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—(See *Veratrina.*) This forms a powerful local stimulant, very useful in *neuralgia*, *amaurosis*, and *paralysis*. It must be employed with care, not permitting it to come in contact with abraded or ulcerated surfaces, wounds, etc.

UNGUENTUM ZINCI OXIDI (U. S. P.)—OINTMENT OF ZINC OXIDE.

SYNONYMS: *Unguentum zinci*, *Ointment of zinc*.

Preparation.—"Zinc oxide, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; benzoinated lard, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Sift the zinc oxide, through a No. 20 sieve, upon the surface of the benzoinated lard, previously melted, and incorporate it by stirring, which is to be continued until the ointment is cool"—(*U. S. P.*). If perfectly pure oxide of zinc be used, a smooth ointment will result, provided it has been carefully sifted, which is difficult to accomplish. This ointment, with age, becomes somewhat tough. It contains 20 per cent of the zinc compound. Five or 10 grains of benzoic acid, added to an ounce of the ointment, prevents it from becoming rancid. Mr. D. Kemp recommends the following formula, as giving a consistent and durable ointment, without requiring any unusual means to preserve it: Take of prepared lard, pure olive oil, each, 2 ounces; white wax, spermaceti, zinc oxide, each, 1 ounce. Melt the fats, oil, etc., in a water-bath at a low heat; strain into a very warm mortar, and, just before cooling, add the zinc, and continue the stirring very briskly till cold.

Action and Medical Uses.—This forms a mild astringent ointment, useful in *porrigo*, *impetigo*, and other *diseases of the skin*, attended with profuse discharges; after extensive *burns*, *blisters*, *sinapisms*, etc.; to *painful ulcers*, with excessive secretion, and to the eye, when affected with *chronic inflammation*, etc.

Related Ointments.—UNGUENTUM CALAMINÆ (N. F.), *Calamine ointment*, *Unguentum zinci carbonatis (impuri)*, *Unguentum calaminare*, *Turner's cerate*. "Prepared calamine, sixteen and one-half grammes (16.5 Gm.) [255 grs.]; ointment (*U.S.P.*), eighty-three and one-half grammes (83.5 Gm. [2 ozs. av., 414 grs.]. Mix them intimately, by trituration, so as to produce a smooth and homogeneous ointment"—(*Nat. Form.*).

UNGUENTUM ZINCI OLEATI, *Ointment of oleate of zinc.*—"Take of oleate of zinc, 1 ounce (av.); soft paraffin, 1 ounce (av.). Mix by aid of a little heat, and stir until nearly cold"—*Br. Pharm.*, 1885). Used like zinc oxide ointment, particularly in *chronic eczemas*. The *British Pharmacopœia* (1898) gives the following directions for UNGUENTUM ZINCI OLEATI (*Zinc oleate ointment*): Take of "zinc sulphate, 2 ounces (Imp.), or 60 grammes (Metric); hard soap, in shavings, 4 ounces (Imp.), or 120 grammes (Metric); distilled water, boiling, soft paraffin, white, of each, a sufficient quantity. Dissolve the zinc sulphate in 4 fluid ounces (or 120 cubic centimeters) of the distilled water. Mix the solutions; collect the precipitated zinc oleate; wash with hot, distilled water until the washings afford little or no reaction for sulphate; dry on a water-bath, and mix with an equal weight of the soft paraffin, melted; stir until cold"—(*Br. Pharm.*, 1898).

UNGUENTUM ZINCI OXIDI COMPOSITUM.—COMPOUND OINTMENT OF ZINC OXIDE.

Preparation.—Take of olive oil, 2 pounds; spermaceti, 12 ounces; white wax, 4 ounces; oxide of zinc, 7 ounces; benzoic acid, 2 drachms; sulphate of morphine, 48 grains; oil of roses, 20 minims. Rub together, in a mortar, until no specks are seen, the oxide of zinc, benzoic acid, sulphate of morphine, and oil of roses. Melt the olive oil, wax, and spermaceti together, and add the above triturated mass to it, stirring constantly till nearly cold (W. S. Merrell, M. D.).

Action and Medical Uses.—This forms a mild stimulating and astringent preparation, which is exceedingly useful in *acute and chronic ophthalmia*, *opacities of the cornea*, *nebula*, *granulations of the lids*, etc. It is likewise useful in many *cutaneous diseases*, and may be advantageously employed as a dressing to *wounds* and *indolent ulcers*.

Related Ointments.—Mild Zinc Ointment. The *Mild zinc ointment*, which has been so favorably received by the profession, was introduced by Prof. R. S. Newton, M. D. It is similar to the above, varying only in the quantity of certain of the ingredients; thus, he uses white wax, 9 ounces; oxide of zinc, 4 ounces; sulphate of morphine, 2 drachms, instead of the quantities named in the above formula. In other respects, the formula is the same. It forms an excellent soothing and anodyne application in cases of painful and irritable *ulcers, burns, scalds*, and wherever such an agent is indicated.

Ophthalmic Balsam.—The Compound Ointment of Zinc, a favorite with many Eclectic physicians, is somewhat similar to a preparation which has been extensively sold under the name of "*Pettit's Ophthalmic Balsam* or *Eye Salve*," and the formula of which is as follows: Take of white precipitate, 3 ounces; oxide of zinc, 4 ounces; benzoic acid, 2 drachms; sulphate of morphine, 48 grains; oil of rosemary, 20 drops. Rub these thoroughly together, in a mortar, until they are well incorporated, and then add them gradually to a warm compound made by melting together olive oil, 2 pounds; spermaceti, 12 ounces; white wax, 4 ounces; stirring constantly until cold.

Ophthalmic Ointment.—A preparation of a similar character, known as *Brown* or *Ophthalmic Ointment*, has enjoyed considerable reputation in the East, in the treatment of ophthalmic diseases. It is composed of red precipitate, 2½ drachms; oxide of zinc, 1 drachm; fresh butter, 3 ounces; white wax, ½ ounce; camphor, dissolved in olive oil, 1 drachm. Mix. It is a French preparation.

UNGUENTUM ZINCI SULPHATIS.—OINTMENT OF SULPHATE OF ZINC.

Preparation.—Take of sulphate of zinc, 20 grains; fresh butter, 2 drachms. Triturate together.

Action and Medical Uses.—This ointment is very beneficial in *eruptions of the skin, fungous growths, gangrenous and indolent ulcers, fistula, hemorrhoids, ulcerations of the cornea*, etc. If it acts too severely, it may be rendered milder by the addition of butter in necessary quantity.

UREA.—UREA.

Formula: CH_4N_2O, or $CO(NH_2)_2$. Molecular Weight: 59.95.

Synonym: *Carbamide.*

Source, History, and Preparation.—Urea is a regular constituent of the human urine, in which it was discovered, in 1773, by Rouelle. It amounts to from 2 to 4 per cent, and varies in proportion with the nitrogen ingested in the body with the food. Urea occurs in the urine of all mammals, especially of the flesh-eaters (carnivora), in smaller quantities in the urine of birds, in sweat, blood, the vitreous humor of the eye (30 per cent of the total solids; Watts' *Dict. of Chem.*, Vol. IV, 1894, p. 829), and other animal fluids. It was synthetically prepared, in 1828, by Wöhler, by evaporating a solution of ammonium isocyanate ($CO:N.NH_4$), resulting in a rearrangement of the molecule—*i. e.*, the formation of *urea* or *carbamide* ($CO:[NH_2]_2$). This was the first organic synthesis effected. Urea may also be prepared by several other synthetic processes, *e. g.*, the interaction of carbonyl chloride ($COCl_2$) and ammonia. It is generally obtained, however, from urine. This is evaporated to a thin syrup; to the cooled fluid, an equal volume of strong nitric acid is added. The brownish, scaly nitrate which falls out, is recrystallized from diluted nitric acid, the crystals dissolved in water, the solution evaporated to dryness with barium carbonate, and the urea abstracted from the residue by means of alcohol. Or, the urea may be precipitated from the concentrated urine by means of oxalic acid, and the oxalate decomposed by calcium carbonate. Another quite practical method consists in first preparing potassium cyanate (CNOK), by fusing potassium ferrocyanide with potassium bichromate, evaporating an aqueous solution of the cyanate with ammonium sulphate to dryness, and extracting the urea with alcohol (see C. A. Bell, *Amer. Jour. Pharm.*, 1875, p. 559).

Description.—Urea forms colorless, odorless, and permanent, quadrangular prisms, having a saline and cooling taste. It is dissolved by its own weight of cold water, and is easily soluble in alcohol, but only slightly soluble in pure ether. Its aqueous solution (in pure water) keeps for a considerable time; putrescent matter, however, quickly causes its decomposition into carbon dioxide and ammonia. Only fresh urine contains it. It melts at 132° C. (269.6° F.), and decomposes by higher heat. It is monobasic, and forms crystallizable salts with acids, of which the oxalate and the nitrate are the most easily obtained. Boiling with diluted acids and alkalies decomposes urea into carbonic acid and ammonia, as follows: $CO(NH_2)_2+H_2O=CO_2+2NH_3$. Chlorine water, hypobromite of sodium, etc., liberate nitrogen and carbonic acid: $CO(NH_2)_2+6Cl+H_2O=CO_2+6HCl+N$ By absorbing the carbonic acid gas in solution of caustic soda, the nitrogen may be collected and measured, and the quantity of urea in urine may thus be determined. Another method is that originally proposed by Liebig, and is based upon the quantitative precipitation of urea by mercuric nitrate. (For details regarding this and other methods, see, among other manuals, Roscoe and Schorlemmer's *Chemistry*, Vol. I, p. 650; also see gasometric method of G. Campari, *Amer. Jour. Pharm.*, 1887, p. 494.)

Action, Medical Uses, and Dosage.—Experimentation upon animals proves this agent to exert a diuretic effect, an increased amount of urea being also voided. In man, however, even as large doses as 75 grains are said not to provoke an increased flow of urine. Notwithstanding, the drug has been employed as a hydragogue-diuretic in some forms of *dropsy*, notably that occurring after *scarlet fever*. It should be remembered, however, that this form of dropsy often tends to spontaneous recovery without the use of drugs. The nitrate, particularly, is used for this purpose. Dose, 2 to 3 grains, every 2 or 3 hours.

Compounds and Related Products.—Acids, metallic oxides, and several neutral salts, *e. g.*, sodium chloride, produce with urea crystallizable compounds. Hydrochloric acid produces deliquescent *Urea hydrochlorate*. Oxalic acid yields *Urea oxalate* ($[CH_4N_2O]_2.H_2C_2O_4$), in scaly crystals, containing over 57 per cent of urea. It is soluble in hot, much less soluble in cold water. *Urea nitrate* ($CH_4N_2O.HNO_3$) forms in scales and prisms, containing nearly 49 per cent of urea. Water and alcohol sparingly dissolve it; it is even less soluble in nitric acid.

FORMAMIDE (CH_3NO, or $CHO.NH_2$).—An oily, colorless fluid, insoluble in ether, but soluble in all proportions in water and alcohol. It is produced by heating ammonium formate ($CHOONH_4$) to a temperature of above 230° C. (446° F.).

HIPPURIC ACID ($C_9H_9NO_3$, or $C_6H_5.CO.NH.CH_2.COOH$), *Benzoylglycocoll.*—Rhombic prisms, fusing at 187° C. (368.6° F.). When heated to near 240° C. (464° F.), it splits into benzoic acid, hydrocyanic acid, and benzo-nitrile ($C_6H_5.CN$). When hippuric acid is acted upon by alkalies or acids, benzoic acid and glycocoll result. It sometimes occurs in the urine of man, especially after the internal administration of such aromatic bodies as toluol, benzoic, and cinnamic acids. In the urine of the herbivora it is quite abundant. It was proposed by Garrod as a remedy for the *uric acid diathesis*, and, in the form of the sodium salt, is now recommended to be given with lithium and potassium compounds for this condition. Dose, 10 grains, 3 times a day.

URETHANUM.—URETHANE.

FORMULA: $C_3H_7NO_2$, or $C_2H_5NH_2CO_2=CO.NH_2.OC_2H_5$. MOLECULAR WEIGHT: 88.94.

SYNONYMS: *Ethyl urethane, Ethyl carbamate.*

Source, History, and Preparation.—Urethanes are the esters of *carbamic acid* ($NH_2.COOH$), the ammonium salt of which (*ammonium carbamate*, $NH_2.COONH_4$) is a constituent of commercial ammonium carbonate (which see). In medicine, the term urethane is confined to the ethyl ester of carbamic acid ($NH_2.COOC_2H_5$). The acid itself is not known in the free state. The ammonium salt may be formed by the action of gaseous ammonia (2 molecules) upon carbonic acid (1 molecule). *Urethane* may be obtained by several methods, *e. g.*, by the union of cyanic acid and ethyl alcohol: $CONH+C_2H_5OH=NH_2.COOC_2H_5$; or by heating, in a sealed tube, a mixture of urea nitrate and ethyl alcohol to a temperature of 120° to 130° C. (248° to 266° F.) for several hours. Urethane is dissolved out from the crystalline mass by means of ether. The reaction is as follows: $NH_2CONH_2.NO_3H+C_2H_5OH=NH_2COOC_2H_5+NO_3NH_4$. It is also produced by the action of ammonia upon ethyl carbonate: $C_2H_5O.COOC_2H_5+NH_3=C_2H_5OH+NH_2.COOC_2H_5$. Urethane was discovered, in 1833, by Dumas.

Description and Tests.—Urethane occurs in non-deliquescent, colorless, and odorless, tabular, or columnar crystals, saline and somewhat cooling to the taste. At 15.5° C. (60° F.), it is soluble in alcohol (0.6 part), liquid carbolic acid (0.8 part), ether (1 part), chloroform (1.5 parts), glycerin (3 parts), castor oil (15 parts), and olive oil (20 parts) (Vulpius). It melts between 47° and 50° C. (116.6° and

122° F.), and boils between 170° and 180° C. (338° and 356° F.), without decomposition; at a lower temperature, it sublimes. When heated upon a platinum foil, it completely volatilizes. When warmed with alkalies, urethane is decomposed into carbonic dioxide, ammonia, and alcohol: $NH_2.COOC_2H_5+H_2O=CO_2+NH_3+C_2H_5OH$. By the action of ammonia upon urethane, urea is formed as follows: $NH_2.COOC_2H_5+NH_3=NH_2.CO.NH_2+C_2H_5OH$. The absence of urea in urethane is established when 5 Cc. of nitric acid, oxalic acid, or mercuric nitrate, fails to produce a white precipitate with a solution of 2 Gm. of urethane in 2 Cc. of cold water.

Action, Medical Uses, and Dosage.—The widely-varying statements concerning the action of this remedy do not inspire confidence in it as a remedial agent. While some assert that, in doses of as high as 70 grains, it produces no ill-results, others, and, notably, Friedlander, speak of its causing vomiting and depression in so small a dose as $\frac{1}{50}$ grain. It was introduced as a hypnotic, and even this property is denied it by many. It appears, however, to have induced sleep in several cases of *insanity*, especially in *melancholia*. It is apt to disagree with the stomach. It more nearly resembles paraldehyde, it is said, as a hypnotic, though less certain of results, and it has the advantage over the latter in being odorless and pleasant to the taste, although commercial specimens have been known to possess an unpleasant odor (see G. Vulpius, *Pharm. Centralhalle*, 1892, p. 223). Upon pain it appears to have no effect, nor does it seem to be of any value in the insomnia of delirium tremens and like conditions. Urethane is reputed to have cured *tetanus* after failure with other remedies; *tetany* is said to have been relieved by it, and, in *chorea*, it has been successfully employed to produce sleep and quietude. The average dose of urethane is from 10 to 15 grains, in capsule or in sweetened aromatic solution. Its effects are best produced by its administration by way of the stomach; hypodermatically, the medicine is less effective, and is generally so administered in about 4-grain doses.

Related Compound.—EUPHORIN, *Phenyl urethane*, *Phenyl carbamate* or *Ethyl carbanilic ether* ($C_6H_5NH.COOC_2H_5$). A crystalline, white powder, feebly aromatic in odor, and leaving a faint, clove-like taste. It is obtained by the interaction of chloro-ethyl carbonate ($Cl.COOC_2H_5$) and aniline, as follows: $Cl.COOC_2H_5+2C_6H_5NH_2=C_6H_5NH.COOC_2H_5+C_6H_5NH_2.HCl$ (aniline hydrochloride). The product is recrystallized from diluted alcohol. It fuses between 49° and 50° C. (120.2° and 122° F.). It is soluble in alcohol, wines, and ether. Cold water sparingly dissolves it. Cold, strong sulphuric acid dissolves it without browning. This agent is reputed destructive to bacteria, and, as an antiseptic, is used like iodoform and similar bodies, particularly where discharges are fetid and purulent. Internally, it has been employed as antipyretic, analgesic, and antirheumatic. It is said to act nicely in *thrush*. The dose ranges from 7 to 15 grains. These are best given in broken amounts, the whole being taken in 24 hours.

URTICA.—NETTLE.

The leaves and root of *Urtica dioica*, Linné.

Nat. Ord.—Urticaceæ.

COMMON NAMES: *Nettle*, *Stinging nettle*, *Great stinging nettle*.

Botanical Source.—This plant is a perennial, herbaceous, dull-green plant, armed with minute rigid hairs or prickles, which transmit a venomous fluid when pressed. The stem is obtusely 4-angled, branching, 2 to 4 feet high, arising from a creeping and branching root, with fleshy shoots and many fibers. The leaves are opposite, petiolate, cordate, lance-ovate, spreading, conspicuously acuminate, coarsely and acutely serrate, the point entire, armed with stings, and are 3 or 4 inches long, and about half as wide. The flowers are small, green, monœcious or diœcious, in branching, clustered, axillary, interrupted spikes, longer than the petioles (W.—L.).

History and Chemical Composition.—This is a well-known plant, common to Europe and the United States, growing in waste places, by woodsides, in hedges, and in gardens, flowering from June to September. A decoction of the plant, strongly salted, will quickly coagulate milk without imparting to it any unpleasant flavor. The leaves and root are generally used, and yield their virtues to water. A fabric, known as nettle-cloth, has been woven from the bast fibers of nettle. The young shoots have been boiled and eaten as a remedy for scurvy. The irritation caused by rubbing the sharp hairs of the nettle on the skin, is believed to be caused by the free *formic acid* which they contain (Gorup Besanez, *Amer. Jour. Pharm.*, 1850, p. 181). According to G. Haberlandt (1886), the poisonous action of the hairs of the stinging nettle is not due to formic acid, but to an unorganized ferment or enzyme. Mr. B. Shoemaker (*Amer. Jour. Pharm.*, 1866, p. 493), who has found starch, gum, albumen, lignin, sugar, and two resins, in the root, believes the diuretic properties of the root to be due to a warm, penetrating, volatile oil. The leaves contain tannic and gallic acids, gum, wax, etc. (Saladin, 1830). L. Reuter (*Amer. Jour. Pharm.*, 1890, p. 11, from *Pharm. Centralh.*, 1890) found the leaves of *U. urens* and *U. dioica* and the seeds of *U. pilulifera* to contain a non-nitrogenous glucosid, giving precipitates with some alkaloidal reagents. The juice of the fresh plant is said to evolve nitrous fumes upon being heated. This is probably due to the action of formic acid upon nitrates (E. Giustianini, *Jahresb. der Pharm.*, 1896, p. 239).

Action, Medical Uses, and Dosage.—Common nettle is astringent, tonic, and diuretic. A decoction is valuable in *diarrhœa* and *dysentery*, with profuse discharges, and in *hemorrhoids*, various *hemorrhages*, and *scorbutic affections*, and has been recommended in *febrile affections*, *gravel*, and other *nephritic complaints*. A strong syrup made of the root, combined with suitable quantities of wild-cherry bark and blackberry root, forms an excellent remedy for all *summer complaints of children*, and *bowel affections of adults*. In *cholera infantum* and other summer disorders of children, with profuse watery or mucous discharges, the following treatment gives excellent results: ℞ Specific urtica, ʒss; water, ℥iii. Mix. Dose, a teaspoonful, every 1 or 2 hours. It is especially applicable in *chronic diseases of the colon*, with increased secretion of mucus. The leaves of the fresh plant stimulate, inflame, and even raise blisters on those portions of the skin with which they come in contact, and have, in consequence, been used as a powerful rubefacient. *Paralysis* is said to have been cured by whipping the affected limbs with them. Applied to *bleeding surfaces*, they are an excellent styptic. The seeds and flowers. given in wine, in doses not to exceed 1 drachm, have been reputed equal to cinchona in *tertian and quartan agues*—larger doses will, it is said, induce a lethargic sleep. The seeds, in doses of 14 or 16, and repeated 3 times daily, are highly recommended as a remedy for *goitre*, and to reduce excessive *corpulence;* they are also considered anthelmintic. The seeds may also be prepared in strong tincture with full strength alcohol, the dose of which, for goitre, would be from a fraction of a drop to 10 drops. Dr. J. D. McCann (*Ec. Med. Gleaner*, 1893, p. 62) praises this agent as a remedy for *eczematous affections*, and relates a case of stubborn *eczema of the face, neck, and ears* that was readily and completely cured by the following local application: ℞ Specific urtica, flʒii; rose water, fl℥i. Mix. Apply every 3 or 4 hours. Several other cases have also yielded to it. A child with "a crust-covered head, with here and there a bleeding surface," that had long resisted treatment, yielded in a short time to softening applications of olive oil, thorough ablutions with soap and water, drying the parts, and applying the solution as above recommended. Some physicians prescribe the remedy internally at the same time that they are using it locally. It is also a remedy for *chronic cystitis*, with mucous discharges. *Warts*, rubbed with the freshly expressed juice of this plant, 3 or 4 times a day, continuing the application daily for 10 or 12 days, disappear without any pain being produced (M. Jaroschevitz). Dose of the powdered root or leaves, from 20 to 40 grains; of the decoction, from 2 to 4 fluid ounces; of specific urtica, $\frac{1}{10}$ to 10 drops.

Specific Indications and Uses.—Chronic diarrhœa and dysentery, with large mucous evacuations; profuse secretion of gastric juice, with eructations and emesis; choleraic discharges; summer bowel diseases of children, with copious watery and mucous passages; chronic eczematous eruptions.

Related Species.—*Urtica urens*, Linné, or *Dwarf nettle*, possesses similar properties, and has been found very efficient in *uterine hemorrhage*. It also allays *urethral and cystic irritation*. It is also reputed galactagogue. It has a branching, hispid, stinging stem, 1 or 2 feet high, with broadly elliptic, acutely serrate leaves, about 5-veined, on short petioles, 1 or 2 inches long, and about two-thirds as broad. Flowers in drooping, pedunculate, nearly simple clusters, 2 in each axil, and shorter than the petioles. This is an annual, introduced from Europe (W.).

Pilea pumila, Gray (*Urtica pumila*), *Cool-weed*, *Rich-weed*, or *Stingless nettle*, has a peculiar, grateful, strong smell, indicating active properties. The herb contains a crystallizable glucosid, and an aromatic, vanilla-like substance (F. R. Weiser, *Amer. Jour. Pharm.*, 1888, p. 390). It is stated that the leaves, bruised, give immediate relief in *inflammations, painful swellings, ecchymoses, erysipelas,* and the topical *poison of rhus;* and that an ointment made from it is beneficial in *inflammatory rheumatism.* This is the *Pilea pumila* of Lindley, and has a smooth, shining, ascending, weak and succulent, often branched, and translucent stem, 4 to 18 inches high, and, together with the whole plant, destitute of stings. Leaves on long petioles, opposite, rhombic-ovate, crenate-serrate, membranaceous, glabrous, pointed, 3-nerved, about 2 inches long, and two-thirds as broad. Flowers monœcious, triandrous, in axillary, corymbed heads, shorter than the petioles. Sepals of the fertile flowers lanceolate, and a little unequal. This plant is worthy of further investigation (W.).

Laportea canadensis, Gaudichaud (*Urtica canadensis*, Linné), has strong bast fibers and stinging hairs, and is adapted to use in making cordage. Other plants yielding cordage-fibers are the RAMIE (*Boehmeria nivea*, Hooker and Arnott), used in manufacturing *Chinese grass-cloth.* The variety *candicans* of Weddell, yields the fiber known as *rhea.* The fibers of these plants are often woven with silk, or substituted therefor. *Urtica cannabina*, Linné, a Siberian species, is also cultivated for its fibers.

Urtica stimulans, Linné; *Urtica crenulata*, Roxburgh; and *Urtica urentissima*, Blume, all of India, are extremely irritating plants, more so than common stinging nettle.

Lamium album (*Urtica iners*, or *Urtica mortua; Nat. Ord.*—Labiatæ), *Henbit.* Florain isolated from this plant a principle which he named *lamine.* The plant has been used, domestically, in *bronchitis, hemorrhages, leucorrhœa,* and *scrofulous disorders.*

Urtica pilulifera, Linné.—India, central Asia, and south Europe. The fruit of this species is regarded in the East as a galactagogue, and diuretic virtues are ascribed to the root. The seeds contain a non-nitrogenous glucosid (Reuter; see p. 2033).

USTILAGO.—CORN-SMUT.

A parasitic fungus, *Ustilago segetum*, Bull (*Ustilago Maydis* [*Maidis*], Léveillé; *Ustilago carbo*, Tulasne), developed upon the fruit of *Zea Mays*, Linné.

Nat. Ord.—Fungi—Ustilagineæ.

COMMON NAMES: *Corn-smut, Corn-ergot, Corn-brand.*

Source, Formation, and History.—*Ustilago* is a parasitic fungus infesting the fruit of the common corn plant (*Zea Mays*, Linné). The "smutted" ear of corn appears blackened and shrivelled, the fungus, called *Ustilago*, from its burnt or charred appearance, exhibiting a smooth, gelatiniform membrane, containing a soot-like powder of minute, dark, spherical spores. Ustilago attacks many plants, as the ears of wheat, oats, and barley, and also various grasses, figs, violets, anemones, etc. The particular species infesting the ears of corn, is the *Ustilago segetum*, Bull. The condition produced is known popularly as the "*smut of corn,*" or "*brand of corn.*" The attack actually begins with the germination of the corn plant, for the hyphæ of the fungus-spores enter the seedling when very young, and grow up *within* the plant, but does not manifest itself until the fruit begins to ripen, when the ears take on the characteristic sooty or smutty appearance, each bad grain being filled to bursting with the powdery spores. Only very young seed ings can be infested by this parasite, for, as the tissues of the plant become harder, the germinal tube, sent out from the sporidium, can not effect an entrance into the tissues. The spores of *Ustilago* are largely conveyed to the plants through the distribution of barn-yard manures, in which the fungus appears to thrive and rapidly multiply. This parasitic disease was thought to be similar to that of ergot (see *Ergota*), but since 1860–66, the matter has been better studied, and the life-history of the fungus well worked out. (For an interesting and popular exposition of the fungous diseases of vegetation, see *Diseases of Plants*, by H. Marshall Ward.)

Fig. 249.

Ustilago segetum.

Description and Chemical Composition.—Ustilago is easily recognized as the large, black, or blackish excrescences (smut of corn) which form on the end of defective ears of corn, and give a dry, black powder, resembling lampblack. The masses are covered with a smooth, gelatin-like membrane, showing a slate-black color, due to the presence of the black spores within. The masses are quite large, sometimes 6 or more inches thick, globose or irregular, showing a lobular or obtusely-branched structure. It has a disagreeable taste, and a heavy, unpleasant odor. Moisture impairs its virtues, which, under the best of keeping, are not retained for more than 1 year.

Mr. John H. Hahn (*Amer. Jour. Pharm.*, 1881, p. 496) obtained from corn-smut, by extraction with ether, 2.5 per cent of a dark-brown fixed oil of acid reaction, insoluble in alcohol, and having the odor of the drug. A variety of substances was isolated from corn-smut by C. J. Rademaker and J. L. Fischer (*ibid.*, 1887, p. 445, from *Medical Herald*, 1887). The authors found fixed oil (6.5 per cent), resin (8 per cent), and wax (5.5 per cent), soluble in petroleum benzin; *trimethylamine* (1.5 per cent), crystallizable *sclerotic* or *maisenic acid* (2 per cent), wax (6.25 per cent), and resin (4.5 per cent), soluble in ether; *sclerotic acid* (0.5 per cent), and resin (3.5 per cent), soluble in alcohol; sugar (3.75 per cent), pectin (2.25 per cent), salts (4.5 per cent), and extractive (9.5 per cent), soluble in water, and a crystallizable alkaloid, *ustilagine*. It is white, bitter, soluble in ether, alcohol, and water, of alkaline reaction, forming crystallizable salts, soluble in water. The above sclerotic acid is probably not identical with that of Dragendorff (see *Ergota*).

Action, Medical Uses, and Dosage.—Ustilago appears to possess decided activity, its effects having been compared with those of ergot and nux vomica combined. Upon the lower animals it acts as a spinal excitant, producing tonic convulsions, and destroying life, either by tetanus or exhaustion. Full doses dilate the pupils. Ecbolic properties are conceded to it, and, by many, it is preferred to ergot for *obstetrical uses*, inasmuch as it appears to be less powerful, and to produce clonic instead of tonic uterine contractions. According to Ellingwood, with whom it is a favorite remedy, it produces perfectly regular intermittent and safe contractions. The following statements (since confirmed by other investigators) have been made concerning this agent: "Its action on the uterus is as powerful as the ergot of rye, and perhaps more" (Lindley). "Its use is attended with shedding of the hair, both of man and beast, and sometimes even of teeth. Mules fed on it lose their hoofs, and fowls lay eggs without any shells" (Rowlin). "It is doubtless by its abortifacient power that it causes the eggs of fowls to be extruded before there has been time for a shell to be formed. By what power does it cause the shedding of the hair of man and brute animals, and the casting off of the hoofs of mules long fed upon it?" (Prof. Tully). "In a cowhouse, where cows were fed on Indian corn infested with this parasite, 11 of their number aborted in 8 days. After their food was changed none of the others aborted" (*Annal. Med. Netr. Belge*, and *Rép. de Ph.*). The better to be convinced of the poisonous nature of this fungus, the author, after having dried and pulverized the drug, administered 6 drachms to two bitch dogs with young, which soon caused them to abort" (Dr. H. W. Burt, *Amer. Homœop. Obs.*, 1868, p. 305).

Ustilago was introduced into practice chiefly through the efforts of the Homœopaths. Inasmuch as it acts promptly upon the gravid uterus, exciting contraction, it may be employed in *labor*, under the same circumstances, and observing the same precautions as named under ergot (see *Ergota*). It likewise controls *postpartum hemorrhages* and *passive hemorrhages from the lungs and bowels*. In minute doses, Prof. Scudder (*Spec. Med.*, p. 261) points out that it may be used "to relieve *false pains*, and unpleasant sensations in the pelvic region, during the latter months of pregnancy." Ustilago, in fractional doses (tincture of ustilago, gtt. x, to water, fl℥iv; dose, a teaspoonful, every 2, 3, or 4 hours), is of value in many disorders in which ergot or belladonna are useful, and sometimes acts better than either. The conditions are those of enfeebled spinal and sympathetic innervation, and sluggish capillary and venous circulation, with a tendency to passive hemorrhages. It serves a useful purpose in *impaired cerebral circulation*, with dizziness, unsteadiness of motion, or lack of command over the intellectual faculties, dull headache in top of head, disordered vision, etc. It is especially applicable in *disorders of the spinal cord and cerebellum*, resulting from *masturbation* and *seminal pollutions.* In the diseases peculiar to women, it has been successfully prescribed when the abdomen was lax and pendulous, the perineum full and relaxed, and the uterus weak, flabby, and increased in size. Thus it has proved useful in the following disorders, and in the reflex disturbances arising from them: *Ovarian irritation, ovaritis, amenorrhœa, dysmenorrhœa, premature menstruation,* and other *menstrual derangements, metrorrhagia,* from *uterine subinvolution, turn of life, uterine catarrh,* and *agalactia.* It also arrests prolonged *lochial discharge,* and gives a healthy tone to the uterine walls. The dose in these conditions should range from 5 to 30 drops of specific ustilago. Ustilago is said to affect the skin and its appendages, therefore it has been suggested in doses of 1 to 5 drops of specific ustilago, in *alopecia, scalp diseases,* with dryness, *urticaria,* with large, pale welts, and in early *dental decay.* Dose of ustilago, 1 to 20 grains; of specific ustilago, 1 to 60 drops; of the fluid extract, 1 to 60 drops; of the tincture, 1 to 60 drops.

Specific Indications and Uses.—Enfeebled spinal and sympathetic innervation; feeble capillary and venous circulation; impaired cerebral circulation, with dizziness and unsteadiness; sleeplessness from atony; uterine derangements, with excessive sanguineous or other discharges, lax or flabby uterine, vaginal, and perineal tissues, with uterine pain; pain in top of head; uterine inertia during labor; postpartum and passive hemorrhages.

UVÆ.—RAISINS.

The dried fruits of *Vitis vinifera,* Linné.

Nat. Ord.—Vitaceæ.

SYNONYM: *Uva passa* (*U. S. P.*, 1870).

ILLUSTRATION: Bentley and Trimen, *Med. Plants,* 66.

Botanical Source.—*Vitis vinifera,* or *European wine grape.* This is a climbing shrub, which has been known in nearly all parts of the globe from a very early period. There are many varieties of it, which will generally be found to agree in most respects with the following description of De Candolle: Leaves lobed, sinuated, toothed, smooth or downy, flat or crisp, pale or deep-green; branches prostrate, climbing, or erect, tender, or hard; racemes or branches loose or compact, ovate or cylindrical; fruit or berries red, yellow, or purple, watery or fleshy, globose-ovate or oblong, sweet, musky, or austere. Calyx somewhat 5-toothed; petals 5, cohering at the point, separating at the base, and dropping off like a calyptra. Stamens 5. Style none. Berry 2-celled and 4-seeded; the cells or seeds are often abortive.

History and Chemical Composition.—The grape-vine grows wild in the south of Asia and in Greece, and was, probably, first cultivated in the East at an exceedingly remote period. Scripture informs us that Noah, after leaving the ark, "planted a vineyard and drank of the wine." At present, it is cultivated in the warm, temperate climates of Europe and America; in this country, notably in California, Ohio, New York, and Virginia. *Vitis vinifera,* grown in the United States, yields the Californian grapes known as the *Mission, Riesling, Gutedel,* etc., while several wild species of this country have been successfully cultivated. Thus, the grapes known as *Concord, Catawba, Isabella, Delaware,* are varieties of *Vitis Labrusca,* Linné (*Fox* or *Plum grape*); the *Taylor* and *Clinton* grapes come from *V. riparia,* Michaux (*Frost grape*); the *Muscadine,* or *Scuppernong,* from *V. vulpina,* Linné; and *Herbemont,* and others from *V. aestivalis,* Michaux (*Summer grape*). (On the early cultivation of the grape near Cincinnati, and diseases of the vine, see E. S. Wayne, *Amer. Jour. Pharm.*, 1855, pp. 494–499; also see an interesting article on mildew and grape culture, by Henry S. Mauger, *ibid.*, 1887, pp. 433–437.) The leaves and the tendrils (*pampini vitis*) of the grape-vine are somewhat astringent, and were formerly employed in diarrhœa, hemorrhages, and other morbid discharges. According to A. Hilger and L. Gross (*Amer. Jour. Pharm.*, 1887, p. 267), the young *shoots* and *leaves* contain potassium bitartrate, calcium tartrate, tartaric and malic acids, quercetin, tannin, starch, gum, dextrose, saccharose, inosit, oxalic and glycolic acids, an ether-soluble substance, ammonium salts, and calcium sulphate and phosphate; in Autumn, malic acid and inosit are absent. The *tendrils* contain much pectin, also sugar, potassium bitartrate, calcium oxalate, and traces of tannin and resin. The *sap*, exuding from cut vines, was found by Hilger and Gross (*loc. cit.*) to contain sugar, inosit, a mucilaginous body, succinic acid, tartrates and citrates, while the aqueous liquid, exuding in spring from the young twigs, contains carbon dioxide, potassium nitrate, ammonium salts, calcium sulphate, phosphate, and tartrate, magnesium phosphate, sugar, inosit, succinic and oxalic acids (Husemann and Hilger, *Pflanzenstoffe*, Vol. II, 1884, p. 888). The juice of the unripe fruit (*agresta*) is called *omphacium*, and contains malic, citric, tartaric, and racemic acids, with bitartrate of potassium, sulphates of potassium and calcium, a little tannic acid, etc. The juice of the ripe fruit is called *must;* when fermented, it is called *wine* (see *Vinum*).

GRAPES.—Ripe grapes are a most delicious and refreshing fruit, the juice of which is especially adapted to patients with *fevers*, and which, in large quantities, proves aperient and diuretic, but, eaten moderately, will be found beneficial to those disposed to *diarrhœa* or *dysentery;* they are useful in many instances of *acidity of the stomach*. The skin and seeds of the grape are indigestible, and apt to occasion serious intestinal disease, and should, therefore, never be swallowed. Dr. Cullen considered ripe, sweet grapes the safest and most nutritive of all fruits. According to J. König (*Die Menschl. Nahrungs- und Genussmittel*, 3d ed., 1893), ripe grapes contain on an average: Water (78.17 per cent), nitrogenous matter (0.59 per cent), free acid (0.79 per cent, or from 0.5 to 1.4 per cent), sugar (14.36 per cent, or from 9.3 to 18.7 per cent), other nitrogen-free substances (1.96 per cent); seeds and skins (3.6 per cent), and ash (0.53 per cent). Hilger and Gross (*loc. cit.*) name the following constituents of the grape: Tartaric and malic acids, free and combined with potassium and calcium, tannic, succinic, glyoxylic, and glycolic acids, inosit, dextrose, lævulose, albuminoids, and traces of quercitrin and quercetin. The skins of grapes contain much tannin, and the red grapes contain a blue coloring matter (*œnocyanin*), which is believed to be identical with the coloring matter of huckleberries. Acids, *e. g.*, tartaric acid, turn it red; ammonia blue (see A. Andrée, *Amer. Jour. Pharm.*, 1880, p. 205, from *Archiv der Pharm.*, 1880). It is supposed to originate from the tannin of the grape (*œnotannin*) by oxidation. The source of the sugar formed during the ripening process of the grape, is not clearly established. It is not derived, however, from the acid of the grape, as was formerly believed. (For researches on the maturing of the grape, see C. Neubauer [1868], E. Mach and C. Portele [1879], and J. König, *loc. cit.*) The stems of grapes contain much tannic acid. The seeds, likewise, are rich in tannic acid, and contain from 10 to 18 per cent of a fatty oil, consisting of the glycerides of palmitic, stearic, oleic, and *erucic* acids ($C_{22}H_{42}O_2$) (A. Fitz, 1871).

RAISINS.—Grapes, when properly dried, are denominated raisins (*Uvæ passæ*), of which there are several kinds known in commerce. The finest are the *Spanish* or *Malaga* raisins (*Uvæ Malacenses*, or *Uvæ passæ majores*), of which there are three kinds—*Muscatels*, *Sun* or *Bloom raisins*, and the *Lexia raisins*. *Corinthian raisins* (*Uvæ Corinthiaceæ*), or *Dried currants* (*Uvæ passæ minores*), are obtained from a very small grape, called the *Black Corinth*, and are produced in Greece, at Zante, Patras, etc. Raisins naturally contain more saccharine matter than fresh grapes, as may be seen by the saccharine efflorescence which is often noticeable upon their surfaces. The amount of sugar in raisins varies from 53 to 61 per cent (J. König, *loc. cit.*). Malaga raisins consist of dried bunches, while Valencia raisins are free from stems. Malaga raisins are large, fleshy, purplish-brown, sweet, and of fine flavor. A yellow-brown raisin, of a musky odor, and less pleasant in taste, is imported from Syria, and known as *Smyrna raisins*. A seedless kind, from Asia Minor, is called *Sultana* or *Seedless raisins*. Since about 1873, large quantities of raisins are being prepared in California from native grapes, chiefly from *Feher Zagos*, *Muscat*, and *Muscatel*, also from seedless *Sultana*. The grapes, at the proper point of ripeness, are exposed, in bunches on trays, to the heat of the sun for 6 or 8 days, and then placed in sweating boxes for about 2 weeks. The bunches are then sorted and packed. By careful manipulation, the raisins will neither be too dry, nor will they mold. They are put on the market either with the grapes attached to the stems, or stemless. (For an interesting description of this flourishing industry, see *Amer. Jour. Pharm.*, 1890, p. 465; also see *ibid.*, 1899, p. 5.)

Action and Medical Uses.—Raisins are used in medicine principally for imparting a flavor to various infusions, decoctions, etc. When eaten freely, they are apt to cause flatulency and other unpleasant symptoms, on account of their difficult digestibility. An excellent, pure, and sparkling wine may be made as follows: Take 12 pounds of good raisins, cut each raisin in two, and put them into a 5-gallon demijohn, nearly filled with clean, soft water; let it stand uncorked for about 14 days, then filter, bottle, and cork well. Upon the residue, after the wine is poured off, put as much water as before, let it stand a sufficient time, and the result will be a good white wine vinegar. Grapes are diuretic, probably owing to the grape-sugar present.

UVA URSI (U. S. P.)—UVA URSI.

"The leaves of *Arctostaphylos Uva ursi* (Linné), Sprengel"– (*U. S. P.*) (*Arbutus Uva ursi*, Linné; *Arctostaphylos officinalis*, Wimmer).

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Bearberry*, *Upland cranberry*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 163.

Botanical Source.—This plant is a small, perennial shrub, having a long, fibrous root. Its stems are woody, trailing, and rooting, the young shoots only turning upward; the bark deciduous and smooth. The leaves are alternate, obovate, acute at base, short petioled, coriaceous, evergreen, glabrous, shining above, paler beneath, entire, in young ones pubescent, the margin rounded, but scarcely reflexed. The flowers are terminal and clustered. Peduncles short, red, reflexed, and furnished at base with a short, acute bract, with 2 minute ones at the sides. Sepals 5, roundish, reddish, and persistent. Corolla ovate or urceolate, white with a reddish tinge, transparent at base, contracted at the mouth, and hairy inside, with 5 short, reflexed segments. Stamens 10, very slightly adhering to the base of the corolla; filaments hairy; anthers reddish, each with 2 horns and 2 pores. Ovary round; style straight, longer than the stamens; stigma simple. Disk a black indented ring. The fruit is small, globular, succulent, drupaceous, depressed, almost scarlet-colored, with an insipid, mealy pulp, and 5 angular seeds (L.).

Fig. 250.

Arctostaphylos Uva ursi.

History and Description.—Uva ursi is a perennial evergreen, common in the northern part of Europe and America, growing on sterile, gravelly ridges, and dry, sandy soils. It flowers from June to September, and ripens its berries during the winter. The leaves are the parts used; the green leaves alone should be selected, picked from the twigs in the fall, and dried by exposure to a moderate heat. They are frequently adulterated with whortleberry or cowberry leaves. These adulterations may be detected by observing that the uva ursi leaf is reticulated beneath, while the whortleberry leaf is merely dotted. The leaves of pipsissewa are longer, cuneate-lanceolate, and sharply serrated. Uva ursi leaves are odorless, except when in powder, which is of a light-brown color, with a shade of greenish-yellow, and has nearly the smell of good grass hay, and to the taste is at first smartly astringent and bitterish, which sensations gradually soften into a liquorice flavor. The leaves yield their properties to water or alcohol, forming, with the latter, a green tincture, which is rendered turbid by water, causing a deposit of green resin. As officially described, uva ursi leaves are "very short-stalked, obovate or oblong-spatulate, coriaceous, from 15 to 20 Mm. ($\frac{3}{5}$ to $\frac{4}{5}$ inch) long, and 5 to 8 Mm. ($\frac{1}{5}$ to $\frac{1}{3}$ inch) broad, obtuse, slightly revolute on the margin, upper surface with depressed veins; lower surface distinctly reticulate; odor faint, hay-like; taste strongly astringent, and somewhat bitter"—(*U. S. P.*).

Chemical Composition.—The leaves of uva ursi contain large quantities of *gallic acid*. The active principle is the crystallizable glucosid, *arbutin*, announced by Kawalier, in 1852. Previously, J. C. C. Hughes (*Amer. Jour. Pharm.*, 1847, p. 88 attributed the diuretic power of the leaves to a crystallizable substance, which he called *ursin*. This substance was subsequently shown by Jungmann (*ibid.*, 1871, p. 205) to have been arbutin mixed with some gallic acid. Diluted acids, as well as the ferment *emulsin*, decompose arbutin into sugar, *hydroquinone* ($C_6H_6O_2$) (*arcturin* of Kawalier), and *methyl-hydroquinone* ($C_6H_5[CH_3]O_2$), which substances may occur in the herb together with arbutin. Upon destructive distillation of an extract of uva ursi leaves, *hydroquinone* can be isolated from the distillate (Uloth, 1859). Other constituents of the leaves are the bitter glucosid *ericolin*, and its decomposition product *ericinol* (Rochleder and Schwarz, 1852, and R. Thal, *Pharm. Zeitschr. für Russland*, 1883, p. 209; also see *Rhododendron*, *Ledum*, etc.); the crystallizable substance *urson*, insoluble in water (H. Trommsdorff, 1854); tannic and malic acids, a small quantity of volatile oil, fatty matter, wax, gum, sugar, coloring matter, etc. (Jungmann, *loc. cit.*). A yellow coloring matter, allied to quercetin, of the formula $C_{15}H_{10}O_7$, was isolated by A. G. Perkin (see *Amer. Jour. Pharm.*, 1898, p. 584). It forms phloroglucin and protocatechuic acid upon fusion with alkali. The ash of the leaves of uva ursi amounts to about 3 per cent. The leaves are free from the poisonous andromedotoxin, which occurs in certain other *Ericaceæ*.

ARBUTIN ($C_{25}H_{34}O_{14}$, Hlasiwetz and Habermann, 1883) also occurs in other Ericaceæ (see *Pyrola*, *Kalmia*, *Gaultheria*, etc.) From the leaves of uva ursi it is obtained by adding solution of subacetate of lead to a decoction of the leaves, removing the lead from the filtrate by sulphide of hydrogen, and evaporating to crystallization. The crystals are purified by treatment with a mixture of ether (8 parts) and alcohol (1 part), and are subsequently crystallized from water. It forms colorless, long, silky needles of bitter taste, neutral reaction, very hygroscopic, easily soluble in hot water and alcohol, hardly soluble in ether. The aqueous solution produces a blue color with ferric chloride, and does not reduce Fehling's solution, nor is it precipitated by the lead acetates. Acids and emulsin decompose it as stated before. In aqueous solution, rendered alkaline by ammonia or caustic potash, arbutin acquires a deep azure-blue color with phosphomolybdic acid (Jungmann, *loc. cit.*).

Action, Medical Uses, and Dosage.—The effects of this medicine depend entirely on its stimulant, astringent, and tonic powers, though, in the smaller doses, it tends to relieve *chronic irritation of the bladder*. As an astringent, it is applicable to all the purposes for which astringents are used, as in *chronic diarrhœa and dysentery*, *menorrhagia*, *diabetes*, *enuresis*, etc. In *chronic affections of the kidneys and urinary passages*, it is frequently useful; in *vesical catarrh*, *chronic gonorrhœa*, *strangury*, *leucorrhœa*, and *excessive mucous and bloody discharges* with the urine. Its tannic acid becomes oxidized and converted into gallic and pyrogallic acids, and humus-like substances, which communicate a dark color to the urine. The keynote to its use is relaxation of the urinary membranes, as is evidenced by catarrhal discharges and a feeling of weight and dragging in the loins and perineum. There is always a feeble circulation and lack of innervation in the urinary tract when uva ursi is indicated. It undoubtedly lessens lithic acid deposits in the urine. In *gonorrhœa*, with bloody and mucous discharges, and pain in the vesical region, it speedily allays all these unpleasant symptoms. *Cystic spasm* is relieved by it, and, when *calculi* are present, it obtunds the cystic membranes to such an extent that the offending material is comfortably borne. It is also a remedy for *passive hemorrhage*, small in amount, and in *chronic affections of the larynx, bronchiæ, and pulmonary tissues*, with excretion and cough. In large doses, uva ursi may cause emeto-catharsis. Arbutin, while undoubtedly diuretic, does not fully represent uva ursi, and the latter is said not to exert a diuretic action in health. Arbutin, in its passage through the system, is decomposed, and gives rise to hydroquinone, to which body has been attributed the retardation of putrescent changes in the urine of persons taking uva ursi. Arbutin may be given to the extent of 10 or 15 grains a day, usually mixed with sugar. Dose of powdered uva ursi, 10 to 60 grains; of the decoction, 1 to 3 fluid ounces, made by boiling 1 ounce of uva ursi with 1½ pints of distilled water down to 1 pint; of the extract, 5 to 15 grains; of the tincture, 5 to 30 drops.

Specific Indications and Uses.—Relaxation of the urinary tract, with pain and mucous or bloody secretions; feeling of weight and dragging in the loins and perineum, when not due to prostatic enlargement; chronic vesical irritation, with pain, tenesmus, and catarrhal discharges.

Related Species and Sophistications.—The leaves of the following North American plants have been used as substitutes or adulterants of uva ursi: *Vaccinium uliginosum*, Linné, *Bog-bilberry*; *Vaccinium Vitis-Idæa*, Linné, *Cowberry*, or *Red whortleberry* (containing *vacciniin* [*arbutin*]; see E. Claassen, *Amer. Jour. Pharm.*, 1870, p. 297; and F. Oelze, *Jahresb. der Pharm.*, 1890, p. 73); *Buxus sempervirens*, Linné, *Box; Leiophyllum buxifolium*, Elliott; *Oxydendron arboreum*, De Candolle, *Sourwood*, or *Sorrel tree;* and *Epigæa repens*, or *Trailing arbutus*, containing *ericolin* and, probably, *arbutin*. Other species related to uva ursi are:

Arctostaphylos glauca, Lindley, *Manzanita.*—California. This shrub-like tree grows in the dry, rocky districts of the Sierras, on the western slopes. The leaves are the parts used, being employed like uva ursi. They are about 2 inches long, leathery, entire, ovate-oblong, and of a light-green hue. J. H. Flint (*Amer. Jour. Pharm.*, 1873, p. 197) found in them nearly 10 per cent of tannin and some *arbutin*, which gave Jungmann's test (see *Uva Ursi*).

Arbutus xalapensis, Kunth, Mexico and western Texas, and *Arctostaphylos tomentosa*, Douglass, of Mexico, both known as *Madrona*, are used like uva ursi; as are also the *Arctostaphylos mucrocifera*, De Candolle, and the *Arctostaphylos polifolia*.

UVULARIA.—BELLWORT.

The root of *Uvularia perfoliata*, Linné.

Nat. Ord.—Liliaceæ.

COMMON NAMES: *Bellwort, Mealy bellwort.*

Botanical Source.—Bellwort has a perennial, creeping root-stalk, and a stem 8 to 14 inches high, dividing at the top into 2 branches. The leaves are clasping-perfoliate, elliptical, rounded at base, acute at apex, 2 or 3 inches long, by one-third as broad, smooth, and glaucous underneath. The flowers are solitary, pale-yellow, about 1 inch long, pendulous from the end of one of the branches; perianth subcampanulate and tuberculate-scabrous within; segments linear-lanceolate, about 1 inch long and twisted; anthers cuspidate, ¾ inch long. Capsule or pod obovate-truncate, and divergently 3-lobed at top; lobes with convex sides (W.—G.).

History.—Bellwort is a smooth, handsome plant, common to the United States, growing in moist copses, woods, etc., and flowering in May. The root is the part employed, which, when recent, is acrid and mucilaginous. It imparts its properties to water.

Action, Medical Uses, and Dosage.—Bellwort is a tonic, demulcent, and nervine, and may be used in decoction or powder, as a substitute for cypripedium. The decoction has proved beneficial in *sore mouth* and *affections of the throat*, also *inflammation of the gums*. A poultice of it is useful in *wounds* and *ulcers*. Boiled in milk, and the decoction drank freely, with a poultice of the root applied to the wound, it has considerable reputation as an alexipharmic in bites of *venomous snakes*. A poultice of the green or dried root, in powder, and mixed with hot new milk, is very highly recommended in all stages of *erysipelatous inflammation*, to be renewed when dry; the same application has been used beneficially in *acute ophthalmia*. An ointment made by simmering the powdered roots and green tops in lard for an hour, over a slow fire, and straining by pressure, is useful in *herpetic affections, sore ears, mouths*, etc., of children, and also in mild cases of *erysipelas*.

VACCINIUM.—BLUE WHORTLEBERRY.

The fruit and root of *Gaylussacia frondosa*, Torrey and Gray (*Vaccinium frondosum*), and of *Gaylussacia resinosa*, Torrey and Gray (*Vaccinium resinosum*).

Nat. Ord.—Ericaceæ.

COMMON NAMES: (1) *Blue whortleberry, Blue dangles, High blueberry, Blue huckleberry;* (2) *Black whortleberry, Black huckleberry.*

Botanical Source.—*Gaylussacia frondosa* is a shrub 3 to 6 feet high, with a grayish bark, and round, smooth, slender and divergent branches. Its leaves are deciduous, obovate-oblong, obtuse, entire, pale, glaucous beneath, covered with minute resinous dots, and the margin being slightly revolute. The flowers are small, nearly globose, reddish-white, in loose, slender, lateral, bracteate racemes; the bracts are oblong or linear, rather deciduous, and shorter than the pedicels; the pedicels are from 5 to 10 lines long, slender, drooping and bracteate near the middle. The corolla is ovoid-campanulate, with acute divisions, inclosing the stamens. The fruit is large, globose, dark-blue, covered with a glaucous bloom, sweet and edible (W.).

Gaylussacia resinosa is a bushy shrub 1 to 3 feet in height. Its branches are cinereous brown and villose when young. The leaves are deciduous, oblong-ovate, or oblong-lanceolate, rather obtuse, entire, petiolate, 1 or 2 inches long, about one third as wide, and thickly covered with shining resinous dots beneath. The flowers are reddish, tinged with green, or yellowish-purple, in lateral, secund, dense, corymbose racemes, small and drooping; the pedicels are about the length of the flowers, and sub-bracteolated; the bracts and bractlets are reddish, small, and deciduous. The corolla is ovoid-conic, at length subcampanulate, 5-angled, contracted at the mouth, longer than the stamens, shorter than the style. The fruit is globose, black, without bloom, sweet and edible (W.).

History and Chemical Composition.—These plants are common to the northern states, growing in woods and pastures, flowering in May and June, and ripening their fruit in August. The fruit, or berries, together with the bark of the root, are the parts used. They yield their virtues to water. To our knowledge, no analysis has yet been made of them. The fruit of the related European plant, *Vaccinium myrtillus*, Linné, contains malic and citric acids, sugar, pectin, coloring matter, iron-bluing tannin, ericolin and kinic acid (see Dragendorff's *Heilpflanzen*, 1898; and Wittstein's *Pharmacognosie*, 1882).

Action, Medical Uses, and Dosage.—Diuretic and astringent. The fruit is very useful, eaten alone, with milk or sugar, in *scurvy*, *dysentery*, and *derangements of the urinary organs*. The berries and roots, bruised and steeped in gin, form an excellent diuretic, which has proved of much benefit in *dropsy* and *gravel*. A decoction of the leaves or bark of the root is astringent, and may be used in *diarrhœa*, or as a local application to *ulcers*, *leucorrhœa*, and *ulcerations of the mouth and throat*.

Related Species.—The different varieties of whortleberry possess similar properties, as the *Gaylussacia dumosa*, Torrey and Gray (*Vaccinium dumosum*), or *Bush whortleberry*; *V. corymbosum*, Linné, or *Giant whortleberry*; *V. Pennsylvanicum*, Lamarck, *Common low blueberry*, or *Black-blue whortleberry*; *V. Vitis-Idæa*, Linné, *Cowberry* or *Bilberry*, and several others. The last-named contains a bitter principle, *vacciniin*, identical with *arbutin* (Edo Claassen; see under *Uva Ursi*). Several species are found growing in the mountainous regions of some of the southern states. Torrey and Gray have removed the *V. frondosa*, *V. resinosum*, and *V. dumosum* from the genus *Vaccinium*, and placed them in a new one called *Gaylussacia*, in honor of the distinguished chemist, Gay-Lussac. Both the berries and root-bark of *V. arboreum*, Michaux, or *Farkleberry*, are very astringent, more so than the other varieties above named, and may be used in all cases where this class of agents is indicated, as in *diarrhœa*, *chronic dysentery*, etc., taken internally; and the infusion will be found valuable as a local application in *sore throat*, *aphthous ulcerations*, some forms of *chronic ophthalmia*, *leucorrhœa*, etc. The leaves of *Vaccinium Vitis-Idæa*, and of *Vaccinium uliginosum*, Linné, have been confounded with those of *Uva ursi*.

Vaccinium macrocarpon, Aiton (*Oxycoccus macrocarpus*), *Cranberry*.—This well-known fruit is frequently applied in domestic practice to *inflammatory swellings*, such as *erysipelas*. Edo Claassen (*Amer. Jour. Pharm.*, 1886, p. 324) finds in the fruit a bitter, non-crystallizable glucosid, which he names *oxycoccin*, resembling *arbutin*. Cranberries are a source of citric acid; L. W. Moody (*ibid.*, 1878, p. 567) found 2.27 per cent. Cranberries in poultice have proved useful in *erysipelatous inflammations*, *tonsilitis*, *scarlatinal sore throat*, and *swelling of the cervical glands*, as well as in *indolent and malignant ulcers*. A split cranberry, held in position by a daub of flour or starch-paste, will quickly relieve the pain and inflammation attending *boils* upon the tip of the nose. This procedure, recently recommended by a distinguished physician, has given good results in our hands.

VALERIANA.—VALERIAN.

"The rhizome and roots of *Valeriana officinalis*, Linné"—(*U. S. P.*).

Nat. Ord.—Valerianeæ.

Common Names and Synonyms: *Valerian*, *Great wild valerian*, *Valerian root*; *Valerianæ rhizoma* (*Br.*), *Radix valerianæ minoris*.

Illustration: Bentley and Trimen, *Med. Plants*, 146.

Botanical Source.—The official valerian, sometimes known as *Great wild valerian*, is a large herb, with a perennial, tuberous, somewhat creeping, fetid root, most aromatic when growing in dry pastures, with numerous long, dark-brown rootlets, and a smooth, hollow, furrowed stem about 4 feet in height. The leaves are all pinnate and opposite; leaflets in from 7 to 10 pairs, lanceolate, coarsely serrated, those of the radical leaves broadest, approaching to ovate, and borne on long foot-stalks. The flowers are flesh-colored, small, fragrant, in terminal cymose, contracted panicles; bracts, ovate-lanceolate, acuminate, herbaceous, membranous at the edge, appressed, and rather longer than the ovary, calyx superior, rolled inward in the form of a rounded, thickened rim, ultimately becoming a sort of pappus to the seed; corolla funnel-shaped and smooth; tube gibbous at the base on that side of the flower turned away from the axis, and hairy internally; limb spreading, divided into 5, nearly equal, concave and linear, with rounded segments. Stamens 3, exserted, subulate, white from the middle of the corolla tube; anthers yellow and oblong; ovary inferior, narrow-oblong, compressed, 1-celled, with a single pendulous ovule; style filiform; stigma divided into 3 filiform lobes. The fruit is light-brown, linear-ovate, compressed with a slight elevated ridge on one side, terminated by the 12 filiform, plumose, recurved segments of the calyx-limb (L.—Wo.).

History and Description.—Valerian is a European plant growing in wet places, or even in dry pastures, flowering in June and July. The plant thrives best in a light, dry soil; that growing in low, wet situations is not so active, therapeutically. Botanists have given distinctive variety names to these two kinds, which differ in habit of growth. Valerian is also cultivated in this country, especially in Vermont and New Hampshire, and is fully equal, if not superior, to that of English growth. The valerian of American growth has almost entirely superseded the foreign in this country. The medicinal part of the plant is the root, which should be gathered soon after the leaves have fallen, and carefully dried. The *U. S. P.* describes the drug to be a "rhizome from 2 to 4 Cm. ($\frac{4}{5}$ to 1$\frac{3}{5}$ inches) long, and 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ inch) thick, upright, subglobular or obconical, truncate at both ends, brown or yellowish-brown, internally whitish or pale-brownish, with a narrow circle of white wood under the thin bark. Roots numerous, slender, brittle, brown, with a thick bark, and slender, ligneous cord. Odor peculiar, becoming stronger and unpleasant on keeping; taste, camphoraceous and somewhat bitter"—(*U. S. P.*). The odor of the dry root is fetid. characteristic, and highly attractive to cats, and, it is said, to rats also. The root imparts its properties readily to water, alcohol, and ammoniated alcohol.

Chemical Composition.—The active properties of valerian are largely due to its volatile oil (about 1 per cent), the characteristic constituent of which is *iso-valerianic acid* (see *Acidum Valerianicum*), combined with *borneol*, in the freshly distilled oil (see *Oleum Valerianæ*). Other constituents are malic acid, resin, sugar, starch, iron-greening tannin (about 1.5 per cent), etc. An alkaloid, *chatinine*, was isolated from valerian by Waliszewski (*Amer. Jour. Pharm.*, 1891, p. 285). In Mexican valerian, R. McLaughlin (*ibid*, 1893, p. 329) found 3.33 per cent of volatile oil, 4.3 per cent of oleoresin, a crystalline, ether-soluble glucosid, wax, fat, etc.

Admixtures and Adulterations.—M. O. Reveil has detected the roots of *Scabiosa succissa*, Linné, and *S. arvensis*, Linné, to the extent of 22 per cent in some valerian. These roots are inodorous, but soon acquire the odor of valerian by contact (*Amer. Jour. Pharm.*, 1855, p. 21). The roots of *Valeriana Phu*, Linné, and *Valeriana dioica*, Linné, are occasionally intermixed with true valerian root. They are weaker in odor and taste. Several *Ranunculaceæ* have been added in Germany with fraudulent intent (Ebermayer). R. Bentley (*Amer. Jour. Pharm.*, 1877, p. 201) calls detailed attention to the dangerous admixture of *Veratrum album;* Charbonnier (1887) detected *Cynanchum Vincetoxicum;* and Bernbeck (1880) *Sium latifolium*, as admixtures.

Action, Medical Uses, and Dosage.—Valerian excites the cerebro-spinal system. Large doses cause headache, mental excitement, visual illusions, giddiness, restlessness, agitation, and even spasmodic movements, and frequently nausea. In medicinal doses it acts as a stimulant-tonic, antispasmodic and calmative, and has been used in *chorea*, *hysteria*, and in the low forms of *fever*, where a nervous stimulant is required. Although sometimes very effectual in curing, it as frequently fails in producing more than temporary benefit. These failures are probably due to the fact that the medicine is often administered without due regard to the indications, and especially the condition of the nerve centers. The cases requiring it are those evidencing enfeebled cerebral circulation; there is despondency and marked mental depression, often amounting to *hypochondria*. In properly selected cases it relieves irritability and pain, and favors rest and sleep. In such cases it is frequently useful in *hemicrania* and other forms of *nervous headache*. Its chief value is in *chorea*, with enfeebled cerebral circulation. ℞ Valerian, macrotys, āā ℥ij; dilute alcohol, Oj; macerate for 2 weeks. Dose, 1 teaspoonful, 3 times a day (Locke). Valerian is adapted to the milder *spasmodic affections*. Prof. Webster states that "it is better calculated to steady that hyperæsthetic state which carries a patient to the very verge of convulsive action than to relax it when it has once taken place"—(*Dynam. Therap.*, 214). Valerian is one of many agents which have been used for the relief of *epilepsy*. The extract of valerian is worthless, but the fluid extract has been found to possess all the medicinal virtues of the root. The powder is apt to irritate the stomach and bowels, its dose is from ½ drachm to 2 drachms, every 3 or 4 hours; the infusion, which is a preferable form, may be given in doses of 1 or 2 fluid ounces; the fluid extract, in doses of from 20 to 60 drops in a little water; the tincture, in doses of 1 or 2 fluid drachms; and the volatile oil, from 2 to 6 drops; ammoniated tincture, 1 to 2 fluid drachms; specific valerian, 2 to 30 drops.

Specific Indications and Uses.—A cerebral stimulant. Hysteria, chorea, hemicrania, all with mental depression and despondency; cerebral anemia; mild spasmodic movements.

Related Species and Drugs.—*Valeriana Phu*, Linné. West Asia and south Europe yields the root above-mentioned as an adulterant. It is known as *Radix valerianæ majoris*. Its odor and taste resemble those of valerian, but are not nearly so strong.

Valeriana celtica, Linné.—Europe. This Alpine plant yields the rhizome known as *Nardus spica celtica*, which has a valerian taste and powerful odor.

Valeriana toluccana, De Candolle; *Valeriana Mexicana*, De Candolle.—Mexico. Used like valerian; yields large amounts of valerianic acid.

Nardostachys Jatamansi, De Candolle (*Valeriana Jatamansi*, Roxburgh).—Mountains of north India. Yields true *spikenard* (*Nardus Indica*, or *Spica Narda*), *Jatamansi*. Its taste is bitter and spicy, and its odor strong and resembling Virginia snakeroot. It has long been used by the Hindus as a medicine and perfume. In 45-grain doses it is employed in colds and coughs as an expectorant, and there is a popular belief in India that it promotes "the growth and blackness of the hair" (*Dymock*). It is chiefly used in making washes and ointments for the hair. Sir W. O. Shaughnessy states that "it is a perfect representative for valerian" (Dymock, *Mat. Med. of West. India*). It yields a brownish volatile oil.

Valeriana Hardwickii, Wallach.—Himalayas. This drug is the *Taggar* of India, and its medicinal properties are similar to those of *jatamansi*. Contains 1 per cent of volatile oil, with valerianic acid, and 3.13 per cent of tannin (J. Lindenberg, *Pharm. Zschr. f. Russland*, 1886, p. 523).

Patrinia scabiosæfolia, Link.—Japan. *Kesso*, or *Japanese valerian*, at first sight very much resembles valerian, and as to taste and odor is almost identical (*Pharmacographia*). It lacks the upright rhizome of the true drug. It was introduced in 1879 into English markets.

Amyl Valerianate.—One part of this ester, dissolved in a mixture of 19 parts of alcohol and 2 per cent of a spirit of amyl acetate (1 in 20) has been praised by Dr. Wade, of Birmingham, in cases to which valerian is applicable. The dose of the above mixture ranges from 6 to 8 drops.

VANILLA (U. S. P.)—VANILLA.

"The fruit of *Vanilla planifolia*, Andrews"—(*U. S. P.*).

Nat. Ord.—Orchideæ.

Common Name: *Vanilla*.

Illustration: Bentley and Trimen, *Med. Plants*, 272.

History and Botanical Source.—The plant which produces vanilla bean is an orchid, native of the tropical forests of Mexico, but now grown in many other parts of the globe, as in Brazil, Honduras, Java, Africa, and the West Indies, though only on the island of Guadaloupe on a commercial scale. Vanilla has probably been in use among the Mexicans from times immemorial, as a flavor to their chocolate, and was made known to the western world by the Spaniards. Hernandez, the Spanish historian, describes it under the botanical name *Aracus aromaticus*, also mentioning its Mexican name, *Tlilxochitl*. Clusius, in 1602, calls it *Lobus oblongus aromaticus*. The generic name of the plant was established, in 1752, by Plumier, and the present name of the species yielding the true Mexican vanilla of commerce, by Andrews, in 1808. (As to priority of synonyms, see George M. Beringer, *Amer. Jour. Pharm.*, 1895, p. 611.) While the *Index Kewensis* enumerates 34 species of vanilla; only very few contribute to the world's supply of the vanillas of commerce—for example, *V. planifolia*, Andrews (Mexico, also cultivated in Réunion, Java, etc.); *V. pompona*, Schiede (southeast Mexico, Panama, Colombia, Venezuela, Surinam, Cayenne, Guadaloupe, etc.); and *V. Gardneri*, Rolfe (Brazil) (R. A. Rolfe, *Kew Bulletin*, 1895, p. 169; see Beringer, *loc. cit.*).

Fig. 251.

Vanilla planifolia.

Vanilla planifolia, Andrews, the official source of the bean, is a climbing vine, with a thick, succulent stem, and entire, thick, smooth, bright-green, pointed leaves, 4 to 9 inches long, and 1½ to 2½ inches broad. Opposite the leaves, it is furnished with numerous aerial roots, with which it clings to its support. The flowers are produced in axillary bunches of 8 or 10; they are of a pale-yellow color, about 2 inches in diameter, have the usual orchidaceous structure, but are more regular in appearance than most orchids. The fruit is a pendant pod, 5 to 10 inches long, and an inch or more in circumference when fresh, and contains myriads of minute seeds. These pods, when properly cured and dried, are the vanilla of commerce. Regarding the mode of sustenance of the vanilla vine, two statements have been made—one, that it is a parasite, deriving its nourishment from the tree to which it clings; the other, that it is an *epiphyte* (as many orchids are), *i. e.*, living entirely on moisture and nourishment derived from the air. Neither opinion is exact. After the vanilla plant has established itself, it will continue to grow even if its connection with the ground is severed, and will throw out new roots, which reach and penetrate the ground. Hence it is, to some extent, epiphytic. But should it fail to establish its connection with the ground, it will finally wither and die. It is in no sense a parasite.

Cultivation and Treatment.—Vanilla is almost exclusively propagated from cuttings, although it can be reared from seeds, but not without considerably delaying the year of the harvest. A warm and moist climate, sandy, moist (not marshy) soil, a mixture of shade and sunshine, the shade predominating, is essential to its successful cultivation. The temperature should average from 75° to 80° F., but should not fall below 65° F. in winter, and the plants should be protected from the salty air of the ocean breezes. If a virgin forest is to be transformed into a vanilla plantation, all superfluous shade must be removed, while, when an open field is to be cultivated, shade trees must first be planted. After about 4 weeks, the cuttings will have taken root, and, in the third year, they begin to bear fruit, and continue to bear for a period of from 30 to 40 years, although with decreasing tendency after the tenth year. In Mexico, the vanilla is permitted to climb the highest trees, while, in Réunion, the expanding vines are so guided as to permit of easy access.

Like most orchids, vanilla depends on insects for fertilization, but in Reunion, where these are absent, artificial fecundation must be resorted to. This is done by slipping aside the labellum, a dividing film, which separates the anther from the stigma, and pressing them lightly together. Care must be taken not to produce, in this way, too many fruits on one stalk, because, in this case, the plants would perish before the pods could ripen. The vine blossoms from March to June, the pod, however, does not ripen until the following January or February. Unfortunately, vanilla in Mexico is picked before it ripens—namely, as early as October or November, chiefly because the crop is in danger of being stolen. This pernicious habit was noticed as early as 1811 by Humboldt.

The value of vanilla depends greatly on the success of the curing process, which requires much skill and experience on the part of the operator. During this manipulation, the flavor of the bean is developed by a peculiar sweating process, a mode of fermentation, which causes the bean to shrivel and to assume a fine chestnut-brown color. This process is carried out differently in different vanilla-producing countries. Ripe vanillas can be cured much more easily than those that are unripe, and the flavor is more permanent. First-grade ripe pods, when stored, become covered with crystals of vanillin in a few months, while the pods, when gathered green, do not form crystals, and are difficult to preserve (Charles E. Hires). The beans are finally sorted into different commercial grades, made into bundles, packed, and conveyed to the shipping ports. (For much interesting information regarding the cultivation and treatment of vanilla, see J. C. Sawer, *Odorographia*, Vol. 1, 1892, pp. 143–173, London; and Charles E. Hires, "A Talk on Vanillas," in *Amer. Jour. Pharm.*, 1893, pp. 571-584; also see a summary on vanilla, with indication of literature, by J. U. Lloyd, *West. Drug.*, Dec., 1897.

Description and Commercial Varieties. The most valued of the vanillas of commerce is the MEXICAN VANILLA. It is the official kind, and is described by the *U. S. P.* as "from 15 to 25 Cm. (6 to 10 inches) long, and about 8 Mm. (⅓ inch) thick, linear, narrowed, and bent or hooked at the base, rather oblique at the apex, wrinkled, somewhat warty, dark-brown, glossy leathery, 1-celled, and containing a blackish-brown pulp, with numerous minute seeds, and more or less acicular crystals; odor and taste peculiar, fragrant"—(*U. S. P.*). Mr. Beringer (On Some Commercial Vanillas, *Amer. Jour. Pharm.*, 1892, pp. 289–294) remarks that the pods of this variety feel firmly plump, and there is a roughness to the touch, which becomes more pronounced as it gets older and dryer. While fresh, the surface is somewhat viscid; the crystals begin to form at the ends, and gradually extend over the surface.

BOURBON VANILLA, from the island of Réunion, is darker than the Mexican bean, and feels smooth and waxy. The odor, while not unpleasant, rather resembles that of tonka bean than Mexican vanilla. Good Bourbon vanilla is likewise covered with crystals ("frosted").

SEYCHELLES AND MAURITIUS VANILLA are sold as inferior Bourbon vanilla in the American market. They are of small size (about 6 inches), pale, smooth, non-waxy, and but faintly odorous.

SOUTH AMERICAN VANILLAS are reddish-brown in color, very pulpy, resinous, and scarcely frosted. Their odor is unpleasant, resembling that of fermented molasses.

TAHITI VANILLA is similar to the former. Its market is the Pacific coast and the western states.

WEST INDIAN VANILLONS, derived from *V. pompona*, Schiede, are exported from Martinique and Guadaloupe, and are collected also from wild vanillas in Mexico. They are only 4 to 5 inches in length, of a twisted appearance, owing to their being tied with twine during the process of curing. The odor is different from vanilla, and, as stated by Beringer (*loc. cit.*) may be compared to a cross between a fermented sugar and heliotrope odor. They are used in the tobacco industry, and, in perfumery, for sachet powders.

Chemical Composition.—The fragrance of vanilla is due to crystallizable *vanillin*, and a small quantity of a balsam, both of which are developed during the curing process. The presence of an odorous resin tends to impair the quality of the bean, according to its quantity. (For a complete analysis of vanilla beans, see W. von Leutner, *Jahresb. der Pharm.*, 1872, p. 36, from *Pharm. Zschr. f. Russland*, 1871.) The "frost" which forms upon vanilla beans, upon storing, was formerly believed to be benzoic acid, until Gobley, in 1859, pointed out its distinction from the latter, and named it *vanillin*. He obtained it by treating an alcoholic extract of vanilla with ether, and recrystallizing the ether extract from hot water with the use of animal charcoal.

VANILLIN ($C_8H_8O_3$) occurs in long, colorless needles, melting at 81° C. (177.8° F.), subliming at a higher temperature, and boiling in an atmosphere of carbon dioxide gas, without decomposition, at 285° C. (545° F.). It is little soluble in cold water (198 parts), much more soluble in boiling water (11 parts), and crystallizing upon cooling. It is easily soluble in ether, alcohol, and chloroform, very little soluble in low-boiling petroleum ether. The researches of Tiemann and Haarmann (1874–76) have shown vanillin to be *methyl-proto-catechuic aldehyde*, or, more exactly, *meta-methoxy-para-oxy-benzoic aldehyde* (C_6H_3[OH].[OCH_3].CHO). Thus it is closely related to *piperonal* (C_6H_4[OCH].[OCH_3].CHO), of heliotrope odor (see *Piperonal*). These authors prepared vanillin synthetically from *coniferin* ($C_{16}H_{22}O_8 + 2H_2O$), a glucosid occurring in the cambium sap of coniferous trees; when treated with the ferment emulsin, it becomes hydrolyzed into dextrose and *coniferyl alcohol*, or *oxy-eugenol* ($C_{10}H_{12}O_3$), which, upon oxidation, yields vanillin. The latter is now prepared synthetically by oxidation of *eugenol* (see *Oil of Cloves*, and diagram, by Prof. V. Coblentz, *Journal of Pharmacology*, 1898, p. 37). Or, it may be obtained from other similarly constituted compounds, *e. g.*, *creosol, guaiacol, caffeic acid*, etc. Owing to its being an aldehyde, vanillin enters quantitatively into a crystallizable, ether-insoluble compound with sodium bisulphite (SO_3HNa), from which vanillin may be regenerated by treatment with diluted acid (Tiemann and Haarmann). Another interesting aldehydic compound of vanillin is that with ammonia, which permits the quantitative separation of vanillin from coumarin, the aromatic principle of the tonka bean. "If vanillin be dissolved in pure, dry ether, and dry ammonia gas be passed through the solution, the aldehyde-ammonia compound of vanillin will be precipitated in almost quantitative proportions. * * * Coumarin, on the other hand, remains wholly (and unchanged) in the ether solution'' (Wm. H. Hess and A. B. Prescott, *Pharm. Review*, 1899, p. 7). By oxidation, vanillin forms odorless, volatile *vanillic acid*, melting at 212° C. (413.6° F.). An alcoholic solution of vanillin produces greenish-blue with ferric chloride; an aqueous solution produces a permanent blue with the same reagent. It dissolves in sulphuric acid with yellow color.

The quality of commercial vanilla beans does not necessarily depend on the quantity of vanillin they contain; thus Tiemann and Haarmann found, in Mexican vanilla, 1.32 to 1.69 per cent, while Bourbon yielded from 0.75 to 2.9 per cent, and Java vanilla from 1.56 to 2.75 per cent of vanillin. Denner (1887) obtained 4.3 per cent from vanilla cultivated at Marburg (Flückiger, *Pharmacognosie des Pflanzenreichs*, 3d ed., 1891). West Indian vanillons contained 0.4 to 0.7 per cent of vanillin, together with a liquid aldehyde, probably benzoic aldehyde; when both are in prolonged contact with each other, an odor resembling heliotrope will be developed.

Benzoic acid, dusted over vanilla beans, with fraudulent intent, may be recognized, according to Messrs. Schimmel & Co. (1888), by abstracting the crystals with sodium carbonate, adding sulphuric acid and metallic magnesium or zinc; if the crystals are benzoic acid, the odor of oil of bitter almonds (benzoic aldehyde) will then be developed. Vanillin is also a constituent of many other vegetable products, such as Siam benzoin (Balsam of Peru, see H. Thoms, *Archiv der Pharm.*, 1899), the sugar beet, asparagus, several kinds of wood, the husks of oats, etc.

Action, Medical Uses, and Dosage.—Aromatic stimulant. Vanilla is said to exhilarate the brain, prevent sleep, increase muscular energy, and stimulate the sexual propensities. Useful, in infusion, in *hysteria*, *rheumatism*, and low forms of *fever*. It is also considered an aphrodisiac, powerfully exciting the generative system. Much used in perfumery, and to flavor tinctures, syrups, ointments, confectionery, etc. Dose, of the powder, from 8 to 10 grains; of the infusion, made in the proportion of ½ ounce to 1 pint of boiling water, ½ fluid ounce, 3 or 4 times a day. To pulverize it, the pods must be cut in small pieces, mixed with sugar, 4 parts, and pounded in an iron mortar, then sifted; the residue to be powdered with more sugar, and so on.

Related Plants.—A plant of the distinct genus SOBRALIA, collected by Prof. Rusby in the Andes, produces a pod which develops the odor of vanilla upon maturity (see *Jour. of Pharmacol.*, 1898, p. 29); likewise, the flowers of a certain orchid, growing in Switzerland, yield considerable quantities of vanillin.

The *Vanilla plant*, or *Southern vanilla*, is the *Liatris odoratissima*, Michaux. The odorous principle of its leaves is *coumarin* (see Charles Falkenhainer, *Amer. Jour. Pharm.*, 1899, p. 133; also see *Liatris*).

A similar odoriferous plant is *Angræcum fragrans*, Du Petit-Thouars, known in Mauritius and Réunion as *faham*. Its odoriferous principle is coumarin; its odor is that of vanilla, tonka, and melilot combined.

VAPORES.—INHALATIONS.

This class of preparations has been official in the *British Pharmacopœias*, but is not recognized in the present *British Pharmacopœia*, 1898. The preceding *British Pharmacopœia* gave directions for the following inhalations: (1) VAPOR ACIDI HYDROCYANICI—*Inhalation of hydrocyanic acid;* (2) VAPOR CHLORI—*Inhalation of chlorine;* (3) VAPOR CONINÆ—*Inhalation of conine;* (4) VAPOR CREASOTI—*Inhalation of creosote;* (5) VAPOR IODI—*Inhalation of Iodine;* and (6) VAPOR OLEO PINI SYLVESTRIS—*Inhalation of fir-wool oil.*

VERATRINA.—VERATRINE.

"A mixture of alkaloids obtained from the seed of *Asagræa officinalis* (Schlechtendal et Chamisso), Lindley (*Nat. Ord.*—Liliaceæ)"—(*U. S. P.*).

SYNONYM: *Veratria.*

Preparation.—The *British Pharmacopœia* (1898) directs the preparation of veratrine as follows: Take of "cevadilla of commerce, 2 pounds (Imp.), or 1 kilogramme (Metric); distilled water; alcohol (90 per cent); solution of ammonia, hydrochloric acid, of each, a sufficient quantity. Macerate the cevadilla with half its weight of boiling distilled water, in a covered vessel, for 24 hours; remove the cevadilla; squeeze it; dry it thoroughly in a warm place; then beat it in a mortar, and separate the seeds from the capsules. Reduce the seed to powder; moisten the powder with the alcohol; pack firmly in a percolator; pass the alcohol through the marc until the percolate ceases to be colored; concentrate the alcoholic solution by distillation, so long as no deposit forms, and pour the residue, while hot, into 12 times its volume of cold distilled water; filter through calico; wash what remains on the filter with distilled water, until the filtrate ceases to precipitate with the solution of ammonia. To the filtrate add solution of ammonia in slight excess; let the precipitate completely subside; pour off the supernatant liquid; collect the precipitate on a filter; wash it with distilled water until the filtrate passes colorless; distribute the moist precipitate through 12 fluid ounces (or 400 cubic centimeters) of distilled water; add gradually, with diligent stirring, sufficient hydrochloric acid to make the liquid feebly but persistently acid; add 60 grains (or 4 grammes) of the purified animal charcoal of commerce; digest with moderate heat for 20 minutes; filter; allow the liquid to cool; add solution of ammonia in slight excess, and when the precipitate has completely subsided pour off the supernatant liquid; collect the precipitate on a filter and wash it with cold distilled water until free from chloride; dry the precipitate, first by imbibition with filtering paper, and then by the application of warmth"—(*Br. Pharm.*, 1898). (For other processes, see this *Dispensatory*, preceding edition.)

Description and Tests.—The *U. S. P.* directs "a white or grayish-white, amorphous or semi-crystalline powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane; having an acrid taste, and leaving a sensation of tingling and numbness on the tongue; permanent in the air. Very slightly soluble in cold or hot water; soluble in 3 parts of alcohol at 15° C. (59° F.), and very soluble in boiling alcohol; also soluble in 6 parts of ether, and in 2 parts of chloroform. When heated to 175° C. (347° F.), veratrine melts, forming a light-brown liquid. Upon ignition, it is consumed, leaving no residue. An alcoholic solution of veratrine has an alkaline reaction upon litmus paper. With nitric acid, veratrine forms a yellow solution. On triturating veratrine with concentrated sulphuric acid, in a glass mortar, the yellow or orange-red solution exhibits, by reflected light, a greenish fluorescence, which becomes more intense upon the addition of more acid, while the liquid is deep red by transmitted light. On heating a small portion of veratrine with a few Cc. of hydrochloric acid, the liquid will acquire a deep-red color"—(*U. S. P.*). Veratrine is also dissolved by glycerin (1 in 96 , and olive oi (1 in 56). Bromine water immediately produces a purple color when added to a fresh sulphuric acid solution of veratrine.

Chemical Composition. Veratrine from sabadilla seeds is a mixture of alkaloids and their derivatives (see details, under *Sabadilla*). Care must be taken to distinguish between the different alkaloids bearing the same name, *veratrine*. The *veratridine* of Bosetti (*Amer. Jour. Pharm.*, 1883, p. 263; also see *Sabadilla*) is identical with the veratrine of Weigelin and E. Schmidt.

G. B. Frankforter and L. B. Pease (*Amer. Jour. Pharm.*, 1899, p. 130 found commercial specimens of veratrine to consist chiefly of an alkaloid identical with the *cevadine* of Wright and Luff; this substance was found associated with from 0.8 to 3.8 per cent of an alkaloid insoluble in ether.

Action, Medical Uses, and Dosage.—Locally, veratrine (or its salts) is an irritant. When applied in alcoholic solution, ointment or oleate, it excites a singular sense of heat and tingling, or prickling pain, which, however, does not last long, but is followed by a coolness and more or less numbness; there is seldom redness or vesication unless the preparation is strong and applied with brisk friction. Taken into the nostrils, even in minute quantity, it occasions severe coryza and excessive sneezing. Muscular twitching has resulted from its application in ointment to the face, and sometimes it gives rise to headache, nausea, griping, slight diarrhœa, and depression of the action of the heart. When swallowed it is a violent, irritant poison, causing great acrimony in the parts over which it passes, salivation, peculiar prickling numbness of tongue and mucous membranes, violent vomiting, profuse and sometimes bloody, and bilious diarrhœa (sometimes constipation); weak, irregular and quick pulse; cardiac depression; pallor of face and great faintness; cold sweats; muscular twitching and aching pain along the spine; contracted abdomen and pupils; and occasional extreme pruritis and tinglings which may persist for weeks. In medicinal doses it produces a feeling of warmth in the stomach and bowels, which extends to the chest and extremities. In poisoning by this agent, the stomach should be thoroughly evacuated, and tannin solutions freely given and pumped out. Stimulation should be resorted to to overcome the depression; for this purpose alcoholics, aromatic spirit of ammonia, ammonium carbonate, artificial respiration, etc., may be employed. Veratrine has been recommended internally in *nervous palpitation*, *palsy*, *epileptic convulsions*, *pertussis*, *gouty*, *rheumatic and neuralgic affections*, *dropsy*, etc.; but its efficacy in these affections, except in *sciatica* and *other forms of serere neuralgia*, is not well established. Besides, it is too dangerous a remedy for internal administration, and is seldom, if ever, so employed by Eclectic physicians. The dose is from $\frac{1}{12}$ to $\frac{1}{6}$ grain, 3 times a day, in pill form. One grain of veratrine may be mixed with 12 grains each of liquorice powder and extract of hyoscyamus, and made into 12 pills; one of these may be given every 3 or 4 hours. It is best used in the form of a salt, as the acetate, tartrate, citrate, or sulphate. Veratrine is more frequently used as a local application than as an internal remedy, and even then is considered by many a very dangerous agent. When so used it is chiefly to allay the pains of *superficial functional neuralgias*, for which it is less effective than aconitine, though the latter should be used only in extreme cases, and very cautiously at that. Veratrine is formed into an ointment, liniment, or tincture, in the proportion of from 5 to 40 grains of veratrine to 1 ounce of lard, or oil, etc., a small portion of which is to be rubbed on the affected part for 10 or 20 minutes each time, repeating the application twice a day. Not over 3 or 4 grains must be used in a day, and in ordinary cases only 1 or 2 grains. If the skin is tender or irritated, still less must be used; and if there be a cut or abrasion, it must not be used at all. It is also applied externally in the above-named forms of disease. The doses of veratrine recommended are: For internal use, $\frac{1}{120}$ to $\frac{1}{4}$ grain; endermically, $\frac{1}{8}$ to $\frac{1}{4}$ grain; hypodermatically, $\frac{1}{6}$ grain. The latter occasions much pain, and may produce a local abscess (see *Mixtures* and *Ointments*).

VERATRUM ALBUM.—WHITE HELLEBORE.

The rhizome and rootlets of *Veratrum album*, Linné.

Nat. Ord.—Liliaceæ (Melanthaceæ).

Common Name and Synonyms: *White veratrum; Rhizoma veratri, Radix hellebori albi.*

Illustration: Bentley and Trimen, *Med. Plants*, 285.

Botanical Source.—Veratrum album is a perennial herb, with a fleshy, oblong, somewhat horizontal, premorse rhizome, about the thickness of a finger, blackish or brownish-white externally, whitish or pale yellowish-white internally, having numerous fleshy, brownish-white fibers or true roots. The stem is straight, round, striated, and from 1 to 4 feet high. The leaves are alternate, plaited, broad-ovate, and acutish. The flowers are yellowish-white, green at the back, 8 lines in diameter, and produced in a terminal panicle; segments spreading, serrulate, and somewhat wavy. In other respects it resembles the *Veratrum viride* (L.).

History and Description.—White hellebore inhabits Europe, especially the Alpine and Pyrenean districts. Under the name *Veratrum californicum*, Durand, this plant is said to have been found in Colorado and other western states. The part used is the rhizome, though the whole plant is highly noxious. The dried root, as it occurs in pharmacy, consists of a single, double, or many-headed rhizome, cylindrical, or in the form of a truncated cone, from 2 to 4 inches by 1 inch, rough, corrugated, grayish or blackish-brown externally, having a faint, unpleasant odor, and a sweetish, bitter, and then intensely disagreeable, and permanently acrid taste. Diluted alcohol is its best solvent. Its powder is somewhat of an ash color.

Fig. 252.

Veratrum album.

Chemical Composition.—Much confusion, as to the active principles of the root of white hellebore, existed prior to the researches of Wright and Luff (*Jour. Chem. Soc.*, 1878, pp. 338–359, and 1879, pp. 405–426; also see *Amer. Jour. Pharm.*, 1878, p. 489, and 1879, p. 367). Contrary to previous statements by Pelletier and Caventou (1819), Weigand (1842), Weppen (1873), and, in accordance with the views of Dragendorff (1872 and Tobien (1877), these authors established the absence of *cevadine*, the active principle of sabadilla seed (see *Veratrina* and *Veratrum Viride*). They believe the poisonous properties of white hellebore to be due to an amorphous alkaloid, *veratralbine* ($C_{26}H_{43}NO_5$). In addition, the authors found three crystallizable alkaloids, *jervine* ($C_{26}H_{37}NO_4$), discovered by E. Simon, in 1837, and called by him *barytine*, because, like barium salts, it formed an almost insoluble sulphate; *pseudo-jervine* ($C_{29}H_{43}NO_7$); and *rubijervine* ($C_{26}H_{43}NO_3$).

The painstaking researches of G. Salzberger (*Archiv der Pharm.*, 1890, pp. 462–483) have thrown further light on this subject. The author discovered a crystallizable base (*protoveratrine*, $C_{32}H_{51}NO_{11}$) of enormous poisonous activity, and extremely sensitive to alkalies. It is permanent in the air, insoluble in water, benzol, petroleum ether, quite soluble in chloroform, and in boiling (96 per cent) alcohol, little soluble in cold ether, easily soluble in dilute acids, except acetic acid. Its alcoholic solution turns red litmus paper blue, and a trace of its powder excites violent sneezing. The crystals dissolve in concentrated sulphuric acid with greenish color, which turns blue, and, later, violet. Warming with concentrated sulphuric acid produces vapors of isobutyric acid, and the liquid turns dark cherry-red. About 0.03 per cent was obtained from the root. In addition, the author found the following crystallizable alkaloids, all being nearly insoluble in ether, and indications of other alkaloids existing in the root: *Protoveratridine* ($C_{26}H_{45}NO_8$), 0.005 per cent, almost insoluble in alcohol and ether, physiologically inert, and probably a decomposition product of protoveratrine; *jervine* (0.1 per cent crude alkaloid), *pseudo-jervine*, and *rubijervine* (0.005 per cent), which he found of the composition and the general properties assigned to them by Wright and Luff. *Jervine* is feebly toxic, and is the most abundant of the veratrum alkaloids. Its salts, with sulphuric, hydrochloric, and nitric acids are very little soluble in water. The two other bases are physiologically inert. Wright and Luff's *veratralbin* is considered by Salzberger as not sufficiently characterized chemically. The root also contains a green, fatty oil and a volatile oil of a delicious and permanent anise flavor.

Action, Medical Uses, and Dosage.—White hellebore is a violent irritant poison, occasioning, when snuffed up into the nostrils, severe coryza. When swallowed, it causes sore mouth, swelling of the tongue, gastric heat, and burning, severe vomiting, and often profuse diarrhœa. Vertigo, weakness, and tremors of the extremities, feeble pulse, loss of voice, dilatation of pupils, spasms of the ocular muscles, blindness, cold sweating, and mental disturbances are also produced. When it proves fatal, narcotic symptoms are superadded, such as prolonged stupor and convulsions. Gastro-intestinal inflammation has also been produced by it. When not fatal, distressing præcordial oppression persists for some time, and there are produced nervous and spasmodic symptoms and prolonged debility. It was formerly administered as an emetic and purgative in *insanity*, as a diaphoretic in *some diseases of the skin*, and as a sternutatory, in combination with some other powder to modify its action, in *headache*, *amaurosis*, and *ophthalmia*. Poisoning by white hellebore may be treated by coffee as a drink and in injection, with stimulants to overcome the depressed condition of the heart and arteries, and opiates and demulcents to relieve internal inflammation. At present it is rarely used, except in the form of decoction or ointment, as an external application to kill *lice*, and cure the *itch*, *pruritis*, and some other *cutaneous affections;* but, used thus, it is not always free from danger. It has been used for the cure of *gout*, as a substitute for the *Eau Médicinale of Husson;* 3 parts of the wine of white hellebore added to 1 part of laudanum, was given in doses of from ½ to 2 fluid drachms. Minute doses of a tincture of Veratrum album are efficient in bowel disorders, with gushing, watery evacuations, there being more or less cramp-like or spasmodic action in the muscular fibers of the intestines and abdominal walls. It has thus been employed in *cholera infantum*, *cholera morbus*, in both of which it also checks the vomiting, and in *Asiatic cholera.* For these uses the 3x dilution may be added to water in the proportion of 30 drops of the tincture to 4 fluid ounces of water, the dose of which, in severe cases, is a teaspoonful every 15 minutes. For its earlier uses, the dose of the powder is from 1 to 8 grains, gradually and cautiously increased, commencing with 1 grain; of the vinous tincture, from 20 to 60 minims. Its use always requires great care.

Specific Indications and Uses.—Gushing watery discharges from the bowels, with spasmodic or cramp-like action of the intestines and abdominal parieties; cold face; sunken eyes; body covered with cold sweat.

Related Species.—*Veratrum album* var. *Lobelianum*, Bernhardt (*Veratrum album* var. *viridiflorum* of Mertens and Koch), is a European plant closely related to white and American hellebore. Its chief difference consists in its having bracts of a greater length, and a simpler inflorescence, the blossoms of which are pale-green. Tobien (1877) found *jervine* and *veratroidine* in both the rhizome and young leaves of this species.

VERATRUM VIRIDE (U. S. P.)—VERATRUM VIRIDE.

"The rhizome and roots of *Veratrum viride*, Solander"—(*U. S. P.*) (*Veratrum album* var. *viride*, Baker; *Melanthium virens*, Thunberg).

Nat. Ord.—Liliaceæ.

Common Names and Synonyms: *American hellebore*, *Swamp hellebore*, *Indian poke*, *Itch weed*, *Green hellebore*, *Green veratrum; Veratri viridis rhizoma* or *radix.*

Illustration: Bentley and Trimen, *Med. Plants*, 286.

Botanical Source.—This plant has a perennial, thick and fleshy rhizome, its upper portion tunicated, its lower half solid, and sending forth a multitude of large, whitish roots. The stem is from 3 to 5 feet high, roundish, solid, striated, pubescent throughout the greater part of its length, and closely invested with the sheathing bases of leaves. The lower leaves are large, from 6 to 12 inches long, half as wide, oval, acuminate, pubescent, strongly plaited and nerved, the lower part of their edges meeting round the stem; the upper leaves are gradually narrower; the uppermost, or bracts, are linear and lanceolate; all alternate. The flowers are numerous, green, in compound racemes axillary from the upper leaves, and terminal; the whole forming a sort of panicle. Peduncles roundish and downy. Bracts are boat-shaped, acuminate, and downy. Pedicels many times shorter than the bracts. The perianth is divided into 6 green, oval, acute, nerved segments, of which the alternate ones are longest; all the segments are contracted at the base into a sort of claw with a thickened or cartilaginous edge. The stamens 6, with recurved filaments and roundish 2-lobed anthers. Carpels 3, cohering, with acute, recurved styles as long as the stamens. A part of the flowers are barren, and have only the rudiments of styles, so that the plant is strictly polygamous. The seed-vessel is composed of 3 capsules, united together, separating at top and opening on their inner side. Seeds flat, winged, and imbricated (L.).

History and Description.—This plant is so closely related to *Veratrum album*, the European species, that some botanists have regarded the two species as identical. Others have declared it a variety of the latter, while still others seem to regard it as distinct. Though very closely related, it differs somewhat in its constituents, probably sufficiently so as to retain it as a distinct species. American hellebore is indigenous to the United States and Canada, growing in swamps, low grounds, and moist meadows, usually associated with Skunk-cabbage (*Symplocarpus fœtidus*, Nuttall), and flowering in June and July. The medicinal virtues of the drug seem to reside in the rhizome alone. In this connection Mr. Frederick V. Coville, botanist to the *United States Department of Agriculture*, in a letter to J. U. Lloyd (Jan., 1899), writes: "I have never been able to understand clearly the poisonous character of this plant. Various of the older authors in the East have stated that the stems and leaves were poisonous. In the mountains of Oregon, however, where the plant grows in abundance, it is considered one of the very best of sheep foods, and passes under the name of *Wild Indian corn*. The sheep fatten on it in the spring and early summer. Either the western plant is a distinct species or variety, which I doubt, or the leaves and stems are not poisonous." At least the *dried* leaf-stalks which sometimes occur attached to the rhizome were found inert by Prof. Maisch, but contained a saponaceous principle (*Amer. Jour. Pharm.*, 1864, p. 98). The official part is the rhizome, which should be gathered in autumn, after the decay of the leaves. As it rapidly loses its virtues, it should be renewed annually, and kept in well-closed vessels. When fresh, it has a very strong, unpleasant odor; when dried, it is nearly inodorous, and has a sweetish-bitter taste, succeeded by a persistent acridity. Its physical and therapeutical properties strongly resemble those of the White hellebore (*Veratrum album*). The drug is officially described as follows: "Rhizome upright, obconical, simple or divided, from 3 to 8 Cm. ($1\frac{1}{5}$ to $3\frac{1}{5}$ inches) long, and 2 to 4 or 5 Cm. ($\frac{4}{5}$ to $1\frac{3}{5}$ or 2 inches) thick; externally, blackish-gray; internally, grayish-white; showing numerous short, irregular wood bundles. Roots emanating from all sides of the rhizome, numerous, shrivelled, light yellowish-brown, about 10 to 20 Cm. (4 to 8 inches) long, and 2 Mm. ($\frac{1}{12}$ inch) thick. Inodorous, but strongly sternutatory when powdered; taste, bitterish and very acrid"—(*U. S. P.*).

Fig. 253.

Veratrum viride.

Chemical Composition.—Thomas R. Mitchell (*Amer. Jour. Pharm.*, Vol. IX, 1837, p. 181) found the rhizome of Veratrum viride to contain gum, resin, starch, red coloring matter, wax, sugar, a bitter principle probably analogous to veratrine, and gallic acid. The alkaloidal constituents were subsequently studied by several investigators, with somewhat contradictory results. (For a summary of these researches see J. U. Lloyd, in *The Western Druggist*, Oct., 1897.) In 1879 Messrs. Wright and Luff found the alkaloids of Veratrum viride to consist to about one-half of *cevadine*, the sternutatory, ether-soluble alkaloid of sabadilla seeds; the other half consisted of the ether-insoluble alkaloids *jervine*, *pseudojervine*, and *rubijervine*, with a small quantity of *veratrine* and a trace of *veratralbine* (compare *Veratrum Album* and *Sabadilla*). The total quantity of alkaloids isolated by Wright and Luff was only 0.08 per cent. S. C. Pehkschen obtained from the rhizome 0.08 per cent of crude total alkaloids (*Amer. Jour. Pharm.*, 1891, pp. 196–200, from *Pharm. Zschr. f. Russland*); they consisted chiefly of *jervine*, with a small quantity of *veratroidine*, an ether-soluble alkaloid obtained by Charles Bullock in 1865 (see *Amer. Jour. Pharm.*, 1875, p. 449; also see A. Tobien, *ibid.*, 1878, p. 122).

Action, Medical Uses, and Dosage.—American hellebore exerts an influence upon the system quite similar to that of White hellebore (*Veratrum album*, which see). Veratrine does not represent the action of this plant, which contains but a small proportion of this body. Applied to the skin, veratrum is rubefacient, and to the nose, excites sneezing. Small doses of veratrum appear, at first, not to affect the frequency of the pulse, but to lower its force; it afterward slows the pulse, it becoming moderately full and soft, and remaining so, unless the patient, during this stage of depression, attempts to rise or makes any exertion when the pulse becomes very rapid, small, thready, and sometimes almost imperceptible. During the stage of depression, there is marked muscular weakness and relaxation, and nausea and vomiting take place, the contents of the stomach being evacuated first, and then those of the gall-bladder. Occasionally, a watery diarrhœa is caused by veratrum, sometimes amounting to hypercatharsis, but, as a rule, purging is not produced. The nausea produced by veratrum is intense, and the vomiting severe and often persistent, making it, therefore, an unsafe emetic. The most characteristic action of veratrum is its effects upon the movements of the heart and upon vascular tonus. The pulse-rate has been lowered to 35 beats a minute with this agent, a corresponding depression of force accompanying this action. When such depression is reached, it is seldom that emesis can be prevented. In large doses, it is a very dangerous agent, yet, singularly, fatalities from its use are rare. Toxic doses produce an exceedingly weak heart-action, almost indistinguishable, running pulse, reduced temperature, cold, clammy sweat, extreme retching, and incessant vomiting, dizziness, faintness, failure of sight, pupillary dilatation, complete muscular prostration, slow, shallow breathing, sleepiness, coma, and unconsciousness, with sometimes stertorous breathing. The prompt emesis induced by this agent, undoubtedly prevents lethal effects. The exact action of the alkaloidal constituents is yet undetermined, as well as the effect each produces in the sum total of the effects of the root. According to Wood, the drug is a spinal and arterial depressant having no direct action upon the spinal centers; the direct action of jervine upon the heart-muscle, and the stimulation of the inhibitory nerves by veratroidine lower the pulse-rate; the force of the heart-beat is lowered by the direct action of jervine upon the heart-muscle, while the same constituent, according to dose, produces a more or less complete vaso-motor paralysis. The depression of the spinal-motor centers is attributed to jervine. The emetic action of veratrum is said to be due to the combined action of veratroidine and the resin. Death from veratrum is caused by asphyxia. All vaso-motor depressants and all agents which diminish the vital force, favor the action of veratrum. Nausea is always the signal for suspension of the administration of the drug. In poisoning by veratrum, withdrawal of the drug and free stimulation will quickly overcome the depression. Large draughts of warm water may be given to encourage and assist emesis until the stomach has been thoroughly washed out. This should be followed by undiluted whiskey or brandy, to check the vomiting. Opium or morphine may be given by mouth or otherwise, ammonia and alcoholics may be used by enema or hypodermatically, and strychnine or digitalis may be given by the latter method. External heat, sinapisms, friction, etc., must be utilized, and, under no circumstances, must the patient be allowed to rise from the recumbent position, not even to raise the head to vomit.

Therapeutically, veratrum is a remedy of great value and power, though quite transient in its effects. Small doses do good work when indicated, but they must follow each other at short intervals, so that a continuous action may be kept up. Owing to its tendency to induce gastric irritability, with nausea, large doses are not tolerated, and small doses are contraindicated when the tongue becomes long and pointed and reddened at the tip, and nausea and other unpleasant gastric phenomena are present. Veratrum increases secretion from the lungs, kidneys, and liver, but depresses the circulatory system. It is not adapted to asthenic troubles, but proves an admirable remedy in *sthenic conditions*, with the full, bounding pulse. Early in the nineteenth century, Prof. Tully called attention to the value of veratrum in *gout*, *rheumatism*, etc., declaring it equal, if not superior, to colchicum. Dr. Osgood (1835) affirmed it to be an excellent agent in all diseases in which it is required to diminish the activity of the heart and arteries, and his observations have been subsequently confirmed. It not only lessens excited cardiac action, but lessens temperature and restores suppressed secretions. (For Norwood's account of the action of veratrum, see *American Dispensatory*, 17th and preceding editions.)

Veratrum is a positive arterial sedative in *sthenic inflammations* and *fevers*, when not contraindicated by gastric irritability. The popularity of veratrum, as a specific agent, is due most largely to the writings of Prof. J. M. Scudder, M. D., who believed that veratrum was preferable to aconite in *sthenic diseases*, *high grades of fever*, *pulmonary and other active inflammations* (see *Aconitum*). He declared it the remedy when there is a frequent, but free, action of the heart, where there is active capillary circulation, and in *serous inflammations*, when there is a full and hard pulse, a full and bounding pulse, or a corded or wiry pulse. In *determination of blood to the brain*, and in *active delirium*, he employed veratrum in conjunction with gelsemium. He also found it of service where it was desirable to increase the action of the excretory organs. He says of veratrum: "It lessens the frequency of the pulse in both large and small doses. In large doses, the sedative action is a real depression of life, and the circulation is really impaired. Such an action may be temporarily borne in sthenic fevers and inflammation, and may be attended with good results. Yet, as it can not be continued for any considerable length of time, and can only be resorted to in high grades of action, it is better to depend upon small doses, which improve innervation through the sympathetic, remove obstructions to the free circulation of blood, also irritability of the circulatory system, the power of which it increases. Veratrum, in small doses, gradually lessens the frequency and hardness of the pulse, and promotes a uniform and equal circulation."

Prof. Scudder further says of veratrum (*Specific Medication*, pp. 262–63): "In small doses, veratrum is a stimulant to all the vegetative processes. Acting through the sympathetic or ganglionic system of nerves, it removes obstruction to the capillary circulation, gives tone to the vascular system, and strength to the heart. As the obstacles to a free circulation are removed, and the vessels through which the blood is distributed and returned, regain their normal condition, there is less necessity for increased action upon part of the heart, and, as the power of the heart is increased, there is less necessity for frequent contraction. I give this as a theory of the action of veratrum, but whether true or not, there is no question with regard to the facts as above stated."

Veratrum is a remedy for active febrile and inflammatory diseases of the respiratory tract of the sthenic type. In these disorders, it moderates the flow of blood, increases secretion, allays nervous irritation, brings down the temperature, and subdues inflammation. The hard, full, bounding pulse is the guide here as elsewhere. Prof. Webster speaks of it as being specially indicated in the early stage of "inflammation of the area of distribution of the bronchial arteries." A gargle of veratrum is useful in *inflamed sore throat*. All *sthenic inflammations of the throat* are controlled by it. It is an excellent agent in *acute tonsilitis*, when indicated, and often painting the tincture alone upon the tonsils will check the disease. Very small amounts, however, should be used in this manner, and then only in the robust. Veratrum, when indicated by the full, bounding pulse, is an excellent sedative in *acute pneumonia* in the first stage, but only in markedly sthenic cases. The dose should be small and frequently repeated, until the temperature and circulation respond, when the pain will be lessened, nervous excitation allayed, secretion re-established, and cough controlled. It is equally of value in *pleurisy* (usually with bryonia), and in *acute bronchitis*, when specifically used. Veratrum is a valuable expectorant, and is of marked value in *chronic pulmonary affections*, to control the circulation, and thereby regulate the temperature, besides acting as a powerful and efficient alterative. In *phthisis*, especially in the early stage, it controls the violent circulation and temperature, facilitates expectoration, and exerts a beneficial influence over the sympathetic system, controlling restlessness and excitement, and quieting cough. It is very frequently of service in *chronic bronchitis*, and in *chronic pneumonia*. It is valuable in *hæmoptysis*, when the circulation is strong and violent. Prof. Howe regarded it as one of the best alteratives that could be used in chronic lung troubles, being especially valuable in *pulmonary consumption* for this, and for the control of the inflammatory condition.

When indicated, veratrum is a remedy of great power in *peritonitis*, especially *puerperal peritonitis* and *pelvic peritonitis*, from septic absorption. Here the inflammation must be speedily checked, and quite large doses may be required—2 drops of specific veratrum may be given every ½ hour (if it does not provoke nausea), and continued until sedation is effected, when the remedy may be continued in fractional doses. Veratrum has won laurels in *peritoneal inflammations*. It is also a remedy of importance in properly-selected cases of *nephritis*, *cystitis*, *hepatitis*, *ovaritis*, and *orchitis*. For inflammations, arising from blows or kicks upon the abdomen, it is the best-known remedy. It is often useful in active forms of *acute gonorrhœa*, and may prevent *chordee*, and, in *acute inflammatory rheumatism*, it may be given to control pain and promote elimination. Veratrum has been justly praised as a remedy for *erysipelas*. It may be used both topically and internally. It is best adapted to that form showing tumefaction and redness, simulating ordinary inflammations. It has been successfully used, internally and locally, for the relief of *poisoning by Rhus Toxicodendron*. *Boils, carbuncles, inflamed pimples, felons, ulcers*, with heat and tumefaction, *cellular inflammations*, and *labial herpes* are well treated by painting specific veratrum upon them.

Prof. A. J. Howe stated that, "as an alterative, Veratrum viride takes a high rank. It improves the appetite, and favors assimilation by exciting to action the lacteals and lymphatic system generally. In *scrofula, constitutional syphilis, cancer*, and *tetter*, it can be employed as an internal remedy to great advantage. It tends to correct the menstrual function, restraining a too frequent and profuse flow, and exciting to greater activity a scanty and tardy menstruation." Veratrum is a useful agent in some nervous disorders. "It relieves irritation of the nervous system, by lessening the momentum of blood to and through the nerve centers" (Scudder). When *convulsive disorders* depend upon an excited circulation, it proves a powerful remedy. Few remedies have been more praised than veratrum in *puerperal eclampsia*. There is marked cerebral engorgement, and the indications for veratrum must be present, as in other disorders, for one to get good results from this agent. The dose must be quite large, and be regulated according to the sedation produced. It is of value in other forms of convulsions, especially in children, when active cerebral hyperemia is a feature. It is of special value in undue *excitement of the spinal nervous system*, in *spinal irritation, spinal convulsions, cerebro-spinal meningitis*, and *acute mania*, all with excited circulation. When *neuralgia* and *headache* are due to irritation of the nerve centers, with hyperemia, it proves a useful drug; usually, however, it is of little value in headache, unless accompanied with elevation of temperature. It will restore quiet and allow sleep in *delirium tremens*, when the pulse is full and bounding, and the eyes red and bloodshot, with evidence of inflammation" (Locke).

Beginning with small doses, and progressively increasing to 12 drops of the tincture, and again reducing the dose, veratrum has been accredited with favorably influencing *exophthalmic goitre*. Veratrum has been given with digitalis in the early stage of *dropsy*, where there is rapid heart-action, and a sedative is required. It is a good remedy in *aneurism*, to retard the velocity of the blood-current, and to reduce the vaso-motor tonus. *Heart disorders* are often relieved by it. Thus it controls *palpitation*, with violent circulation, and especially the irritable heart, produced by the use of tobacco. Palpitation, due to *cardiac hypertrophy*, is quieted by it, when valvular incompetence is not a factor. "In these cases, the pulse is full, strong, and intense, the carotids pulsate forcibly, the eyes are bloodshot, and there is cough, headache, and weight in the upper epigastrium, while the heart may beat so violently as to shake the bed, and sleep is entirely prevented. This remedy relieves the excitement, the heart-action becomes normal, the cough improves, and the patient is in every way better" (Locke). The dose for this purpose is 1 drop, in water, 5 or 6 times a day.

Prof. Foltz (*Dynam. Therap.*) always employs veratrum after cataract operations, and uses, locally, for *mastoid disease*, the following: R Aconite, veratrum, āā, flʒii to flʒiv; aqua, fl℥iv. Mix. The dose of tincture of veratrum is from 1 to 10 drops (gradually increased until some effect is produced), every 2, 3, or 4 hours; of the extract, or inspissated juice (both of which are seldom used), ¼ grain, carefully increased as required; of the powdered root (seldom used), from 4 to 10 grains; of the fluid extract, from a fraction of a minim to 5 minims; of specific veratrum, from a fraction of a minim to 5 minims.

Specific Indications and Uses.—Pulse frequent and full; tissues full, not shrunken; surface flushed with blood; pulse rapid, bounding; pulse rapid, full, corded, or wiry; marked arterial throbbing; increased arterial tension, with bloodshot eyes; sthenic fevers and inflammations; erysipelas, appearing like ordinary inflammation; red stripe along center of tongue; irritation of nerve centers, due to an excited circulation; convulsions from active, cerebral hyperemia.

VERBASCUM.—MULLEIN.

The leaves and tops of *Verbascum Thapsus*, Linné (*Verbascum Schraderi*, G. Meyer). *Nat. Ord.*—Scrophulariaceæ.

Botanical Source.—Mullein is a biennial plant, with a straight, tall, stout, woolly, generally simple stem, occasionally with 1 or 2 branches above, winged by the decurrent bases of the leaves, and from 3 to 5 feet high. Its leaves are alternate, oblong, acute, decurrent, indented at the margin, rough, and densely tomentose on both sides. The flowers are of a golden-yellow color, rotate, nearly sessile, in a dense, spiked, club-shaped raceme; calyx 5-parted and downy; corolla 5-lobed, rotate, lobes broad, rounded, and somewhat unequal; stamens 5, the two lower smooth, the rest downy. Capsule or pod ovoid-globose, 2-valved, and many-seeded (W.—G.).

Fig. 254.

Verbascum Thapsus.

History, Description, and Chemical Composition.—Mullein is common to the United States, growing in recent clearings, along the sides of roads, in uncultivated fields, etc., flowering from June to August. Some botanists consider it to have been introduced from Europe. The leaves and flowers are the parts used. They have a faint, rather pleasant odor, resembling that of a mild narcotic, and a somewhat bitterish, albuminous taste, and yield their virtues to boiling water. The leaves of *V. Thapsus* contain a trace of volatile oil, wax, some tannin, resin soluble in ether (0.78 per cent), resin insoluble in ether (1 per cent), sugar, etc., and an amorphous, non-glucosidal, bitter principle, soluble in water, ether, alcohol, and chloroform (A. Latin, *Amer. Jour. Pharm.*, 1890, p. 71). The flowers, according to E. L. Janson (*ibid.*, p. 600), besides mucilage, dextrose, etc., contain glucosidal coloring matters, mixed with resins; the seeds, which have a somewhat acrid taste, yielded 20.75 per cent of a green, fatty oil; their acrid principle is soluble in alcohol, water, and petroleum ether. The corolla of *Verbascum phlomoides*, Linné, and *Verbascum thapsiforme*, Schrader (*Verbascum Thapsus*, G. Meyer), are the official species of the *German Pharmacopœia*.

Action, Medical Uses, and Dosage.—Mullein is demulcent, diuretic, anodyne, and antispasmodic. It is likewise said to possess marked antiperiodic virtues. Besides, it is mildly nervine, controlling irritation, and favoring sleep. Upon the upper portion of the respiratory tract its influence is pronounced, particularly where the larynx and trachea are involved. The infusion is useful in *coughs, protracted colds, catarrh, hemoptysis, diarrhœa, dysentery*, and *piles*. It is applicable to dry, hoarse coughs, which occur chiefly at night, as well as to cough associated with an abundant catarrhal discharge. Its diuretic properties are rather weak, yet it is very useful in allaying the acridity of urine, which is present in many diseases. It may be boiled in milk, sweetened, and rendered more palatable by the addition of aromatics, for internal use, especially bowel complaints. A fomentation of the leaves also forms an excellent local application for *inflamed piles, ulcers*, and *tumors*. The leaves and pith of the stalk form a valuable cataplasm in *white swellings*, and when infused in hot vinegar or water it makes an excellent poultice to be applied to the throat in *tonsilitis, malignant sore throat*, and *mumps*. The seeds, it is said, will rapidly pass through the intestines, and have been successfully used in *intestinal obstructions*. They are narcotic, and have been used in *asthma, infantile convulsions*, and to poison fish. The infusion may be drank freely. The flowers, placed in a well-corked bottle, and exposed to the action of the sun, are said to yield an excellent relaxing oil. This oil is also valuable in some cases of *deafness*, used locally for its effect upon the membrana tympani, and upon the secretion of cerumen. The same oil, in doses of 1 to 10 drops, is said to give excellent results in *nocturnal enuresis* and in *vesical irritation*, caused by alkaline urine; it is also reputed a good agent to control painful micturition, in *lithæmia, chronic cystitis*, and *urinary calculus*. The leaves, dried and smoked like tobacco, are often useful in *asthma* and *laryngeal affections*. The dose of specific verbascum is from 1 to 30 drops.

Specific Indications and Uses.—To quiet nervous irritation, bronchial irritation and cough, and urinary irritation with painful micturition.

VERBENA.—VERVAIN.

The root of *Verbena hastata*, Linné.

Nat. Ord.—Verbenaceæ.

COMMON NAMES: *Common vervain, Wild hyssop, Simpler's joy, Vervain.*

Botanical Source.—Vervain, sometimes known by the names of *Wild hyssop*, or *Simpler's joy*, is an erect, tall, elegant, and perennial plant, with an obtusely 4-angled stem, 3 or 4 feet high, having opposite, paniculate branches above. The leaves are opposite, petiolate, lanceolate, acuminate, rough, and incisely serrate; the lower ones are often lobed, or somewhat hastate. The flowers are small, purplish-blue, sessile, tetrandrous, in long, erect, slender, imbricated, terminal and axillary, panicled spikes. Calyx 5-toothed; corolla funnel-form; limb 5-cleft, and nearly equal; seeds 4 (W.—G.).

History and Description.—Vervain is indigenous to the United States, growing along roadsides, and in dry, grassy fields, flowering from June to September. The root is the part used; it is woody and fibrous, faintly odorous, and of a bitter, somewhat astringent, nauseous taste, and imparts its properties to water. Sometimes the leaves are used instead of the root, but they are less active.

Action, Medical Uses, and Dosage.—Vervain is tonic, emetic, expectorant, and sudorific. In small doses a tincture of verbena relieves gastric irritation. As an emetic and sudorific it has proved beneficial in *intermittent fever*, given in warm infusion or in powder. In all cases of *colds* and *obstructed menstruation* it may be used as a sudorific. Taken cold, the infusion forms a good tonic in some cases of *debility*, *anorexia*, and during *convalescence from acute diseases*. It has been reputed valuable in *scrofula*, *visceral obstructions*, *gravel*, and *worms*. The following application has been recommended as effectual in promoting the absorption of the blood effused in *bruises*, and in allaying the attendant pain: Take of vervain, senna, and white pepper, of each, equal parts. Make a cataplasm by mixing with the white of eggs. Dose of the powdered root, from 20 to 40 grains; of the infusion, from 2 to 4 fluid ounces, 3 or 4 times a day, or oftener if it is desired to cause emesis.

Related Species.—There are several species of Verbena, as the *V. urticæfolia*, Linné, or *Nettle-leaved vervain*, with white flowers; the *V. officinalis* var. *spuria*, Linné, with blue flowers, and others, the roots of which possess similar properties, but in a milder degree than the *V. hastata*. The root of *V. urticæfolia*, boiled in milk and water, with the inner bark of *Quercus alba*, and the decoction drank freely, is said to be efficacious in cases of *poisoning by Rhus Toxicodendron*. The root of *V. urticæfolia*, Linné, according to R. M. McFarland (*Amer. Jour. Pharm.*, 1892, p. 401), contains a glucosid having the nauseous, bitter taste of the drug; it is insoluble in ether and petroleum ether, soluble in alcohol and chloroform. Resins and an acid crystalline principle, mucilage, sugar, etc., were also present. The *V. officinalis*, Linné, is a European plant, possessing similar properties with the above, but less active. (Regarding useful plants of Verbenaceæ, see Prof. Maisch, *Amer. Jour. Pharm.*, 1885, pp. 330–335.)

Agnus Castus (*Vitex Agnus Castus*, Linné) (*Nat. Ord.*—Verbenaceæ), *Chaste tree*.—Mediterranean Europe. A small plant of disagreeable odor, bearing terminal spikes of blue or purple flowers, and having berries somewhat like peppercorns, also possessing a pungent taste. Landerer (1835) found the fruit to contain a volatile principle, an acrid oil, and a crystalline, bitter substance named *viticin* and *castin* (see *Amer. Jour. Pharm.*, 1885, p. 332). A tincture of the fresh berries is employed. This agent is reported galactagogue and emmenagogue, and is also said to repress the sexual passions, for which purpose the ancient Athenian women employed it. It has been suggested in small doses in *impotence* and *sexual melancholia*. It is probably a remedy for *sexual irritability*, with nervousness, or melancholia, or mild dementia. A tincture of the root of *Castus indicus* has been employed as an antidote to *venomous bites* and *stings*, and in drop doses has been given for giddiness and salivation.

VERBESINA.—VERBESINA.

The leaves and tops of *Verbesina virginica*, Linne.

Nat. Ord.—Compositæ.

COMMON NAMES: *Crown beard*, *Gravel weed*.

Botanical Source.—This is a tall, perennial plant, found growing in open situations in the southern part of the United States. It has a pubescent, branched stem, which is winged by the decurrent leaves, and grows from 3 to 6 feet high. The alternate leaves are ovate, downy beneath, and irregularly toothed or lobed. They taper at the base to a winged leaf-stalk, and the lower ones are decurrent on the stem. The flower-heads are numerous, and borne in dense, compound terminal corymbs. They have pale-yellow disks, and a few white, oval, fertile rays. The fruit is a flattened, narrowly-winged achenium, bearing a couple of erect awns. The genus Verbesina is an extensive family of American plants, found mostly in Mexico and South America. Three species are indigenous to the United States, *V. virginica*, Linné; *V. Siegesbeckia*, Michaux; and *V. sinuata*, Elliott: all natives of the southern states. Of their chemical constituents nothing is known.

Action, Medical Uses, and Dosage.—This article was introduced into our materia medica in 1880. According to Dr. J. C. Kendrick, of Texas, who has made extensive use of it in his practice, a strong decoction proves a certain diuretic; he has found it almost a specific in *gravel* and in *vesical tenesmus*. He believes that it exerts a solvent effect upon *calculi in the bladder*, but it will require repeated and careful trials before such a belief can be accepted; nevertheless, it certainly deserves to be tested in the cases he has named. The decoction may be used freely.

Related Species.—*Verbesina sinuata*, Elliott. This plant has been found to possess antisyphilitic properties. The root is made into an infusion, which must be drank freely and as largely as the stomach will bear. It is somewhat spicy and agreeable to the taste, and is reputed efficient in both the primary and constitutional forms of the disease.

VERNONIA.—IRON WEED.

The root of *Vernonia fasciculata*, Michaux.

Nat. Ord.—Compositæ.

Botanical Source.—This is an indigenous, perennial, coarse, purplish-green weed, with a tall, striate or grooved, tomentose stem, from 3 to 10 feet in height. The leaves are 4 to 8 inches long by 1 or 2 inches broad, narrow lanceolate, tapering to each end, serrulate, alternate, and smooth above; the lower ones are petiolate. The flower-heads are numerous, in a compact or loose, somewhat fastigiate cyme. The corolla is showy, dark-purple, tubular, and twice as long as the involucre. The involucre is smooth, and ovoid-campanulate; scales appressed, all but the lowest rounded and obtuse, and without appendages (W.—G.).

History.—Iron weed is a very common plant in the western states, growing in the woods and prairies, and along river streams, and flowering from July to September. The root, which is the part used, is bitter, and imparts its properties to water or alcohol.

Action, Medical Uses, and Dosage.—Iron weed is a bitter tonic, deobstruent, and alterative. In powder or decoction, the root is beneficial in *amenorrhœa*, *dysmenorrhœa*, *leucorrhœa*, and *menorrhagia*. In *intermittent*, *remittent and bilious fevers*, the decoction or a saturated tincture has been recommended. Said to have been useful in *scrofula*, and some *cutaneous diseases*. Dose of the decoction, 1 to 2 fluid ounces; of the tincture, 1 to 2 fluid drachms. The leaves or powdered root in the form of poultice make an excellent discutient application to *tumors*.

Related Species.—*Vernonia Noveboracense*, Willdenow, growing in the eastern, western and middle states, and its variety, *V. præalta*, bearing purple flowers, and the *V. tomentosa*, with some other species possess similar medicinal properties (see *Vernonia anthelmintica*, under *Spigelia*). The root of *V. nigritiana*, Oliver, of west Africa, is used in Senegambia, under the name of *batiatior*, as a febrifuge. It contains the glucosid *vernonin* (Heckel and Schlagdenhauffen, *Amer. Jour. Pharm.*, 1889, p. 40).

VERONICA.—SPEEDWELL.

The tops and leaves of *Veronica officinalis*, Linne.

Nat. Ord.—Scrophulariaceæ.

Botanical Source.—This is a roughish-pubescent plant, the stem of which is prostrate, rooting at the base, and from 6 to 12 inches long, with ascending branches. The leaves opposite, vary from ovate to obovate, generally elliptical, short-petioled, obtuse, serrate, mostly narrowed to the base, and 1 inch or 1½ inches long. The flowers are pale-blue, in long, axillary, erect, dense, many-flowered, pedunculate racemes, the pedicles being shorter than the calyx. Calyx 4-parted; corolla rotate. The pods or capsules are puberulent, obovate-triangular, emarginate, strongly flattened, and several-seeded (W.).

History, Description, and Chemical Composition.—Speedwell is a native of Europe, and now very common in North America, growing on dry hills, and in woods and open fields, flowering from April to August. The leaves and tops are employed; they have a faint odor, and a slightly bitter and aromatic taste; water extracts its virtues. J. B. Enz (Wittstein's *Vierteljahrsschrift*, 1858, p. 182; also see F. F. Mayer, *Amer. Jour. Pharm.*, 1863, p. 299) found the fresh juice and extract from the herb to contain a bitter principle soluble in water and alcohol, but scarcely in ether; precipitable by salts of lead, but not by tannin; an acrid principle and a red coloring matter, all contained in the precipitate with neutral acetate of lead, together with malic, tartaric, and citric acids; also, acetic and lactic acids, and a tannin striking a green color with iron; a crystallizable, apparently fatty acid, soluble in alcohol and ether; a soft, dark-green, bitter resin, and mannit. Prof. Mayer found in the dry herb an alkaloid, and obtained a very small yield of a saponaceous principle.

Action, Medical Uses, and Dosage.—Speedwell is an expectorant, alterative, tonic, and diuretic. It was formerly administered in *coughs*, *catarrhs*, *renal*, and *skin diseases*, *jaundice*, etc. Likewise reputed beneficial in *scrofula*, and other diseases where alteratives are indicated, especially the *V. peregrina;* to be given internally, and used as a wash.

Related Species.—*Veronica Beccabunga*, Linné, or *Brook-lime*, is found in most of the eastern and northern states, growing in small streams and near water-courses; this, together with the *Veronica Americana*, Schweinitz; *V. Anagallis*, Linné; *V. scutellata*, Linné; *V. agrestis*, Linné, *Neckweed;* and *V. peregrina*, Linné, possess somewhat similar properties. They all impart their virtues to water. *V. parviflora*, Vahl, indigenous to New Zealand, yields a drug called *koroniko*, which J. Jardine (*Amer. Jour. Pharm.*, 1883, p. 576) praises as being useful in *chronic dysentery*. *Veronica Beccabunga* is antiscorbutic, diuretic, febrifuge, and emmenagogue, and is said to be beneficial in cases of *amenorrhœa*, *scurvy*, *dyspepsia*, *fevers*, and *coughs*. It relieves irritation in several *chronic skin diseases*. The decoction of the plants may be used freely. Brook-lime has no odor, but a saline, bitterish, feebly pungent taste.

VIBURNUM OPULUS (U. S. P.)—VIBURNUM OPULUS.

"The bark of *Viburnum Opulus*, Linné"—(*U.S.P.*) (*Viburnum Oxycoccus*, Pursh).
Nat. Ord.—Caprifoliaceæ.

COMMON NAMES: *High cranberry*, *Viburnum* (*Pharm.*, 1880), *Cramp bark*.

Botanical Source.—This is the *Viburnum Oxycoccus* of Pursh. It is a nearly smooth and upright shrub or small tree, rising 5 to 12 feet in height. The stems are several from the same root, and branched above. The leaves are 3-lobed, 3-veined, broadly wedge-shaped or truncate at base, and broader than long; the lobes divaricate, acuminate, crenately-toothed on the sides, and entire in the sinuses; the petioles have 2 or more glands at the base, and are channelled above. The flowers are white or reddish-white, in rayed, pedunculated cymes; marginal flowers large and sterile; inner flowers much smaller and fertile. Fruit ovoid, red, very acid, ripens late, and remains upon the bush after the leaves have fallen. It resembles the common cranberry, and is sometimes substituted for it. The *V. roseum*, *Snowball*, or *Guelder-rose tree*, is a cultivated European variety, with the whole cyme turned into large sterile flowers (W.—G.). This variety is now largely cultivated in American gardens for its beauty.

History and Description.—This is a handsome, indigenous shrub, growing in low, rich lands, woods, and borders of fields, in the northern part of the United States and Canada, flowering in June, and presenting at this time a very showy appearance. The flowers are succeeded by red and very acid berries, resembling low cranberries, and which remain through the winter. The bark is the official part. As demanded by the *U. S. P.*, it is in "flattish or curved bands, or occasionally in quills, sometimes 30 Cm. (12 inches) long, and from 1 to 1.5 Mm. ($\frac{1}{25}$ to $\frac{1}{16}$ inch) thick; outer surface ash-gray, marked with scattered, somewhat transversely elongated warts of a brownish color, due to abrasion, and more or less marked with blackish dots, and chiefly in a longitudinal direction with black, irregular lines or thin ridges; underneath the easily-removed corky layer of a pale-brownish or somewhat reddish-brown color; the inner surface dingy-white or brownish; fracture tough, the tissue separating in layers; inodorous; taste somewhat astringent and bitter"—(*U. S. P.*). It has been frequently put up by the Shakers, and is then sold somewhat flattened from pressure. It yields its properties to water or diluted alcohol. *Viburine* is the name that was once given to a secret nostrum, purporting to be obtained from this plant. (For the histology of this species and *V. prunifolium*, see L. E. Sayre, *Amer. Jour. Pharm.*, 1895, p. 386, and 1896, p. 225; also see R. H. Denniston, *Pharm. Archives*, 1898, p. 137.)

Chemical Composition.—The berries of *V. Opulus* contain *valerianic acid* (Dumas; *phocenic acid* of Chevreul, identical with the volatile acid from the fat of the dolphin), and a red coloring matter (Leo, 1834). The bark of this species also contains valerianic acid, identified by Monro (1845), and previously believed to differ from it (*viburnic acid* of Krämer, 1834). In addition, H. Krämer found iron-bluing tannin, and a peculiar, bitter, neutral principle (*viburnin*), an amorphous, white powder, soluble in ether and alcohol, slightly soluble in water (see review of "The Useful Species of Viburnum," by Prof. Maisch, *Amer. Jour. Pharm.*, 1878, p. 49).

Action, Medical Uses, and Dosage.—High cranberry bark is a powerful antispasmodic, and, in consequence of this property, it is more generally known among American practitioners by the name of *Cramp bark*. It is very effective in relaxing *cramps* and *spasms* of all kinds, as *asthma*, *hysteria*, *cramps of the limbs* or other parts in females, especially during pregnancy, and it is said to be highly beneficial to those who are subject to *convulsions during pregnancy*, or at the time of parturition, preventing the attacks entirely, if used daily for the last 2 months of gestation. Like Viburnum prunifolium, it is a remedy for the prevention of *abortion*, and to prepare the way for the process of parturition. It allays uterine irritation with a tendency to terminate in *hysteria*, while in the neuralgic and spasmodic forms of *dysmenorrhœa*, it is a favorite remedy with many physicians. It has been used in *spasmodic contraction of the bladder*, and in *spasmodic stricture*. The doses employed are from a fraction of a drop to 20 drops of specific viburnum. The action of this agent closely resembles that of the black haw, and there is reason to believe that they are often used interchangedly for similar purposes (see *Viburnum Prunifolium*). The following forms an excellent preparation for the relief of spasmodic attacks, viz.: Take of cramp bark, 2 ounces; scullcap, skunk-cabbage, of each, 1 ounce; cloves, ½ ounce; capsicum, 2 drachms. Have all in powder, coarsely bruised, and add to them 2 quarts of good sherry or native wine. Dose, 1 or 2 fluid ounces, 2 or 3 times a day. Dose, of the decoction or vinous tincture of cramp bark, 2 fluid ounces, 2 or 3 times a day; specific viburnum, $\frac{1}{16}$ to 30 drops. "It may be proper to remark here that I have found a poultice of low cranberries very efficient in *indolent and malignant ulcers;* and, applied round the throat in the inflammation and swelling attending *scarlatina maligna*, and other diseases, it gives prompt and marked relief. Probably the high cranberries will effect the same results" (J. King). (See *Vaccinium Macrocarpum* and *Cataplasma Oxycocci*.)

Specific Indications and Uses.—Cramps; uterine pain, with spasmodic action; pain in thighs and back; bearing down, expulsive pains; neuralgic or spasmodic dysmenorrhœa. As an antiabortive.

VIBURNUM PRUNIFOLIUM (U. S. P.)—BLACK HAW.

"The bark of *Viburnum prunifolium*, Linné"—(*U. S. P.*).

Nat. Ord.—Caprifoliaceæ.

COMMON NAMES: *Black haw*, *Sloe*, *Stag bush*, *Sloe-leaved viburnum*.

Botanical Source.—This shrub or tree, also known by the name of *Sloe*, is indigenous to this country, growing to the height of from 10 to 20 feet. Its branches are spreading, some of them often stinted and naked, giving the plant an unthrifty aspect. The leaves are about 2 inches long, nearly as wide, roundish-ovate, smooth, shining above, obtuse at both ends, acutely serrate, with uncinate teeth, and situated on short petioles, slightly margined with straight, narrow wings. The flowers are white, in large, terminal, sessile cymes. The fruit consists of ovoid-oblong, sweet, edible, blackish berries (W.—G.). It contains a single stony nut. There is a variety in the south called the Possum haw (*V. prunifolium* var. *ferrugineum*), differing from the black haw in having lance-oval leaves, rusty beneath, and tasteless fruit.

History and Description.—*Viburnum prunifolium* belongs to the honey-suckle family—an extensive family, numbering about 80 species, distributed over North and South America, Europe, and Asia. About 12 species are indigenous to the United States, forming, in the northern states, a considerable portion of the undergrowth of woods. The *V. prunifolium*, the most valuable of the genus Viburnum, is popularly known as the Black haw, the Sloe-leaved viburnum, and the Sloe. It grows from Connecticut to Illinois, and in the south, where it is most abundant. It thrives in dry woods and thickets, and on rocky hillsides in fertile soil, reaching a height of from 10 to 20 feet. The branches are spreading, somewhat stunted, and often give to the shrub an unthrifty appearance. It flowers from March to June, and presents, at this time, a very handsome appearance. It is usually found in woods and thickets. The bark of the roots, stem, and branches are medicinal, but that of the root is preferred by Eclectics. It is fawn-colored externally, with a feeble odor, and a very bitter, slightly aromatic taste. As described by the *U. S. P.*, viburnum occurs "in thin pieces or quills, glossy purplish-brown, with scattered warts, and minute black dots; when collected from old wood, grayish-brown; the thin, corky layer easily removed from the green layer; inner surface whitish, smooth; fracture short; inodorous, somewhat astringent, and bitter"—(*U. S. P.*). Water or alcohol extracts its properties. The leaves of the black haw have been used for tea. The bark is readily pulverized when dry, and affords a reddish-colored powder, tinged with gray. (As to its distinction from *V. Opulus*, see literature indicated under the latter; also see *Chemical Composition*, below.)

Chemical Composition.—According to analysis by Herman Van Allen (*Amer. Jour. Pharm.*, 1880, pp. 439–443), the bark of *V. prunifolium* contains a brown, bitter resin; a greenish-yellow, bitter resin, identical with Krämer's *viburnin* (see *V. Opulus*); a volatile acid, answering to all the tests of *valerianic acid;* tannic, oxalic, citric, and malic acids, sulphates and chlorides of calcium, magnesium, potassium, and iron. Prof. L. E. Sayre (*Amer. Jour. Pharm.*, 1895, p. 392) reports on the quantity of chloroformic extract obtainable from *V. Opulus* (5.98 per cent) and *V. prunifolium* (9.46 per cent), and their solubilities toward water, petroleum spirit, and alcohol (80 per cent), successively employed. Water extracted only about 0.1 per cent in both cases; petroleum spirit removed from the former 1.66 per cent, from the latter, 7.8 per cent; alcohol then extracted 2.44 per cent of resin from the former, and only 0.75 per cent from the latter.

Action, Medical Uses, and Dosage.—Of the physiological action of this agent little is known. To the taste it is bitter, and slightly aromatic. Large doses sometimes produce nausea and vomiting, and by some observers is said to produce contraction of the uterine muscular tissue. That it has a decided affinity for the female reproductive organs is well established. By Dr. D. L. Phares, of Mississippi, who brought the remedy forward, it was described as having nervine, antispasmodic, tonic, astringent, and diuretic properties. To these Prof. King adds alterative. Decoctions of the drug were formerly used as a gargle in *aphthæ*, as a wash in *indolent ulcers*, and in various *ophthalmic disorders*. By its astringency it has proved of value in *diarrhœa* and *dysentery*. It has been recommended in *jaundice*, but we have a better agent in chionanthus. *Palpitation of the heart* is said to have been relieved by it. Such cases are sympathetic disturbances, generally near the menstrual period. Its principal use at the present day is in disorders of the female organs of reproduction. As a uterine tonic it is unquestionably of great utility. It restores normal innervation, improves the circulation, and corrects impaired nutrition of these organs. In the *hyperæsthetic*, or *irritable condition of the uterus* incident to highly nervous women, or as the result of overwork, it will be found an admirable agent. It is called for in weakened conditions of the body, with feeble performance of the uterine functions. In *dysmenorrhœa*, with deficient menses, *uterine colic*, and in those cases where there are severe lumbar and bearing-down pains, it will prove an efficient drug. Helonias is also an excellent agent in the latter condition. It is specifically indicated in cramp-like menstrual pains—pains decidedly expulsive and intermittent in character—and in the various painful contractions of the pelvic muscles, so common to disorders of women. *Uterine congestion* and *chronic uterine inflammation* are often greatly relieved by specific black haw. It acts promptly in *spasmodic dysmenorrhœa*, especially with excessive flow. *Menorrhagia* due to malaria is promptly met with Viburnum prunifolium. It is a good remedy for *uterine hemorrhage*, attending the menopause. In *amenorrhœa* in pale, bloodless subjects, the menses are restored by it. *Cramps of limbs* attending pregnancy yield to both black haw and cramp bark. It is considered almost specific for *cramp in the legs*, not dependent on pregnancy, especially when occurring at night. The condition for which black haw is most valued is that of *threatened abortion*. It is the most prompt drug in the materia medica to check abortion, provided the membranes have not ruptured. In all cases of *habitual abortion* it should be given in small doses for a considerable length of time. The abundant testimony as to its value in this condition alone gives it a high place among drugs. By its quieting effects upon the irritable womb, women who have previously been unable to go to full term have been aided by this drug to pass through the pregnancy without mishaps which would otherwise have proven disastrous to both child and mother. Small doses of the specific black haw should be administered throughout the dangerous period, and may be continued with good results until parturition. Dr. Phares, who introduced it as an antiabortive, states that it will prevent abortion, whether habitual or otherwise—whether threatened from accidental cause or criminal drugging. He considered it to completely neutralize the effect of the cotton bark when this is used for the purpose of causing abortion. It was for a long time customary for planters to compel their female slaves "to drink an infusion of black haw daily whilst pregnant to prevent abortion, from taking the cotton-root" (Scudder, *Spec. Med.*, 266). It has been used to control *postpartum hemorrhage*, but is less effective than ergot and cinnamon. It assists in reducing the size of the womb in *subinvolution* of that organ. Viburnum is of some value in nervous disorders, and has been advised in *chorea*, *hysteria*, *hystero-epilepsy*, *petit mal*, and *paralysis agitans*. It is of service only when these troubles are associated with menstrual wrongs. Viburnum Opulus resembles this agent very closely in its effects, and may be used in the above-named conditions, for which the black haw is useful.

Black haw is said to be of value in *sterility*. Some cases of *spermatorrhœa* are benefited by it. *False pains* of pregnancy are readily controlled, and for *after-pains* it is nearly as valuable as macrotys, or actæa. Black haw promptly allays *ovarian irritation*. The late Prof. Howe considered it one of the very best uterine tonics, and incorporated it with wild cherry and aromatics in his Black Haw Cordial. This he recommended to allay the pangs of *dysmenorrhœa;* to arrest *leucorrhœa*, and to alleviate pelvic discomfort; and as a remedy of value in *chlorosis* and the *debility of the second climacteric*. Prof. Howe compounded the cordial to meet the wants of the alcoholic tippler. It allays the gnawing sensations in the stomach, and relieves the faucial discomfort met with in the inebriate. Specific black haw, in drop doses, is a valuable drug in *obstinate singultus*. The black haw is steadily growing in favor with all schools of medicine. The usual prescription is: ℞ Specific black haw, ʒss to ʒi, aqua ℥iv. Mix. Sig. Teaspoonful every 1 to 4 hours, according to case under treatment. The infusion may be given in ½-fluid-ounce doses, several times a day; or the tincture in doses of 1 fluid drachm, 4 or 5 times a day. The powder may be given in ½ or 1-drachm doses; specific black haw, $\frac{1}{10}$ to 30 drops; Howe's black haw cordial, 1 to 2 fluid drachms.

Specific Indications and Uses.—Uterine irritability, and hyperæsthesia; threatened abortion; uterine colic; dysmenorrhœa, with deficient menses; severe lumbar and bearing-down pains; cramp-like, expulsive menstrual pain; intermittent, painful contractions of the pelvic tissues; after-pains and false pains of pregnancy; obstinate hiccough.

Related Species and Pharmaceutical Preparations.—Several species of Viburnum have been used for medicines, but at present the number is narrowed down to two—*V. prunifolium* and *V. Opulus*. The American Indians, and subsequently the Dutch, employed the *V. acerifolium*, Linné (*Maple-leaved arrow-wood*, *Dockmackie*), as a local application to *tumors*. The bark of the *V. dentatum*, Linné (*Tily* of the Indians), was used by the aborigines as a diuretic.

Viburnum dentatum, *Arrow-wood* or *Mealy-tree*, called by the former name on account of its long, straight, slender branches, or young shoots, is a somewhat smooth shrub, 6 to 12 feet in height, growing in low grounds, damp woods and thickets, throughout the United States, with roundish-ovate, dentate-serrate, furrow-plaited leaves, on long, slender petioles. The leaves are 2 or 3 inches in diameter; upper pair oval, the veins beneath prominent, parallel, pubescent in their axils; flowers white, in pedunculate cymes, appear in June; fruit small, ovoid-globose, dark-blue berries (W.—G.). The bark of this tree is ash-colored, and is employed as a diuretic and detergent, and was once extolled as an internal and external agent to cure *cancer;* the infusion to be used freely. It may also be used in extract, pills, or plaster.

V. Lentago (*Sweet viburnum, Nanny berry, Sheep berry*) was formerly esteemed a valuable antiperiodic. *Viburnum Lantana*, Linné, of Europe, has properties analogous to those of our *V. Opulus*. J. B. Enz (1863) found the red berries of *V. Lantana* to contain iron-greening tannin, valerianic acid, acetic and tartaric acids, a bitter principle, an acrid principle, fatty oil, red coloring matter, resin, sugar, gum, etc.

Viburnum obovatum, Walter, a southern states shrub closely allied to *V. prunifolium*, is used by the people in *malarial conditions.* Its leaves are more persistently bitter than its bark (see *V. Opulus*).

HELONIAS CORDIAL.—This agent is prepared by the Wm. S. Merrell Chemical Co., Cincinnati, Ohio, and represents the active constituents of Helonias dioica, Viburnum Opulus, Caulophyllum thalictroides, and Mitchella repens. It is useful in a large range of *functional disorders of the female reproductive organs*, and reflex troubles arising therefrom.

CELERINA.—This preparation is a nerve tonic, stimulant, and antispasmodic. It represents the combined virtues of celery, kola, coca, viburnum, and aromatics. Celerina is a specialty of the Rio Chemical Co., St. Louis, Mo. It is employed in various nervous affections with *loss of nerve power* in any organ, and as a remedy for the *exhaustion following alcoholic excesses.* Dose, 1 to 2 fluid drachms, 3 times a day.

ALETRIS CORDIAL.—A specialty of the Rio Chemical Co., of St. Louis, Mo., is a preparation of Aletris farinosa, and aromatics. It is designed as a uterine tonic and restorative, and may be employed in *leucorrhœa, amenorrhœa, dysmenorrhœa, sterility,* and in those cases where there is a disposition to *miscarriage.* The dose is 1 fluid drachm, 3 or 4 times a day.

VIBURNUM CORDIAL (Howe).—Recent bark of root of black haw, 20 ounces; recent bark of root of wild cherry, 40 ounces; Ceylon cinnamon, 10 ounces; cloves, 5 ounces; sugar, 7½ pounds; brandy, 2 gallons; water, 1½ gallons. Mix the crushed drugs with the mixed brandy and water; add the sugar, and stir together for 14 days. Then express and filter. (For uses of Howe's Viburnum cordial, see page 2061.)

VINA MEDICATA.—MEDICATED WINES.

By medicated wines we mean vinous tinctures of those medicinal agents which are capable of yielding their virtues to wine, either pure or diluted. As a rule vinous tinctures are much inferior to alcoholic, on account of their tendency to decomposition, and the uncertainty of their strength, and should therefore be made without heat, in limited quantities at a time, and kept cool in well-closed bottles. Wines owe their solvent properties largely to the alcohol which they contain, as well as to the acid (chiefly acid tartrate of potassium) which they usually hold in greater or less proportion; and in the selection of them for medicinal purposes, the purest qualities only should be chosen. *Native wine* forms an elegant medicated wine, when the article is to be used immediately; but if the compound be allowed to stand for any time fermentation and decomposition take place; hence the necessity for the official *stronger wine.* Medicated wines, like tinctures, may be prepared by maceration, or by percolation, or by dissolving the substance in wine.

I. BY MACERATION.—The powdered article or articles are placed in wine, and are allowed to macerate in a closed glass bottle, usually for 14 days, with occasional agitation; after which the articles are expressed if necessary, and filtered through paper or a fine muslin cloth.

II. BY PERCOLATION.—The powdered article or articles are first covered with wine, and allowed to stand until they are moistened throughout, which generally requires from 24 to 36 hours; the whole is then transferred to a percolator, and wine gradually poured on and allowed to percolate or filter until the requisite amount has passed.

The following wine is official, but is not employed in Eclectic practice:

VINUM ANTIMONII (*U. S. P.*), *Wine of antimony, Antimonial wine.*—"Antimony and potassium tartrate, four grammes (4 Gm.) [62 grs.]; boiling distilled water, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with eight hundred cubic centimeters (800 Cc.) [27 fl℥, 24 ♏] of white wine; dissolve the antimony and potassium tartrate in the boiling distilled water, and add the solution to the mixture. When the liquid is cold filter it through paper, and add enough white wine, through the filter, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

VINUM.—WINE.

Vinum Album (*U. S. P.*), *White wine.*—"An alcoholic liquid, made by fermenting the juice of fresh grapes, the fruit of *Vitis vinifera* (*Nat. Ord.*—Vitaceæ), freed from seeds, stems, and skins. When white wine is prescribed without further specification, it is recommended that a dry white wine of domestic production (such as California Riesling, Ohio Catawba, etc.) be employed. White wine should be preserved in well-closed casks, filled as full as possible, or in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Vinum Rubrum (*U. S. P.*), *Red wine.*—"An alcoholic liquid, made by fermenting the juice of fresh colored grapes, the fruit of *Vitis vinifera* (*Nat. Ord.*—Vitaceæ), in the presence of their skins. When red wine is prescribed without further specification, it is recommended that a dry red wine of domestic production (such as a native Claret, Burgundy, etc.) be employed. Red wine should be preserved in well-closed casks, filled as full as possible, or in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Source and Preparation.—Wines, in general, include the fermented juices of all sweet fruits, such as grapes, apples, pears, blackberries, currants, gooseberries, etc. In the special and commonly accepted sense, wine is the alcoholic liquid, produced by spontaneous fermentation of the juice of the grape. The grapes are harvested after they have reached their full maturity. The quality of the wine may be judged beforehand, by the ratio of acid to sugar in the grape; in good seasons, this ratio is about 1 to 30 and higher, in medium years, 1 to 16, in poor years, 1 to 12, below which the ratio seldom falls. If the ratio is 1 to 10, the wine will be sour.

In making *White Wine* (see article on "Ohio Wines," by James O. Howells, in *Amer. Jour. Pharm.*, 1885, p. 324), unripe or decayed grapes are rejected, and the *must* is obtained by passing the grapes between horizontal wooden rollers, placed above large vats. The must represents the liquid portion of the grape (see *Uva*), and the yield is from 60 to 70 per cent. Must contains from 18 to 24 and as high as 30 per cent of sugar, and from 0.4 to 1 per cent of acid, consisting chiefly of potassium bitartrate, with free tartaric and malic acids. The must is allowed to stand in the vats for about 18 to 36 hours, in order to induce slight fermentation, which facilitates the settling of the marc. The must is then drawn off, and the remaining mass expressed in large wine-presses. The must is put into large casks, which are kept nearly full, and a uniform temperature of about 15° C. (59° F.), or less, is maintained. Spontaneous fermentation then proceeds, induced by the access of spores from the air or the grapes to which they adhere. The dextrose of the must is converted into alcohol and carbonic acid, with a small percentage of glycerin and succinic acid (see *Alcohol*). At the temperature indicated, fermentation is moderate, and the yeast and lees settle to the bottom of the cask (*bottom* or *low fermentation*), while, at higher temperatures (15° to 25° C., or 59° to 77° F.), the yeast rises to the surface, and the fermentation is quite rapid (*surface* or *high fermentation*). The former is practiced in Germany, France, and some parts of the United States, while Spanish, Italian wines, etc., are fermented by the second method, and yield a product richer in alcohol, but nearly devoid of the fragrance, or *bouquet*, possessed by the other class of wines. The bottom fermentation lasts from 2 to 4 weeks. The product, called *young wine*, must be transferred to fresh casks ("racking off"), without delay, in order to prevent the formation of acetic acid. The second stage, a *still fermentation* (*after-fermentation*), sets in, lasting for several months, during which time potassium bitartrate (*cream of tartar, argol*) is thrown out in proportion as the quantity of alcohol, in which it is insoluble, increases. Thus it is seen that, in making wine from the grape, a large part of its acidity is automatically thrown out. The aroma (bouquet) of the wine is developed during the third stage of fermentation, which lasts for several years, then the wine is *bottle-ripe*. Meanwhile, it must be repeatedly racked off, in order to separate the lees, which are liable to cause undesirable changes in the wine if in too prolonged contact with it. In order to obtain a clear, limpid wine, it is usually treated with isinglass or gelatin (*fining*).

Red Wines (*e. g.*, American Claret, Burgundy, Bordeaux, etc.) are made from red grapes in the same manner, except that the must is allowed to ferment in contact with the marc, whereby the coloring matter of the skins is dissolved by the alcohol as it forms. This also increases the amount of tannin in the wine, hence the acerbity of some red wines. Precautions must be taken by mechanical means to prevent the marc from rising to the surface, which would induce souring. When the first fermentation is finished, the marc is pressed off, and the wine is put into casks to undergo after-fermentation.

Sweet Wines (*e. g.*, Sherry, Port, Sweet Catawba, Lachrymæ Christi, Tokay, etc.) are made by adding concentrated grape juice or pure cane sugar to the must, whereby a certain percentage remains unfermented, or fermentation of the natural must is checked at a certain stage by the addition of alcohol; or lastly, sugar may be added to the completely fermented wine. Sweet wines are usually made stronger in alcohol than dry wines, in order to prevent subsequent fermentation of their sugar contents.

Effervescing Wines (*Champagnes*) are made from carefully selected wines that have already passed through the first and second fermentation. The clear wines are put into strong bottles, with the addition of a definite quantity of "liqueur," consisting of pure cane-sugar solution and cognac, etc., securely corked and arranged horizontally on wooden racks, where they are exposed to the temperature of summer heat, which induces fermentation of the added sugar. Gradually the bottles are inclined neck downward. The wine becomes clear and limpid, and the yeast and lees settle on the cork. Finally, by quick manipulation, the cork is taken out, the yeast ejected by the pressure of the gas, the loss of wine replaced by "liqueur," and the bottles are again securely corked and stored. The pressure in the bottles is from 4 to 6 atmospheres. Champagne wines are now frequently imitated by impregnating wines with carbonic acid gas.

Diseases and Improvement of Wines.—Wine is subject to various accidents during its manufacture and storage. Of these, the formation of acetic acid or *souring* has been noted above. It takes place quite readily in wines that are weak in alcohol and in tannin. The *ropiness*, *bitterness*, and other defects of wines are mostly due to the access of foreign ferments. In order to guard against these, it is a common practice in the cellar treatment of wines to fumigate the casks with sulphur dioxide from burning strips of sulphur prior to filling them with wine. Another and very efficient method of preserving wine consists in *Pasteurizing*, *i. e.*, the wine contained in bottles or casks is exposed to a temperature of about 60° C. (140° F.), and subsequently kept out of contact with air. The addition of burnt gypsum (plaster of Paris) to the must (*plastering*) is said to bring about a more rapid fermentation, a brighter color and better keeping qualities. The practice is in use especially in southern Europe, and is objectionable, because it converts the potassium bitartrate of the wine into acid potassium sulphate ($KHSO_4$), which remains in solution while neutral calcium tartrate is precipitated. The former salt, if present in large quantities, is not a harmless ingredient (see pharmacopœial limitation, below).

It is often desirable that a poor quality of wine be improved, especially when due to an unfavorable season. Several methods are in use, some of which are rational and ought to be considered perfectly legitimate. Among the more important processes are:

Chaptalizing (named after Prof. Chaptal, of Montpellier). This consists in adding sugar, and neutralizing an excess of tartaric acid by the addition of a calculated amount of calcium carbonate in the form of marble dust or the pure precipitated carbonate. By this method, no calcium enters the wine, unless it contains acetic acid. In the absence of the latter, the method is quite applicable, especially when the excess of acidity is due to free tartaric acid, the amount of which, however, must be accurately determined. Liebig proposed to remove excess of tartaric acid by the addition of a calculated quantity of neutral potassium tartrate, the purpose being to convert the undesirable excess of the free tartaric acid into the little soluble bitartrate. When the free acid is malic acid, this process is not applicable.

Petiotizing (Pétiot, a Burgundy landowner) consists in subjecting the pressed-out marc to a second and probably third fermentation in contact with water and sugar. Advantage is taken of the fact that the first fermentation does not remove all the coloring matter, tannin and bitartrate from the marc. A great number of the French Bordeaux wines of the market are made by this profitable method.

Gallizing (named after its advocate, Dr. Ludwig Gall) aims to correct the composition of a poor quality of must by the addition of sufficient water and sugar to bring it to a normal composition. Dr. Gall considers a normal must to contain 24 per cent of sugar, 0.6 per cent of acid, and 75.4 per cent of water. Analysis of the must will establish the quantities of sugar and water needed for correction. Any excessive addition of water and sugar is indicated by the deficiency in extractive matter (see analysis, page 2066).

Scheelizing (named after Scheele) consists in adding a certain amount of glycerin to the wine in order to correct the taste of very acid, thin wines.

Description, Chemical Composition, and Tests.—There is considerable diversity in the different wines in regard to their flavor and the relative proportions of their constituents, owing to differences in the grape, the climate, soil and management. Wines may be generally classed according to their color into *white* and *red* wines; according to their saccharine contents into *dry* and *sweet* wines, the former being practically free from sugar; according to the quantity of alcohol they contain, we have *light* and *strong* or *generous* wines; another well-known distinction is that between *still* and *sparkling* wines (*Champagnes*). Certain famous wines are named according to the country or district of their origin, *e. g.*, Port, Sherry, Madeira, etc.

American Wines.—In the '50s, the chief American grape used in wine-making was the *Catawba grape*, introduced to the notice of wine-growers by Major Adlum, of Washington, D. C. It was then much cultivated in the vicinity of Cincinnati (see Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1854, p. 411; and E. S. Wayne, *ibid.*, 1855, p. 494). Now we have many American pure wines from native grapes (see *Uvæ*), produced in the wine districts of Virginia, the Lake Erie regions and especially California, the output of the latter state alone in 1893 having been 20,000,000 of gallons. The *U. S. P.* directs the preferment of American-grown wines. *Catawba wines* are rather acid, and, with other American wines, compare favorably in strength, bouquet and appearance with the best wines of central and southern Europe. *American Claret* is a dry, red wine of moderate alcoholic strength. Its French equivalent is *Red Bordeaux wine.* As to foreign wines, suffice it to allude to a few of the more largely employed wines of southern Europe; also see interesting article on "Wines on the Rhine," by Charles A. Lee, in *Amer. Jour. Pharm.*, 1863, p. 324.

Sherry Wine (*Vinum Xericum* of the *Br. Pharm.*, 1898). The original Sherry comes from the vicinity of the Spanish city, Xeres de la Frontera. It is of a pale yellowish-brown or deep-amber color, feebly acid and of an agreeable aroma. According to König (*Die Menschl. Nahrungs- und Genussmittel*, 3d ed., 1894), the alcoholic strength of commercial Sherry varies from 18 to 25 per cent by volume, and its extractive matter from 3 to 5 per cent. Its specific gravity ranges from 0.978 to 0.995. The *British Pharmacopœia* (1898) requires it to contain "not less than 16 per cent of ethyl hydroxide by volume." The *German Pharmacopœia* directs that the southern wines (Sherry, Port, Madeira, Marsala) "should contain in one liter not less than 140 Cc. and not more than 200 Cc. of alcohol." The same authority gives the following directions: "The quantity of sulphuric acid in one liter of wine should not exceed the quantity contained in 2 grammes of potassium sulphate." This is intended to limit excessive plastering, which is practised with many southern wines, especially all genuine Sherry wines (J. König, *loc. cit.*). Imitations of Sherry are numerous, and are often made from cheap wines, with the addition of sugar, raisins, cloves, St. John's bread, etc. The *British Pharmacopœia* (1898) gives directions for the testing of Sherry for salicylic acid. On the Sherry wine industry in Spain, see interesting article in *Western Druggist*, 1897, p. 462, from U. S. Consular reports.

Madeira Wine.—This wine is grown in the Canary Islands, and is obtained by adding to the must a certain quantity of alcohol, which shortens the time of the fermentation. At a later stage, alcohol is again added. The wine has from 18 to 20 per cent alcohol, and from 4 to 6 per cent extract (J. König, *loc cit.*). A special kind of *Dry Madeira* is less sweet and more astringent. Commercial Madeira is also much adulterated.

Malaga Wine (*Vinum Malacense*) is made in the Spanish province of Malaga. It is a sweet wine, of light or dark color, and contains from 13 to 19 per cent of alcohol, by volume, and from 14 to 21 per cent of extract (J. König, *loc. cit.*). Its composition and appearance is regulated in the place of its manufacture by the addition of alcoholized must (for sugar), and an alcoholic extract of the dark grape (for color). A very dark Malaga is made from *arrope*, *i. e.*, a sugar-coloring made from concentrated must by aid of heat. It is an article of commerce in Spain.

Port Wine (*Vinum Portense*) comes from the valley of the river Douro, and enters commerce through Oporto, hence its name. The juice ferments in contact with the fresh grapes, and the wine is finally drawn off; then alcohol is added. In bad seasons all sugar is consumed in the fermentation; then an addition of concentrated must (*jeropiga*), or sugar, is made, The port wine of commerce contains from 15 to 24 per cent of alcohol by volume, and from 3 to 8 per cent of extract. It has been the practice in Portugal to color the wine with the juice of elderberries It acquires its best flavor by age, and deposits a large quantity of coloring matter during its storage in bottles. Port wine of commerce is very seldom genuine. The American port wines are made from grapes grown from vines that were originally imported from Portugal. They resemble true port wine in flavor and appearance, but contain less alcohol (about 14 to 16 per cent by volume).

Marsala Wine is made near the city of Marsala in Sicily. The must is allowed to ferment to a certain degree; then alcohol is added to interrupt fermentation.

For further details regarding the manufacture and treatment of wines, see for example, Prof. S. P. Sadtler's *Handbook of Indust. Org. Chem.*, 2d ed., 1895, and the special literature on the subject indicated therein on page 246.

The Chemical Composition of the different wines is very variable. Their constituents are as follows: Water (80 to 90 per cent), alcohol (5 to 15 per cent by weight, or 6.2 to 18.8 per cent by volume), glycerin (0.2 to 0.8 per cent), volatile acids (*e. g.*, acetic, œnanthic, etc.) being one-fourth of the total acidity; carbonic acid gas in young wines; aldehydes; œnanthic ether of vinous odor consist of caprinic and caprylic esters; unknown volatile substances constituting the "bouquet" of wines; dextrose (grape sugar) in small quantities, except in sweet wines; bitartrate of potassium, tartaric, malic and phosphoric acids, partly free, partly combined with potash, lime, soda, aluminum, magnesium, iron, and manganese; phosphate of calcium constituting from 20 to 60 per cent of the weight of the ash; sulphates, and traces of chlorides; coloring matters; pectin and gum (imparting "body" to the wine); tannin, amounting to from 0.1 to 0.2 per cent in red wines, while mere traces (about 0.01 per cent) occur in white wines (adapted from C. A. Crampton's report in *Foods and Food Adulterants*, Part III, *Bull. No.* 13, *United States Department of Agriculture*, 1887). The quantitative composition of some representative wines is given in the subjoined table.

The Analysis of Wine takes into account the determination of specific gravity (is usually below 1, but in most sweet wines above 1), alcohol, extractive or total solids (fixed for the *U. S. P.* wines between the limits of 1.6 to 3.5 per cent for red, and 1.5 to 3.0 for white wines); acidity (limited for the *U. S. P.* wines between 0.5 and 0.9 per cent in both kinds, calculated as tartaric acid); sugar, glycerin, tannic acid, and ash, and the search for special adulterants, such as artificial coloring matters (see *Amer. Jour. Pharm.*, 1887, p. 200, *ibid.*, 1892, p. 626, and *Proc. Amer. Pharm. Assoc.*, 1897, p. 536); preservatives, such as salicylic acid, etc. E. Claassen tests wine for salicylic acid by acidulating it with dilute sulphuric acid, and shaking with a mixture of equal volumes of ether and benzin. Evaporation of the ethereal layer leaves a residue producing a violet color with dilute solution of ferric chloride (*Digest of Criticisms on the U. S. P.*, Part I, 1892).

While we can not here enter into the interesting but extensive field of wine analysis, we may state that a uniform method of wine analysis has been elaborated by a German commission (see Dr. Max Barth, *Die Weinanalyse*, Leipzig, 1884; also see extensive comment by C. A. Crampton, *loc. cit.*), and has become official in Germany by an act of 1892. The method is more or less followed also in the United States. (In this connection, see Nessler and Barth, on the "Analysis of Wine," in *Amer. Jour. Pharm.*, 1882, pp. 444–454.) The *U. S. P.* makes the following requirements for white and red wines:

I. Vinum Album (*U. S. P.*), *White wine.*—"A pale amber-colored or straw-colored liquid, having a pleasant odor free from yeastiness, and a fruity, agreeable, slightly spirituous taste without excessive sweetness or acidity. The specific gravity, at 15.6° C. (60° F.), should not be less than 0.990, nor more than 1.010. If a portion of white wine be evaporated, the residue, when dried during 12 hours on a water-bath, should not amount to less than 1.5 nor more than 3 per cent. To neutralize 50 Cc. of white wine should require not less than 3 nor more than 5.2 Cc. of normal potassium hydrate V.S. (limit of free acid), phenolphtalein being used as indicator. If 10 Cc. of white wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride T.S., only a faint, greenish-brown color may make its appearance (absence of more than traces of tannic acid). Tested by the following method, white wine should be found to contain not less than 10 nor more than 14 per cent, by weight (equivalent to 12.4 to 17.3 per cent, by volume), of absolute alcohol: Take the specific gravity (to 4 decimals) of a sufficient portion of the white wine, carefully measured, at the temperature of 15.6° C. (60° F.), evaporate the white wine in a tared capsule to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60° F.), then take the specific gravity (to 4 decimals) again. The difference between the two specific gravities, deducted from 1.0000, corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the wine under examination, the corresponding percentage being ascertained by referring to the alcoholometric tables"—(*U. S. P.*).

II. Vinum Rubrum (*U. S. P.*), *Red wine.*—"A deep-red liquid, having a pleasant odor, free from yeastiness, and a fruity, moderately astringent, pleasant, and slightly acidulous taste, without excessive sweetness or acidity. The specific gravity, at 15.6° C. (60° F.), should not be less than 0.989, nor more than 1.010. If a portion of red wine be evaporated, the residue, when dried during 12 hours on a water-bath, should not amount to less than 1.6 per cent, nor more than 3.5 per cent. To neutralize 50 Cc. of red wine should require not less than 3 nor more than 5.2 Cc. of normal potassium hydrate V.S. (limit of free acid), eosin or fluorescein being used as indicator. If 10 Cc. of red wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride T.S., the liquid should acquire a brownish-green color (due to tannic acid). With lead acetate T.S., red wine forms a heavy precipitate, which may vary in color from bluish-green to green. If 2 Cc. of red wine be mixed, in a test-tube, with 2 drops of chloroform and 4 Cc. of normal potassium hydrate V.S., and the mixture carefully heated, the disagreeable odor of isonitril should not become perceptible (absence of various aniline colors). If 50 Cc. of red wine be treated with a slight excess of ammonia water, the liquid should acquire a green or brownish-green color; if it be then well shaken with 25 Cc. of ether, the greater portion of the ethereal layer removed, and evaporated in a porcelain capsule with an excess of acetic acid and a few fibers of uncolored silk, the latter should not acquire a crimson or violet color (absence of fuchsine). If 25 Cc. of red wine, heated to about 45° C. (113° F.), be well agitated with 25 Gm. of manganese dioxide, the liquid filtered off, and acidulated with hydrochloric acid, it should not acquire a red color (absence of sulphofuchsine). Tested by the following method, red wine should be found to contain not less than 10 nor more than 14 per cent, by weight (equivalent to 12.4 to 17.3 per cent, by volume), of absolute alcohol: Take the specific gravity (to 4 decimals) of a sufficient portion of the red wine, accurately measured, at the temperature of 15.6° (60° F.), evaporate the wine, in a tared capsule, to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60° F.), then take the specific gravity (to 4 decimals) again. The difference between the two specific gravities, deducted from 1.0000, corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the wine under examination, the corresponding percentage being ascertained by referring to the alcoholometric tables"—(*U. S. P.*).

The distillation method, for the determination of alcohol in wines, is carried out as follows: 100 Cc. of the sample are rinsed into a flask with about 50 Cc. of water; the flask is connected with a Liebig's condenser, exactly 100 Cc. are distilled off, measured at the same temperature as the original bulk was measured;

then the specific gravity is taken, either by means of an alcoholometer, or, preferably, by means of a picnometer. The alcoholic strength of the distillate may then be read from alcohol tables, *e.g.*, Hehner's table (see C. A. Crampton, *loc. cit.*, p. 285).

The following table, by J. König (*loc. cit.*), gives the average composition of some European sweet wines of commerce:

WINES.	Specific Gravity.	Alcohol (by weight). Per cent.	Extract.	Sugar.	Acid—Tartaric.	Glycerin.	Nitrogenous substance.	Mineral matters.	P_2O_6.	SO_3.	K_2O.
Tokay..........	1.0870	9.44	23.63	19.44	0.57	0.62	0.37	0.32	0.054	0.054	0.116
Port	1.0081	16.69	8.05	5.82	0.40	......	......	0.23	0.031	0.023	0.102

(For a great number of tabulated analyses of all grades of American wines, by Henry B. Parsons [1880] and C. A. Crampton [1887], including the experimental results obtained by Prof. E. W. Hilgard, in the Viticultural Laboratory of the University of California, see Mr. C. A. Crampton's report, *loc. cit.*)

Action, Medical Uses, and Dosage.—In moderate quantities, wine operates as a stimulant to the nervous and vascular systems, and the secreting organs. It quickens the action of the heart and arteries, diffuses an agreeable warmth over the body, promotes the different secretions, communicates a feeling of increased muscular force, excites the mental powers, and banishes unpleasant ideas. In a state of health, its use can be in no way beneficial, but on the contrary, its habitual employment in many cases proves injurious by exhausting the vital powers and inducing disease. The actual amount of injury it may inflict will, of course, vary with the quantity and quality of the wine taken, and according to the greater or less predisposition to disease which may exist in the system. Maladies of the digestive organs, and of the cerebro-spinal system, gout, gravel and dropsy, are those most likely to be induced or aggravated by it. Intoxication in its varied forms is the effect of excessive quantities of wine. Wine, however, possesses a tonic influence not observed after the use of ardent spirit, and differs from it, likewise, in not inducing disease of the liver. Dr. McCulloch observes: "It is well known that diseases of the liver are the most common and the most formidable of those produced by the use of ardent spirit; it is equally certain that no such disorders follow the intemperate use of pure wine, however long indulged in. To the concealed and unwitting consumption of spirit, therefore, as contained in the wines commonly drunk in this country, is to be attributed the excessive prevalence of those hepatic affections which are comparatively little known to our Continental neighbors" (the French).

As a medicinal agent, wine is employed principally as a cordial, stimulant, and tonic; some, however, possess acid and astringent properties. Wine is useful in low forms of *fever* to support the vital powers, promote sleep, and relieve delirium and subsultus tendinum; it is also useful as a stimulating tonic in convalescence from fevers, and from various chronic diseases. It is often given with the best effects in cases of *extensive ulceration*, *copious suppuration*, *gangrene of the extremities*, and after *profuse hemorrhages*, *severe operations*, or *extensive injuries*. Whenever it causes dryness of the tongue, thirst, quick pulse, restlessness or delirium, its use should be immediately dispensed with, as well as in active inflammations. In *tetanus*, its free use has at times produced an apparent alleviation of the disease (P). The best wines for practical use are, *Port*, *Sherry*, or *Madeira*, among the stronger wines; and among the weaker, *Claret*, *Hock*, *Moselle*, and *Champagne*. *Port* is a red or dark-purple, somewhat astringent wine, and may be used as a stimulant tonic in cases of *debility*; it is apt, however, to cause constipation, and usually disagrees with weak stomachs. *Sherry* is a dark yellowish-brown white wine, having a pleasant and peculiar flavor, and containing a very small amount of free acid; it is best adapted for *gouty patients*, and those disposed to *acid stomach*, or *uric acid deposits*. *Madeira* is somewhat of the color of Sherry, is feebly acid, and more stimulating than Sherry; it is better adapted for old persons and *weak, broken-down constitutions*, and for invalids. *Teneriffe* is similar to Madeira wine, but less stimulating. Among the weaker wines, none are equal to the *Claret* or *Bordeaux* wine; this wine is acid and slightly astringent, and is the least injurious among the wines. It may be used, as well as the Rhine and Moselle wines where the *urine deposits phosphates*, in *low fevers*, etc., but should not be used in gout, and uric acid deposits *Champagne* is more apt to cause headache than any other wine, yet it is a good excitant and diuretic, useful in *hypochondria*, *low stage of fevers*, *excessive debility*, and in *excessive vomiting* during *pregnancy* or at other times. *Catawba* wines are rather acid, and may be used as a substitute for Madeira and Claret. The dose of wine varies from a teaspoonful to a wineglassful, to be repeated every 1, 2, or 4 hours, according to the circumstances of the case; it may be given alone, or mixed with water and sweetened, and if not contra-indicated, some nutmeg may be grated upon it. Wine may also be added to soups, gruels, milk, etc., and to nutritive and stimulating enemas. Wine is sometimes employed in the preparation of medicated wines, but from its liability to undergo decomposition, it is much more objectionable as a solvent than diluted alcohol. In obstinate cases of *conjunctivitis*, of 1 or 2 years' standing, apparently unyielding to all treatment, I have found permanent cures to be rapidly effected by allowing the patient a free use of the ripe Catawba grape; the children thus cured were of a strumous disposition. In some cases, it was astonishing to witness the rapidity with which the cure progressed (J. King).

Related Wines.—Raisin Wines. This class of wines is now frequently made in France, owing to the destruction of large tracts of vineyards by diseases of the vine and other accidents (see *Amer. Jour. Pharm.*, 1898, p. 48). M. Palangié (*Amer. Jour. Pharm.*, 1889, p. 245, from *Jour. de Pharm. et Chim.*) recommends the following: Take Corinth raisins, 25 kilogrammes; sugar, 4 kilogrammes; fresh grapes, 1 kilogramme; tartaric acid, 25 Gm. Exhaust the raisins with 3 waters; press and unite all the liquors in a cask. Dissolve the sugar and tartaric acid in water, and boil for a few minutes; add this to the other liquors, with water to make 1 hectoliter; then add the grapes, previously bruised, and keep the mixture at a temperature of 25° C. (77° F.). In 48 hours from the beginning of fermentation, the air in the cask must be renewed, and this must be repeated daily until fermentation ceases. The wine should stand for a month before bottling. The taste of these wines is tart and sweetish; their flavor recalls that of raisins.

Malton Wines.—These alcoholic preparations, invented by Dr. Sauer in 1895, are made from infusion of barley malt, and are distinguished from ordinary wines by containing *lactic* instead of tartaric acid; much scientific skill is required in their preparation. The process is carried out in three phases: (1) Producing solution of maltose (17 to 20 per cent) by making an infusion of malted barley; (2) producing lactic acid by the addition of a pure culture of lactic ferments at 50° C. (122° F.), until a percentage of 0.6 to 0.8 of acid is obtained, when the souring is interrupted by exposure to a temperature of 75° C. (167° F.); (3) cooling the "wort" rapidly to 25° C. (77° F.), and adding specially cultivated yeast from genuine southern wines, as Sherry, Port, etc.; then allow to ferment by "high fermentation," from time to time adding maltose in the form of vacuum-concentrated wort. The unusual yield of 18 per cent of alcohol by volume is easily obtained by this process. Fermentation lasts from 3 to 5 weeks; then draw off and treat as any other wine. These wines, though retaining a slight taste of extract of malt, are said to have the pronounced character of the genuine wines from the pure yeast of which they are made (see report on these wines, by W. Möslinger, in *Forschungsberichte über Lebensmittel*, 1896, p. 313).

Hoochinoo.—The spirituous beverage of the Alaskans, about corresponding in alcoholic strength with Sherry wine (Marshall).

VINUM ALBUM FORTIUS (N. F.)—STRONGER WHITE WINE.

Preparation.—"White wine, eight hundred and seventy-five grammes (875 Gm.) [1 lb. av., 14 ozs., 378 grs.]; alcohol, one hundred and twenty-five grammes (125 Gm. [4 ozs. av., 179 grs.]. Mix them. When tested for alcohol, stronger white wine should contain not less than twenty (20) per cent, nor more than twenty-five (25) per cent of absolute alcohol, by weight" (*Nat. Form.*).

Pharmaceutical Uses.—This preparation was official in the *U. S. P.*, 1880, and was used in the preparation of medicated wines, where a fortified white wine was demanded. In the present Pharmacopœia (1890), however, the official formulas separately direct the addition of a definite amount of alcohol to the wine when fortification of the latter is necessary.

VINUM ALOES (N. F.)—WINE OF ALOES.

Preparation.—"Purified aloes (*U. S. P.*), sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; cardamom, ten grammes (10 Gm.) [154 grs.]; ginger, ten grammes (10 Gm.) [154 grs.]; stronger white wine (F. 440), a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the aloes, cardamom, and ginger, and reduce them to a moderately coarse (No. 40) powder. Macerate the powder with nine hundred grammes (900 Gm.) [1 lb. av., 15 ozs., 327 grs.] of stronger white wine for 7 days, with occasional agitation, and filter through paper, adding, through the filter, enough stronger white wine to make the filtered liquid weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Aloe.*) A preparation of repulsive taste, employed to overcome *constipation*, when associated with *flatulence* or *menstrual tardiness*. Dose, as a laxative, about 4 fluid drachms.

VINUM AROMATICUM.—AROMATIC WINE.

Preparation.—Take of lavender, origanum, peppermint, rosemary, sage, wormwood, of each, 1 part; stronger white wine, a sufficient quantity to make 100 parts. "Mix the solid ingredients, and reduce them to a coarse (No. 20) powder. Moisten the powder with 4 parts of stronger white wine, pack it moderately in a conical glass percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh 100 parts"—(*U. S. P.*, 1880).

Action and Medical Uses.—This preparation was one of a class of vulneraries once in vogue as applications to *wounds*, *ulcers*, *chancres*, etc. It has been dismissed from the Pharmacopœia.

VINUM AURANTII (N. F.)—WINE OF ORANGE.

Preparation.—"Oil of bitter orange, one cubic centimeter (1 Cc.) [16 ♏]; alcohol, ten cubic centimeters (10 Cc.) [162 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the purified talcum, first with the alcohol, in which the oil of bitter orange had previously been dissolved, and afterward with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of sherry wine, gradually added. Filter the mixture through a wetted filter, returning the first portions of the filtrate until it runs through clear, and lastly, pass enough sherry wine through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Pharmaceutical Uses.—This preparation is employed as a flavoring substance and excipient in some of the official preparations.

Related Preparation.—VINUM AURANTII COMPOSITUM (N. F.), *Compound wine of orange*, *Elixir aurantiorum compositum* (*Ger. Pharm.*), *Compound elixir of orange*. "Bitter orange peel, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; absinthium, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; menyanthes, leaves, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; cascarilla, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; cinnamon (cassia), forty grammes (40 Gm.) [1 oz. av., 180 grs.]; gentian, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; potassium carbonate, ten grammes (10 Gm.) [154 grs.]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the six first-named drugs to a moderately coarse (No. 40) powder, mix with this the potassium carbonate, moisten the mixture with sherry wine, and let it macerate during 24 hours. Then pack it in a percolator, and percolate with sherry wine, in the usual manner, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of product are obtained. *Note.*—The *German Pharmacopœia* directs to macerate the orange peel, cinnamon, and potassium carbonate with the sherry wine, and then to add the other drugs in the form of extracts. The proportions above given produce a product practically identical with that of the *German Pharmacopœia*"—(*Nat. Form.*). This preparation may be employed as a gastric tonic.

VINUM CARNIS (N. F.)—WINE OF BEEF.

SYNONYM: *Beef and wine.*

Preparation.—"Extract of beef, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; hot water, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour hot the water upon the extract of beef contained in a mortar or other suitable vessel, and triturate until a smooth mixture results. Then gradually add, while stirring, nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of sherry wine. Transfer the mixture to a bottle, set this aside for a few days in a cool place, if convenient, then filter, and pass enough sherry wine through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 2 grains of extract of beef. *Note.*—The extract of beef suitable for this or similar preparations is that which is prepared by Liebig's method"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent is designed for a tonic and nutritive preparation. The dose is from 1 to 4 fluid drachms.

VINUM CARNIS ET FERRI (N. F.)—WINE OF BEEF AND IRON.

SYNONYM: *Beef, wine, and iron.*

Preparation.—"Extract of beef, thirty-five grammes (35 Gm.) 1 oz. av., 103 grs.]; tincture of citro-chloride of iron (F. 407), thirty-five cubic centimeters (35 Cc.) [1 fl℥. 88 ♏]; hot water, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour the hot water upon the extract of beef contained in a mortar or other suitable vessel, and triturate until a smooth mixture results. Then gradually add, while stirring, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of sherry wine. Next add the tincture and enough sherry wine to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Transfer the mixture to a bottle, set this aside for a few days in a cold place, if convenient, filter, and pass enough sherry wine through the filter to restore the original volume. Each fluid drachm represents 2 grains of extract of beef, and 2 minims of tincture of citro-chloride of iron"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Tonic, nutrient, and restorative. Dose, 1 to 4 fluid drachms.

VINUM CARNIS, FERRI, ET CINCHONÆ (N. F.)—WINE OF BEEF, IRON, AND CINCHONA.

SYNONYM: *Beef, wine, iron, and cinchona.*

Preparation.—"Extract of beef, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; tincture of citro-chloride of iron (F. 407), thirty-five cubic centimeters (35 Cc.) [1 fl℥. 88 ♏]; quinine sulphate, two grammes (2 Gm.) [31 grs.]; cinchonidine sulphate, one gramme (1 Gm.) [15 grs.]; citric acid, seventy-five centigrammes (0.75 Gm.) [12 grs.]; hot water, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; angelica wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Dissolve the citric acid and the quinine and cinchonidine sulphates in the hot water, and pour the solution upon the extract of beef contained in a mortar, or other suitable vessel. Triturate the liquid with the extract, until they form a smooth mixture, then gradually add, while stirring, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of angelica wine, and afterward the tincture of citro-chloride of iron. Transfer the mixture to a bottle, set this aside for a few days in a cool place, if convenient, filter, and pass enough angelica wine through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 2 grains of extract of beef, 2 minims of tincture of citro-chloride of iron, and small quantities of cinchona alkaloids. *Note.*—Angelica wine is a variety of sweet California wine"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Tonic, nutritive, and restorative. Dose, 1 to 4 fluid drachms.

VINUM CINCHONÆ AROMATICUM.—AROMATIC WINE OF CINCHONA.

Preparation.—Take of powdered red Peruvian bark, 4 ounces; coriander, bruised, 1 drachm; cinnamon bark, in powder, 2 drachms; diluted alcohol, a sufficient quantity. Macerate the articles in alcohol (about 1 pint), then place in a percolator, and exhaust with diluted alcohol. Evaporate to expel the alcohol, and filter to separate the resin, which will give about ½ pint of liquid. To this add sherry or Madeira wine, sufficient to make the whole amount to ½ gallon; white sugar, ½ pound; tartaric acid, 1 drachm.

Action, Medical Uses, and Dosage.—This is a pleasant aromatic tonic, and may be used, in doses of from 1 to 4 fluid ounces, 3 or 4 times a day, in all cases where a tonic and gentle stimulating action is desired. Catawba wine may be substituted for the sherry or Madeira, when the compound is to be immediately administered.

VINUM COLCHICI RADICIS (U. S. P.)—WINE OF COLCHICUM ROOT.

Preparation.—"Colchicum root, in No. 30 powder, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of white wine. Moisten the powder with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of the menstruum, pack it moderately in a conical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and afterward enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The want of uniformity of strength in the colchicum bulb brought to this country, requires it to be used in large amount, as compared with its menstruum, in order to secure an efficient vinous solution of it. Wine of colchicum root has been used in *gout*, *gouty rheumatism*, and *neuralgia*. Its effects will be much more decided in many instances, by associating it with a solution of sulphate of morphine, and exhibiting it in conjunction with magnesia or magnesium sulphate. Overdoses may occasion serious results. The dose is from 5 to 60 minims, every 3 or 4 hours, or oftener when the symptoms are urgent, continuing its use until its peculiar effects have manifested themselves.

VINUM COLCHICI SEMINIS (U. S. P.)—WINE OF COLCHICUM SEED.

Preparation.—Colchicum seed, in No. 30 powder, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of white wine. Macerate the powder with nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of the mixture during 7 days, in a closed vessel, with occasional agitation. Then filter through paper, adding, through the filter, first, the remainder of the menstruum, and afterward enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

It is very necessary that the seeds be ground fine in order that the colchicine may be more thoroughly exhausted, or after having macerated the seeds in the wine a few days they may be taken out and crushed while wet (Maisch). This is the preparation usually called in this country *Wine of Colchicum*.

Action, Medical Uses, and Dosage.—Colchicum seed are not so apt to deteriorate as the bulb, and preserve their activity unchanged for a much longer period; consequently they do not require to be used so largely, in proportion to their menstruum, as the bulb. This medicated wine may be employed for the same purposes as the wine of the bulb, or the tincture of the seed. In overdoses it is capable of producing death. The dose varies from ½ to 1 fluid drachm. The seeds should always be bruised to obtain their full medicinal activity

VINUM ERGOTÆ (U. S. P.)—WINE OF ERGOT.

Preparation.—"Ergot, recently ground, and in No. 30 powder, one hundred and fifty grammes (150 Gm. [5 ozs. av., 127 grs.]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of white wine. Moisten the powder with forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏] of the mixture, pack it moderately in a conical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and afterward enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*). The official wine contains about 15 per cent of ergot. In preparing it the drug should be finely ground, not bruised.

Action, Medical Uses, and Dosage.—This may be used during labor, as a parturient, in doses of 2 or 3 fluid drachms; in other instances it may be given in doses of 1 or 2 fluid drachms, 3 or 4 times a day, and gradually increased if desirable. It is less used than other preparations of ergot.

VINUM ERYTHROXYLI (N. F.)—WINE OF ERYTHROXYLON.

SYNONYM: *Wine of coca.*

Preparation.—"Fluid extract of erythroxylon (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; sugar, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; claret wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sugar in about six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of claret wine, add the alcohol and fluid extract, and enough claret wine to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Let the mixture stand a few days in a cold place, if convenient, then filter, and pass enough claret wine through the filter to restore the original volume. Each fluid ounce represents 30 grains of erythroxylon (coca). *Note.*—In place of claret wine, any other palatable wine may be used, according to the demand or preference of the prescriber or consumer"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Coca.*) Dose, 1 to 2 fluid drachms.

Related Preparation.—VINUM ERYTHROXYLI AROMATICUM (N. F.), *Aromatic wine of erythroxylon, Aromatic wine of coca.* "Fluid extract of erythroxylon (*U. S. P.*) sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; compound elixir of taraxacum (F. 111), ten cubic centimeters (10 Cc.) [162 ♏]; syrup of coffee (F. 367) twenty-five cubic centimeters (25 Cc.) [406 ♏]; port wine, one hundred and sixty-five cubic centimeters (165 Cc.) [5 fl℥, 278 ♏]; aromatic elixir (*U. S. P.*), three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏]; sherry wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the five first-named ingredients with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of sherry wine. Let the mixture stand several days in a cold place, if convenient, then filter, and pass enough sherry wine through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid ounce represents 30 grains of erythroxylon coca)"—(*Nat. Form.*). Dose, 1 to 2 fluid drachms.

VINUM FERRI.—WINE OF IRON.

SYNONYMS: *Vinum chalybeatum, Vinum martiatum.*

Preparation.—"Take of iron, in wire, 1 ounce (Imp.), or 50 grammes (Metric); sherry, 1 pint (Imp.), or 1000 cubic centimeters (Metric); set aside for 30 days in a closed vessel, the iron wire being almost but not quite immersed in the sherry wine, and the vessel frequently shaken, and the stopper occasionally removed;

then filter"—(*Br. Pharm.*, 1898). The natural salt of the wine—acid potassium tartrate—slowly acts upon the iron, dissolving it, while hydrogen is evolved. A double salt, iron and potassium tartrate is formed, of course in variable amount, depending upon the amount of the acid tartrate contained in the wine. On account of its variability, this wine has been discarded by the *U. S. P.*

Action, Medical Uses, and Dosage.—A mild chalybeate. Dose, 1 to 4 fluid drachms.

VINUM FERRI AMARUM (U. S. P.)—BITTER WINE OF IRON.

SYNONYM: *Vinum chinæ ferratum.*

Preparation.—"Soluble iron and quinine citrate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; tincture of sweet orange peel, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; syrup, three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the soluble iron and quinine citrate in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of white wine. Add to this the tincture of sweet orange peel and the syrup, and lastly, enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Set the mixture aside for several days, then filter, and pass enough white wine through the filter to restore the original volume"—(*U. S. P.*). Each fluid drachm contains nearly 3 grains of iron and quinine citrate.

Action, Medical Uses, and Dosage.—A chalybeate tonic for *debilitated and anemic individuals.* Dose, 1 or 2 fluid drachms.

VINUM FERRI CITRATIS (U. S. P.)—WINE OF FERRIC CITRATE.

Preparation.—"Iron and ammonium citrate, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; tincture of sweet orange peel, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; syrup, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the iron and ammonium citrate in seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of white wine. Add to this the tincture of sweet orange peel and the syrup, and lastly, enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Set the mixture aside for several days, then filter, and pass enough white wine through the filter to restore the original volume"—(*U. S. P.*). Each fluid drachm contains about 2¼ grains of iron and ammonium citrate.

Action, Medical Uses, and Dosage.—This preparation is intended as a means of obtaining a uniform vinous solution of ferric citrate. It is a mild chalybeate, and may be given in doses of from 1 to 4 fluid drachms.

VINUM FRAXINI AMERICANÆ (N. F.)—WINE OF WHITE ASH.

Preparation.—"Fraxinus (bark), in No. 40 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; stronger white wine (F. 440), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powdered fraxinus with one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of stronger white wine, macerate it during 3 days in a well-covered vessel; then pack it in a percolator, and gradually pour on stronger white wine until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of percolate are obtained. Keep the product in well-stoppered bottles, which should be completely filled and stored in a cool place. Each fluid drachm represents 30 grains of fraxinus (bark). *Note*—Fraxinus bark is the inner bark of the trunk or root of *Fraxinus Americana*, Linné (white ash)"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Fraxinus.*) Dose, 1 to 2 fluid drachms.

VINUM HELLEBORI COMPOSITUM.—COMPOUND WINE OF HELLEBORE.

Preparation.—Take of black hellebore (in coarse powder), logwood chips or raspings, helonias root (in powder), each, 2 ounces; sherry wine, 1½ pints, or a sufficient quantity. Form into a medicated wine by maceration or percolation, as explained under *Vina Medicata*, and make 1½ pints of the preparation.

Action, Medical Uses, and Dosage.—This preparation is tonic and cathartic, exerting a direct influence on the female reproductive organs. It has proved serviceable in *menstrual derangements*, as *amenorrhœa*, *dysmenorrhœa*, and some *painful uterine affections*. The dose varies from ½ to 1 or 2 fluid ounces, every 3 or 4 hours.

VINUM HYDRASTIS COMPOSITUM.—COMPOUND WINE OF GOLDEN SEAL.

SYNONYM: *Wine bitters.*

Preparation.—Take of golden-seal root, tulip-tree bark, bitter root, each, in fine powder, 1 drachm; prickly ash berries, sassafras bark, capsicum, each, in fine powder, ½ drachm; sherry wine, 3 pints, or a sufficient quantity. Form into a medicated wine by maceration or percolation, as explained under *Vina Medicata*, and make 3 pints of the preparation.

Action, Medical Uses, and Dosage.—This is useful in *dyspepsia*, and in all cases where tonics are required, with gentle stimulation. The dose varies from ½ to 1 or 2 fluid ounces, every 3 or 4 hours.

VINUM IPECACUANHÆ (U. S. P.)—WINE OF IPECAC.

Preparation.—"Fluid extract of ipecac, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; alcohol, one hundred cubic centimeters (100 Cc.) [3 fl℥. 183 ♏]; white wine, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]: to make one thousand cubic centimeters (1000 Cc.) [33 fl℥. 391 ♏]. Mix them. Set the mixture aside for a few days, then filter"—(*U. S. P.*). This wine contains in each fluid drachm the active constituents of about 5 grains of ipecac.

Action, Medical Uses, and Dosage.—(See *Ipecacuanha.*) This wine contains all the medicinal qualities of the drug, and, as an emetic, is sometimes preferred in infantile cases. An adult may take 1 fluid ounce for a dose, when vomiting is required; a child 1 or 2 years old may take 1 fluid drachm, repeating it every 10 or 20 minutes, until it vomits. From 10 to 30 minims have an expectorant and diaphoretic effect, if repeated at regular intervals of every 1 or 2 hours.

VINUM OPII (U. S. P.)—WINE OF OPIUM.

SYNONYMS: *Laudanum liqidum Sydenhami, Sydenham's laudanum.*

Preparation.—"Powdered opium, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; cassia cinnamon, in No. 60 powder, ten grammes (10 Gm.) [154 grs.]; cloves, in No. 30 powder, ten grammes (10 Gm.) [154 grs.]; alcohol, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; white wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the alcohol with eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of white wine. To the mixed powders add nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of the menstruum, and macerate during 7 days, with occasional agitation. Then transfer the mixture to a filter, and, when the liquid has drained off, gradually pass through the filter, first, the remainder of the menstruum, and afterward enough white wine to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. If 100 Cc. of wine of opium be assayed by the process given under *Tinctura Opii*, it should yield from 1.3 to 1.5 Gm. of crystallized morphine"—(*U. S. P.*). This is a pleasant vinous tincture of opium, containing in each 10 minims the activities of 1 grain of opium. With age it deposits insoluble extractive, and sometimes a little narcotine. This preparation is one of the forms of *Sydenham's laudanum* (*Tinctura Opii Crocata*, or *Saffronized tincture of opium*), the true form of which is a vinous tincture, made according to the *Parisian Codex*, by macerating, for 2 weeks, 2 ounces of opium, 1 ounce of saffron, and 1 drachm, each, of bruised cinnamon and cloves in 1 pint of sherry wine; then filter. A fluid drachm of this laudanum is equivalent to 3 grains of opium.

Action, Medical Uses, and Dosage.—This is one of the most eligible of the liquid preparations of opium, having a more agreeable taste and smell, and being much less liable to nauseate than tincture of opium. It is occasionally used in *conjunctivitis*, to constringe diluted vessels and relieve pain. The dose is from 5 to 16 minims.

VINUM PEPSINI (N. F.)—WINE OF PEPSIN.

Preparation.—"Pepsin (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; glycerin, fifty cubic centimeters (50 Cc.) [1 fl℥, 331 ♏]; hydrochloric acid (*U. S. P.*), four cubic centimeters (4 Cc.) [65 ♏]; water, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; purified talcum (F. 395), sixteen grammes (16 Gm.) [247 grs.]; stronger white wine (F. 440), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the water, glycerin, and hydrochloric acid, and agitate the pepsin with the mixture until it is completely disintegrated and apparently dissolved. Then add enough stronger white wine to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]; mix the liquid intimately with the purified talcum, allow it to stand for a week, if convenient, frequently shaking, then filter, and pass enough stronger white wine through the filter to restore the original volume. Each fluid drachm represents 1 grain of pepsin (*U. S. P.*)"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Pepsinum.*) A preparation of pepsin of questionable utility. Dose, 1 to 4 fluid drachms.

VINUM PHYTOLACCÆ COMPOSITUM.—COMPOUND WINE OF POKE.

SYNONYM: *Rheumatic liquid.*

Preparation.—Take of inspissated juice of poke berries, white turpentine, each, 4 ounces; sherry or native wine, 2 gallons. Macerate for 14 days, with occasional agitation, and filter (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This is an excellent preparation for *chronic rheumatism*, *chronic gonorrhœa*, *syphilitic pains*, etc. The dose is from ½ to 1 fluid ounce, 2 or 3 times a day.

VINUM PICIS (N. F.)—WINE OF TAR.

Preparation.—"Tar, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏], pumice, in moderately fine powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; stronger white wine (F. 440), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Upon the tar, contained in a suitable vessel, pour two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of cold water, and triturate the mixture thoroughly; then pour off the water and throw it away. Mix the remaining tar thoroughly with the powdered pumice, and add one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of stronger white wine. Stir frequently during 4 hours, then transfer the mixture to a wetted filter, and, after the liquid has passed, pour on enough stronger white wine to make the filtrate measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Tar.*) When used internally, the dose may range from 1 to 2 fluid drachms. Externally, it is useful in certain *skin affections*, requiring the effects of tar and stimulation.

VINUM PRUNI VIRGINIANÆ (N. F.)—WINE OF WILD CHERRY.

Preparation.—"Wild cherry, in No. 40 powder, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; sugar, one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 grs.]; water, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; alcohol, seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; angelica wine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sugar in the water. Moisten the wild cherry with a sufficient quantity of this solution, and allow it to macerate during 1 hour. Then transfer it to a percolator, pour upon it the remainder of the solution, and afterward enough angelica wine, until nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏] of percolate are obtained. Add to this the alcohol, mix the purified talcum intimately with the liquid, then filter, returning the first portions of the filtrate until it runs through clear, and finally pass enough angelica wine through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 15 grains of wild cherry"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Prunus Virginiana.*) A good tonic and sedative. Dose, 1 to 4 fluid drachms.

VINUM PRUNI VIRGINIANÆ FERRATUM (N. F.)—FERRATED WINE OF WILD CHERRY.

Preparation.—"Tincture of citro-chloride of iron (F. 407), eighty-five cubic centimeters (85 Cc.) [2 fl℥, 420 ♏]; wine of wild cherry (F. 452), enough to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the tincture with enough wine of wild cherry to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 5 minims of tincture of citro-chloride of iron and 13¾ grains of wild cherry"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This preparation combines the tonic properties of the iron with the sedative and tonic virtues of wild cherry. The dose may range from 1 to 2 fluid drachms.

VINUM QUININÆ.—WINE OF QUININE.

Preparation.—"Take of sulphate of quinine, 20 grains; citric acid, 30 grains; orange wine, 1 pint (Imp.). Dissolve, first the citric acid, and then the sulphate of quinine, in the wine; allow the solution to remain for 3 days in a closed vessel, shaking it occasionally, and afterward filter. Each fluid ounce contains 1 grain of sulphate of quinine"—(*Br. Pharm.*, 1885). The *Vinum Quininæ* of the present *British Pharmacopœia* (1898) is prepared from the hydrochloride, as follows: Take of "quinine hydrochloride, 20 grains (Imp.), or 2 grammes (Metric); orange wine, 1 pint (Imp.), or 875 cubic centimeters. Dissolve; set aside; filter, if necessary"—(*Br. Pharm.*, 1898).

Action, Medical Uses, and Dosage.—A convenient form for administering quinine citrate. Dose, 2 fluid drachms to 1 fluid ounce.

VINUM RHEI (N. F.)—WINE OF RHUBARB.

Preparation.—"Rhubarb, in No. 30 powder, one hundred grammes (100 Gm). [3 ozs. av., 231 grs.]; calamus, in No. 30 powder, ten grammes (10 Gm.) [154 grs.]; stronger white wine (F. 440), a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Moisten the mixed powders with fifty grammes (50 Gm.) [1 oz. av., 334 grs.] of stronger white wine, pack the mixture in a conical glass percolator, and gradually pour enough stronger white wine upon it to make the filtered liquid weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*Nat. Form.*). This is based on the *U. S. P.* (1880) formula.

Action, Medical Uses, and Dosage.—(See *Rhei* and *Calamus.*) Laxative and carminative. Dose, 1 to 4 or more fluid drachms.

VINUM SAMBUCI.—WINE OF ELDER.

SYNONYM: *Hydragogue tincture.*

Preparation.—Take of elder bark, parsley root, each, in coarse powder, 1 ounce; sherry wine, 1 pint, or a sufficient quantity. Form into a medicated wine by maceration or percolation, as explained under *Vina Medicata*, and make one pint of the preparation.

Action, Medical Uses, and Dosage.—Wine of elder is useful in *dropsical diseases*, especially *ascites*, and *dropsy* supervening upon *scarlatina* or other *exanthematous diseases.* Dose, 2 fluid ounces, 3 or 4 times a day.

VINUM SYMPHYTI COMPOSITUM.—COMPOUND WINE OF COMFREY.

Preparation.—Take of comfrey root, Solomon's-seal root, helonias root, each, in coarse powder, 1 ounce; chamomile flowers, calumba root, gentian root, cardamom seeds, sassafras bark, each, in coarse powder, ½ ounce; sherry wine, 4 pints; boiling water, a sufficient quantity. Place the herbs in a vessel, cover with boiling water, and let the compound macerate for 24 hours, keeping it closely covered; then add the sherry wine. Macerate for 14 days; express and filter. Malaga wine, which is sometimes used in this preparation, is inferior to sherry wine, and more liable to decomposition. The addition of sugar to this wine of comfrey is apt to disagree with many persons, and thus destroy its efficiency. This preparation is sometimes called *Restorative Wine Bitters*, but is much superior to the article formerly known by this name.

Action, Medical Uses, and Dosage.—This is a most valuable tonic in all diseases peculiar to females, especially *leucorrhœa*, *amenorrhœa*, *weakness of the back*, etc. The dose is from ½ to 2 fluid ounces, 3 or 4 times a day.

VIOLA.—VIOLET.

The whole plant of *Viola pedata*, Linne; *Viola odorata*, Linné, and other species of *Viola.*

Nat. Ord.—Violaceæ.

COMMON NAMES: (1) *Blue violet*, *Bird's-foot violet;* (2) *Sweet violet*, *Sweet-scented violet.*

Botanical Source.—*Viola pedata*, *Blue violet*, or, as it is sometimes called, *Bird's-foot violet*, is an indigenous, stemless plant, glabrous, with the leaves and scapes all from perennial, fleshy, premorse, subterranean root-stocks. The leaves are pedately 5 to 9-parted; the lobes, linear-lanceolate, obtuse, and nearly entire. The petioles are armed with long, ciliate stipules at base. Flowers large, very showy, 1 inch broad, pale or deep lilac-purple, and fragrant. The peduncles are somewhat 4-sided, and much longer than the leaves. Segments of the calyx are linear, acute-ciliate, and emarginate behind. Petals veinless, entire and beardless. Spur or beak obscure. Stigma large, flattened at the sides, obliquely truncate, and pierced at the top (W.—G.). *Viola odorata* is a small, creeping plant, with flagelliform runners; its leaves are roundish-cordate; sepals 5, ovate and obtuse; petals 5; spur very blunt. Its flowers are fragrant, deep-purple, often white, occasionally lilac, and borne on radical, furrowed, quadrangular peduncles. The bracts are inserted above the middle of the scape. Capsules turgid, hairy, bursting with elasticity, many-seeded, and 3-valved. Seeds turbinate and pale (L.—De Candolle).

History and Description.—The *Blue violet* is common to the United States, growing from Maine to Florida, and west to Missouri, in dry woods and pastures, and sandy places, flowering in May and June. Occasionally a second flowering occurs in August and September. The herb and root are used, and impart their virtues to water. The taste of the flowers is sweet and mucilaginous; of the rhizome, bitter, mucilaginous, and sub-acrid. The *Viola odorata*, or *Sweet violet*, of Europe, is much cultivated in this country on account of its beautiful flowers, which appear in April and May. The flowers of this species are made into a syrup which is official in the *French Codex*. Of fresh violet petals (the deep-blue ones only, deprived of the calyx), take 10 parts, and boiling water, 20 parts. Infuse, and add to 21 parts of infusion 38 parts of sugar. Both of these plants possess similar properties; the flowers are commonly employed, but the whole plant is medicinal. The flowers should be gathered as soon as they are fully expanded, the sepals removed, and then carefully dried. According to P. L. Simmonds (*Amer. Jour. Pharm.*, 1891, p. 201), the whole plant of *Viola odorata* is sold in a dry state in all the bazars of Bengal, and is given in infusion as a diaphoretic in fevers. In large doses it nauseates and often produces vomiting. The Romans had a wine of violet flowers, and it is said they are still used in the preparation of sherbets.

Chemical Composition.—The root, leaves and seeds of these odoriferous plants are emetic in larger doses. Boullay (1828) found the whole plant of *V. odorata* to contain an acrid and poisonous principle which he called *violine*. It resembles emetine in its action, is a pale-yellow or white powder of bitter and acrid taste, more soluble in water than emetine, insoluble in ether, quite soluble in alcohol, and forming an insoluble compound with tannin solution. It also exists in other plants of this family, particularly in the rhizomes of the perennial, and especially the stemless species of violet. It is not present, however, in the pansy (see below). The root also contains starch, yellow coloring matter, gum, traces of volatile oil, etc. The flowers contain a blue coloring matter, turning green with alkalies. As to the odoriferous principle of the violet, it has not yet been definitely established whether it is identical with the synthetical violet perfume from orris root. (Regarding the latter, see Henry Kraemer, *Amer. Jour. Pharm.*, 1895, pp. 346–356.) K. Mandelin (*Dissert.*, 1881; see *Amer. Jour. Pharm.*, 1882, p. 11) found the leaves of *V. odorata* to contain a substance which, after boiling, yielded salicylic acid (also see *Related Species*, below). Boiling water extracts the virtues of these plants.

Action, Medical Uses, and Dosage.—The flowers and seeds of *V. odorata* act as laxatives in doses of 3 or 4 drachms, rubbed up with sugar and water; the root in ½ or 1-drachm doses is emeto-cathartic, but it is uncertain in its action. The odorous emanations from the flowers have caused faintness and giddiness, and in one case were supposed to have brought on apoplexy. The seeds have been recommended in *uric acid gravel*. *Blue violet* is mucilaginous, emollient, and slightly laxative; also antisyphilitic and useful, when combined with *Corydalis formosa*, in *syphilis*. Has been used in *pectoral, nephritic and cutaneous affections*, especially *crusta lactea*. The plant should be used when fresh, as drying destroys its active properties. Prof. Scudder says of it that "it stimulates waste and secretion, relieves nervous irritability, and improves nutrition"—(*Spec. Med.*). The *V. tricolor*, or pansy, may be used as a substitute. The roots of these plants are bitterish and slightly acrid, and in doses of from 8 to 10 grains are tonic; from 25 to 30 grains, purgative; and from 40 to 60 grains, emetic.

Related Species.—*Viola tricolor*, Linné (*Herba jaceæ*); *Heartsease, Johnny jump-up, Pansy*. The wild-growing species of pansy is official in the *German Pharmacopœia*, and its variety *arvensis* in the *French Codex*. Its corolla has the 3 colors—blue, yellow, and purple. According to Boullay (1828), no emetic *violine* (see above) is present, but a yellow coloring principle and an abundance of mucilage was found. The yellow principle has since been shown by Mandelin (*Pharm. Zeitschrift für Russland*, 1883, p. 329) to be a glucosid *violaquercitrin* ($C_{42}H_{42}O_{24}$). From hot solution it forms fine yellow acicular crystals, soluble in alkalies and reprecipitated by acids; when boiled with diluted acids it is split into quercetin, glucose, and a fluorescent body. Previously (1881), Mandelin obtained free salicylic acid from the dried herb varying from 0.06 to 0.14 per cent. It occurs in several other species of Viola. Griffith and Conrad (1884) found 0.13 per cent in the leaves, 0.08 per cent in the stems, and 0.05 per cent in the root; the flowers contained but a trace. The fresh leaf-buds, when rubbed between the fingers, exhibit a distinct odor of methyl salicylate (see monograph on *Viola tricolor*, by Henry Kraemer, *Dissert.*, Marburg, 1897). The immoderate use of Viola tricolor is said to derange the gastro-intestinal functions, and to induce diuresis, sweating, and a pustular skin eruption. It imparts to the urine a feline odor. Its chief use is as a remedy for the *moist eczematous eruptions* which are prone to occur on the scalp and face of children. From 5 to 10 drops of a strong tincture may be added to 4 fluid ounces of water, the dose of the mixture being a teaspoonful every 4 hours. In Europe it is used as a blood purifier, and in *catarrhal affections of the bronchiæ and intestines.*

Viola sagittata, Aiton, var. *ovata*, or *Rattlesnake violet*, has been highly recommended in the *bites of rattlesnakes*, the infusion to be freely administered; and the infusion used internally, with a fomentation of the leaves locally applied, has proved efficient in *obstinate chronic ophthalmia;* a similar course is reputed very valuable in *scrofulous diseases.* Probably all the species possess analogous properties; they are undoubtedly more active agents than are generally supposed, and deserve further investigation.

Viola cucullata, Aiton, is our *Common blue violet*, abundant everywhere, and a very variable species.

Anchietæa salutaris, St. Hilaire (*Noisettia pyrifolia*, Martius).—A Brazilian shrub, the root of which is emeto-cathartic. Sugar, starch, gum, tannin, resin, and a pale-yellow, crystalline basic *anchietine* (0.40 per cent) were found in the root by Peckolt in 1859 (*Archiv der Pharm.*, Vol. CXLVII, p. 271). The base has a nauseous, persistently pungent taste, is freely soluble in alcohol, sparingly in boiling water; insoluble in ether; forms a characteristic hydrochloride, and produces violet, subsequently turning to black, with sulphuric acid. From the fact that this root will salivate, it has been used in powder and alcoholic tinctures for the relief of *cutaneous disorders* and *syphilis.*

Ionidium Marcucci, Bancroft (*Ionidium parviflorum*, Ventenat), South America, near Mount Chimborazo.—The *cuichunchulli* of the Indians, much used in South America in *cutaneous disorders*, and said to be peculiarly efficient in *elephantiasis.* Small doses of the root are diaphoretic, sialagogue, and diuretic, while large doses prove emetic and purgative.

Ionidium Ipecacuanha, Ventenat.—A Brazilian root, used as a substitute for ipecacuanha (see *Ipecacuanha*). It contains an emetic alkaloid not identical with emetine or violine (see J. B. Barnes, *Pharm. Jour. Trans.*, Vol. XV, 1884–85, p. 515).

VISCUM.—MISTLETOE.

The leaves and branches of *Viscum flavescens*, Pursh (*Phoradendron flavescens*, Nuttall).

Nat. Ord.—Loranthaceæ.

COMMON NAMES: *Mistletoe, American mistletoe.*

Botanical Source and History.—This is the *Viscum verticillatum* of Nuttall, and *Viscum album* of Walter. It is a yellowish-green, succulent parasite, growing on the branches and trunks of old trees, especially apple trees, elms, oaks, hickories, etc. The stems are jointed, 1 or 1½ feet in length, rather thick, with many round, spreading, opposite, and sometimes verticillate, terete branches. The leaves are opposite, cuneate-obovate, 3-veined, obtuse, smooth, entire, contracted at the base into a short petiole, and 9 to 16 lines long by 4 to 9 broad. The flowers are small, greenish-white; the sterile ones mostly 3-parted, in axillary, solitary spikes, and about as long as the leaves. The fruit is globose, yellowish-white, smooth, semitransparent, with a viscous pulp, is borne in clusters, and contains 1 fleshy seed. It remains throughout the winter (W.—G.).

Fig. 255.

Viscum flavescens.

Viscum album, Linné, is the European species employed. It differs in the shape of its leaves, which are lance-shaped or spatulate. It grows upon apple, plum, pear and other fruit trees, as well as upon birches, beeches, poplars, etc.

Description.—This parasitic shrub is found growing on various trees; but that which is found on the oak is preferred. The bark and leaves have an unpleasant odor, and a mawkish, bitterish taste. The proper time for collection is in November, when it should be gradually dried, pulverized, and kept in a well-stoppered bottle. It should never be kept more than a year, as age impairs its active qualities. The mistletoe growing on the water or black elm (*Ulmus nemoralis*), and on the water oak (*Quercus aquatica*), is reputed to possess the most energetic medicinal virtues.

Chemical Composition.—All parts of the plant contain *viscin;* also called *bird-glue;* curiously miscalled *birdlime* (from the German *Vogelleim*), deriving its name from the fact that it has been used in Germany in catching small birds. It is very adhesive, soft, and elastic, having a greenish or brownish color; insoluble in water and fixed oils, slightly soluble in alcohol, very soluble in ether. According to Henry, the berries contain viscin, green wax, gum, bassorin, brown extractive, salts, etc. P. Reinsch (*Neues Jahrbuch f. d. Pharm.*, Vol. XIV, 1860, pp.

129–153) obtained crude *viscin* from the berries and the bark. The former yield a purer product, but are difficult to obtain in quantity, as they invariably grow on high trees. The scrapings from the bark are first kneaded with gradually increased quantities of water, which removes gum, albumen, sugar, chlorophyll, tannin, and salts; the residual mass is treated with alcohol, which removes yellow wax; the residual crude viscin is then dissolved by ether, which, upon evaporation, leaves a residue which, when washed with alcohol and water, and heated for some time to 120° C. (248° F.), constitutes pure *viscin*, a clear, tasteless, and odorless mass of the consistency of honey, and capable of being drawn out into threads. In the above treatment, ether leaves undissolved a mixture of plant fibers and a yellowish-brown, exceedingly sticky mass, which is soluble in oil of turpentine. Reinsch calls it *viscaoutchin*.

Action, Medical Uses, and Dosage.—Narcotic, antispasmodic, diaphoretic, and tonic. This plant possesses toxic properties. Vomiting, catharsis, with tenesmus and sometimes bloody stools, pupillary contraction, muscular spasm, prostration, coma, convulsions, and death have been reported from eating the leaves and berries. Viscum has been beneficially employed in *epilepsy*, *hysteria*, *insanity*, *paralysis*, and other *nervous diseases*. In using this agent, it is always necessary to regulate the condition of the stomach and bowels, and the menstrual discharge, and other faulty secretions, and remove *worms*, if any are present, previous to its exhibition. It is asserted of some value as an oxytocic, and to restrain *postpartum and other uterine hemorrhages*. It produces intermittent contractions, and by some physicians, especially Dr. Ellingwood, is declared to be safer, in many respects, than ergot. It is useful in *amenorrhœa* and *dysmenorrhœa*. It is also reputed a heart tonic. According to Dr. Tascher, it is a remedy for *cardiac hypertrophy* and *dropsy*, associated with enlarged heart. Cardiac hypertrophy, valvular insufficiency, feeble pulse, œdema, dyspnœa, and inability to lie down, were the symptoms of the cases favorably influenced by 20 to 30-drop doses of the fluid extract. Dr. Ellingwood advises it with strychnine to support the weak, irregular, and rapid heart-action, with tendency to collapse, in *typhoid fever*. It may be given in doses of from 30 to 60 grains, and gradually increased to 3 or 4 drachms, 3 or 4 times a day, and if it produces sleep or other narcotic effects, the doses must be diminished; fluid extract, 10 to 40 drops; specific mistletoe, 1 to 15 minims. Preparations of the fresh plant should be used, as the drug loses its properties when old. The powder is best given in an infusion of valerian.

Specific Indications and Uses.—Determination of blood to brain, flushed face, and oft-recurring headache; tearing, rending rheumatic or neuralgic pains, coming on in paroxysms; weak, irregular heart-action, with dyspnœa, cardiac hypertrophy, and valvular insufficiency.

Related Species.—*Loranthus europæus*, Linné. East and south Europe. This is a larger shrub, and thicker than the mistletoe. Its berries are light-yellow, and its bark grayish or deep-brown. Oak and chestnut trees support it. It is the plant alluded to by older writers as the *Viscum quercinum*.

VITELLUS (U. S. P.)—YOLK OF EGG.

"The yolk of the egg of *Gallus Bankiva* var. *domestica*, Temminck (*U. S. P.*) (*Phasianus Gallus*, Linné).

Class: Aves. *Order*: Gallinæ.

Synonym: *Ovi vitellus.*

Source.—The *Common hen*, or Dunghill-fowl, *Gallus Bankiva* (*Phasanius Gallus*), supposed to have been originally the *jungle-fowl* of India, is now domesticated almost everywhere. Its egg is the part used in medicine; less frequently the eggs of ducks and geese are in domestic use.

Description and Chemical Composition.—According to J. König (*Die Menschl. Nahrungs-und Genussmittel*, 3d ed., Vol. II, 1894, p. 201), the average weight of a hen's egg is about 53 grammes, the limits being from 30 to 70 grammes. It consists of the *egg-shell* with its lining membrane (11.5 per cent), the *egg-white* or *albumen* (58.5 per cent), and the *yolk* (30 per cent).

I. Testa Ovi (*Putamen ovi, Egg-shell*) is composed chiefly of calcium carbonate (89 to 97 per cent), calcium and magnesium phosphate (0.5 to 5 per cent), magnesium carbonate (0 to 2 per cent), and organic substance (2 to 5 per cent). The carbonate of calcium renders the shell absorbent and antacid. The albuminous membrane (*Pellicula ovi, Membrana putaminis*) which lines the inner surface of the shell, is a keratin-(horn) like substance, soluble in alkalies, from which solution it is precipitated by acids. At the broad end of the egg it forms an air space, the *Follicula aëris*.

II. Albumen Ovi (the *White* or *Glaire of egg, Ovalbumen*) is an almost colorless, transparent, odorless, liquid mass, consisting of a thin, alkaline fluid, rendered viscous on account of being enclosed in cells forming a network of delicate membranes. This fluid contains on an average 85.75 per cent of water, 12.67 per cent of nitrogenous matter, 0.25 per cent of fat, and 0.59 per cent of salts, which consist for the most part (about 92 per cent) of the chlorides of potassium and sodium. The yolk of the egg (see below) has a markedly different composition. The albumen of the white of egg (ovalbumen) corresponds to the formula $C_{144}H_{122}N_{18}S_2O_{44}$ (see J. König, *loc. cit.*), containing 1.6 per cent of sulphur. This element is partly liberated in the form of hydrogen sulphide when the egg decomposes. Ovalbumen, however, is not a simple compound; its chief constituent is *ovalbumin*, probably a mixture also; it is soluble in water, and coagulates by exposure to a temperature of 60° to 70° C. (140° to 158° F.). It is precipitated from aqueous solution by the addition of alcohol, hydrochloric acid, excess of sodium sulphate and ammonium sulphate, not by sodium chloride, and forms precipitates with tannic acid, creasote, mercuric chloride, salts of copper, chlorides of gold and tin, the acetates of lead, potassium ferrocyanide in acetic acid solution, etc. It is not precipitated by concentrated solution of magnesium sulphate at 20° C. (68° F.), and may be separated by means of this behavior from *ovoglobulin*, another nitrogenous constituent of the egg-white, forming about 0.67 per cent of the latter. *Ovomucoid* is a mucous substance rich in nitrogen (12.65 per cent) and sulphur (2.2 per cent), also contained in ovalbumen. (For further details regarding these albuminous compounds and their reactions, see Hammarsten and Mandel, *Physiological Chemistry*, 2d ed.. 1898, pp. 410–416, or similar publications.)

The reactions of ovalbumen differ somewhat from those afforded by *seralbumen*, or the albumen contained in the serum of the blood; unlike seralbumen, ovalbumen in aqueous solution is precipitated by ether and concentrated hydrochloric acid, and both differ somewhat from the albumen in the urine accompanying Bright's disease. To test a specimen of urine for albumen, apply the exceedingly sensitive *Heller's test*, as follows: Place 3 Cc. of strong nitric acid into a test-tube, add 1 Cc. of water, cool, and carefully filter into this liquid the urine, employing two layers of filtering paper, and taking care that the urine runs down the sides of the test-tube and forms a layer above the nitric acid. If albumen is present, a white ring is formed at the zone of contact. This test in case of a positive result may be supplemented by the *heat test:* Slightly acidulate the urine if alkaline with acetic acid, filter, if necessary, through a double filter into a test-tube, add about one-tenth its volume of a saturated solution of sodium chloride, and heat the upper part of the liquid over a small flame; if a cloudiness appears, which is not dissolved after cooling by the addition of nitric acid (phosphates), the turbidity will be due to albumen.

When the white of eggs is placed in thin layers on glass, and dried in the air, it becomes solid without losing its transparency or property of dissolving in water, and may be preserved in this manner for a long time; these dried fragments (*albumen ovi siccum*) will be found to answer as a substitute for the original white, when formed into a solution with water. They are insoluble in ether or alcohol. White of egg kept in its original condition speedily decomposes.

III. Vitellus Ovi, the *Yolk of egg*, is enclosed within a fine membrane, and consists of minute cells holding albuminous matter with yellow oil. It becomes solid (coagulates) by heat. Triturated with water, yolk of egg produces a thick, opaque solution, much used in pharmacy for suspending oily and resinous substances in the former fluid. Heat solidifies it, and its oil (*oil of eggs*) may then be obtained by expression; or, the oil may be prepared by boiling the yolk hard, then digesting it with ether or alcohol, filtering and distilling off the solvent, when the oil remains. When extracted by means of ether, it contains chiefly triolein (about 83 per cent), solid fats (about 16 per cent), cholesterin (1.6 per cent), lecithin (0.2 per cent), and coloring matters (M. Kitt, *Pharm. Centralhalle*, 1897, p. 340, from *Chem. Zeitg.*). J. König (*loc. cit.*) gives the following average composition of the yolk of eggs: Water, 51.8 per cent; *vitellin*, 15.8 per cent; *nuclein*, 1.5 per cent; palmitin, stearin and olein, 20.3 per cent; the crystallizable alcohol, *cholesterin* ($C_{26}H_{44}O$), 0.4 per cent; glycero-phosphoric acid, 1.2 per cent; *lecithin*, 7.2 per cent; *cerebrin*, 0.3 per cent; coloring matters (*luteines*) 0.5 per cent; salts, 1.0 per cent, consisting chiefly of phosphates of calcium, potassium and sodium. *Vitellin* (of Gobley) is a peculiar albuminous body, resembling the albumins of the globulin group (see Hammarsten and Mandel, *loc. cit.*); like these, it is insoluble in water, but is soluble in a 10 per cent sodium chloride solution, from which it is precipitated by dilution with water. It coagulates at a temperature of 70° to 75° C. (158° to 167° F.). *Lecithin*, a rather complex waxy compound occurring also in the brain, nerves, muscles, blood, etc., was first obtained by Gobley from the ether extract of the yolk. Its molecule combines the radicals of glycerin, phosphoric acid, oleic acid, palmitic acid and the base *choline* ($C_5H_{14}NO_2$) (see under *Trimethylamine*). When boiled with baryta water, it is split into the above-named fatty acids, glycero-phosphoric acid and choline.

Eggs may be preserved for some time by coating them with wax, gum, fat, paraffin, linseed oil (recommended by Violette), or similar substances, which render the shell impervious to water and air. Packing the eggs in salt or milk of lime, placing the pointed end downward, has been common practice. (Also see J. König, *loc cit.*, and *Amer. Jour. Pharm.*, 1899, pp. 7 and 24.)

Action and Medical Uses.—Eggs have been much employed in medical practice. The shells, when reduced to a very fine powder, may be used in *acid conditions of the digestive organs*, in the same doses as prepared chalk. The albumen or white is useful as a demulcent in *diseases of the intestinal mucous membrane*, and is a valuable agent in the treatment of *poisoning by bichloride of tin*, the *soluble salts of copper*, and *bichloride of mercury;* its efficiency in these cases is owing to its combining with the oxide or chloride of the metal, forming comparatively harmless compounds. In cases of redness or *excoriation* from pressure, it forms a good local application, when used in the form of a liniment, made by agitating it briskly with its own volume of alcohol. It is also employed as a clarifying agent for wines, and some other liquids. Its efficacy depends on its coagulation, by which it entangles in its meshes the impurities with which it either rises to the surface or precipitates. When the liquid to be clarified does not spontaneously coagulate the albumen, it is necessary to apply heat (P.). The white is also used for diffusing throughout water substances which are not dissolved by it. Mixed with a small quantity of alum, a coagulum (*alum curd*) is formed which has been found efficient as a local application in some *inflammations of the eye*, after the more severe symptoms have been subdued. It is likewise valuable in this form for the treatment of *erysipelas*, *scalds*, and *burns*, and *poisoning by rhus* when located near the eyes. The yolk is a mild nutrient, and generally does not offend the stomach; added to an infusion of ginger, and thoroughly beaten up with it, it has been found serviceable in *dyspepsia*. It answers the purpose much better than the white in the preparation of mixtures, emulsions, etc. Its powers as an antidote to poison are the same as those of the white. Contrary to the generally accepted notion, the hard-boiled yolk is easy of digestion. The oil obtained from the hard-boiled yolk has been found serviceable in *cracked nipples*. A non-collegiate practitioner in this country acquired some celebrity in the treatment of *dyspepsia*, loss of appetite, *constipation*, *hemorrhoids*, etc.; the agent he employed was a powder composed of equal parts of the inner skin of chickens' gizzards (*ingluvies pulli*), dried and pulverized, sulphur, and resin, of which from 5 to 10 grains were to be taken 3 or 4 times a day (see *Ingluvin*).

An artificial serum has been used to moisten the hands with during the manipulation of the abdominal contents while operating for removal of the ovaries, etc., and for other purposes; it is composed of common salt, 1 drachm; white of egg (albumen) 1½ drachms; pure water, 1 pint. Mix. During an operation in which this fluid is employed it should be constantly maintained at a blood-warm temperature. White of egg forms a good cement for mounting certain specimens for microscopic investigation.

WINTERA.—WINTER'S BARK.

The bark of *Drimys Winteri*, Forster (*Wintera aromatica*, Murray).

Nat. Ord.—Magnoliaceæ.

COMMON NAMES AND SYNONYMS: *Winter's bark*, *Winter's cinnamon*, *Cortex winteri*, *Cortex magellanicus*, *Cortex winteranus*.

Botanical Source.—This is a very large (or very small, according to locality of growth) evergreen, aromatic tree, varying in size from 6 to 50 feet high. The bark of the trunk is gray and wrinkled; that of the branches smooth and green. Branches rather erect, and scarred by the traces of fallen leaves. The leaves are alternate, oblong, obtuse, with a midrib, but otherwise veinless, glabrous, and finely dotted beneath. The flowers are small, on axillary or somewhat terminal peduncles, which are approximated, usually 1-flowered and simple; occasionally divided a little above the base into long pedicels. Sepals 2 or 3; petals 6, and oblong; fruits 4 or 6, obovate, baccate, and many-seeded (L.).

History.—This tree inhabits the southern parts of South America, Chili, Peru, Terra del Fuego, etc., and takes its name from its discoverer, Capt. Winter, who commanded the *Elizabeth* in Capt. Drake's voyage through the Straits of Magellan in 1578. Winter employed it to cure scurvy. Owing to the difficulty of obtaining the true bark, and the ease with which other barks, notably canella bark, could be substituted for it, the true bark was lost sight of for many years; hence the conflicting descriptions in the literature of the drug. Forster (1773) first correctly established its botanical identity. As a remedy for gastric debility and diarrhœa, it is largely employed in South America.

Description.—The authors of *Pharmacographia* thus describe true Winter's bark, as found by them upon many examinations: "The bark is in quills, or channelled pieces, often crooked, twisted or bent backward, generally only a few inches in length. It is most extremely thick ($\frac{1}{10}$ to $\frac{3}{10}$ inch), and appears to have shrunk very much in drying; bark $\frac{1}{4}$ inch thick, having sometimes rolled itself into a tube only 3 times as much in external diameter. Young pieces have an ashy-gray suberous coat beset with lichens. In older bark the outer coat is sometimes whitish and silvery, but often more of a dark rusty-brown, which is the color of the internal substance, as well as of the surface of the wood. The inner side of the bark is strongly characterized by very rough striæ, or, as seen under a lens, by small, short, and sharp longitudinal ridges, with occasional fissures indicative of great contraction of the inner layer in drying. In a piece broken or cut transversely, it is easy to perceive that the ridges in question are the ends of rays of the white fiber which diverge toward the circumference in radiate order, a dark-rusty parenchyme intervening between them. No such feature is observable in either *Canella* or *Cinnamodendron*. Winter's bark has a short, almost earthy fracture; an intolerably pungent, burning taste, and an odor which can only be described as terebinthinous"—(*Pharmacographia*, 2d ed., p. 19).

Chemical Composition.—Winter's bark was examined in 1820 by M. Henry, who found in it a reddish-brown, inodorous, acrid resin (10 per cent), a pale-yellow volatile oil (1.2 per cent), tannic acid, oxide of iron, starch, coloring matter, and various salts. The volatile oil appears to be a mixture of several bodies; P. N. Arata and F. Canzoneri found the oil from a genuine specimen to contain a sesquiterpene which they named *winterene* ($C_{15}H_{24}$) (*Amer. Jour. Pharm.*, 1890, p. 354).

Action, Medical Uses, and Dosage.—Stimulant, aromatic, stomachic, and tonic, and may be substituted in all cases for the canella, cascarilla, and cinnamon barks. It was highly recommended by its discoverer as an antiscorbutic. Thirty grains is the dose of the powdered bark. It is seldom used in this country. A vinous tincture (bark, ℥i to sherry wine, ℥viij) may be employed in drachm doses.

Related Drugs and Substitutes.—Another tree inhabiting Chili, *Drimys Mexicana*, Sessé (*Drimys Chilensis*, of De Candolle), has a bark possessing analogous virtues. This species and *Drimys granatensis*, Linné filius, are regarded as mere varieties of the *Drimys Winteri*. The second is now adopted by the *French Codex* as the source of the drug of commerce, which this authority states has the same properties as the original drug from the Straits of Magellan, and even excels the original drug in keeping qualities.

Cinnamodendron corticosum, Miers, of Jamaica, has been sold extensively as Winter's bark, and at one time wholly replaced the true article. *Canella alba*, Linné, at one time was erroneously believed to be the source of the commercial drug (D. Hanbury, 1862; see his *Science Papers*).

The barks of *Drimys lanceolata* and *Drimys axillaris*, Forster, both of Australia, are aromatic and pungent, and the fruit of the first-named is said to be employed as a condiment.

MALAMBO BARK is the name of a substitute for Winter's bark which appeared on the American market about 1856. It was identified by Prof. E. S. Wayne (see *Amer. Jour. Pharm.*, 1857, pp. 1-8, and D. Hanbury, *ibid.*, p. 212).

XANTHIUM.—SPINY CLOT-BUR.

The whole plant of *Xanthium spinosum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAME: *Spiny clot-bur.*

Botanical Source.—Xanthium spinosum is a weed known as "*Spiny clot-bur*," and is naturalized in the United States, in many places near the seacoast, the seed having been introduced in ballast. The stem is an annual, from 1 to 3 feet high, much branched, and armed with numerous spines. The spines are of a light straw color, and are divided, about a quarter of an inch from the base, into three slender, sharp, diverging branches. The leaves are lanceolate, acute, tapering to a short leaf-stalk at the base; they are entire or have 2 teeth, or often lobes, near the base. The under surface is covered with a close, white tomentum. The flowers are small, monœcious, the sterile being borne near the apex, the fertile at the base, of the branchlets. The fruit is a rough, oblong bur, armed at the apex with a short beak, and densely covered with equal hooked prickles.

Chemical Composition.—In 1876 (*Jahresb. der Pharm.*, p. 117) Dragendorff communicated the result of an analysis of the plant made by him in 1866. He obtained small quantities of a probably evanescent alkaloid soluble in alcohol and water. The herb contains considerable quantities of potassium nitrate. Yvon (*ibid.*) believes the alkaloidal reactions to be due to a non-alkaloidal resin soluble in ether and alcohol. About 10 per cent of starch is present.

Action, Medical Uses, and Dosage.—This plant was recommended as a specific in the treatment of *hydrophobia* by Dr. Grzyvala; the assertion being made that in one hundred cases and upward of persons who had been bitten by rabid dogs, the administration of this article effected recovery without a single failure. The dose was 10 grains of the plant, in powder, repeated several times a day. Experiments by other physicians have failed to sustain this assertion, and for this purpose the plant has passed into disrepute. It, however, is reputed sialagogue, sudorific, and somewhat diuretic, resembling to a considerable extent the action of pilocarpus, besides being antiperiodic. Prof. Scudder (*Spec. Med.*, p. 266) writes of it, that it "may be employed as a prophylactic against *ague*, as an antiperiodic when the patient is subject to profuse sweatings, and to prevent the recurrence of *chills* when they have been broken. It may be employed in any disease where there is nervous excitement attended by sweating." Clot-bur has a soothing action upon the urinary tract, and has recently proved a good remedy for *passive hematuria*. Some have reported success with it in *postpartum hemorrhage*, but it is not likely to supplant other well-known remedies for this purpose. Dr. George W. Homsher, of Camden, Ohio, attributes a specific action to this agent in *irritable conditions of the bladder*, particularly *chronic cystitis*. In cases benefited by it there is an excess of mucus and a uric acid diathesis, the bladder walls are thickened, urination is tenesmic and frequent, and gravel or minute calculi may pass continually. It is frequently used with red onion. Prof. Bloyer has used this combination with success in similar conditions, with bloody urine. Clot-bur was long ago employed in the treatment of *gonorrhœa*. Dose of the powder, 5 to 10 grains; of the tincture (fresh plant in flower, ℥viij to strong alcohol, Oj), $\frac{1}{4}$ to 10 drops; specific xanthium spinosum, $\frac{1}{10}$ to 10 drops.

Specific Indications and Uses.—Ague, with profuse sweatings; prophylactic against ague, and to prevent a recurrence of chills; nervous excitation, with copious sweating. Bloody urine; urine heavily loaded with mucus and gravelly deposit; urination painfully tenesmic and frequent.

Related Species.—*Xanthium strumarium*, Linné, *Cockle-bur, Clot-bur.* A common weed growing in wastes throughout Europe, north Asia and North America. Our indigenous plant has two varieties, the *echinatum*, Gray, and *canadense*, Miller. The fruit has been analyzed by Zander (*Amer. Jour. Pharm.*, 1881, p. 271), who isolated 1.27 per cent of a yellow, non-crystalline glucosid, *xanthostrumarin*, soluble in alcohol, chloroform, ether, benzene, and water. With the group reagents for alkaloids it forms precipitates, except with gelatin and tannin. Among other constituents were found albuminoids, 36.64; fatty matter, 38.6; ash, 5.18; sugar and resin. A peculiar principle, differing perhaps from xanthostrumarin of Zander, and about 14.5 parts of fixed oil were obtained by Chatham in 1884 (*ibid.*, p. 134).

XANTHORRHIZA.—SHRUB YELLOW ROOT.

The rhizome and roots of *Xanthorrhiza* (*Zanthorhiza*) *apiifolia*, L'Heritier (*Xanthoriza simplicissima*, H. Marshall; *Marbosia tinctoria*, Wm. Bartram; *Xanthorrhiza tinctoria*, Woodhouse).

Nat. Ord.—Ranunculaceæ.

Common Names: *Shrub yellow root*, *Southern yellow root*, *American shrub yellow root*, *Parsley-leaved yellow root*, *Yellow wort*, and *Yellow root.*

Illustration: Lloyd's *Drugs and Med. of N. A.*, Pl. 25; Bentley and Trimen, *Med. Plants*, 9.

Botanical Source.—This is a small, deciduous, indigenous shrub, 1 to 3 feet in height, with a thick, horizontal, deep-yellow rhizome, throwing up numerous suckers. The stem is short, woody, leafy above, with a light-gray (Lloyd) bark, and a bright-yellow wood. The leaves are pinnate, of about 3 pairs with an odd one, glabrous, about 8 inches long, including the long petioles; they are 2 or 3 inches long, ovate or rhomboidal, sessile, incisely-lobed, and dentate, sometimes divided almost to the base on one side, pale-green, smooth above and slightly pubescent beneath. The flowers are small, dull purplish-brown, in axillary, compound, drooping racemes, appearing with the leaves. Calyx of 5 sepals, regular, spreading, and deciduous; corolla of 5 obovate, concave, 2-lobed petals, smaller than the sepals, and raised on a claw. Ovaries from 5 to 9. Follicles or capsules inflated, compressed, spreading, 1½ inches long, 1-celled, 2-valved, and opening at the apex; seeds, oval and flattened (L.—W.—G.).

Fig. 256.

Xanthorrhiza apiifolia.

History and Description.—This plant is found along river banks in the mountains of Pennsylvania to Florida, being chiefly confined to the mountains. It is also found in some of the western and southwestern states, flowering in March and April. The root is the medicinal part; it varies in length from 4 to 12 inches, is about 6 lines in diameter, is bright-yellow (light-brown when dried), and exceedingly bitter. Water extracts its virtues, and sulphate of iron is not incompatible with its infusion. The bark of the stem is equally as efficient as the root. The Indians were well acquainted with it as a dye; it dyes silk a bright-yellow, and wool a dark-brown or dun color. The plant is generally known in the south as yellow root, a name borne farther north by hydrastis.

Chemical Composition.—The root contains berberine, to which undoubtedly its tonic properties are due. The presence of this principle was suspected in the drug by Wm. S. Merrell; it was isolated by G. Dyson Perrins (*Pharm. Jour. and Trans.*, May, 1862), who obtained but a very small amount of it. J. U. Lloyd obtained, on a large scale, 1.1 per cent of berberine monosulphate. Gum and bitter resin were early pointed out by Dr. Woodhouse (see Lloyd's *Drugs and Med. of N. A.*, Vol. I, p. 297). Mr. Samuel S. Jones (*Amer. Jour. Pharm.*, 1886, p. 161) made a complete quantitative analysis of the root. In addition to starch, dextrin, sugars, etc., he found several resins, and 0.28 per cent of total alkaloids. In the mother liquor from berberine sulphate, the author found an amorphous alkaloid not identical with berberine.

Action, Medical Uses, and Dosage.—Yellow root is a pure, bitter tonic, considered by the late Prof. Barton to be superior to calumba. It may be used for all purposes in which the other simple tonic bitters are applicable. Of xanthorrhiza, Prof. J. U. Lloyd (*Drugs and Med. of N. A.*, Vol. I, p. 289) very justly remarks that "although we find xanthorrhiza most favorably introduced by the leaders of medicine of the early part of the century, and although it has been official in the Pharmacopœia since its first issue (1820) until discarded in 1880, it has failed to obtain a foothold. It has never been a favorite with either botanic or Eclectic physicians, and it is hardly recognized by them. In this connection we must revert to the fact that, although known to the Eclectics, and possessing berberine in nearly as great proportion as hydrastis, they persistently refused to use it in place of that drug, asserting that its action was not at all similar. The investigations of Profs. Bartholow, Sattler, Shoemaker, and others (see *Hydrastis*, in *Drugs and Med. of N. A.*), now show that these conclusions were rational, as at least one of the very active principles of hydrastis is entirely absent from xanthorrhiza." Dose of the powder, 20 to 40 grains, 3 times a day; of the decoction, 1 or 2 tablespoonfuls; of the tincture, which is its most eligible form, from 1 to 3 fluid drachms. It contains a bitter resin, which would probably form an excellent tonic.

XANTHOXYLUM (U. S. P.)—XANTHOXYLUM.

The bark of *Xanthoxylum americanum*, Miller (*X. fraxineum*, Willdenow; *X. fraxinifolium*, Marshall; *X. ramiflorum*, Michaux; *X. tricarpum*, Hooker; *X. Clava-Herculis*, Lamarck; *Thylax fraxineum*, Rafinesque), and of *Xanthoxylum Clava-Herculis*, Linné (*X. fraxinifolium*, Walter; *X. aromaticum*, Willdenow; *X. carolinianum*, Lamarck; *X. tricarpum*, Michaux; *X. Catesbianum*, or *Pseudopetalon glandulosum*, or *P. tricarpum*, *Kampmannia fraxinifolia*, Rafinesque; *Fagara fraxinifolia*, Lamarck). The berries are also employed, but are not official.

Nat. Ord.—Rutaceæ.

COMMON NAMES: (1) *Prickly ash*, *Toothache tree* (or *bush*), *Northern prickly ash*, *Yellow wood*, *Angelica tree*, *Suterberry;* (2) *Southern prickly ash*, *Toothache tree*, *Angelica tree*, *Suterberry*.

ILLUSTRATIONS: (1) Bigelow, *Amer. Med. Bot.*, Vol. III, 156; (2) Willdenow, *Sp. Plant.*, Vol. IV, 214.

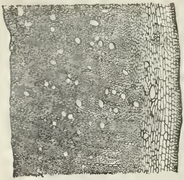
Botanical Source.—*Xanthoxylum americanum* is an indigenous shrub, 10 or 12 feet in height, with alternate branches, which are armed with strong, conical, brown prickles, with a broad base, scattered irregularly, though most frequently in pairs at the insertion of the young branches. The leaves are alternate and pinnate; the leaflets about 5 pairs, with an odd one, nearly sessile, ovate, acute, with slight vesicular serratures, and somewhat downy underneath; the common petiole round, usually prickly on the back, though sometimes unarmed. The flowers are borne in small, dense, sessile umbels, near the origin of the young branches; they are small, greenish, diœcious or polygamous, appear before the leaves, and have a somewhat aromatic odor. In the sterile flower the calyx is 5-leaved, with oblong, obtuse, erect segments, 5 stamens with subulate filaments, and sagittate, 4-celled anthers; the ovary is abortive. In the hermaphrodite or perfect flower, the calyx and stamens are like the last, ovaries 3 to 4, pediceled, with erect, converging styles nearly as long as the stamens. Fertile or female flowers grow upon a separate tree, are apetalous, with a smaller and

Fig. 257.

Xanthoxylum americanum.

more compressed calyx, and 5 pediceled ovaries, with styles converging into close contact at top, and a little twisted; stigmas obtuse. Each fertile flower is succeeded by as many capsules as it had ovaries. Capsules stipitate, oval, covered with excavated dots, varying from green to red; 2-valved and 1-seeded; seeds oval and blackish (L.—W.—G.).

Fig. 258.

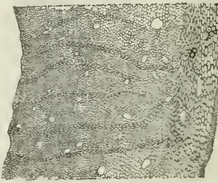


Xanthoxylum americanum, L. (Northern prickly ash).

Xanthoxylum Clava-Herculis ranges from a shrub to a small-sized tree, yet sometimes attaining a height of 45 feet. The bark is beset with verrucose prickles. The petioles and branches are armed with larger prickles. The leaves are odd-pinnate; the leaflets from 5 to 17 in number, ovate-lanceolate, unequilateral, the terminal one only being equilateral, shining and smooth on the upper surface, and having crenate-serrulate margins. The flowers are plentiful, of a greenish hue, appear before the leaves, and have but 3 pistils.

History.—Northern prickly ash, a well-known shrub of the rue family, furnishes a drug that ranked among the most important during the early investigations of our indigenous remedies by the "Eclectic Fathers." It was an especial favorite with Prof. John King. The shrub is common in thickets, rocky woods, and along river banks from Virginia northward to Canada, and westward to the Mississippi, though scarce east of the Hudson valley. It grows to the height of 5 to 10 feet. The flowers, which appear in April and May before the leaves have expanded, are axillary, small, and of a greenish color. On account of its pinnate leaves and spiny, prickly stems, it is best known to the common people as Prickly ash. To distinguish it from a southern species (*Xanthoxylum Clava-Herculis*), which is known as Southern prickly ash, it is sometimes called Northern prickly ash. Its reputed efficacy in toothache has given it the name of Toothache tree. In common with some other plants, it is also known as Yellow wood, a name giving the literal meaning of Xanthoxylum (Greek: *xanthos*, yellow; *xylon*, wood). All parts of the shrub are aromatic and pungent, and the leaves and berries have a decided odor of lemons. Water and alcohol extract its virtues. The therapeutic principle of the berries resides in the capsule surrounding the seeds. This principle has been found to be a volatile oil. The whole plant possesses medicinal virtues; the fragrance of the fruit and leaves is due to a volatile oil. Both the bark and fruit (berries) are employed medicinally.

Fig. 259.



Xanthoxylum Clava-Herculis, L. (Southern prickly ash).

Description.— Bark. The two official barks are thus described: "*Xanthoxylum americanum* (Northern prickly ash) is in curved or quilled fragments, about 1 Mm. ($\frac{1}{25}$ inch) thick; outer surface brownish-gray, with whitish patches, and minute, black dots, faintly furrowed, with some brown, glossy, straight, 2-edged spines, linear at the base, and about 5 Mm. ($\frac{1}{5}$ inch) long; inner surface whitish, smooth; fracture short, non-fibrous, green in the outer and yellowish in the inner layer; inodorous; taste bitterish, very pungent. *Xanthoxylum Clava-Herculis* (Southern prickly ash) resembles the preceding, but is about 2 Mm. ($\frac{1}{12}$ inch) thick, and is marked by many conical, corky projections, sometimes 2 Cm. ($\frac{4}{5}$ inch) high, and by stout, brown spines, rising from a corky base. Xanthoxylum should not be confounded with the bark of *Aralia spinosa*, Linné (*Nat. Ord.*—Araliaceæ), which is nearly smooth externally, and beset with slender prickles in transverse rows"—(*U. S. P.*).

Berries.—The fruit, or berries, as met with in commerce, consist of open, bivalved, oval capsules, about 3 lines in length and 2 in diameter, brownish, and covered with excavated dots externally, whitish-yellow, and smooth internally, and usually with a portion of the stalk appended; they inclose an oval, shining, black, wrinkled seed, which, in the dried state, is hollow, and grayish-yellow or light brownish-yellow internally, inodorous, very brittle, and having the peculiar taste of the capsule in a very faint degree. This seed is more often absent than present in the capsule, from whose opening it escapes, and may be generally found separated from it, but mixed up with the mass. The medicinal virtues of the fruit reside in the capsules, which have a faintly aromatic, peculiar odor, and a warm, pungent, peculiar, aromatic, and pleasant taste, both of which properties are more energetic in the recent than in the dried fruit. They depend upon a volatile oil for their properties, which they yield to alcohol or ether.

Chemical Composition.—The bark of *Xanthoxylum fraxineum*, Willdenow, (Northern prickly ash) was first investigated by Dr. Edward Staples (*Amer. Jour. Pharm.*, 1829, p. 163), who isolated therefrom a crystallizable principle, which he called *xanthoxylin*. From the same source, E. T. Moffit (*ibid.*, 1886, p. 417) and, previously, J. U. Lloyd (*ibid.*, 1876, p. 226, and 1890, p. 229) obtained a similar substance. It forms colorless, tasteless needles, insoluble in cold water, very slightly soluble in boiling water, quite soluble in boiling alcohol; it is physiologically inert (Lloyd). A similar principle was derived from the bark of *X. carolinianum* (Southern prickly ash) by George H. Colton (*ibid.*, 1880, p. 191). E. G. Eberhardt (*ibid.*, 1890, p. 231) showed the non-identity of the principles derived from different species, while those obtained by various authors, from the same species, were shown to be identical. Probably the *xanthoxyloïne* of Witte (*Dissert.*, 1876; see *Jahresb. der Pharm.*, 1877, p. 178) is identical with the xanthoxylin of Staples, Lloyd, and Moffit. Witte found it to have the formula $C_{14}H_{14}O_{2}$, and to melt between 131° and 131.5° C. (267.8° and 268.7° F.). Eberhardt observed a melting point of 129.5° C. (265.1° F.) with Lloyd's recrystallized specimen. According to Moffit (*loc. cit.*), the bark also contains a bitter, yellowish alkaloid, soluble in alcohol, water, and chloroform, insoluble in benzin and ether. It is probably related to berberine; a similar alkaloid, insoluble in chloroform, was found by Colton (*loc. cit.*) in northern bark. Additional constituents are fixed oil, an acrid resin, some sugar, tannin, gum, albuminoids, coloring matter, forming a precipitate with basic lead acetate, ash (about 12 per cent), but no starch (Moffit). In the Caribbean Xanthoxylum (*Xanthoxylum carribæum*, Lamarck) Chevallier and Pelletan (1826) found the alkaloid *xanthopicrite*, which Perrins (1862) showed to be identical with *berberine*. In recent years Prof. Schaer (*Beiträge zur Geschichte des Berberins*, Zürich, 1893) again demonstrated the presence of berberine in certain South American Xanthoxylum barks.

Action, Medical Uses, and Dosage.—Physiologically, prickly ash acts upon the secretions, the nervous and circulatory systems. The bark, when chewed, imparts an aromatic, sweetish taste, followed by bitterness and persistent acridity. Its sialagogue properties are remarkable, inducing a copious flow of saliva, together with a great quantity of mucus from the buccal glands. This is brought about both by its local and systemic action. In the stomach it creates a sense of warmth, and the flow of both gastric and intestinal juices is augmented. There is increased biliary and pancreatic activity. Under its action the kidneys become more active, and an increased urinary product results. Cardiac action is increased, the pulse becomes slightly accelerated, and the integumentary glands give out an abundant secretion. Therapeutically, the bark is sialagogue, alterative, diaphoretic, and especially stimulant to the mucous surfaces. It is also emmenagogue and carminative, and the berries are said to possess antiseptic properties. To increase its diaphoretic power, it should be administered with plenty of hot water, at the same time subjecting the patient to a warm foot-bath. Prof. King cautions us that there is a material difference, in their influence on the system, between the tincture of the bark, or that of the berries, which should always be kept in view. The properties of the bark, as given by him, are stimulant, tonic, alterative, and sialagogue; of the berries, stimulant, carminative, and antispasmodic, acting especially on mucous tissues. Prickly ash has been deservedly valued in domestic practice as a remedy for *chronic rheumatism*, and was once quite popular as a masticatory for the relief of *toothache*. It undoubtedly has some value in rheumatic complaints, and may be combined with phytolacca when the indications for that drug are present. Its value in chronic rheumatism is very likely due to its eliminative power. It is best adapted to debilitated patients, and to cases of transient and fugitive forms of rheumatism, particularly *lumbago*, *torticollis*, *myalgia*, and *muscular rheumatism*. It may be used externally and administered internally, and in many cases will assist the action of macrotys. Its use in *odontalgia* will be confined to those cases where there is dull, grumbling pain due to peridental inflammation, the parts being dry and shining, and the buccal secretions scanty. Owing to its eliminative powers, it has been quite extensively used in constitutional *syphilis* and *scrofula*, and as a remedy for the former ranks with guaiac, stillingia, sarsaparilla, and mezereon. It is one of the constituents of "Trifolium Compound," and other alterative mixtures. Prof. King states that "combined with equal parts of pulverized blue flag and mandrake, it will bring on salivation, and is useful on this account in the treatment of *scrofulous*, *syphilitic*, and other diseases where there is a want of susceptibility to the influence of other alterative agents; the mixture must be given in small doses, and repeated at short intervals. Externally, it forms an excellent stimulating application to *indolent and malignant ulcers*." Xanthoxylum is serviceable in many disorders of the mouth and throat, as well as of the entire alimentary tract. It has some reputation as a local stimulant for *paralysis of the tongue*, though its value here is overrated. In like manner it has been employed in *neuralgia*, and *paralytic conditions of the vocal apparatus and organs of deglutition*. That it will relieve an unpleasant dryness of the mouth and fauces is well established. It is a remedy of value in *pharyngitis*, especially the chronic variety, the mucous surfaces presenting a glazed, shining, dry condition, with thin, adherent scales of dried mucus. In both *pharyngitis* and *post-nasal catarrh* a decoction locally, and specific xanthoxylum (bark) internally, will be found to aid a cure in those cases having dryness of mucous membranes as a distinctive feature. Prickly ash is unmistakably an admirable gastro-intestinal tonic. It will find a place in the treatment of *atonic dyspepsia* and *gastric catarrh*. Many chronic affections of the mucous tissues are benefited by it, the cases being those of enfeeblement and relaxation, with hypersecretion. *Constipation* due to deficient intestinal secretion has been overcome by its use alone. It is more especially indicated when accompanied by a flatulent distension of the abdomen. As an agent for *flatulence*, the preparation from the berries will give the best results. Lack of secretion in any part of the intestinal tract calls for a preparation of prickly ash bark. Both the bark and the berries may be required in some instances. *Icterus*, the result of *biliary catarrh*, is specifically influenced by xanthoxylum, as well as that form resulting from malarial impression. In *spasm of the bowels*, *colic*, *cholera infantum*, and *cholera morbus*, specific xanthoxylum (berries) will be found valuable in atonic cases. It is useful to restore the bowels to their normal state after severe attacks of *dysentery*, and has been of particular service as a remedy for *epidemic dysentery*. Prof. John King introduced the saturated tincture of the berries to the profession in Cincinnati, in 1849, as a remedy for *Asiatic cholera*. In his article on prickly ash berries in the *College Journal* for 1856 (p. 86), he writes: "I have used this tincture for some years past, and had the pleasure to introduce it to the profession in this city during the year 1849, both in the treatment of *tympanitic distension of the bowels* during *peritoneal inflammation* and in *Asiatic cholera*. In *tympanites* it may be administered by mouth and by injection; internally, from $\frac{1}{2}$ to 1 fluid drachm may be given in a little sweetened water, repeating the dose every $\frac{1}{2}$ or 1 hour. At the same time, $\frac{1}{2}$ fluid ounce may be added to the same quantity of water and used as an injection, repeating it every 15 or 30 minutes, according to its influence and the severity of the symptoms, and should there be pain 10 to 20 drops of laudanum may be added to every third or fourth injection. The action is usually prompt and permanent, and, as far as my experience has gone, I prefer it, in a majority of cases, to oil of turpentine and other remedies advised in this condition. In Asiatic cholera during 1849–50 it was much employed by our physicians in Cincinnati, and with great success—it acted like electricity, so sudden and diffusive was its influence over the system. In this disease the tincture was given in teaspoonful doses, and repeated, according to circumstances, every 5, 10 or 20 minutes, at the same time administering an injection, prepared as above, after each discharge from the bowels, and causing it to be retained by the bowels as long as possible." Prof. King likewise valued it in *atonic diarrhœa* and in *typhoid conditions* requiring a stimulant, believing it to have an advantage over all other drugs for that purpose. In the tympanitic conditions incident to *cholera infantum* and other forms of *diarrhœa*, he combined equal parts of olive oil and tincture of prickly ash berries and had the little patient's abdomen freely rubbed with it, in a downward direction only, for 1 or 2 hours, until the flatulent state was over, claiming thereby to have saved many a little one who would otherwise have gone to an early grave. To prevent a return of the tympanitic distension he used the tincture by mouth and per rectum. Combined with diuretics and tonics, prickly ash has been employed in *dropsy* and in *malarial manifestations*, and is in good repute as a remedy for *functional dysmenorrhœa*. For the latter purpose about 20 drops of specific xanthoxylum (bark) should be administered at a dose, and repeated as often as necessary. Both the bark and berries give good results in *neuralgic dysmenorrhœa* with marked pain and hypersensitiveness. Xanthoxylum is a valuable nerve stimulant, and may be administered for some length of time without ill effects. It is valuable in all cases of prostration, and has been recommended in "*hemiplegia*, *locomotor ataxia*, and all depressed conditions of the vital forces." *Pains* down the anterior portions of the thighs, as well as *after-pains*, accompanied with dorsal or sacral pain, are relieved by it. It relieves neuralgic pains in anemic and delicate persons. Owing to its action on blood stasis, overcoming capillary engorgement, it has been found useful in determining the rash to the surface in the *eruptive diseases*, and is especially serviceable in cases of retrocession of the eruption. It is a remedy that is neglected, but should be borne in mind during the prevalence of summer diseases. The dose of specific xanthoxylum (berries) is from 5 to 30 drops; of specific xanthoxylum (bark), from 2 to 20 drops; of the powder, from 10 to 30 grains, 3 times a day. The *oil of xanthoxylum* may be used for the same purpose as the berries, in doses of from 2 to 10 drops, in mucilage, or on sugar; and its tincture, made according to the formula below (see *Preparation*), may be administered in the same doses as the tincture of the berries.

Specific Indications and Uses.—Xanthoxylum is specifically indicated (in the smaller doses) in hypersecretion from debility and relaxation of mucous tissues; atonicity of the nervous system (larger doses); in capillary engorgement in the exanthemata, sluggish circulation, tympanites in bowel complaints, intestinal and gastric torpor (with deficient secretion), dryness of the mucous membrane of mouth and fauces (with glazed, glossy surfaces), flatulent colic, Asiatic cholera, uterine cramps, and neuralgia. For the painful bowel disorders, the preparations of the berries are to be preferred.

Preparation.—An *ethereal oil* has been made from the bark, by filtering its ethereal tincture, and then evaporating or distilling off the ether. The oil is dark greenish-black in bulk, yellowish-green in thin layers; very fluid, possessing an odor of ether, and the peculiar taste of the bark in an eminent degree. It is soluble in alcohol, ether, and alkaline solutions, and will probably be found to possess the active principle of the bark in a concentrated form.

Related Species.—*Xanthoxylum floridanum*, Nuttall (probably identical with Lamarck's *X. caribæum*), *Yellow thorn*, *Yellow Hercules' club*, *Satin wood*. Florida and West Indies. Yields a paralyzing and lethal alkaloid.

Xanthoxylum piperitum, De Candolle, of Japan, *X. alatum*, Roxburgh, of north India, and other species, yield aromatic, pungent berries, employed as condiments. They are also used as bitters and aromatics (Dymock). Stenhouse (1854 and 1857) distilled the fruits with water, and obtained an essential oil. The yield is over 3 per cent, and chiefly contains the aldehyde, *citral* (Schimmel & Co., October, 1890). The oil separates into crystals of a stearopten, called, by Stenhouse, *xanthoxylin* ($C_{20}H_{24}O_8$), and a colorless liquid, *xanthoxylene* ($C_{10}H_{16}$), which boils at near 162° C. (324° F.). It is a hydrocarbon, perhaps identical with pinene or camphene.

Xanthoxylum senegalense, *Artar root*.—Giacosa and Soave (*Amer. Jour. Pharm.*, 1890, p. 500) have examined this root, and find, besides a fixed oil and a crystalline neutral compound, two alkaloids—amorphous *artarine* (0.4 per cent), agreeing in composition with *methyl hydroberberine* ($C_{21}H_{23}NO_4$); the second, a blood-red alkaloid is present in smaller quantity, and forms acicular crystals, readily soluble in water. One of the alkaloids is a cardiac stimulant, resembling veratrine in its action.

Xanthoxylum pterota, Kunth.—Southern United States, south to Brazil. Yields pungent leaves and bark, and has a hard, dense-yellow wood.

Xanthoxylum Naranjillo is said to resemble jaborandi, as a sialagogue, diuretic, and diaphoretic.

Xanthoxylum Rhetsa, De Candolle (aromatic stimulant), *X. zeylanicum* (aromatic bitter), *X. Budrunga* (stimulant, digestive, and stomachic), and *X. hastile* (an aromatic stimulant) are employed more or less in India (Dymock, *Mat. Med. of Western India*).

ZEA (U. S. P.)—ZEA.

"The styles and stigmas of *Zea Mays*, Linné"—(*U. S. P.*).

Nat. Ord.—Gramineæ.

COMMON NAME: *Corn-silk.*

Botanical Source.—Indian corn is a monœcious, paniceous grass, annual, with a fibrous root, and an erect, leafy stem, channelled on one side, 5 to 10, and, in some varieties, 15 to 20 feet high. The male flowers are terminal and racemose; the female axillary and densely spiked. Stamens 3. Ovary sessile and ovate. Style 1, long and capillary. Stigma ciliated. Caryopsides roundish or reniform, arranged on a large cylindrical receptacle or rachis, popularly called the cob, generally in 8 rows. The ordinary color of the ripe grains or caryopsides is yellow, but they are frequently met with white, parti-colored, red, purple, or even black (W.—P.).

History.—Corn is a native of the warm latitudes of America, and its varieties are exceedingly numerous. It is extensively cultivated in the United States, and also in various parts of the world, and is much used in these countries as one of the principal articles of diet. It is very nourishing and digestible, and is used in many forms in this country, as bread, mush, puddings, cakes, etc. It is incapable of being made into light or raised bread, on account of its small quantity of gluten. *Roasting-ears*, or *hot corn*, as it is called in this country, consists of the young ears, which are gathered just previous to becoming ripe and hard, and boiled in water. They form an agreeable and nutritious food, but should not be used by those disposed to looseness or other intestinal derangements. The parts used in medicine are *corn-meal* and the styles and stigmas, the latter two constituting the official *Zea*, which is thus described:

Description.—*Zea*, or *Stigmata maydis*, is "thread-like, about 15 Cm. (6 inches) long, and 0.5 Mm. ($\frac{1}{50}$ inch) broad, yellowish or greenish, soft-silky, finely hairy, and delicately veined longitudinally; inodorous; taste sweetish"—(*U. S. P.*).

Chemical Composition.—GRAIN OF MAIZE contains moisture (13.3 per cent), starch (50 to 67 per cent, and more), nitrogenous matters (about 10 per cent), fatty or oily substance (3.8 to 9 per cent), and mineral matters (about 1.5 per cent), consisting chiefly of potassium phosphate. The *oil of maize* occurs mainly in the embryo, and can not be obtained from the corn by mere pressure. The grains are allowed to sprout to a certain extent; the germ containing over 15 per cent of the oil, is separated by machinery from the starchy part, and is then softened by steam and subjected to hydraulic pressure, which separates the oil and yields a press-cake, rich in albuminoids, and retaining 4 to 5 per cent of oil. Or, the oil is yielded as a by-product in the manufacture of corn-starch (see J. M. Maisch, *Amer. Jour. Pharm.*, 1885, p. 404, and J. U. Lloyd, *ibid.*, 1888, p. 325; also see C. E. Bowers, *ibid.*, 1889, p. 503). Oil of maize has been used as a lubricant, and in the manufacture of soap. It is a bland, non-drying, yellowish oil, having a specific gravity of 0.92. It is readily saponifiable, and does not easily become rancid upon exposure to the air. Prof. Lloyd recommends its use especially in the making of ammonia liniment.

CORN-SILK (*Zea*).—C. J. Rademaker and John L. Fischer (*Amer. Jour. Pharm.*, 1886, p. 369) found corn-silk to contain 5.25 per cent of a light-yellow fixed oil, resin, a crystallizable acid (*maizenic acid* of Vautier), soluble in water, ether, and alcohol, insoluble in petroleum spirit; and sugar, gum, albuminoids, etc. No volatile oil could be found. J. M. Hillan (*ibid.*, 1884, p. 571), by distillation with alkali, obtained a basic distillate, yielding a crystalline acetate, which formed precipitates with solution of iodine and with Mayer's solution. The same author found 83.3 per cent of moisture, and in the dried corn-silk 12.5 per cent of ash. Sugar was observed in green but not in the dried corn-silk. (For pharmaceutical preparations from corn-silk, see Geo. W. Kennedy, *Amer. Jour. Pharm.*, 1883, p. 242.)

Action, Medical Uses, and Dosage.—Corn-silk is diuretic and slightly anodyne, and, for the former purpose, has been found useful in many urinary troubles, associated with renal and cardiac disorders. In southern France, the inhabitants use it as a domestic remedy for *calculi*, *gravel*, and *strangury*. It has been found of value by physicians in the treatment of *cystic irritation*, due to phosphatic and uric acid concretions, and in both *acute and chronic inflammations of the bladder*, whether traumatic or idiopathic. *Dropsy*, when due to cardiac or renal origin, and particularly after such urinary disorders as those above mentioned, and *pyelitis, catarrh of the bladder*, and *urinal retention* appear to be benefited by the diuretic action of this drug, which action is said to be quite positive. Besides its diuretic effects, the drug seems to be a cardiac stimulant as well. In fact, its diuretic action is largely due to its tonic action upon the heart and blood vessels. It is especially of value in the *bladder disorders of children*, in *gonorrhœa*, and in cases where decomposition of the urine is prone to take place within the bladder. The active virtues are attributed to the maizenic acid, which may be given in ⅙-grain doses. However, the infusion of the fresh "silk" (silk ℥ii to boiling water Oj) is the most active preparation, and should be freely administered. The fluid extract, which is said to well represent the drug, may be given in doses of ½ to 2 fluid drachms, every 2 to 4 hours.

Corn-meal forms a very palatable and nutritious gruel for the sick, and, in the form of mush, is an excellent diet for convalescents, as well as a good emollient poultice for *ulcers, swellings, rheumatic pains*, etc. An infusion of parched corn is useful in allaying the *nausea* and *vomiting* attendant upon many diseases. It may be drank freely. (For the parasitic fungus growing on corn [*Ustilago Maydis*], see *Ustilago*.)

ZINCI ACETAS (U. S. P).—ZINC ACETATE.

Formula: $Zn(C_2H_3O_2)_2+2H_2O$. Molecular Weight: 218.74.

"Zinc acetate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—"Take of carbonate of zinc, 2 ounces (av.); acetic acid, 5 fluid ounces, or a sufficiency; distilled water, 6 fluid ounces. Add the carbonate of zinc in successive portions to 3 ounces of the acetic acid previously mixed with the water in a flask; heat gently, add by degrees the remainder of the acid till the carbonate is dissolved; boil for a few minutes, filter while hot and set it aside for 2 days to crystallize. Decant the mother liquor; evaporate to one-half, and again set it aside for 2 days to crystallize. Place the crystals in a funnel to drain, then spread them on filtering paper on a porous tile, and dry them by exposure to the air at ordinary temperatures"—(*Br. Pharm.*, 1885). The following reaction takes place: $ZnCO_3+2C_2H_4O_2=Zn(C_2H_3O_2)_2+H_2O+CO_2$. If evaporation is conducted at the boiling temperature, acetic acid is liable to be lost, and an insoluble basic acetate is formed. This is obviated by adding a slight excess of acetic acid. If concentration is carried too far, the salt will crystallize with less than 2 molecules of water. Zinc acetate may also be prepared by the interaction of zinc sulphate and lead acetate, double decomposition taking place as follows: $ZnSO_4+Pb(C_2H_3O_2)_2=Zn(C_2H_3O_2)_2+PbSO_4$. If the solution contains a slight excess of lead, this may be removed by digesting it with pure metallic zinc. If the zinc acetate solution contains ferric salt, this may be precipitated by means of freshly prepared zinc hydroxide or carbonate (compare Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1846, p. 241).

Description and Tests.—As officially described, zinc acetate forms "soft, white, 6-sided, monoclinic plates, of a pearly luster, having a faintly acetous odor, and an astringent, metallic taste. Exposed to the air, the salt gradually effloresces, and loses some of its acid. Soluble, at 15° C. (59° F.), in 2.7 parts of water, and in 36 parts of alcohol; in 1.5 parts of boiling water, and in somewhat less than 3 parts of boiling alcohol. Protracted boiling with water renders the salt less soluble, acid being lost and a basic salt formed. When heated, the salt is partially fused, losing water and acid. At a higher temperature it is decomposed, evolving acetone and other combustible vapors, and leaving a residue of zinc oxide. The aqueous solution reddens litmus paper. In the aqueous solution (1 in 20) of the salt, hydrogen sulphide T.S., as well as ammonium sulphide T.S., produces a pure white precipitate; potassium ferrocyanide T.S. also causes a white precipitate. Potassium hydrate T.S., or ammonium carbonate T.S., when added to a small quantity, produces a white precipitate, which dissolves upon the addition of an excess of the reagent. The addition of a little ferric chloride T.S. produces a red color"—(*U. S. P.*). The red color is due to the formation of ferric acetate. The presence of the acetic acid radical may also be shown by means of sulphuric acid, which liberates acetic acid. The precipitate of zinc hydroxide ($Zn[OH]_2$) caused in solution of zinc acetate by potassium hydrate, is soluble in excess of the alkali, with the formation of a double compound (ZnO_2K_2). If cadmium or magnesium are present, the hydroxides of these metals will not dissolve in an excess of the precipitant. "The aqueous solution (1 in 20), acidulated with hydrochloric acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.)"—(*U. S. P.*). Arsenic and cadmium would produce a yellow color, while lead, copper, bismuth, etc., would impart a black or at least a dark tint to the white zinc sulphide. "If the aqueous solution be completely precipitated by hydrogen sulphide T.S. (without having been acidulated), the filtrate should, after evaporation, leave no fixed residue (absence of aluminum, iron, alkalies, alkaline earths, etc.). The aqueous solution should remain perfectly clear after the addition of either barium chloride T.S. (absence of sulphate), or silver nitrate T.S. (absence of chloride)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—As an internal medicine acetate of zinc, in doses of 1 or 2 grains, gradually increased, is said to be tonic and antispasmodic, and has been used in the same cases in which the oxide or sulphate of zinc is employed. In large doses it causes vomiting and purging. Zinc acetate will control *passive hemorrhages*. It is principally used in solution as an astringent application in *chronic ophthalmia*, *leucorrhœa*, *gleet*, and *chronic gonorrhœa*. Two or more grains of the acetate may be dissolved in 1 fluid ounce of pure water and used as a wash, or by injection. Seldom employed.

ZINCI BROMIDUM (U. S. P.)—ZINC BROMIDE.

FORMULA: $ZnBr_2$. MOLECULAR WEIGHT: 224.62.

SYNONYM: *Zincum bromatum.*

"Zinc bromide should be kept in small, glass-stoppered bottles"—(*U. S. P.*).

Preparation.—This salt may be prepared either by the direct union of zinc and bromine, or by the double decomposition of crystallized zinc sulphate (240 parts) and potassium bromide (100 parts). In the latter process (see L. Lyons, *Amer. Jour. Pharm.*, 1880, p. 75), just sufficient water to dissolve the salts is employed, and the solutions are added to each other while hot. After cooling, twice the bulk of alcohol is added, and the potassium sulphate removed by filtration through asbestos. Lastly, the solution is evaporated to dryness. Theoretically, the following reaction takes place: $ZnSO_4+7H_2O+2KBr=ZnBr_2+K_2SO_4+7H_2O$. In order to prevent the formation of an alcohol-soluble double compound ($ZnBr_2.BrK$), an excess of zinc sulphate must be employed, which is the case in the above proportions. It is best prepared, however, by digesting granulated zinc in hydrobromic acid, whereby hydrogen gas is evolved, and filtering the solution through asbestos, evaporating carefully, rendering slightly acid with hydrobromic acid, and finally drying the salt by evaporation over a water-bath. This salt does not readily crystallize from water.

Description and Tests.—"A white, granular powder, odorless, and having a sharp, saline and metallic taste. Very deliquescent. Readily soluble in water and alcohol. When heated to 394° C. (741.2° F.), the salt fuses, and, with careful increase of heat, may be sublimed in the form of needle-shaped prisms. The aqueous solution gives a slightly acid reaction with litmus paper. A 5 per cent aqueous solution of the salt yields a pure white precipitate with hydrogen sulphide T.S., ammonium sulphide T.S., or potassium ferrocyanide T.S. Silver nitrate T.S. produces a yellowish-white precipitate, insoluble in ammonia water. If a few drops of copper sulphate T.S. be mixed with 5 Cc. of the aqueous solution (1 in 20) of zinc bromide, and then some sulphuric acid be carefully poured into the mixture so as to form a separate layer, a deep brownish-red color will appear at the line of contact, and will disappear when the mixture is shaken. If to the aqueous solution (1 in 20) a little starch T.S. be added, and then some chlorine water, drop by drop, the liquid should assume a pure-yellow color, free from any shade of blue (absence of iodine). After acidulation with hydrochloric acid, the aqueous solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.). On adding ammonium carbonate T.S. to the aqueous solution of zinc bromide, a white precipitate is produced, which should completely redissolve in an excess of the reagent (absence of iron, aluminum, calcium, etc.). If from this solution in ammonium carbonate T.S. all the zinc be precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation (absence of alkalies, magnesium, etc.). If 0.3 Gm. of the dry salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require 26.7 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to not less than 99.95 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This agent was introduced to fulfil the indications of zinc and bromine, but has failed to become an established remedy. It has, however, been asserted to have proved useful in *epilepsy*, but it is not well borne by the patient. Dose, 1 to 5 grains.

ZINCI CARBONAS PRÆCIPITATUS (U. S. P.)—PRECIPITATED ZINC CARBONATE.

Synonyms: *Zinci carbonas præcipitata* (*U. S. P.*, 1870), *Carbonate of zinc*, *Zinci carbonas* (*Br.*), *Zincum carbonicum*.

Source.—Zinc carbonate occurs native, both in Europe and this country, as *zinc-spar* or *calamine* ($ZnCO_3$), and, together with zinc silicate, as *siliceous calamine*. Both, when ground, constitute the *Lapis calaminaris* of commerce. It should be free from barium sulphate. Quite recently, a spurious calamine was recorded (E. H. Gane, *Bull. Pharm.*, 1900, p. 123, from *Amer. Druggist*), consisting entirely of barium sulphate, and being colored with ferric oxide. Calamine has also been employed medicinally in the form of the calcined ore, and then consists chiefly of an impure oxide of zinc (see *Zinci Oxidum*). The zinc carbonate now employed medicinally is that obtained by precipitation.

Preparation.—Precipitated carbonate of zinc is prepared by adding to a hot solution of pure, iron-free zinc sulphate (10 parts) a hot solution of crystallized sodium carbonate (10.5 parts), with constant stirring. A precipitate of basic carbonate of zinc, of variable composition is formed, *e. g.*, $2ZnCO_3+3Zn(OH)_2$, while some carbonic acid is liberated, according to the following equation: $5ZnSO_4+5Na_2CO_3+3H_2O=2ZnCO_3+3Zn(OH)_2+3CO_2+5Na_2SO_4$. After effervescence has ceased, boil for 15 minutes, then let the precipitate subside, withdraw the supernatant liquid, and wash the precipitate with fresh portions of boiling water, until the washings are no longer precipitated by chloride of barium. Allow the precipitate to drain on a calico strainer, and dry at a moderate temperature. Ammonium carbonate can not be used in the preparation of this substance, because it is soluble in excess of the precipitant.

Description and Tests.—Precipitated carbonate of zinc is "an impalpable, white powder, of somewhat variable chemical composition, without odor or taste. Permanent in the air. Insoluble in water or alcohol; soluble in diluted acids with copious effervescence; also soluble in ammonia water, and in ammonium carbonate T.S. When strongly heated, the salt loses water and carbon dioxide, and leaves a residue of zinc oxide, which is yellow while hot, but becomes white on cooling. When a small portion of the salt is moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid-green color"—(*U. S. P.*). This compound, called *Rinmann's green*, is characteristic for zinc. The reaction is analogous to that for aluminum compounds, which form a blue mass, called *Thénard's blue*. The *U. S. P.* further directs for precipitated zinc carbonate: "For making tests of identity and purity, add 10 Cc. of diluted sulphuric acid and 10 Cc. of water to 1.25 Gm. of the salt, and, after effervescence has ceased, remove the undissolved excess by filtration. In a portion of the filtrate a pure white precipitate is produced by potassium ferrocyanide T.S., or by ammonium sulphide T.S. In another portion of the filtrate, acidulated with hydrochloric acid, no color or turbidity should be produced by the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.). Another portion of the filtrate should yield with ammonium carbonate T.S. a white precipitate, which should redissolve completely in an excess of the reagent (absence of iron, aluminum, calcium, etc.). No insoluble residue should be left, if 0.5 Gm. of zinc carbonate be dissolved in 10 Cc. of diluted sulphuric acid (absence of lead). If 1 Gm. of the salt be placed in a flask with 10 Cc. of boiling water, and 2 drops of phenolphtalein T.S. be added, not more than 1 Cc. of decinormal oxalic acid V.S. should be required to discharge the red color (limit of alkali)"—(*U. S. P.*).

Action and Medical Uses.—Prepared calamine is used as a dusting powder for children, and as a mild desiccant and astringent application in *chafings*, *intertrigo*, *excoriated nipples*, *ophthalmia tarsi*, *simple ulcerations*, etc. The precipitated carbonate of zinc is used for similar purposes.

ZINCI CHLORIDUM (U. S. P.)—ZINC CHLORIDE.

FORMULA: $ZnCl_2$. MOLECULAR WEIGHT: 135.84.

"Zinc chloride should be kept in small, glass-stoppered bottles"—(*U. S. P.*).

Preparation.—Chloride of zinc may be obtained by heating zinc in a current of chlorine gas; or by sublimation of a mixture of zinc sulphate and calcium chloride. It is usually prepared by dissolving metallic zinc, or zinc oxide, or zinc carbonate in solution of hydrochloric acid, and evaporating to dryness. If metallic zinc is employed, the following reaction takes place: $Zn+2HCl=ZnCl_2+H_2$. If the zinc contains iron, the latter is removed from the solution by first converting the ferrous chloride into ferric chloride by the use of chlorine water, and then precipitating the iron by means of zinc carbonate, a corresponding quantity of zinc going into solution; if lead is present, this is likewise precipitated. (For detailed directions, see *Br. Pharm.*, 1885.) The solution of zinc chloride should not be filtered through paper, as this would dissolve and cause a dark color to be imparted to the finished product; either glass wool or asbestos should be employed. Upon evaporating the solution, care must be taken that no decomposition takes place with escape of hydrochloric acid and formation of an insoluble basic salt. In this case the addition of a little hydrochloric acid will restore the normal salt. Pencils of chloride of zinc may be made by incorporating with the salt its own or twice its weight of well-dried wheat flour, rolling the mass into cylinders, and, after drying these in an oven, coating them with white wax in order to protect them from moisture (see *Amer. Jour. Pharm.*, 1883, p. 309, and 1878, p. 345).

Description.—The *U. S. P.* describes chloride of zinc as "a white, granular powder, or porcelain-like masses, irregular, or molded into pencils, odorless, of such intensely caustic properties as to make tasting dangerous, unless the salt be dissolved in much water, when it has an astringent, metallic taste. Very deliquescent. Soluble in about 0.3 part of water at 15° C. (59° F.), forming a clear solution, which, on protracted boiling, deposits a basic salt; very soluble in alcohol. When heated to 115° C. (239° F.), zinc chloride fuses to a clear liquid. At a higher temperature it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide. The aqueous solution reddens blue litmus paper"—(*U. S. P.*). The dense, white fumes evolved upon heating chloride of zinc consist of a mixture of zinc chloride and chlorine; the residue consists of zinc oxychloride of variable composition, until finally zinc oxide remains. A concentrated solution of zinc chloride when mixed with oxide of zinc forms a plastic mass, which hardens soon afterward, a basic chloride, *e. g.*, $ZnCl.OH$, being formed. With ammonium chloride, zinc chloride forms a compound which is useful in soldering metals. It acts by removing the film of metallic oxide, which is converted into soluble metallic chloride. A solution of chloride of zinc (200 grains to the Imperial pint) was patented (1840) by Sir William Burnett, to prevent dry rot in wood, and as a disinfectant and antiseptic. This compound has also been known by the names of *muriate*, *hydrochlorate*, or *butter of zinc*, and *Burnett's Antiseptic Fluid* (see *Amer. Jour. Pharm.*, 1847, p. 269, and 1866, p. 363).

Tests.—The aqueous solution with a little acetic acid should give no violet color (iron) with tannic acid. Tannic acid gives in the pure solution a dirty white precipitate of tannate of zinc which is dissolved by acetic acid. If hydrogen sulphide is passed into the solution of zinc chloride acidified with hydrochloric acid, and causes a yellow precipitate soluble in concentrated hydrochloric acid, cadmium is present. "A 5 per cent aqueous solution of the salt yields with potassium ferrocyanide T.S. a pure white precipitate, and with ammonium carbonate T.S. a white precipitate which redissolves in an excess of the reagent"—(*U. S. P.*). An insoluble white residue would point to calcium, also to cadmium; in the latter case, solution of hydrogen sulphide would color the precipitate a bright yellow (cadmium sulphide, CdS). With a 5 per cent aqueous solution of zinc chloride "silver nitrate T.S. produces a white precipitate insoluble in nitric acid. The aqueous solution (1 in 20) should be clear, or at most only very slightly opalescent; and, if it be mixed with an equal volume of alcohol, a single drop of hydrochloric acid should suffice to render 10 Cc. of the mixture perfectly clear (limit of oxychloride). If to the aqueous solution, acidulated with hydrochloric acid, an equal volume of hydrogen sulphide T.S. be added, it should not become colored or turbid (absence of arsenic, cadmium, lead, copper, etc.)"—(*U. S. P.*). (Compare *Zinci Acetas.*) "If ammonium carbonate T.S. be added to the solution, the precipitate should be of a pure white color, and redissolve completely in an excess of the reagent (absence of iron, aluminum, calcium, etc.). If from this solution in ammonium carbonate T.S. the zinc be completely precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation (absence of alkalies, magnesium, etc.)"—(*U. S. P.*). If a residue remains after ignition of the evaporation-residue, the presence of magnesium may be ascertained by dissolving the residue in hydrochloric acid, adding aqua ammoniæ, ammonium chloride, filtering, if necessary, and adding ammonium phosphate solution. A crystalline precipitate would indicate magnesium. The *U. S. P.* further directs for zinc chloride that "the aqueous solution should not be rendered turbid by the addition of barium chloride T.S. (absence of sulphate)"—(*U. S. P.*). This test was introduced on account of the manufacture of some commercial zinc chloride from zinc sulphate (see *Preparation*, preceding page; also *Digest of Criticisms on the U. S. P.*, Part I., 1897). "If 0.3 Gm. of dry zinc chloride be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require 44.1 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to not less than 99.84 per cent of the pure salt"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Large doses of chloride of zinc act as an irritant poison, producing a burning sensation in the stomach, nausea, vomiting, anxiety, short breathing, small quick pulse, cold sweats, fainting, and convulsions; in small doses it has been given in *scrofula*, *chorea*, *epilepsy*, and other *nervous diseases*. It is seldom now employed as an internal medicine. Its principal use is as an external agent; from 1 to 5 grains dissolved in 1 fluid ounce of water may be used as an application to *syphilitic and scrofulous ulcers*, to the vaginal walls in *leucorrhœa*, to the *os uteri in ulceration*, as a urethral injection in *gonorrhœa* and *gleet*, and to the eye in the relaxed and congested conditions of the arteries in inflammations of that organ. A solution of 1 grain to 4 fluid ounces of water may be used as an injection in *chronic cystitis*. Its local action on living tissues, when not diluted, is that of a caustic or escharotic, depending partly on its affinity for albumen and gelatin, with which it forms difficultly soluble compounds; so that when placed in contact with living parts into whose composition these organic compounds enter, the chloride exercising its affinity, destroys the life of the part, unites with the albuminous and gelatinous matters present, decomposes the carbonate and hydrosulphide of ammonium found in the secretion from *malignant ulcerations*, and forms a white eschar, which separates in from 10 to 12 days. Its action is accompanied with a violent burning pain for several hours, or until it has destroyed the parts. Beside corroding the parts with which it is in immediate contact, it exercises an influence over the vital actions of neighboring parts, and produces no constitutional symptoms from its absorption. Perhaps no escharotic has been more generally employed for the destruction of *malignant growths* than zinc chloride usually, however, combined with other agents. It is adapted to cases of *epithelioma* and *carcinoma* that can not be removed by the knife, or in which the patient will not submit to such a surgical procedure. It is also a good application for the destruction of *chancre* and *chancroid*. When used for the destruction of malignant growths the chloride must be thoroughly applied, crowding the paste prepared with it and mucilage, or other of the combinations below named, well into every part of the tumor, and persisting in the application until every vestige of the growth is destroyed. This procedure causes intense pain, but less severe than that produced by arsenic, besides which it does not produce poisonous effects through its absorption. It does not cause hemorrhage even when applied in the region of large blood vessels, a sort of mummefying action being exerted on the latter, causing them to shrivel and become hard, thin, and cord-like. In recent times it has become quite popular with physicians to treat *malignant and other affections of the uterine cavity* with applications of zinc chloride. In such instances it is customary to curette well the interior of the organ, after which is applied a preparation containing the chloride, usually mixed with the oxide and common flour, made into a tampon with gauze, and introduced into the cavity, from which it may be withdrawn by means of an attached string. This is left *in situ* for a few hours, care being taken that it does not come into contact with the vesico-vaginal or recto-vaginal septum. After removal of the tampon the parts are dressed with iodoform or other medicated gauze. Chloride of zinc is a safe escharotic, inasmuch as its action does not extend further than the area of application. When applied so as to act deeply it causes the tissues to become hard and tough, and in the course of a week or two the uniform eschar separates, leaving a granulating surface which heals rapidly. For *cancers* and *malignant ulcers* the following have been used: (1) Take 1 part of chloride of zinc, and mix it with 2, 3, or 4 parts of flour, forming a paste with as little water as possible; a stronger preparation is made by mixing together 2 parts chloride of zinc, and 1 part chloride of antimony, with flour in quantity proportioned to the desired strength (Dr. Canquoin). This paste must be continued after the removal of the eschar formed, until all the morbid tissue has been removed. (2) Take of chloride of bromine 3 parts, chloride of zinc 2 parts, chloride of antimony 1 part, chloride of gold 1 part, powder of liquorice sufficient to make into a paste (Landolfi). (For manner of using, see *College Journal of Medical Science*, Cincinnati, Ohio, 1856, p. 98; and Braithwaite's *Retrospect*, Part XXXIII, 1856, p. 48.) A *cauterizing paste*, used in the London hospitals, is composed of chloride of zinc, 12 parts; chloride of antimony, 8 parts; pulverized starch, 4 parts; glycerin, a sufficient quantity to form a paste. This has been successful as a local application to *cancer*. When to be used as an escharotic, chloride of zinc may be formed into cylinders, which will be much more manageable than the salt alone, by the following plan of M. Sommié: Soften gutta percha with boiling alcohol, then incorporate it in a warm porcelain mortar with an equal portion of chloride of zinc, in a fine state of division. Then rapidly roll out the mass on a porphyry slab in the manner of making pastilles, and form it into cylinders of the size of a quill, and of various lengths; keep these in wide-mouthed bottles with a little powdered chalk. Cooke's method of applying this salt was to saturate lint with the deliquesced chloride, which, after being dried, could be kept in a paper or wooden box, and when desired for use could be cut to any size desired. This method is applicable to *gangrenous ulcerations*. For cutting it, however, a good steel instrument should not be used, as the salt has a destructive action on metals. The dose internally, of chloride of zinc, is 1 or 2 grains, dissolved in sufficient water. Very weak solutions of chloride of zinc, 2 to 4 grains to the fluid ounce of water, have been used successfully, by injections, in obstinate *gonorrhœa* and *gleet*. Solutions of carbonate of sodium, or carbonate of potassium, or of soap, may be freely given in cases of poisoning by chloride of zinc; these change it into an insoluble carbonate.

Related Compound.—Escatol. This name was used by the late Prof. A. J. Howe, M. D., for a compound of salicylic acid, chloride of zinc, and petrolatum. He prescribed several strengths, the variation being in the proportion of the ingredients: "It may be applied to an *ulcer* in the nose successfully, and the agent will not attack the sound mucous membrane. I will mention a few morbid states where the escharotic exerts a curative power. A few daily applications cured a *bleeding wart* in a man's beard, and *seed-warts* on the hands. It destroyed *moles* on a woman's chin after 2 weeks' use. It removed *scaly ulcers of a lupoid nature* on an old man's face. It caused an obstinate *eczema* on a lady's neck to get well. It cured a *rodent ulcer of the nipple*. It destroyed a patch of '*ringworm*' on a man's thorax, and a sluggish *ulceration of the leg*, which may have been epitheliomatous. It will destroy *polypus of the nose* without other agency, whether operative or therapeutic. I employ the escharotic (escatol) upon *fistulous surfaces* after they have been incised, and on all sluggish *traumatisms*, to arouse a healing action. It is one of the few things I have learned tentatively. I keep a jar of it in stock, and deal it out in small boxes to patients. I apply it to *fissures of the anus*, and *wounds* made in the excisions of *cancerous growths*. *Syphilitic ulcerations of the mouth, fauces and pharynx*, and, *of the velum*, yield to daily dressings with this escharotic unguent" Prof. A. J. Howe, M.D.).

ZINCI IODIDUM (U. S. P.)—ZINC IODIDE.

FORMULA: ZnI_2. MOLECULAR WEIGHT: 318.16.

"Zinc iodide should be kept in small, glass-stoppered bottles"—(*U. S. P.*)

Preparation.—This salt may be prepared by placing 2 parts of iodine and 1 part of granulated zinc in water, warming carefully until the solution is colorless, evaporating to dryness, and, if crystals are desired, fusing the residuum, which forms beautiful prismatic crystals of anhydrous iodide of zinc on cooling. Iodide of zinc may also be obtained by placing 2 parts of zinc and 17 parts of iodine into a flask, and heating; in this way the salt sublimes in the form of white acicular crystals. Or it may be obtained by dissolving zinc carbonate or oxide in solution of hydriodic acid.

Description and Tests.—"Iodide of zinc is a white, granular powder, odorless, and having a sharp, saline and metallic taste. Very deliquescent, and liable to absorb oxygen from the air, and to become brown from liberated iodine. Readily soluble in water, alcohol or ether. When heated to about 446° C. (834.8° F.) the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decomposed, and leaves a residue of zinc oxide. The aqueous solution reddens blue litmus paper. A 5 per cent aqueous solution of the salt yields a pure white precipitate with potassium ferrocyanide T.S., or with ammonium sulphide T.S. With silver nitrate T.S. it yields a pale-yellow precipitate, insoluble in ammonia water; with mercuric chloride T.S. a scarlet-red precipitate, soluble in potassium iodide T.S. The aqueous solution, acidulated with hydrochloric acid, should not be colored or rendered turbid by hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.), nor by barium chloride T.S. (absence of sulphate). If ammonium carbonate T.S. be added to the aqueous solution, a pure white precipitate will form, which should redissolve completely in an excess of the reagent (absence of iron, aluminum, calcium, etc.). If from the solution in ammonium carbonate T.S. all the zinc be precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation (absence of alkalies, magnesium, etc.). If 0.5 Gm. of dry zinc iodide be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, not more than 31.4 Cc. nor less than 31.0 Cc. of decinormal silver nitrate V.S. should be required to produce a permanent red color (31.4 Cc. corresponding to 100 [99.9] per cent, and 31.0 Cc. to 98.62 per cent, of pure zinc iodide)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Internally, iodide of zinc has been used as a tonic in *spasmodic affections* occurring in patients of a *strumous diathesis*. It is usually administered in syrup, which preserves it from the action of the air. The syrup may be prepared in the same manner as that of iodide of iron. Dr. A. T. Thompson recommended iodine, 4 drachms; powdered zinc, 2 drachms; to be agitated in 4 fluid ounces of distilled water, until the solution is colorless; then filter, and add 12 fluid ounces of syrup. The dose is from 10 to 40 drops, 3 times a day, in water. Mr. A. B. Taylor recommended another formula for preparing this medicinal syrup (see *Amer. Jour. Pharm.*, 1852, p. 33). Externally, an ointment (1 part of the iodide to 8 parts of lard) has been recommended as an application to *tumors* by friction: 1 or 2 grains, dissolved in 1 fluid ounce of water, has been used with benefit in *gonorrhœa* (injecting 1 or 2 teaspoonfuls into the urethra, 2 or 3 times a day. Twenty or 30 grains, dissolved in 1 fluid ounce of water, has been found useful in *enlargement of the tonsils;* it must be applied by means of a small probang, or camel's-hair pencil, and after several days the deliquesced iodide should be used instead, applying it by means of a camel's-hair pencil (J. J. Ross).

ZINCI OXIDUM (U. S. P.)—ZINC OXIDE.

FORMULA: ZnO. MOLECULAR WEIGHT: 81.06.

SYNONYMS: *Flores zinci*, *Flowers of zinc*, *Lana philosophica*, *Philosopher's wool*, *Pompholyx*, *Nix alba*, *Nihilum album*, *Zinc white.*

"Zinc oxide should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Zinc oxide may be prepared either in the dry or in the wet way. When metallic zinc is exposed to a white heat with access of air, it burns with a brilliant light, forming white flakes of zinc oxide, which, when obtained in this way, have been called *Lana philosophica*, *Flowers of zinc*, *Zinc white*, etc. Zinc white is official in the *German Pharmacopœia*, under the name *Zincum Oxidatum Crudum*. It is directed that it should not be used internally. Oxide of zinc is found in an impure form in the chimneys of zinc and brass furnaces (see *Tutty*, following page). Zinc oxide, intended for internal application, is mostly obtained in the wet way. Basic zinc carbonate (see *Zinci Carbonas Præcipitatus*) is first prepared, and then ignited in a crucible, a flask, or a flat porcelain dish, whereby it loses water and carbonic acid gas (see directions in *U. S. P.*, 1870, and *Br. Pharm.*, 1885; also Wittstein, *Amer. Jour. Pharm.*, 1852, p. 361; and Charles Caspari, *ibid.*, 1859, p. 435). The powder thus obtained should be impalpable; too high a heat is liable to render it gritty. It may also become gritty upon prolonged keeping; in this case, recalcining is said to restore its fineness (Speidel, 1875).

Description.—Pure oxide of zinc is "an amorphous, white powder, without odor or taste. It gradually absorbs carbon dioxide from the air. Insoluble in water or alcohol. Soluble, without effervescence, in diluted acids; also in ammonia water, and in ammonium carbonate T.S. When heated, it assumes a yellow color, which disappears again on cooling. If a small portion of the salt be moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid-green color"—(*U. S. P.*). (Compare *Zinci Carbonas Præcipitatus.*) Heated on charcoal before the blowpipe, zinc oxide is reduced, and the metal is completely burned and volatilized; a small portion of the oxide condensing, forms a yellow ring on the cold charcoal, becoming white on cooling. Zinc oxide, as such, is permanent toward heat.

Tests.—If the oxide be digested with water, the solution, when filtered and evaporated, should leave no residue; should any occur and effervesce with diluted acids, it is due to carbonate of sodium. If the oxide, when treated with diluted sulphuric acid, evolves hydrogen sulphide gas, recognizable by its blackening a strip of paper saturated with solution of lead acetate, zinc sulphide is present (see Schneegans, *Pharm. Jour. Trans.*, Vol. II, 1896, p. 50). If the oxide effervesces with diluted acids, it contains either carbonate of zinc, calcium, or magnesium. To determine whether either of the latter is present, the nitric acid solution is supersaturated with ammonia water, precipitated with hydrosulphide of ammonium, filtered, the excess of hydrosulphide of ammonium driven off by boiling, and oxalate of ammonium added; a precipitate indicates calcium; after filtering this, any precipitate caused by phosphate of ammonium is due to magnesium.

The *U. S. P.* directs the following tests: "For making tests of identity and purity, digest 1 Gm. of zinc oxide, during 1 hour, with occasional agitation, in a mixture of 10 Cc. of diluted sulphuric acid and 10 Cc. of water; then remove the undissolved zinc oxide by filtration. In a portion of the filtrate a pure white precipitate is produced by potassium ferrocyanide T.S., or by ammonium sulphide T.S. In another portion of the filtrate, acidulated with hydrochloric acid, no color or turbidity should be produced by an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.). Another portion of the filtrate should yield with ammonium carbonate T.S., a pure white precipitate, which should redissolve completely in an excess of the reagent (absence of iron, aluminum, calcium, etc.). If from this solution in ammonium carbonate T.S., the zinc be completely precipitated by ammonium sulphide T.S., the filtrate should, on evaporation, leave no fixed residue (absence of alkalies, magnesium, etc.). In another portion of the filtrate, silver nitrate T.S. should not produce a turbidity (absence of chloride). If zinc oxide be agitated for some time with water, and a drop of phenolphtalein T.S. be added, no red color should appear (absence of alkaline carbonate, etc.). If 10 Cc. of diluted sulphuric acid be added to 0.5 Gm. of zinc oxide, no effervescence should occur (absence of carbonate), and a perfectly clear solution should result (absence of lead, silicate, etc.). If zinc oxide be dissolved in diluted hydrochloric acid, the solution should remain perfectly clear after the addition of barium chloride T.S. (absence of sulphate)"—(*U. S. P.*). To insure the absence of metallic zinc, the *British Pharmacopœia* (1898) directs that zinc oxide "should be entirely soluble when rubbed and, if necessary, warmed with solution of ammonia, mixed with strong solution of ammonia (absence of metallic zinc)"—(*Br. Pharm.*, 1898). A test for arsenic is recommended as follows: On mixing 1 Gm. of the oxide with 3 Cc. of solution of stannous chloride, no brown coloration should appear within 1 hour (*Digest of Criticisms on the U. S. P.*, Part I, 1897; from *Apoth. Ztg.*, 1894). (For examinations of commercial specimens of zinc oxide, see *Amer. Jour. Pharm.*, 1881, p. 534; *ibid.*, 1888, p. 608, and 1894, p. 492.)

Action, Medical Uses, and Dosage.—Oxide of zinc, in large doses, produces irritation, vomiting, and sometimes purging. Continued small doses may occasion nausea and other gastric unpleasantness, with eructations and vomiting, heat in the stomach, elevated temperature, thirst, mental confusion, disordered hearing and sight, convulsions, and disturbed circulation; larger doses cause diarrhœa, œdema, and a general marasmic state. In small doses of from 2 to 10 grains, it has been used in *epilepsy*, *chorea*, *catalepsy*, *pertussis*, *hysteria*, *neuralgia*, *gastrodynia*, etc., as a tonic, antispasmodic, and sedative. Long used, it acts as a slow poison, causing *tabes sicca*. It is seldom used internally, as its effects are very uncertain, and its efficacy in *epilepsy* has been very much overrated. It has been used with varying success in *diarrhœa* and *dysentery*, and it appears to exert a considerable influence for good in *chronic alcoholism*, with tremors, vertigo, insomnia, tinnitus, and hallucinations. Three or four 1-grain doses of the oxide, taken during the evening, give beneficial results in *colliquative sweating*. The indications for the internal administration of zinc oxide, in gastric disorders, are *nervous dyspepsia*, with full abdomen and broad tongue. It is also useful in *gastric ulcers*, and in *chronic gastritis*, with free secretion of mucus. Here the dose should range from ½ to 1 grain. Applied to *ulcerated or other secreting surfaces*, it acts as a desiccant and astringent, and has been found useful as an application to *excoriations*, *moist skin*, *eruptions*, *balanitis*, *chaps and cracks of the nipples*, *simple ulcerations*, *burns* and *scalds*, *ophthalmic and cutaneous affections*, etc. In *eczema*, *impetigo*, and *ophthalmia tarsi* it has been found especially useful. An impure oxide of zinc, known by the name of *Tutty*, is occasionally used for similar purposes, but it is inferior to the pure oxide.

Specific Indications and Uses.—Nervous dyspepsia, with broad tongue and full abdomen; gastric ulcer; chronic gastritis, with hypersecretion of mucus; night-sweats.

Related Preparation.—TUTTY, *Impure zinc oxide*, *Tutia*, *Cadmia fornacum*. When lead ores, containing zinc as an impurity, undergo smelting, this oxide is formed, and collects in the chimney of the furnace in the form of heavy, hard, and brittle incrustations. It is grayish externally, yellowish internally, and consists of zinc oxide with some carbonate, and small quantities of metallic zinc. A spurious tutty, more friable, of an earthy odor, and readily disintegrating in water, has been prepared from copper filings and blue clay. Tutty was formerly used in fine powder, or in ointment, as a topical desiccant.

ZINCI PHOSPHIDUM (U. S. P.)—ZINC PHOSPHIDE.

FORMULA: Zn_3P_2. MOLECULAR WEIGHT: 257.22.

SYNONYM: *Phosphuret of zinc*.

"Zinc phosphide should be kept in small, glass-stoppered vials"—(*U. S. P.*).

Preparation.—This compound may be obtained either by adding dry phosphorus (26 parts), little by little, to fused zinc (74 parts), a direct union taking place; or, according to Currie and Vigier, vapors of phosphorus are conducted over fused zinc in an atmosphere of dry hydrogen. Great danger, however, attends this process, as a violent explosion may occur. Proust prepared the compound by conducting a mixture of nitrogen and hydrogen phosphide gas over zinc, contained in a redhot porcelain tube, the apparatus being previously filled with nitrogen gas. Metallic zinc is often present in the product, and may be separated by powdering and sifting the preparation; the zinc phosphide is easily differentiated by its appearance, which is that of reduced iron.

Description and Tests.—"A gritty powder of a dark-gray color, or crystalline fragments of a dark, metallic luster, and having a faint odor and taste of phosphorus. In contact with the air it slowly emits phosphorous vapor. Insoluble in water or alcohol; soluble in diluted hydrochloric or sulphuric acid, with evolution of hydrogen phosphide. When strongly heated, with exclusion of air, it melts, and finally sublimes. When heated in air, it becomes oxidized to zinc phosphate. If 0.5 Gm. of zinc phosphide be dissolved in 15 Cc. of diluted hydrochloric acid, heat being applied to expel all of the hydrogen phosphide gas, a clear solution should result, leaving no residue (absence of insoluble impurities). A portion of this solution should yield a pure white precipitate with potassium ferrocyanide T.S. (absence of iron or copper), or with ammonium sulphide T.S. (absence of lead or copper). If another portion of this solution be mixed with an equal volume of hydrogen sulphide T.S., no color or turbidity should appear (absence of arsenic, cadmium, lead, copper, etc.)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Zinc phosphide was introduced as a remedy for *nervous affections*, but has failed to fulfil all that its introducers claimed for it. It is, however, a useful agent in debilitated conditions, with impaired nutrition of the brain and spinal cord. Thus it has proved beneficial in *paralysis agitans*, *progressive locomotor ataxia*, *spinal irritation*, *cerebral exhaustion from brain-fag*, or *anemia*, and in *aphasia* and *cerebral degeneration*, or "*softening of the brain.*" In cerebral exhaustion, pallor, depression, and insomnia are the indications for its selection; it is also, according to Goss, a remedy for *vertigo*, with pain in the cerebellar, medullary, and cervico-spinal tracts. The dose may range from 1 grain of the 3 x or 2 x triturations to $\frac{1}{10}$ grain of the phosphide, 4 times a day. If the drug causes diarrhœa or vomiting it should be withdrawn. *Zinc hypophosphite*, in doses of 1 grain in syrup, has been recommended as being less irritant than the phosphide.

Specific Indications and Uses.—Cerebral anemia; brain-fag, with pallor, depression, and sleeplessness; pain in cerebellum, medulla, and cervical portion of spinal cord; cerebral softening.

ZINCI SULPHAS (U. S. P.).—ZINC SULPHATE.

FORMULA: $ZnSO_4+7H_2O$. MOLECULAR WEIGHT: 286.64.

SYNONYMS: *Vitriolum album*, *White vitriol.*

"Zinc sulphate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Zinc sulphate is usually prepared by dissolving metallic zinc in dilute sulphuric acid, whereby hydrogen gas is evolved. An excess of zinc insures the absence of lead in the solution. In order to remove iron, the solution is first treated with chlorine water, which converts the ferrous into ferric chloride; the iron is then precipitated as hydroxide by the addition of pure zinc oxide or freshly prepared basic zinc carbonate. Filter from the precipitate and evaporate the solution until it commences to crystallize. (For detailed directions, see *Br. Pharm.*, 1885.) The *white vitriol* (*crude white vitriol*) of commerce is an impure sulphate of zinc; it is prepared by roasting the native sulphide of zinc, or *zinc blende*, in a reverberatory furnace, then exposing it to the air in a moist state until the sulphide is converted by oxidation into the sulphate; this is lixiviated, and the solution, concentrated by evaporation, is poured into molds, where it concretes into cakes like loaf sugar. In this state it contains many impurities, as copper, lead, cadmium, and especially iron, in the form of sulphates; it may be purified by redissolving it, and treating with chlorine and carbonate of zinc, as mentioned before, which will precipitate the iron as well as the other foreign metals; the solution is then evaporated to crystallization.

Description.—Pure sulphate of zinc forms colorless, rhombic prisms or needle-like crystals, resembling magnesium sulphate, when produced from concentrated solutions by disturbed crystallization. As required by the *U. S. P.*, sulphate of zinc forms "colorless, transparent, rhombic crystals, without odor, and having an astringent, metallic taste. Efflorescent in dry air. Soluble in 0.6 part of water at 15° C. (59° F.), and in 0.2 part of boiling water; also soluble in about 3 parts of glycerin; insoluble in alcohol. When rapidly heated, the salt melts. At a higher temperature it is partly decomposed, losing both water and sulphuric acid. When very gradually heated to 50° C. (122° F.), it loses 5 molecules of its water (31.3 per cent) without melting. At 100° C. (212° F.) a sixth molecule is lost, while the last may be removed by a current of dry air at 110° C. (230° F.). The aqueous solution gives an acid reaction with litmus paper" (*U. S. P.*).

Tests.—The aqueous solution of sulphate of zinc is precipitated white by caustic potash or soda, or alkali carbonates, hydroxide of zinc being thrown down in the former, basic carbonate in the latter case; the hydroxide is soluble in an excess of the alkali. If iron or magnesium salts be present, their hydroxides will not be redissolved by the alkali (compare with *U. S. P.* tests below). The solution of zinc sulphate will be colored blue by excess of aqueous ammonia when copper is an impurity; if iron be present, ferrocyanide of potassium will cause a bluish-white precipitate. Either of these reagents produce a white precipitate with a solution of pure sulphate of zinc. Hydrogen sulphide gas throws down white sulphide of zinc, precipitation being complete only in neutral or acetic acid solutions.

From the above reactions it follows that zinc sulphate is incompatible with solutions of ammonia, soda, and potassa, and their carbonates; also with alkali sulphides, phosphates, acetate of lead, lime-water, vegetable astringent infusions (tannate of zinc being precipitated), milk, mucilage, etc.

The *U. S. P.* gives the following tests of identity and purity: "A 5 per cent aqueous solution yields a pure white precipitate with potassium ferrocyanide T.S.; also with ammonium sulphide T.S., and with barium chloride T.S. If a small portion of the salt be moistened with a drop of cobaltous nitrate T.S., and heated before the blowpipe, it will assume a vivid green color"—(*U. S. P.*). (See *Zinci Carbonas Præcipitatus.*) "No residue should be left on dissolving 1 Gm. of the salt in 20 Cc. of water (absence of lead and other insoluble matters). The aqueous solution (1 in 20), after being acidulated with hydrochloric acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, copper, etc.). The aqueous solution should yield with ammonium carbonate T.S. a pure white precipitate, which should redissolve completely in an excess of the reagent (absence of iron, aluminum, calcium, etc.). If from this solution in ammonium carbonate T.S., the zinc be completely precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation (absence of alkalies, magnesium, etc.). The aqueous solution (1 in 20) should not be rendered turbid by silver nitrate T.S. (absence of chloride). If 1 Gm. of zinc sulphate, in small fragments, be agitated for some time with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus paper (absence of free acid)"—(*U. S. P.*). "A readily applied and sensitive test for free acid is the addition of a drop of methyl-orange solution to an aqueous solution of the salt. In presence of acid, the solution is reddened" (C. E. Smith, *Digest of Criticisms on the U. S. P.*, Part II., 1898). The presence of free acid is due to the addition of an excess of acid in the preparation of zinc sulphate, the purpose being to convert the basic zinc sulphate that may have been formed by the addition of too much zinc carbonate into the neutral salt (see *Preparation*, preceding page; also see test for free acid, in *Amer. Jour. Pharm.*, 1888, p. 344).

Action, Medical Uses, and Dosage.—In large doses sulphate of zinc is an irritant poison, causing vomiting, purging, coldness of the extremities, fluttering pulse, and great depression; but seldom occasioning death. In doses of from 10 grains to ½ drachm it occasions prompt vomiting, and on this account, as well as for the absence of that distressing nausea which usually follows other emetics, it is generally used to dislodge *narcotic poisons* from the stomach; its promptness and want of nausea prevents any great degree of absorption of the poison to be removed. It should not be employed to remove irritant poisons. It is likewise employed as an emetic in *pseudo-membranous croup*. In doses of from 1 to 5 grains it is reputed tonic, astringent, and antispasmodic, and has been used in *dyspepsia*, *gastric catarrh*, *chronic dysentery*, and *diarrhœa*, *chronic bronchial affections* with profuse secretions, *gleet*, *leucorrhœa*, *intermittent fever*, *chorea*, *hysteria*, *epilepsy*, *spasmodic asthma*, *whooping-cough*, etc. Like chloride of zinc, it has a great affinity for albumen and fibrin. By quite a large class of practitioners its internal use is entirely dispensed with for other agents of a more desirable character. Used in solution varying from 1 to 6 or 8 grains of the salt to 1 fluid ounce of water, it has proved beneficial as a collyrium in *chronic ophthalmia*, as an injection in *chronic gonorrhœa*, *gleet*, and *leucorrhœa*, as a gargle in *ulceration of the throat*, and *relaxed uvula*, and as a wash for *rectal ulcerations* and other *ulcers* attended with profuse discharge, or with loose, flabby granulations. It is not well adapted for *acute conjunctivitis*. Applied to *gangrenous* or *mortified parts*, powdered sulphate of zinc corrects the fetor, and arrests further decomposition; it should be applied over the affected part, and then be covered with flour paste, or an elm poultice. Used in this manner, it is also useful in *malignant ulcerations*, to check *hemorrhages*, etc. Combined with powdered bloodroot, it has been successfully used in *nasal polypi*, and also in *phagedenic chancres*. Sulphate of zinc was at one time a secret remedy for *cancerous tumors*. *Anhydrous sulphate of zinc*, in the form of powder or paste, has been successfully employed as a local application in *lupus*, *condylomata*, *warts*, *ulcers of the cervix uteri*, *callous ulcers*, *fistula in ano*, *vascular tumor in the meatus urinarius of females*, etc. It is very painful, but acts promptly and efficiently. The powder should be impalpable, and the paste may be made by adding a sufficient quantity of glycerin to it. In cases where large doses of sulphate of zinc have been swallowed, the vomiting usually prevents any dangerous effects; any inflammation or irritation, however, that may be produced should be met with mucilaginous drinks, opiates, etc., and be treated upon general principles. The dose for internal administration is from ¼ grain to 5 grains; it is seldom, however, used internally, except when used as an emetic, the dose then ranging from 10 to 30 grains, in warm water.

ZINCI SULPHOCARBOLAS.—ZINC SULPHOCARBOLATE.

FORMULA: $Zn2C_6H_5SO_4$. MOLECULAR WEIGHT: 410.18.
SYNONYM: *Zinc sulphophenate.*

Preparation.—Sulphocarbolate of zinc is made by double decomposition of a solution of sulphocarbolate of calcium with the exact quantity of sulphate of zinc, filtering and evaporating. In like manner other sulphocarbolates may be prepared as desired (also see *Sodii Sulphocarbolas*). The *British Pharmacopœia* (1898) directs that "zinc sulphocarbolate, or zinc phenol-para-sulphonate ($Zn[OH.C_6H_4.SO_3]_2.H_2O$) may be obtained by heating a mixture of phenol and sulphuric acid, and saturating the product with zinc oxide"—(*Br. Pharm.*, 1898).

Description.—According to the same authority, zinc sulphocarbolate occurs in "colorless, transparent, tabular, efflorescent crystals; soluble in 2.5 parts of alcohol (90 per cent), and in 2 parts of water. The aqueous solution is colored violet by test solution of ferric chloride, and affords a white precipitate with solution of ammonium hydrosulphide. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminum, calcium, magnesium, sodium, potassium, ammonium, acetates, or chlorides, and only the slightest reactions with the tests for sulphates"—(*Br. Pharm.*, 1898). From calcium sulphate it may be separated by means of alcohol (see Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1870, p. 135).

Action, Medical Uses, and Dosage.—Sulphocarbolate of zinc possesses both antiseptic and astringent properties, and is less irritating in its effects than carbolic acid. As a local application it has proven, in many instances, to be superior to the sodium salt. As a spray or wash, it will be found useful in *surgical dressings*, in certain *pseudo-membranous exudations*, in *gangrenous conditions*, and in *chronic ophthalmia;* in injection it will prove useful in *chronic gonorrhœa*, *leucorrhœa*, and *gleet*. As an astringent it may be advantageously substituted for sulphate of zinc in urethral injections, possessing all its benefits without any of its inconveniences. The strength of the solution in water will vary from 1 to 5 parts of the salt to 100 or more parts of water. The chief field for the exhibition of this drug is in *septic conditions of the intestinal tract*, and in the *fevers* arising therefrom. Dr. W. H. Halbert, of Nashville, Tenn. (*Ec. Med. Jour.*, 1895, p. 72), gives clearly the uses of this salt, to which article the reader is referred. Dr. Halbert, whose experience in the treatment of *typhoid and similar fevers* has been large, believes that if given early it will abort typhoid fever, basing his belief upon the theory that there must be a septic condition of the intestines to give rise to such fevers. The cases of well-developed typhoid fever reported as benefited were those in which there was high temperature, full abdomen, with marked tympanites, bowels loose—from 8 to 10 foul-smelling evacuations daily, and in some cases hemorrhage. These were promptly controlled with 2½-grain doses every 2 hours, the temperature dropping, the discharges gradually checking, and the tympanitic condition being quickly overcome. He is positive that it checks fermentative changes in the bowels, but that it is useless in all bowel disorders if there be no sepsis. In typhoids it prevents *hemorrhage* by controlling the bowel lesions before destructive action has set in. Dr. Halbert ranks it next to turpentine and baptisia as an intestinal antiseptic, but calls attention to the fact that many can not take the former, while the latter is sometimes not powerful enough to meet the conditions. From sulphocarbolate of zinc he has seen no bad results. He also advises it in *cholera infantum*, *cholera morbus*, *septic diarrhœa*, *dysentery*, *malignant dysentery*, *chronic dysentery*, and *tuberculosis* with dysenteric complications. It appeared to benefit *peritonitis*. He suggests its probable utility in *cholera* and *yellow fever*. Dr. Halbert employs pills of zinc sulphocarbolate chiefly, but in cholera morbus and cholera infantum he gives the agent in solution. Prof. R. L. Thomas, M. D., uses this agent quite extensively, and has formulated the following specific indications for its use: "Tongue pallid, moist, pasty, and dirty." He has tried it when the tongue was red, but failed to get results. Following the indications given, he declares it a very good remedy in *typhoid fever*, and has had excellent results from its use in the *intestinal complications of la grippe*, and in *dysentery*. He employs a trituration of equal parts of sugar of milk and sulphocarbolate of zinc, the dose of which is from 2 to 5 grains. The crude article in powder causes too much burning. The dose of sulphocarbolate of zinc may range from 1 to 10 grains, in pill, solution, or trituration. The most commonly employed doses range from 1 to 3 grains.

Specific Indications and Uses.—"Tongue pallid, moist, pasty, and dirty" (Thomas); intestinal sepsis, with copious, foul-smelling alvine discharges; tympanitis; septic fever and hemorrhage in typhoid fever, and other septic bowel disorders. It is of decided value as an intestinal antiseptic.

ZINCI VALERIANAS (U. S. P.)—ZINC VALERIANATE.

FORMULA: $Zn(C_5H_9O_2)_2+2H_2O$. MOLECULAR WEIGHT: 302.56.

SYNONYMS: *Valerianate of zinc*, *Zincum valerianicum*.

"Zinc valerianate should be kept in small, well-stoppered bottles"—(*U. S. P.*).

Preparation.—Zinc valerianate may be obtained by dissolving freshly precipitated and well-washed basic zinc carbonate in an aqueous solution of (iso-) valerianic acid (see *Acidum Valerianicum*), and evaporating to crystallization. The *British Pharmacopœia* (1885) prepares the anhydrous salt ($Zn[C_5H_9O_2]_2$) by the double decomposition between sulphate of zinc and valerianate of sodium (see *Sodii Valerianas*). D. Vitali (*Pharm. Jour.*, Vol. VIII, 1899, p. 56, London) obtains the salt by dissolving sodium valerianate (100 parts) and zinc sulphate (117.4 parts) separately, in the smallest possible volume of water, by the aid of heat, mixing the solution, evaporating to dryness, on the water-bath, below 70° C. (158° F.), and extracting the powdered residue, at 70° C. (158° F.), with alcohol (95 per cent). On evaporation, zinc valerianate crystallizes out. (Also see Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1845, p. 2, for its preparation from valerian.)

Description.—Anhydrous valerianate of zinc ($Zn[C_5H_9O_2]_2$) crystallizes in snow-white, exceedingly light plates, of a mother-of-pearl luster, and resembling boric acid. Cold ether dissolves $\frac{1}{300}$, boiling ether $\frac{1}{20}$ of its weight. The hydrated salt is not different in appearance from the anhydrous, its formula is $Zn(C_5H_9O_2)_2.2H_2O$.

The salt recognized in the *French Codex* contains $12H_2O$. At 100° C. (212° F.), it loses its water of crystallization, or about 45 per cent of its weight. It is soluble in 50 parts of cold water.

The salt recognized by the *U. S. P.* forms "white, pearly scales, having the odor of valerianic acid, and a sweetish, astringent and metallic taste. On exposure to the air, it slowly loses valerianic acid. Soluble, at 15° C. (59° F.), in about 100 parts of water, and in 40 parts of alcohol; somewhat more soluble in absolute alcohol. Boiling renders the solution turbid from loss of acid and formation of a basic salt. When heated, the salt melts. At a higher temperature, it is decomposed, giving off inflammable vapors, and finally leaving a residue of zinc oxide. The aqueous solution reddens blue litmus paper"—(*U. S. P.*).

Tests.—"If 0.5 Gm. of zinc valerianate be dissolved in a mixture of 0.5 Cc. of hydrochloric acid and 4.5 Cc. of water, the valerianic (isovalerianic) acid will be liberated, and float as an oily layer on the surface of the liquid. After its removal, the clear solution should be neither colored nor rendered turbid by the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, cadmium, lead, copper, etc.). Zinc valerianate should dissolve without residue in ammonia water (absence of iron, etc.). If from this solution the zinc be completely precipitated by ammonium sulphide T.S., the precipitate should have a pure white color, and the filtrate should leave no fixed residue on evaporation (absence of alkalies, magnesium, etc.). If 0.5 Gm. of zinc valerianate be triturated with 2 Cc. of water and 0.2 Cc. of ferric chloride T.S. added, the filtrate should not show a red color (absence of acetate). If a concentrated solution of copper acetate in water be added to a concentrated, aqueous solution of zinc valerianate, the mixture should remain perfectly clear (absence of butyrate)"—(*U. S. P.*). In the latter test, the presence of butyrate would cause a bluish-white precipitate (Larocque and Hurant; see this *Dispensatory*, preceding edition). F. Sutton (*Amer. Jour Pharm.*, 1866, p. 537) detects the presence of excess of zinc oxide (if the salt be roughly prepared by triturating valerianic acid with zinc oxide), by treating with diluted solution of citric or tartaric acid, which dissolves zinc valerianate without liberating valerianic acid, while zinc oxide is not dissolved.

Action, Medical Uses, and Dosage.—Valerianate of zinc has been employed as an antispasmodic in *neuralgia*, especially *spinal neuralgia* and *neuralgia of the fifth nerve*, *chorea*, *epilepsy*, *neuralgic and nervous headaches*, *hysteria*, *sciatica*, *ovaralgia*, *angina pectoris*, and other nervous diseases. The dose is from 1 to 3 grains, 2 or 3 times a day, in pill form, or in solution. By some practitioners, it is said to have produced no beneficial results. As a topical astringent and sedative, a collyrium composed of from 2 to 4 grains of the salt, in 1 or 2 fluid ounces of distilled water, has been employed in *chronic conjunctivitis*. Its intolerable odor is largely a bar to its use.

Specific Indications and Uses.—"Colic, reflex from ovarian or uterine disease; headache; paleness; dizziness; sleeplessness; anemia. Three to 5 grains of third decimal trituration every 2 hours" (Watkins, *Comp. of Ec. Med.*, p. 453).

ZINCUM (U. S. P.)—ZINC.

SYMBOL: Zn. ATOMIC WEIGHT: 65.10.

SYNONYMS: *Spelter*, *Spiauter*.

"Metallic zinc in the form of thin sheets, or in irregular, granulated pieces, or molded into thin pencils, or in a state of fine powder"—(*U. S. P.*).

Source, History, and Preparation.—Zinc ore (*cadmia*) was described by Dioscorides and Pliny as having the property of coloring copper yellow (*i. e.*, forming what is now known as brass); the name *cadmia* was then also applied to the deposit which formed in the flues of brass foundries (see *Tutty*). The name zinc first occurs in the writings of Basil Valentine, and the metal was obtained on a large scale at Bristol, England, as far back as 1743 (see Roscoe and Schorlemmer's *Chemistry*). Zinc occurs in nature in the form of oxide (*zincite*, *red zinc ore*, ZnO), as sulphide (*zinc blende*, or *black jack*, ZnS), as sulphate (*white vitriol*, $ZnSO_4+7H_2O$), as carbonate (*zinc spar*, also called *calamine*, *galmei*, *smithsonite*, $ZnCO_3$), as silicate (*siliceous calamine*, $Zn_2SiO_4+H_2O$), as aluminate (*Gahnite*, $ZnO+$

Al_2O_3), as *Franklinite* ($ZnO.FeO.Fe_2O_3$), etc. The chief zinc-producing countries are Silesia, Carinthia, Belgium, Rhenish Prussia, England, and many parts of the United States. When zinc is obtained from the carbonate (calamine), or the sulphide (zinc blende), the ores are previously roasted to drive off carbon dioxide from the former, and sulphur (as dioxide) from the sulphide. The resulting oxide is then reduced with charcoal to metallic zinc, which distills, and is condensed and collected, melted, and cast into ingots. Distillation is carried out in cylindrical tubes (*Belgian process*), or in muffles (*Silesian process*). (For details, see Roscoe and Schorlemmer's *Chemistry*.) During the distillation of the zinc, part of it burns, and the oxide, mixed with some zinc (*Silesian zinc-flowers*), is found in the receiver.

Crude zinc is liable to contain the following impurities: Iron, lead, copper, sulphur, phosphorus, arsenic, antimony, cadmium, and charcoal. To purify the zinc for medicinal purposes, it is subjected to redistillation in a retort consisting of a closed crucible, through the bottom of which an iron tube is fitted, projecting somewhat over half way into the crucible, and dipping into a vessel with water below. The crucible being heated, the zinc is vaporized, and passes down through the tube into the water. A chemical method recommended to purify zinc of its most objectionable impurities consists in oxidizing the melted zinc with potassium nitrate, and subsequently fusing it with zinc chloride; this removes arsenic, antimony, sulphur, and phosphorus, while iron, lead, and copper are not affected (Lescoeur, *Amer. Jour. Pharm.*, 1893, p. 175).

ZINCUM GRANULATUM, or *Granulated zinc*, is prepared by fusing, in an earthenware crucible, commercial metallic zinc, and pouring the melted liquid into cold water. The zinc, in granular condition, is then drained from the water and dried.

ZINC DUST is obtained either by distillation of zinc, and removing the zinc oxide that is formed by partial combustion, by means of ammonium chloride and aqueous ammonia; or, by powdering zinc in a mortar at a temperature above 200° C. (392° F.), and below 400° C. (752° F.), just short of its melting point (see *Description*, below). Zinc dust is a useful agent in effecting reductions in organic chemistry by dry distillation. Zinc is extensively used in the arts in the form of *galvanized iron* (iron-coated with zinc), for a variety of purposes. With copper it forms the alloy known as *brass* (20 parts zinc, 80 parts copper), and also enters into a number of other alloys.

Description.—As described by the *U. S. P.*, zinc is "a bluish-white metal, showing a crystalline fracture, and having a specific gravity, ranging from 6.9 when it is cast to 7.2 after it is rolled. Soluble in diluted sulphuric or hydrochloric acid, with evolution of hydrogen gas. When heated above 100° C. (212° F.), and not above 150° C. (302° F.), the metal becomes malleable and ductile; above 200° C. (392° F.) it becomes sufficiently brittle to be powdered in an iron mortar; at 412° to 415° C. (773.6° to 779° F.) it melts, and at 940° C. (1724° F.) it boils, and may be readily distilled"—(*U. S. P.*). In the air zinc gradually loses its luster, becoming covered with a thin gray coating of oxide, of a similar nature to the scum which forms on fusing; if this scum be removed when the metal is at a bright-red heat, the latter ignites and burns with a clear, greenish-white flame to oxide (see *Zinci Oxidum*). Zinc containing traces of other metals is readily soluble in dilute nitric, hydrochloric and sulphuric acids, with evolution of hydrogen gas and formation of the respective zinc salts. In the case of nitric acid, the nascent hydrogen induces secondary reactions, with formation of the lower nitric oxides, and even nitrogen, and finally ammonia (see C. Montemartini, *Amer. Jour. Pharm.*, 1892, p. 619). Chemically pure zinc is not soluble in dilute sulphuric acid, while commercial zinc even decomposes water upon boiling (*ibid.*, 1886, p. 127, from *Chemiker Zeitung*). Zinc is also soluble in solutions of caustic alkalies. Metallic zinc throws out arsenic, cadmium, copper, lead, etc., from their solutions and replaces them. Metallic zinc is not used in medicine; several of its salts, however, are employed, and are described under separate headings. They are mostly soluble in water, acid in reaction, and have an unpleasant metallic taste. The salts of zinc with volatile acids leave a residue of zinc oxide when they are heated to redness. The chloride, when thus heated (see *Zinci Chloridum*), is partly volatilized unchanged.

Tests.—When a salt of zinc is mixed with sodium carbonate and heated on charcoal in the reducing flame of a blowpipe, a non-volatile film of zinc oxide is deposited on the coal; this film is yellow when hot, and white when cold. (For another dry-way test [formation of Rinmann's green], see *Zinci Carbonas Præcipitatus.*) Solutions of zinc salts form a precipitate of zinc hydroxide ($Zn[OH]_2$) with caustic soda or potassa, or aqua ammoniæ. The precipitate is soluble in excess of the precipitant, and in ammonium salts (thus differing from cadmium, iron, etc.). From neutral solutions of zinc salts, ammonium sulphide precipitates characteristic white zinc sulphide (Zn_2S+HO). The sulphides of lead, copper, bismuth, iron, etc., are black, those of arsenic and cadmium are yellow. Zinc sulphide is readily soluble in mineral acids, insoluble in acetic acid; hence it is not precipitated by hydrogen sulphide gas when the solutions are acidulated with mineral acids; it is precipitated, however, when acidulated by acetic acid (compare *U. S. P.* tests, below). Potassium cyanide precipitates from solutions of neutral zinc salts white zinc cyanide ($Zn[CN]_2$), soluble in excess of potassium cyanide, forming a double salt ($Zn[CN_2].2[CN]K$). From this solution, hydrogen sulphide gas or ammonium sulphide produces no precipitate (difference from cadmium). As stated before, impurities liable to occur in zinc are: Iron, lead, copper, arsenic, sulphur, phosphorus, antimony, cadmium, and carbon. To establish the absence of these, the *U. S. P.* directs the following tests: "When zinc is dissolved in diluted hydrochloric acid, the hydrogen gas which is evolved should not have any disagreeable odor, nor should it color a strip of paper moistened with lead acetate T.S. (absence of sulphur), or with silver nitrate T.S. (absence of arsenic, antimony, phosphorus). The solution should be clear and colorless, and should yield a pure white precipitate with potassium ferrocyanide T.S., and with ammonium sulphide T.S. If an equal volume of hydrogen sulphide T.S. be added to the solution, neither color nor turbidity should be perceptible (absence of arsenic, cadmium, lead, copper, etc.). If ammonia water be added to the solution, a white precipitate should form, which should redissolve completely in an excess of the reagent, yielding a clear, colorless solution (absence of more than traces of iron, lead, copper, etc.)"—(*U. S. P.*). (For additional special tests, see this *Dispensatory*, preceding edition.)

Zinc Compounds.—ZINCI CYANIDUM ($Zn[CN]_2$), *Zinc cyanide, Zinci cyanuretum, Cyanuret of zinc.* To a solution of 1 part of chloride of zinc in 10 parts of distilled water, add solution of cyanide of potassium, in small quantities at a time, so long as any precipitate occurs, being careful not to add an excess of the cyanide, which would redissolve the precipitate: filter, wash the precipitate, and dry it. The chloride of zinc is preferable to the employment of the sulphate, because the resulting potassium chloride can be washed out better than the sulphate. Another method of preparing zinc cyanide consists in precipitating solution of acetate of zinc with aqueous hydrocyanic acid. It forms a snow-white, odorless, tasteless powder, insoluble in water or alcohol, but is soluble in ammonium and potassium cyanides, caustic potash and aqua ammoniæ. If a strong mineral acid be added to it, it is decomposed, hydrocyanic acid being developed, and a soluble salt of zinc obtained. This salt has been proposed in Germany as a substitute for prussic acid. Dr. Henning, who used it with much success, asserts that it is not only of service in those cases in which hydrocyanic acid is commonly exhibited, but also in *verminous diseases of children.* He gave it in 1-grain doses, mixed with pulverized jalap; and in the nervous affection called *cramp of the stomach*, he administered an antigastralgic powder, composed of cyanide of zinc, 3 grains; calcined magnesia, 24 grains; powdered cinnamon, 12 grains. Mix and divide into 12 powders, of which the patient takes 1 every 4 hours. This salt has also been recommended in *chorea, epilepsy* and other nervous and spasmodic diseases. The dose is $\frac{1}{8}$ grain, 3 times a day, in pill or powder, cautiously increased to 1 grain. Even $\frac{1}{2}$-grain doses may produce nervous trembling, congestion of the brain, and sleepiness. In *neuralgia*, and especially of the fifth nerve, it appears to be of some value, while in *nervous affections of the heart*, with arythmic movements, pain, and palpitation, $\frac{1}{4}$-grain doses, every 1 or 2 hours, have been recommended.

ZINCI ET POTASSII CYANIDUM ($K_2Zn[CN]_4$), *Zinc and potassium cyanide.*—This salt may be obtained in permanent white or colorless crystals, having a sweet, metallic taste, upon evaporating an alkaline liquid produced by dissolving cyanide of zinc in an aqueous solution of cyanide of potassium. It has an advantage over zinc cyanide in being readily soluble in water. Its uses and doses are the same as those for zinc cyanide. By the addition of dilute acids, zinc cyanide is reprecipitated from the solution.

ZINCI FERROCYANIDUM ($Zn_2Fe[CN]_6$ $3H_2O$). *Zinc ferrocyanide, Zinci ferrocyanuretum, Ferrocyanuret of zinc.* Dissolve ferrocyanide of potassium, 30 parts, in boiling water, and gradually add to it a solution of sulphate of zinc, 40 parts, in boiling water; add these solutions together while hot, and continue dropping in the last-named solution as long as it causes a precipitate; filter, wash the precipitate until free from potassium sulphate, and dry it. It forms a tasteless, white powder, insoluble in water or alcohol, and unaffected by very dilute acids. When warmed with diluted sulphuric acid, it decomposes, liberating hydrocyanic acid. It is dissolved by strong alkali. Its action is similar to that of the cyanide of zinc, and it is used in the same diseases, in doses of 1 grain, gradually increased to 3 or 4 grains. It may be given in powder with magnesia and cinnamon, in pill form, or suspended in water.

Zinci Lactas ($Zn[C_3H_5O_3]_2.3H_2O$), *Lactate of zinc.*—Easily prepared by dissolving pure oxide or carbonate of zinc in diluted lactic acid, and evaporating to crystallization. It forms short needles, or 4-angled crystals, having a sourish, metallic taste, and acid reaction. Quite soluble in hot water (6 parts), but less soluble in cold water (about 60 parts), and scarcely soluble in alcohol. Its uses are similar to those of zinc oxide (which see), but it is recommended as preferable on account of its supposed milder effects upon the stomach. Dose, ¼ to 1 grain, 4 or 5 times a day.

Zinci Phosphas ($Zn_3[PO_4]_2.4H_2O$), *Zinc phosphate, Trizincic orthophosphate.*—Prepared by the interaction of an alkali phosphate and zinc sulphate, the following reaction taking place: $3ZnSO_4 + 2PO_4HNa_2 = (PO_4)_2Zn_3 + 2Na_2SO_4 + H_2SO_4$. The precipitate is at first gelatinous, but soon becomes crystalline. It is a white powder, soluble in diluted acids, but not in water. Like other phosphates, this agent has been used in *nervous disorders*, and especially in *epilepsy* of menstrual origin. It has also been thought of value in *insanity* following *fevers*.

Zinci Salicylas ($Zn[C_7H_5O_3]_2.2H_2O$), *Zinc salicylate.*—This salt may be prepared by boiling for several minutes a solution of sodium salicylate (34 parts), and zinc sulphate (29 parts) in water (125 parts). Allow to cool, wash the crystals with cold water, and recrystallize from boiling water (L. van Itallie, *Amer. Jour. Pharm.*, 1889, p. 180; also see *ibid.*, 1886, pp. 246 and 599). F. Vigier (*Amer. Jour. Pharm.*, 1878, p. 182) prepares the salt by adding oxide of zinc to a boiling solution of salicylic acid in water. Vigier's salt crystallizes with 3 molecules of water. Long, satin-like, acicular crystals, having a sweetish and bitterish styptic or metallic taste. Alcohol, ether, methyl alcohol, and hot water freely dissolve it; cold water less readily (1 in about 25). This agent is used locally as an antiseptic and astringent, a ½ to 1 per cent solution being reputed useful in *gonorrhœa*, *conjunctivitis*, and *common and malignant ulcers*.

ZINGIBER (U. S. P.)—GINGER.

"The rhizome of *Zingiber officinale*, Roscoe"—(*U. S. P.*) (*Amomum Zingiber*, Linné).

Nat. Ord.—Scitamineæ.

Illustration: Bentley and Trimen, *Med. Plants*, 270.

Botanical Source.—The ginger plant has a perennial, tuberous root or rhizome: the stems are erect, oblique, round, annual, and invested by the smooth sheaths of the leaves, 2 or 3 feet in height. The leaves are subsessile, on long sheaths, alternate, lanceolate, linear, acute, smooth above and nearly so beneath, bifarious, 4 to 6 inches long by 1 inch broad; the sheaths smooth and crowned with a bifid ligula. Scapes radical, solitary, a little removed from the stems, 6 to 12 inches high, enveloped in a few obtuse sheaths, the uppermost of which end in tolerably long leaves, and terminate in oblong spikes, about the size of the thumb. Exterior bracts imbricated, 1-flowered, obovate, smooth, membranous at the edge, faintly striated lengthwise; interior enveloping the ovary, calyx, and the greater part of the tube of the corolla. The flowers are small, and of a dingy-yellow color. Calyx tubular, opening on one side, 3-toothed; corolla with a double limb, outer of three, nearly equal, oblong segments: inner a 3-lobed lip, of a dark-purple color. Sterile stamens subulate; filament short. Anther oblong, double, crowned with a long, curved, tapering, grooved horn. Ovary oval, 3-celled, with many ovules in each; style filiform; stigma funnel-shaped, ciliate and lodged just under the apex of the horn of the anther (L.).

Fig. 260.

Zingiber officinale.

History and Description.—The native country of ginger is unknown, though supposed to be Asia. It is cultivated in the tropical regions of Asia and America, and also at Sierra Leone, on the west African coast. The flowers and stalks have a fragrant odor, which is especially developed when they are rubbed or bruised. The fresh root is perennial, firm, knotted, of a compressed, roundish form, beset with transverse rugæ, covered with ash-colored bark, partly of a purplish tinge, and sends off many long fibers and offsets. The internal substance of the younger roots is softish, fleshy, and greenish; of the older it is compact, fibrous, whitish, and, when powdered, has a yellowish appearance (T.). The root forms the ginger of commerce, and is gathered from December to March, or soon after the decay of the stalks. The growth of ginger exhausts the soil to such an extent that, in Jamaica, each succeeding season a new field is planted, for which the ground is supplied by cutting down the forests and burning the timber. The second year's growth on the same field yields an inferior product (*ratoon* or *blue ginger*). Yet, by judicious treatment and alternation with other crops (*e. g.*, arrow root), ginger can be grown in the same field for many years (see Wm. Fawcett, *Amer. Jour. Pharm.*, 1894, pp. 184 and 593). The rhizomes, dug up, washed, and scraped, *e. g.*, deprived of their epidermis, and then dried in the sun and open air, are termed *White ginger* (*uncoated* or *scraped ginger*). When picked, cleaned, scalded gradually in boiling water, and then dried in the sun, they form the *Black ginger* (*coated, unscraped*) of commerce. The *White ginger* is the official kind, and the best grade is that grown in Jamaica (*Jamaica ginger*). The *U. S. P.* describes it as being "about 5 to 10 Cm. (2 to 4 inches long, 10 to 15 Mm. ($\frac{2}{5}$ to $\frac{3}{5}$ inch) broad, and 4 to 8 Mm. ($\frac{1}{6}$ to $\frac{1}{3}$ inch) thick, flattish, on one side lobed or clavately branched; deprived of the corky layer; pale-buff colored, striate, breaking with a mealy, rather fibrous fracture, showing numerous small, scattered resin-cells and fibro-vascular bundles, the latter enclosed by a nucleus sheath; agreeably aromatic, and of a pungent and warm taste"—(*U. S. P.*). Black gingers are the *African*, the *East Indian*, and some grades of *Cochin ginger*. White Cochin ginger is next in quality to Jamaica ginger. *Green ginger* is sometimes imported from Jamaica; it consists of soft and juicy rhizomes with buds, which have merely been washed after collection. *Preserved ginger*, or *succades*, consist of young rhizomes preserved in syrup. Large quantities are sent to England from the East. Bleaching the ginger, by means of chlorinated lime, is often practiced, also whitewashing the ginger with diluted milk of lime. This procedure, however, does not improve the article. Age, and especially exposure, impair the active properties. Water, proof-spirit, and alcohol take up the virtues of ginger. The best ginger is that which cuts pale, but bright; its quality, however, must be judged by its color, odor, taste, heaviness, and freedom from perforation by insects. (For interesting details regarding the cultivation, etc., of the various commercial grades of ginger, see P. L. Simmonds, *Amer. Jour. Pharm.*, 1891, p. 528; as to Jamaica ginger, see W. Fawcett [*loc. cit.*], and F. B. Kilmer, "In the Land of Ginger—Jamaica," *Amer. Jour. Pharm.*, 1898, p. 65.)

Chemical Composition.—The aroma of ginger resides in a volatile oil (*oil of ginger*); the rhizome yields from 2 to 3 per cent. It is thickish, greenish-yellow, bland to the taste, and has the specific gravity of 0.875 to 0.885. Its lower fractions contain the hydrocarbons *dextro-camphene* and *phellandrene*; the bulk of the oil boils between 256° and 266° C. (492.8° and 510.8° F.) (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 406). The pungency of ginger is due to an oleoresin, which may be extracted, together with the volatile oil, by ether, alcohol, acetone (see T. H. W. Idries, *Amer. Jour. Pharm.*, 1898, p. 466), and other solvents. Ginger was carefully investigated by J. C. Thresh (*Pharm. Jour. Trans.*, Vol. X, 1879–80, pp. 171 and 191; and Vol. XII, 1881–82, pp. 243 and 721). The oleoresin, abstracted by ether, contained volatile oil, inert neutral resin, inert acid resins, fat, and the pungent, active principle, *gingerol* (0.6 to 1.4 per cent), a viscid, odorless liquid of neutral reaction, non-glucosidal, soluble in diluted and strong alcohol, benzol, volatile oils, carbon disulphide, caustic potassa and ammonia, and glacial acetic acid; very slightly soluble in petroleum ether. The ether-insoluble part of ginger contained mucilage, starch (13 to 18 per cent), a trace of alkaloid, etc., and left, upon incineration, 3.5 to 5 per cent of ash. R. G. Davis (*Amer. Jour. Pharm.*, 1895, p. 520) finds the ash to vary from 3.6 to 6.5 per cent. According to Jones (*Archiv der Pharm.*, 1886, p. 769, from *The Analyst*, 1886), the quantity of starch in ginger is much greater than had hitherto been believed; he found 52.92 per cent. The amount of oleoresin obtainable from different grades of ginger, is not necessarily a criterion of the quality of the article. Dr. S. J. Riegel (*Amer.*

Jour. Pharm., 1891, p. 533) found Jamaica ginger to yield 5 per cent of oleoresin, obtainable by alcohol, ether, or chloroform, while the inferior East Indian ginger yielded to the same solvents 8 per cent of the oleoresin. A similar conclusion was previously reached by F. M. Siggins (*ibid.*, 1888, p. 278), as well as by Thresh, and later by W. S. Glass (*ibid.*, 1897, p. 320). The latter author remarks that the extract from the inferior (African) variety, though larger in quantity, presents an unsightly, brown appearance. (On the examination of a ginger from Fiji, being remarkably rich in active constituents, see E. H. Gane, *Pharm. Jour. Trans.*, Vol. XXII, 1892, p. 802.) The oleoresin of ginger represents the medicinal virtues of the drug (compare *Oleoresina Zingiberis*). (On chemical methods for the detection of exhausted ginger, see B. Dyer and J. F. H. Gilbard, *Proc. Amer. Pharm. Assoc.*, 1894, p. 936; and A. H. Allen and C. G. Moore, *Amer. Jour. Pharm.*, 1894, p. 342.)

Action, Medical Uses, and Dosage.—Ginger is stimulant, rubefacient, errhine, and sialagogue. When chewed it occasions an increased flow of saliva, and when swallowed it acts as a stimulating tonic, stomachic, and carminative, increasing the secretion of gastric juice, exalting the excitability of the alimentary muscular system, and dispelling gases accumulated in the stomach and bowels. It is much used to disguise other drugs, concealing their nausea, or preventing their tendency to cause tormina. When taken into the nostrils it causes severe sneezing. It has been used in combination with astringents or other agents, in *diarrhœa* and *dysentery;* prepared with rhubarb, in the form of cordial or syrup, few articles are more valuable in *cholera morbus* and *cholera infantum*, when there is coldness of the surface and extremities, and nausea and vomiting accompany. It is eminently useful in *habitual flatulency, atonic dyspepsia, hysteria*, and enfeebled and relaxed habits, especially of old and gouty individuals; and is excellent to relieve *nausea, pains and cramps of the stomach and bowels*, and to obviate tenesmus, and especially when those conditions are due to *colds*, or to the ingestion of unripe or otherwise unwholesome fruit. Ginger is occasionally of value in *fevers*, particularly where the salivary secretions are scanty and there is pain and movement of gases within the intestines. Here, though a stimulant, it will assist in producing sedation by re-establishing secretion and relieving the distressing gastro-intestinal annoyances. Ginger, in the form of "ginger tea," is popular and efficient as a remedy for breaking up *colds*, and in relieving the pangs of *disordered menstruation*. Combined with black-willow bark, it forms an excellent poultice to *indolent ulcers;* and has been used as a sialagogue to relieve *paralytic affections of the tongue, toothache*, and *relaxed uvula*. Ginger in powder, formed into a plaster with warm water, and applied on paper or cloth to the forehead, has relieved violent *headache*. Cakes made of ginger and molasses, with flour, etc., are very beneficial to the stomach, when eaten in moderation. Dose of ginger, in powder, from 10 to 30 grains; of the infusion, prepared by adding ½ ounce of the powdered or bruised root to a pint of boiling water, 1 or 2 fluid ounces. A large quantity of ginger, taken internally, might produce serious effects.

Specific Indications and Uses.—Loss of appetite; flatulence; borborygmus; spasmodic gastric and intestinal contractions; painful menstruation; acute colds; cool extremities; and cold surface in children's diseases.

Preparations of Ginger.—GINGER WINE. A good ginger wine may be made by boiling ½ pound of the best ginger, bruised, in 6 gallons of water, for ½ hour, and then filtering the decoction. Place the decoction in a demijohn, and add to it 6 pounds of raisins, cut in two, and the thin rinds of 5 lemons. Let this stand until vinous fermentation has ensued, then filter, add 1 pint of French brandy, and 1½ ounces of good isinglass previously dissolved in some of the wine. Place this in a strong vessel, cork it well and securely, and keep it for 6 months in a cool cellar (the longer the better); then carefully remove the wine from any sediment which may have formed, and bottle it for use. It improves by age.

GINGER BEER.—A good ginger beer may be prepared as follows: Take of white sugar, 2 pounds; lemon juice or cream of tartar, 14 drachms; honey, 12½ drachms; bruised ginger, 13 drachms; water, 2 gallons. Boil the ginger in 2 pints of the water for ½ hour; add the sugar, lemon juice, and honey, with the remainder of the water, and strain; when cold, add the white of an egg, and 24 minims of essence of lemon; let it stand for 4 days, and then bottle.

ETHEREAL EXTRACT OF GINGER.—Ethereal extract of ginger is made by placing 4 ounces of ginger in 6 ounces of ether, in a percolator; evaporate the percolate by means of a water-bath; 1 part of this is equivalent to 16 parts of ginger.

Related Drugs.—Zerumbet Root. This drug is the tuberous rhizome of *Zingiber Zerumbet*, Roscoe (*Amomum Zerumbet*, Linné). The root is flattish and spongy, of a yellowish hue internally, with light-brown bundles of fibro-vascular structure, and brownish externally. The odor is pleasant, and the taste, besides being bitter, resembles somewhat that of ginger. It is indigenous to Java.

Cassumunar Root.—The product of *Zingiber Cassumunar*, Roxburgh, a native of India. This and the preceding root have been confounded with each other. Cassumunar root is about 2 inches broad, compressed, jointed, and beset with white tubers, and many fleshy, white radicles. Externally, it is pale-brown and scaly, and ligneous and yellow within. Its taste is hot, pungent, and spicy, and its odor camphoraceous. Neither root is now in commerce.

Zedoaria, *Zedoary*.—The rhizomes of *Curcuma Zedoaria*, Roscoe (*Amomum Zedoaria*, Willdenow), and *Curcuma Zerumbet*, Roxburgh (*Amomum Zerumbet*, Kœnig), both of the natural order *Scitamineæ*, furnish respectively the *Radix zedoariæ longæ*, and *Radix zedoariæ rotundæ*, as formerly named. Both plants are indigenous to India and the East Indies. The ovate, or pyriform tuberous rhizome, is from 1½ to 2 inches long, and is generally cut, for the purpose of drying, into transverse, and occasionally into longitudinal sections. Zedoary is found in commerce, usually in the form of discs, almost circular, from ⅙ to ⅖ inch in thickness, and from ½ to 1½ inches in diameter. Externally, grayish-brown; internally, grayish. The endoderm near the edge is darker in color. Throughout the interior with the woody bundles are seen many orange-colored small resin cells. The discs are hard and compact, break with a short, mealy, or wax-like fracture, have a distinctive aromatic odor, and a pungent, bitterish, camphoraceous, aromatic taste. They contain starch granules (13 per cent) not unlike those of ginger; a soft, pungent resin (3 per cent); mucilage (9 per cent); bitter extractive; and a camphoraceous, volatile oil which may be obtained by distilling with water. The round zedoary, recognized by the *French Codex*, is ascribed to *Curcuma aromatica* of Roscoe, and is said to furnish the yellow discs sometimes found in the commercial zedoaria. Zedoary, though milder and less acrid, has properties very similar to those of ginger. It is employed chiefly as a carminative and stomachic. The dose of the powder is 5 to 30 grains; of the infusion (℥ss to wine or water Oss), 2 to 4 fluid drachms.

APPENDIX.

LIST OF REAGENTS.

(U. S. P.)

I. PRELIMINARY REMARKS.

Official Substances as Reagents.—Some official substances (chemicals, chemical solutions, etc.) are sufficiently pure to be used as reagents, if they comply with the tests of purity prescribed by the Pharmacopœia. In the case of others, the presence of certain impurities, though immaterial for their use as medicines, renders their employment as reagents unsuitable. Whenever a greater degree of purity is required than is provided for by the text of the Pharmacopœia, it will be specially mentioned in the following lists.

Abbreviations and Signs Used:

T. S.=Test solution.
V.S.=Volumetric solution.
$\frac{N}{1}$=Normal (see under "Volumetric Solutions" in List III).
$\frac{N}{2}$=Seminormal; $\frac{N}{10}$=Decinormal; $\frac{N}{100}$=Centinormal.
$\frac{2}{N}$=Double-normal (sometimes written: 2 N).

Asterisk (*) *in front* of a figure denotes that the quantity or value expressed by the figure is approximate. In the case of a volumetric solution, for instance, *25 Cc. means "about 25 Cc.," and this is to be interpreted as standing for "24.5 to 25.5 Cc.," the allowable variation in such cases being 2 per cent either way. In the text of the Pharmacopœia, this is expressed by saying "about 25 Cc.," or "about 16 per cent of iron," etc.

Keeping of Reagents.—Reagents should be kept in bottles made of glass free from lead and arsenic, and proof against corrosion by acids and alkalies, preferably in those made of Bohemian glass.

The bottles should be closed by well-ground glass stoppers. Stoppers of bottles containing alkali hydrates, ammonium sulphide, ammonia water, tannic acid, and other substances rapidly attacking ground glass surfaces, should be lubricated with a thin film of petrolatum.

Reagents easily affected by light, such as hydrogen sulphide T.S., ammonium sulphide T.S., chlorine water, etc., should be kept in bottles made of dark amber-colored glass.

Note.—As some of the following test solutions are in certain cases directed in definite quantities in lieu of regular volumetric solutions, it is important that they should always be prepared of the *exact strength prescribed.*

II. REAGENTS AND TEST SOLUTIONS.

Note.—The reagents are arranged in alphabetical order. The test solutions are usually mentioned in connection with the principal chemical or other substance from which they are prepared. The volumetric solutions will be found in List III Nos. 116–135).

Whenever *water* is required or mentioned as a solvent in the tests given in the Pharmacopœia, or in the preparation of any reagent, it is understood that *distilled water* shall be used.

1. Absolute Alcohol (Ethyl alcohol, C_2H_5OH=45.9).—Use the official absolute alcohol (*Alcohol Absolutum*).

2. Acetic Acid ($HC_2H_3O_2$=59.86).—Use the official acetic acid (*Acidum Aceticum*).

3. Albumen Test Solution.—Carefully separate the white of a hen's egg from the yolk, shake it thoroughly with 100 Cc. of water, and filter. This solution should be freshly made when required.

4. Aluminum (Metallic aluminum, Al=27.04) in the form of foil, wire, or ribbon. It should be tested for arsenic by Fleitmann's method (see below, No. 13), when no color should be imparted to the silver nitrate within 2 hours.

5. Ammonia Water (NH_3=17.01).—Use the official ammonia water (*Aqua Ammoniæ*).

6. Ammonium Carbonate Test Solution.—Dissolve 10 Gm. of ammonium carbonate ($NH_4HCO_3NH_4NH_2CO_2$=156.77 [*Ammonii Carbonas, U. S. P.*]) in a mixture of 10 Cc. of ammonia water and 40 Cc. of water.

For detecting arsenic sulphide in presence of antimony sulphide, the addition of ammonia water is omitted, and 10 Gm. of the salt are dissolved in a sufficient quantity of water to make 100 Cc.

7. Ammonium Chloride Test Solution.—Dissolve 10 Gm. of ammonium chloride (NH_4Cl=53.38 [*Ammonii Chloridum, U. S. P.*]) in enough water to make 100 Cc.

8. Ammonium Molybdate Test Solution.—Dissolve 1 Gm. of finely powdered ammonium molybdate ($[NH_4]_2MoO_4$=195.76) in 6.7 Cc. of hot water, using a little ammonia water, if necessary, to effect solution. Then gradually pour the liquid into a mixture of 3.3 Cc. of nitric acid (specific gravity 1.414) and 3.4 Cc. of water. Preserve the test solution in the dark, if a sediment should form in it after some days, carefully decant the clear solution from it.

9. Ammonium Oxalate Test Solution.—Dissolve 4 Gm. of pure, crystallized ammonium oxalate ($[NH_4]_2C_2O_4+H_2O$=141.76), free from metals, chloride, and sulphate, in enough water to make 100 Cc. Or, dissolve 4 Gm. of pure oxalic acid (see below, No. 121) in 100 Cc. of water, add 20 Cc. of ammonia water, boil to expel excess of ammonia, and bring the volume to 113 Cc. On evaporating a portion of the test solution, and igniting the residue, it should be completely volatilized (absence of fixed impurities).

10. Ammonium Phosphate Test Solution.—Dissolve 1 Gm. of ammonium phosphate ($[NH_4]_2HPO_4$=131.82), together with 2 Cc. of ammonia water, in enough water to make 100 Cc. This solution does not keep well. It should be freshly made when required, or frequently renewed.

10b. Ammonium Sulphate ($[NH_4]_2SO_4$=131.84).—The purified salt, leaving no residue upon ignition.

11. Ammonium Sulphide Test Solution.—Saturate 3 parts of pure ammonia water with pure, washed hydrogen sulphide, and add to the solution (which now contains ammonium sulphhydrate, NH_4HS=50.99) 2 parts of ammonia water, which converts the greater portion of the ammonium sulphhydrate into ammonium sulphide ($[NH_4]_2S$=68.0). The solution should be perfectly clear and colorless, and, on being evaporated, leave no residue. It should not be rendered turbid either by magnesium sulphate T.S. (absence of free ammonia), or by calcium chloride T.S. (absence of ammonium carbonate). It should be protected against air and light by being kept in small, dark amber-colored bottles, in a dark place. As soon as a notable deposit of sulphur has made its appearance in the solution, it should be rejected.

Ammonium polysulphide test solution is occasionally required. This is a yellow liquid, prepared by dissolving a small quantity of pure sulphur in the preceding, colorless ammonium sulphide test solution.

12. Arsenic Test, Bettendorff's.—To a small quantity of the liquid to be tested, which should contain much pure concentrated hydrochloric acid, or should be a solution of the substance to be tested in pure, concentrated hydrochloric acid, add an equal volume of a saturated solution of freshly prepared stannous chloride in pure, concentrated hydrochloric acid, together with a small piece of pure tin foil. The presence of arsenic is revealed by the production of a brown color or a brown precipitate, the appearance of which is hastened by a gentle heat (see *Stannous Chloride*, No. 108).

13. Arsenic Test, Fleitmann's.—Into a test-tube of at least 15 Cm. in length, and 15 to 18 Mm. in diameter, place a single, solid piece of zinc (see below, No. 115), weighing about 1 to 1.25 Gm., and add about 5 Cc. of potassium hydrate T.S. (*Liquor Potassæ, U. S. P.*), both ingredients having previously been proven free from arsenic by having been subjected, alone, to the test about to be described, during at least 2 hours, with negative result. Now add the liquid to be tested, which must not contain any free acid, nor very materially increase the volume of the contents of the test-tube. Immediately secure over the mouth of the test-tube a previously prepared cap made of three thicknesses of pure filter paper free from dust, and apply to the upper filter paper a drop of a saturated, aqueous solution of silver nitrate acidulated with nitric acid (see *Silver Nitrate T.S.*, No. 96). Then place the tube at once, upright, into a box containing sand heated to about 90° C. (194° F.), and fitted with a cover, so as to exclude light and dust, and permit the reaction to proceed for such a time as may be specially prescribed in each case. The presence of arsenic (but not of antimony) is revealed by the production, upon the moistened paper cap, of a brown or black stain. In absence of arsenic, if the test has been carefully conducted, the spot will remain colorless. In place of zinc, metallic aluminum, best in form of wire, cut into small pieces, may be employed (Gatehouse's modification). The method of testing, and the results, are the same as in Fleitmann's test.

14. Arsenic Test, Gutzeit's.—Into a test-tube of at least 15 Cm. in length, and 15 to 18 Mm. in diameter, place a single, solid piece of zinc (see below, No. 115), weighing about 1 to 1.25 Gm., and add about 5 Cc. of a mixture, previously prepared and kept in readiness for this purpose, of 10 Cc. of pure sulphuric acid of specific gravity 1.835, and 190 Cc. of water, the ingredients having previously been proven free from arsenic by having been subjected, alone, to the test about to be described, during at least 2 hours, with negative results. Now add the liquid to be tested, which should not be alkaline, nor exceed 1 Cc. About 1 Cm. below the open end of the test-tube insert a loose plug, about 1 Cm. long, of glass-wool or cotton, which has been moistened with 0.5 Cc. of lead acetate T.S. Then secure over the mouth a cap made of three thicknesses of clean filter paper, and apply to the upper one a drop of a saturated, aqueous solution of silver nitrate, acidulated with nitric acid (see *Silver Nitrate T.S.*, No 96). Place the tube into a box to exclude light, and let the reaction proceed as long as may be prescribed in each case. The presence of arsenic is shown by the production, upon the moistened paper cap, of a bright yellow stain which becomes black or brown by application of water. Antimony colors the spot black or brown at once without showing a yellow color while dry. In this case, traces of arsenic may be overlooked; it is therefore advisable to subject a fresh portion of the specimen to Fleitmann's test (see No. 13), which responds only to arsenic. If the plug moistened with lead acetate T.S. be strongly colored, so that doubt exists whether the coloration is due to metallic silver reduced by arsenic, or to silver sulphide, produced by the escape of H_2S through the plug, moisten the silver stain with diluted nitric acid, which will dissolve the metallic silver reduced by arsenic, but will not affect the black silver sulphide. Or else, put on a new cap of filtering paper, moistened with a drop of lead acetate T.S. If this remain colorless, sulphide is absent.

15. Barium Carbonate.—Pure barium carbonate ($BaCO_3$ 196.75) prepared by dissolving 12 parts of pure, crystallized barium chloride in 20 parts of boiling water, then adding a solution of 5 parts of ammonium carbonate in 10 parts of boiling water, and afterward 5 parts of ammonia water; finally washing the precipitate thoroughly and drying it.

16. Barium Chloride Test Solution.—Prepared from pure barium chloride ($BaCl_2+2H_2O$ 243.56). The aqueous solution of the salt should be perfectly neutral, and should not yield a precipitate with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of metals, etc.). The aqueous solution, after being precipitated by diluted sulphuric acid in slight excess, yields a filtrate which should not leave any permanent residue when evaporated and heated on platinum-foil (absence of other fixed bases and salts). Diluted alcohol, after remaining in contact with it for several hours, should, upon ignition, show a pure yellowish-green colored flame, without red streaks (absence of traces of strontium). To prepare the test solution, dissolve 12.2 Gm. of the salt in enough water to make

100 Cc. (This solution is of normal strength$=\frac{N}{1}$V.S., so as to permit of its use for volumetric purposes also.)

17. Barium Hydrate Test Solution.—A saturated solution of barium hydrate (barium hydroxide, $Ba[OH]_2=170.82$) in water. This solution rapidly absorbs carbon dioxide from the air. It is preferably prepared freshly as wanted.

18. Barium Nitrate Test Solution.—Prepared from pure barium nitrate ($Ba[NO_3]_2=260.68$). This salt should respond to the same tests as barium chloride (see No. 16). In addition, its aqueous solution, slightly acidulated with nitric acid, should not be rendered turbid by silver nitrate T.S. (absence of chloride . To prepare the test solution, dissolve 1 Gm. of the salt in water to make 15.3 Cc. (This solution is of half normal strength$=\frac{N}{2}$V.S., so as to permit of its use for volumetric purposes also.)

19. Benzin, or Petroleum Ether.—Use the official benzin (*Benzinum*).

20. Benzol, or Benzene.— Benzol ($C_6H_6=77.82$) is a colorless, transparent liquid of a peculiar, aromatic odor, of a specific gravity of 0.8846 at 15° C. (59° F.), congealing at 0° C. (32° F.), and boiling at 80.37° C. (176.7° F.). It is insoluble in water, but soluble in 4 parts of alcohol, and in ether. In concentrated sulphuric acid it should dissolve without producing a color. On shaking 2 Cc. of benzol with 0.5 Cc. of sulphuric acid and 1 drop of fuming nitric acid, no green or blue tint should be produced (absence of thiophene).

21. Brazil Wood Test Solution.—(See under *Indicators*, No. 49.)

22. Bromine Water (Bromine Test Solution, $Br=79.76$).—An aqueous solution of bromine (*Bromum, U. S. P.*), prepared by dissolving 1 Cc. of bromine in enough water to make 100 Cc.

23. Calcium Chloride Test Solution.—Dissolve 10.925 Gm. of crystallized calcium chloride ($CaCl_2+6H_2O=218.41$) in enough water to make 100 Cc. (This solution is of normal strength$=\frac{N}{1}$V.S., so as to permit of its use for volumetric purposes also.)

24. Calcium Hydrate Test Solution (Lime-water, $Ca[OH]_2=73.83$).—Use the official lime-water (*Liquor Calcis*).

25. Calcium Sulphate Test Solution.—Introduce transparent crystals of native gypsum (selenite, $CaSO_4+2H_2O=171.65$) into a flask filled with water, and decant the clear, saturated solution when required. One part of gypsum requires, at 15° C. (59° F.), 398 parts of water for solution.

26. Carbon Disulphide.—Use the official carbon disulphide (*Carbonei Disulphidum*).

27. Chlorine Water (Chlorine Test Solution, $Cl=35.37$).—Use the official chlorine water (*Aqua Chlori*). Since it rapidly deteriorates by keeping, it should be frequently renewed or freshly prepared when required.

28. Chloroform ($CHCl_3=119.08$).—Use the official chloroform (*Chloroformum*).

29. Cobaltous Nitrate Test Solution ($Co[NO_3]_2+6H_2O=290.14$).—The crystallized, commercial salt is sufficiently pure, if, after it is dissolved in water, and the cobalt completely precipitated by ammonium sulphide T.S., the filtrate leaves no residue on evaporation. To make the test solution, dissolve 1 Gm. of the salt in 10 Cc. of water.

30. Cochineal Test Solution.—(See under *Indicators*, No. 50.)

31. Copper (Metallic copper, $Cu=63.18$) in the form of wire, foil, or turnings. The commercial article, brightened, if necessary, by scouring with diluted hydrochloric acid, is suitable for all purposes except testing for arsenic. If required for this purpose, the absence of arsenic must first be proven. A small portion (about 0.5 Gm.) of the copper is to be dissolved in hot, concentrated sulphuric acid, and this solution subjected to Gutzeit's test (see No. 14). No color should be imparted to the silver nitrate within 2 hours (absence of arsenic).

82. Cupric Ammonium Sulphate Test Solution.—A solution of cupritetrammonium sulphate ($Cu[NH_3]_4SO_4+H_2O=245.0$). To copper sulphate T.S add ammonia water, until the precipitate first formed is nearly, but not completely redissolved, then filter. This solution is apt to decompose on keeping. It should be made freshly when required.

33. Cupric Sulphate Test Solution.— Dissolve 10 Gm. of cupric sulphate ($CuSO_4+5H_2O=248.8$ [*Cupri Sulphas, U. S. P.*]) in enough water to make 100 Cc.

34. Cupric Tartrate Test Solution.—(See below, under *Volumetric Solutions*, No. 117.)

35. Corallin Test Solution.—(See under *Indicators*, No. 51.)

36. Diphenylamine, and Diphenylamine Test Solution.—(See under *Indicators*, No. 52.)

37. Eosin Test Solution.—(See under *Indicators*, No. 53.)

38. Ether.—Use the official ether (*Æther*). It should be strictly neutral to litmus paper.

39. Ferric Ammonium Sulphate Test Solution.—Dissolve 10 Gm. of ferric ammonium sulphate (*Ferri et Ammonii Sulphas, U. S. P.*) in enough water to make 100 Cc.

40. Ferric Chloride Test Solution.—Dissolve 10 Gm. of ferric chloride ($Fe_2Cl_6+12H_2O$ = 539.50 [*Ferri Chloridum, U. S. P.*]), in enough water to make 100 Cc.

41. Ferrous Sulphate Test Solution.—Dissolve a clear crystal of ferrous sulphate ($FeSO_4+7H_2O$ = 277.42 [*Ferri Sulphas, U. S. P.*]) in about 10 parts of water previously boiled to expel air. This solution should be freshly prepared immediately before use.

42. Ferrous Sulphide (FeS = 87.86).—A heavy solid, in form of black or brownish-black irregular masses, or fused into sticks, soluble in sulphuric or hydrochloric acid with copious evolution of hydrogen sulphide. On dissolving 2 Gm. of ferrous sulphide in pure nitrohydrochloric acid diluted with a little water, evaporating the solution to dryness, and testing the residue for arsenic by Gutzeit's method (see No. 14), no color should be imparted to the silver nitrate within 2 hours.

43. Fluorescein Test Solution.—(See under *Indicators*, No. 54.)

44. Gelatin Test Solution.—Dissolve 1 Gm. of isinglass (*Ichthyocolla, U.S.P.*) in 50 Cc. of water, by the aid of a gentle heat, and filter if necessary. This solution should be freshly made when wanted for use.

45. Gold Chloride Test Solution.—The commercial chloride of gold, usually prepared by dissolving gold in nitrohydrochloric acid and carefully evaporating to dryness, mostly consists of aurochloric acid ($HAuCl_4+2H_2O$ = 375.1), which is converted into neutral auric chloride ($AuCl_3$—302.81), by fusing it at a temperature not exceeding 150° C. (302° F.), moistening the residue (now consisting of auric and aurous chloride) with enough hot water to produce a syrupy liquid (whereby the aurous chloride is decomposed into auric chloride and metallic gold), and then pouring off the clear liquid from the precipitate. To prepare the test solution, dissolve the liquid finally obtained in the before-mentioned process in 20 volumes of water. Or, dissolve 1 Gm. of dry auric chloride in 30 Cc. of water.

46. Hydrochloric Acid, Pure, for Tests (HCl—36.37).—In addition to the tests prescribed for this acid in the text of the *Pharmacopœia*, it is required to conform to the following more rigorous tests, before it can be employed as a reagent: The addition of 1 Cc. of barium chloride T.S. to 1 Cc. of the acid diluted with 9 Cc. of water should cause no turbidity within 24 hours (absence of sulphuric acid). A crystal of diphenylamine dropped into the acid should not turn blue (absence of free chlorine). On substituting it for sulphuric acid in Gutzeit's test, as described under No. 14, no color should be imparted to the silver nitrate within 2 hours (absence of arsenic or antimony).

47. Hydrogen Sulphide (H_2S = 33.98).—A gas generated by treating ferrous sulphide with diluted sulphuric acid, and washing the gas by passing it through water.

48. Hydrogen Sulphide Test Solution (or Hydrosulphuric acid, H_2S = 33.98).—A saturated, aqueous solution of hydrogen sulphide. To prepare about 1 liter of the solution, treat 20 Gm. of ferrous sulphide, in a suitable apparatus, with a mixture of 20 Cc. of pure sulphuric acid (specific gravity 1.835) 250 Cc. of water, pass the gas through a wash bottle containing a small quantity of water, and conduct it into a bottle of the capacity of about 1½ liters, containing 1 liter of water. When the gas is no longer absorbed, transfer the solution to small, dark amber-colored bottles, to be filled nearly to the top, pass a stream of hydrogen sulphide for a few minutes through each, and then at once stopper them tightly, and preserve them afterward in a cool and dark place. Before putting them aside, introduce into one of these bottles a few drops of hydrochloric acid, and keep it in a warm place during 24 hours, after which time no precipitate should be found in it (absence of arsenic). Before any of the solution is used, it should be ascertained that it still retains a strong odor of hydrogen sulphide, and that, when it is added to an equal volume of ferric chloride T.S., a copious precipitate of sulphur is formed at once.

INDICATORS FOR ACIDIMETRY, ALKALIMETRY, ETC. (Nos. 49-59).

Note.—Each test solution used as indicator should be examined as soon as prepared, and afterward from time to time, as to its neutrality. If necessary, it should be brought, by the cautious addition of diluted sulphuric acid, or of a diluted solution of an alkali, to such a point that, when a few drops of it are added to 25 Cc. of water, a single drop of a centinormal acid or alkali V.S., respectively, will distinctly develop the corresponding tints.

Since many of the colored test solutions are injured by exposure to light, it is best to preserve them in dark amber-colored vials. Papers prepared with them should be kept in dark bottles or paper boxes.

49. Brazil Wood Test Solution.—Boil 50 Gm. of finely cut Brazil wood (the heart-wood of *Peltophorum dubium* [Sprengel] Britton, *Nat. Ord.*—Leguminosæ) with 100 Cc. of water during half an hour, replacing the water from time to time. Allow the mixture to cool; strain, wash the contents of the strainer with water until 100 Cc. of the strained liquid are obtained, add 25 Cc. of alcohol, and filter. This solution turns purplish-red with alkalies, and yellow with acids.

50. Cochineal Test Solution.—Macerate 1 Gm. of unbroken cochineal (*Coccus, U. S. P.*), during 4 days, with 20 Cc. of alcohol, add 60 Cc. of water; then filter. The color of this test solution turns violet with alkalies, and yellowish-red with acids. As an indicator, it is used chiefly when ammonia or alkaline earths are present.

51. Corallin Test Solution.—Dissolve 1 Gm. of corallin (a coloring matter derived from coal-tar, and containing rosolic and para-rosolic acids) in 10 Cc. of alcohol and enough water to make 100 Cc.

52. Diphenylamine ($[C_6H_5]_2NH=168.65$) is in form of grayish-white or colorless crystals, of a peculiar, aromatic odor, melting at 54° C. (129.2° F.), slightly soluble in water, more soluble in acids. It is used either in the dry state, or in solution in dilute sulphuric acid, as a test for nitric acid (in sulphuric acid, water, etc.), or for chlorine (in hydrochloric acid). To test a solution for the presence of nitric acid, a small portion of it is mixed with 1 or 2 drops of diphenylamine T.S., and then concentrated sulphuric acid, *free from nitrose*, is poured in so as to form a layer beneath the solution. The presence of nitric acid is shown by a deep-blue color at the zone of contact.

Diphenylamine test solution is prepared by dissolving 0.1 Gm. of diphenylamine in 50 Cc. of diluted sulphuric acid. The solution should be colorless.

53. Eosin Test Solution.—Dissolve 1 Gm. of commercial "yellowish" eosin ($K_2C_{20}H_6Br_4O_5$) in 30 Cc. of water. This solution is red by transmitted light, and shows a strong green fluorescence by reflected light. Acids destroy the fluorescence, and alkalies restore it.

54. Fluorescein Test Solution.—Agitate 1 Gm. of fluorescein ($C_{20}H_{12}O_5$) with 100 Cc. of diluted alcohol, until the latter is saturated; then filter. This solution shows a strong green fluorescence, by reflected light, in presence of the least excess of an alkali.

55. Litmus Paper and Test Solution.—Exhaust coarsely powdered litmus with boiling alcohol (which removes a peculiar, red coloring matter, erythrolitmin), and digest the residue with about an equal weight of cold water, so as to dissolve the excess of alkali present. The blue solution thus obtained, after being acidulated, may be used to make *red litmus paper*. Finally extract the residue with about 5 times its weight of boiling water, and filter. Preserve the filtrate, as *test solution*, in wide-mouthed bottles stoppered with loose plugs of cotton to exclude dust but to admit air.

Litmus Paper, Blue.—Impregnate, with the test solution just described, strips of white, unsized paper, free from wood pulp, but not too porous, and dry them by suspending them on strings of clean twine.

Litmus Paper, Red.—Prepare this with the same kind of paper and in the same manner as described in the preceding paragraph. To impregnate the paper, either use the blue solution obtained from litmus, by treating the mass, after extraction by alcohol, with cold water, acidulating the same with just enough hydrochloric acid to impart to it a distinctly red tint; or, use the regular test solution, after acidulating it in the same manner.

Neither blue nor red litmus paper should have a very intense color.

Preserve the test paper in paper boxes or bottles, so as to exclude dust and acid or ammoniacal vapors.

56. Methyl Orange Test Solution.—Dissolve 1 Gm. of methyl orange (the sodium or ammonium salt of dimethylamidoazobenzolsulphonic acid, $HC_{14}H_{14}N_3SO_3$ = 304.47; also known as helianthin, or tropæolin D, or Poirrier's Orange 3 P) in 1000 Cc. of water. Add to it, carefully, diluted sulphuric acid, in drops, until the liquid turns red and just ceases to be transparent; then filter. The solution acquires a yellow color when brought in contact with alkali hydrates, carbonates, or bicarbonates. Carbonic acid does not affect it, but sulphuric, hydrochloric, and other acids change its color to crimson. It is not suited for use with organic acids.

57. Phenolphtalein Test Solution.—Dissolve 1 Gm. of phenolphtalein ($C_{20}H_{14}O_4$) in 100 Cc. of diluted alcohol. The solution is colored deep purplish-red by alkali hydrates or carbonates; bicarbonates and most other salts do not produce such color; acids render the reddened solution colorless. It is not suitable as an indicator for ammonia or bicarbonates.

Phenolphtalein Paper is prepared by impregnating white, unsized paper with the test solution and drying it.

58. Rosolic Acid Test Solution.—Dissolve 1 Gm. of commercial rosolic acid (chiefly methylaurin, $C_{20}H_{16}O_3$ = 303.28) in 10 Cc. of diluted alcohol, and add enough water to make 100 Cc. The solution turns violet-red with alkalies, yellow with acids. In place of rosolic acid, commercial pæonin (also known as aurin R) (chiefly $C_{19}H_{14}O_3$—289.31) may be employed.

59. Turmeric Tincture.—Digest any convenient quantity of ground curcuma root (from *Curcuma longa*, Linné, *Nat. Ord.*—Scitamineæ) repeatedly with small quantities of water, and throw this liquid away. Then digest the dried residue for several days with 6 times its weight of alcohol, and filter.

Turmeric Paper.—Impregnate white, unsized paper with the tincture, and dry it. The tincture, as well as the paper, turns brown with alkalies, and the yellow color is restored by acids. Boric acid, however, even in presence of hydrochloric acid, turns the color to reddish-brown, and this is changed to bluish-black by ammonia.

60. Indigo Test Solution.—Place 6 Gm. (3.3 Cc.) of fuming sulphuric acid into a beaker well cooled by immersion in water, and stir into it, very gradually, 1 Gm. of finely powdered Bengal indigo. Set the mixture aside for 2 days, then pour it into 20 Cc. of water, and decant. Or, dissolve 1 Gm. of commercial indigo-carmine (the sodium or potassium salt of sulphindigotic acid) in 150 Cc. of water.

61. Iodine Test Solution.—For preparing the ordinary test solutions (as a reagent for starch, alcohol by iodoform test, etc.), iodine (I = 126.53), fulfilling the requirements of the Pharmacopœia (see *Iodum, U. S. P.*), is sufficiently pure. For this purpose dissolve 1 Gm. of iodine and 3 Gm. of potassium iodide in 50 Cc. of water. For use in volumetric analysis, or in other cases where the ordinary impurities present in official iodine are objectionable, *Purified iodine* must be employed (see under No. 120).

62. Iron, Metallic (Fe = 55.88).—Bright and perfectly clean iron in the form of wire, sheet, or filings, according to the uses to be made of it. For making solutions of pure iron salts, fine, thin, bright wire (so-called florists' wire) should be used. For detecting copper, bright pieces of sheet-iron or knitting-needles are used; for detecting nitric acid, by reduction to ammonia, iron filings are preferable.

63. Lead Acetate Test Solution.—Dissolve 10 Gm. of clear, transparent crystals of lead acetate ($Pb[C_2H_3O_2]_2+3H_2O$ = 378.0 [*Plumbi Acetas, U. S. P.*]), free from adhering lead carbonate, in enough water to make 100 Cc. Preserve the solution in well-stoppered bottles.

64. Basic Lead Acetate Test Solution.—Use the official solution of lead subacetate (*Liquor Plumbi Subacetatis*).

65. Litmus Paper and Test Solution.—(See under *Indicators*, No. 55.)

66. Magnesia Mixture.—Dissolve 10 Gm. of magnesium sulphate (*Magnesii Sulphas, U. S. P.*), and 20 Gm. of ammonium chloride (*Ammonii Chloridum, U. S. P.*), in 80 Cc. of water, add 42 Cc. of ammonia water, set the mixture aside for a few days in a well-stoppered vessel, and filter. It should never be used freshly made.

67. Magnesium Sulphate Test Solution.—Dissolve 10 Gm. of magnesium sulphate ($MgSO_4+7H_2O=245.84$ [*Magnesii Sulphas, U. S. P.*]) in enough water to make 100 Cc.

68. Mercuric Chloride Test Solution.—Dissolve 5 Gm. of mercuric chloride ($HgCl_2=270.54$ [*Hydrargyri Chloridum Corrosivum, U. S. P.*]) in enough water to make 100 Cc.

69. Mercuric Potassium Iodide Test Solution.—Use the decinormal mercuric potassium iodide volumetric solution (No. 121).

70. Alkaline Mercuric Potassium Iodide Test Solution (Nessler's Solution).—Dissolve 5 Gm. of potassium iodide (*Potassii Iodidum, U. S. P.*) in 5 Cc. of hot water, and add to this a hot solution of 2.5 Gm. of mercuric chloride (*Hydrargyri Chloridum Corrosivum, U. S. P.*) in 10 Cc. of water. To the turbid, red mixture add 16 Gm. of potassium hydrate (*Potassa, U. S. P.*) dissolved in 40 Cc. of water, and finally make up the volume to 100 Cc. A surplus of red mercuric iodide deposits on cooling, and may be left in the bottle, the clear solution being decanted as needed.

71. Mercurous Nitrate Test Solution ($Hg_2[NO_3]_2+2H_2O=559.3$).—Into a porcelain capsule put 1 Gm. of pure mercury with 0.5 Cc. of pure nitric acid and 0.5 Cc. of distilled water, and place it for 24 hours into a cool, dark room. Separate and drain the crystals, and dissolve them in 100 Cc. of water. Preserve the solution in a dark amber-colored bottle, into which a small globule of mercury has been placed.

72. Methyl Alcohol ($CH_3OH=31.93$).—For the identification of salicylic acid, the rectified, commercial wood alcohol, having a specific gravity of about 0.820, is sufficiently pure, if it forms a clear, transparent mixture with an equal volume of distilled water.

73. Methyl Orange Test Solution.—(See under *Indicators*, No. 56.)

74. Nitric Acid, Pure, for Tests ($HNO_3=62.89$).—In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous test before it can be used as a reagent: On supersaturating 0.5 Cc. of the acid with pure potassium hydrate T.S., and testing a portion of this solution by Fleitmann's method (see under No. 13), no color should be imparted to the silver nitrate within 2 hours (absence of arsenic).

75. Fuming Nitric Acid (Red Fuming Nitric Acid).—The commercial acid will answer, if it is of specific gravity 1.450, or over. It should be carefully kept in glass-stoppered bottles, in a cool place.

76. Oxalic Acid Test Solution.—Use the decinormal volumetric solution (No. 123).

77. Phenolphtalein Test Solution.—(See under *Indicators*, No. 57.)

78. Picric Acid Test Solution.—Dissolve 1 Gm. of pure, distinctly crystalline picric acid (trinitrophenol, $C_6H_2[NO_2]_3OH=228.57$) in 100 Cc. of water. cool the solution, and filter, if necessary.

79. Platinic Chloride Test Solution.—Heat 1 Gm. of pure platinum, in chips, with 6 Cc. of concentrated hydrochloric acid to 80° C. (186° F.), and very gradually add 1 Cc. of strong nitric acid (specific gravity 1.414) until very nearly all the platinum is dissolved. Evaporate the solution to dryness on a water-bath, moisten the residue with a few drops of hydrochloric acid, and again evaporate to expel the excess of acid. Dissolve the residue in 20 Cc. of water. The *test solution* may also be prepared by dissolving 1.7 Gm. of neutral platinic chloride ($PtCl_4=335.78$), or 2.6 Gm. of chloroplatinic acid ($H_2PtCl_6+6H_2O=516.28$), in 20 Cc. of water. On evaporating a small portion of the solution to dryness and igniting the residue, pure, metallic platinum should be left behind, which should yield nothing soluble to nitric acid.

80. Potassium Carbonate Test Solution.—Dissolve 10 Gm. of anhydrous potassium carbonate (K_2CO_3=137.91 [prepared from *Potassii Carbonas, U. S. P.*]) in enough water to make 100 Cc.

81. Potassium Chromate Test Solution.—Dissolve 1 Gm. of potassium chromate (K_2CrO_4=193.9) in enough water to make 10 Cc. On adding silver nitrate T.S. to a little of the solution, a red precipitate is produced which should be completely dissolved by nitric acid (absence of chloride). Another portion of the solution, mixed with an equal volume of diluted hydrochloric acid, should yield no precipitate with barium chloride T.S. (absence of sulphate).

82. Potassium Cyanide Test Solution.—This should be freshly prepared, when required, by dissolving 1 Gm. of potassium cyanide (KCN=65.01 [*Potassii Cyanidum, U. S. P.*]) in 4 parts of water.

83. Potassium Bichromate.—Use the official potassium bichromate ($K_2Cr_2O_7$=293.78 [*Potassii Bichromas*]).

84. Potassium Bichromate Test Solution.—Dissolve 10 Gm. of potassium dichromate (*Potassii Bichromas, U. S. P.*) in enough water to make 100 Cc.

85. Potassium Ferricyanide Test Solution.—Dissolve 1 part of potassium ferricyanide ($K_6Fe_2[CN]_{12}$=657.7) in about 10 parts of water. This solution should be made freshly, when required, as it is rapidly decomposed by light. A freshly-prepared, aqueous solution, when mixed with some ferric chloride T.S. and diluted with water, should show a brown tint, free from turbidity, or a shade of green.

86. Potassium Ferrocyanide Test Solution.—Dissolve 10 Gm. of potassium ferrocyanide ($K_4Fe[CN]_6+3H_2O$=421.76) in enough water to make 100 Cc.

87. Potassium Hydrate Test Solution (KOH=55.99).—Use the official solution of potassa (*Liquor Potassæ*). For use in Fleitmann's test for arsenic (see above, No. 13), it should have previously been subjected, by itself, to this test, for at least 2 hours, with negative result (absence of arsenic).

88. Potassium Iodide Test Solution.—Dissolve 16.556 Gm. of potassium iodide (KI=165.56 [*Potassii Iodidum, U. S. P.*]) in enough water to make 100 Cc., and keep the solution in dark amber-colored, well-stoppered bottles, to prevent the formation of iodate. The solution should be frequently renewed, or freshly prepared when required. (This solution is of normal strength=$\frac{N}{1}$V.S., so as to permit of its use for volumetric and gasometric purposes also.)

89. Potassium Nitrate.—The dry salt (KNO_3=100.92 [*Potassii Nitras, U.S.P.*]), responding to the tests of purity required by the Pharmacopœia, particularly to those for absence of chloride and sulphate.

90. Potassium Permanganate ($KMnO_4$=157.67).—See below, under No. 127.

91. Potassium Sulphate Test Solution.—Dissolve 1 Gm. of potassium sulphate (K_2SO_4=173.88 [*Potassii Sulphas, U. S. P.*]) in enough water to make 115 Cc. (This solution is of decinormal strength=$\frac{N}{10}$V.S., so as to permit of its use for volumetric purposes also, as a substitute for decinormal sulphuric acid, when it is desired not to disturb the neutrality of a liquid.)

92. Potassium Sulphocyanate Test Solution (KSCN=96.99).—Use the decinormal volumetric solution (No. 129).

93. Pyrogallol.—Use the official pyrogallol ($C_6H_3[OH]_3$=125.7 [*Pyrogallol*]).

94. Rosolic Acid.—(See under *Indicators*, No. 58.)

95. Silver Ammonium Nitrate Test Solution.—Dissolve 1 Gm. of silver nitrate (*Argenti Nitras, U. S. P.*) in 20 Cc. of water, and add ammonia water, drop by drop, until the precipitate first produced is almost, but not entirely, redissolved. Filter the solution, and preserve it in dark amber-colored and well-stoppered bottles.

96. Silver Nitrate Test Solution ($AgNO_3$=169.55).—For ordinary purposes, use the decinormal volumetric solution (see No. 130). For Gutzeit's test (No. 14), use a saturated solution of silver nitrate in water acidulated with about 1 per cent of nitric acid.

97. Silver Sulphate Test Solution.—Dissolve 1 Gm. of silver nitrate (*Argenti Nitras, U. S. P.*) in 0.5 Cc. of warm water, and add 1.5 Cc. of pure, concentrated sulphuric acid. On cooling, small transparent crystals of silver sulphate (Ag_2SO_4=311.14) separate. Carefully pour off the acid liquid, wash the crystals repeatedly, by decantation, with cold water, transfer them to a bottle, add 100 Cc. of water, and agitate so as to produce a saturated solution. For use, decant a sufficient quantity of the latter.

98. Sodium Acetate Test Solution.—Dissolve 10 Gm. of sodium acetate (*Sodii Acetas, U. S. P.*) in enough water to make 100 Cc.

99. Sodium Bitartrate Test Solution.—Dissolve 150 Gm. of tartaric acid (*Acidum Tartaricum, U. S. P.*) in 100 Cc. of hot water, and divide the solution into two equal portions. Neutralize one of these accurately with sodium bicarbonate (which will require about 84 Gm. of this salt), and then add the other portion of the acid solution. On cooling, crystals of sodium bitartrate ($NaHC_4H_4O_6+H_2O=189.6$) will separate. Remove these, dry them, and keep them in well-stoppered bottles. The *test solution* is freshly prepared, when required, by dissolving 1 Gm. of the salt in 4 Cc. of water.

100. Sodium Carbonate.—The anhydrous salt ($Na_2CO_3=105.85$) conforming to the tests of purity prescribed by the Pharmacopœia for *Sodii Carbonas*, but absolutely free from chloride or sulphate.

101. Sodium Carbonate Test Solution.—Dissolve 10.6 Gm. of anhydrous sodium carbonate (No. 100; $Na_2CO_3=105.85$) in enough water to make 100 Cc. (This solution is of double-normal strength$=\frac{2}{N}$V.S., so as to permit of its use for volumetric purposes also.)

102. Sodium Cobaltic Nitrite Test Solution ($Co_2[NO_2]_6 6NaNO_2+H_2O=824.32$).—Dissolve 4 Gm. of cobaltous nitrate ($Co[NO_3]_2+6H_2O=290.14$) and 10 Gm. of sodium nitrite ($NaNO_2=68.93$) in about 50 Cc. of water; add 2 Cc. of acetic acid, and dilute with enough water to make 100 Cc. Should any of the nitrous acid be lost by keeping the solution, a few drops of acetic acid may be added.

103. Sodium Hydrate Test Solution ($NaOH=39.96$).—Use the official solution of sodium hydrate (*Liquor Sodæ, U. S. P.*).

104. Sodium Hyposulphite (or Thiosulphate, $Na_2S_2O_3+5H_2O=247.64$).—(See below, under No. 133.)

105. Sodium Nitrite ($NaNO_2=68.93$).—The purest commercial salt, generally in form of pencils, is sufficiently pure.

106. Sodium Nitroprusside Test Solution.—Dissolve 1 part of sodium nitroprusside ($Na_2Fe[NO][CN]_5+2H_2O=297.67$) in 10 parts of water immediately before using.

107. Sodium Phosphate Test Solution.—Dissolve 10 Gm. of sodium phosphate ($Na_2HPO_4+12H_2O=357.32$ [*Sodii Phosphas, U. S. P.*]) in enough water to make 100 Cc.

108. Stannous Chloride Test Solution.—Heat pure tin (see No. 113), in form of foil or granules, with concentrated hydrochloric acid, taking care that the metal be in excess. When the acid is saturated, crystals of stannous chloride ($SnCl_2+2H_2O=225.46$) begin to form. Remove and drain these, dissolve them in 10 parts of water, and preserve the solution in well-stoppered bottles, into each of which a granule of pure tin, or a piece of pure tin-foil, has previously been introduced.

For Bettendorff's test (see above, No. 12), pure, concentrated hydrochloric acid is saturated with the freshly-prepared crystals.

109. Starch Test Solution.—Mix 1 Gm. of starch with 10 Cc. of cold water, and then add enough boiling water, under constant stirring, to make about 200 Cc. of a thin, transparent jelly. If it is desired to preserve this test solution for any length of time, 10 Gm. of zinc chloride ($ZnCl_2=135.84$ [*Zinci Chloridum, U. S. P.*]) should be added to it, and the solution transferred to small bottles, which should be well stoppered.

110. Sulphuric Acid, Pure, for Tests ($H_2SO_4=97.82$).—The sulphuric acid of the Pharmacopœia, which may have a specific gravity as low as 1.835, will answer as a reagent for most purposes, provided it is of the required degree of purity. But when "concentrated" sulphuric acid is specially directed in a test, it is intended that the strongest obtainable, pure acid, of a specific gravity of not less than 1.840, be employed.

In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be employed as a reagent. If 1 Cc. of diphenylamine T.S. (see No. 52) be carefully poured, as a separate layer, upon 5 Cc. of sulphuric acid, contained in a test-tube, no distinct blue color should appear in the zone of contact (absence of nitric acid). If a few crystals of pyrogallol (*Pyrogallol, U. S. P.*) be dissolved in about 1 Cc. of pure water, and this solution be carefully poured, as a separate layer, upon some of the sulphuric acid, contained in a test-tube, no brown color should appear in the zone of contact (absence of nitric or nitrous acid). If a small portion of the acid be subjected to Gutzeit's test, as described under No. 14, no color should be imparted to the silver nitrate within 2 hours (absence of arsenic, etc.).

If it is impossible to obtain any sulphuric acid which will comply with each of these requirements, two kinds of the acid may be kept, one absolutely free from arsenic, for making the arsenic tests; the other free from nitrose (nitric and nitrous acids), for the detection of nitric acid.

111. Tannic Acid Test Solution.—Dissolve 1 Gm. of tannic acid ($HC_{14}H_9O_9 = 321.22$ [*Acidum Tannicum, U. S. P.*]) in 1 Cc. of alcohol, and enough water to make 10 Cc., immediately before use.

112. Tartaric Acid Test Solution.—Dissolve 1 part of tartaric acid ($H_2C_4H_4O_6 = 139.64$ [*Acidum Tartaricum, U. S. P.*]) in 3 parts of water. In the volumetric estimation of soda in potassa, directed by the preceding text of the Pharmacopœia, the tartaric acid test solution employed for precipitating the potassa should contain 3 Gm. of the acid in 20 Cc. Since fungous growths rapidly destroy the solution of tartaric acid, it should be prepared only as wanted.

113. Tin.—Pure metallic tin ($Sn = 118.8$) in form of granules. Its solution in hydrochloric acid should not be precipitated by potassium sulphate T.S. (absence of lead), and, when examined by Gutzeit's test, as described under No. 14, it should not cause silver nitrate to become colored within 2 hours (absence of arsenic).

114. Turmeric Paper and Tincture.—(See under *Indicators*, No. 59.)

115. Zinc.—Metallic zinc ($Zn = 65.1$) preferably in the form of thin pencils, about 5 Mm. in diameter, prepared by fusing the metal and casting it in molds, or in form of thin sheets. It should respond to all the tests required by the text of the Pharmacopœia, and in addition, when examined by Gutzeit's test, as described under No. 14, it should not cause the silver nitrate to become colored within 2 hours (absence of arsenic).

116. Zinc-Iodide-Starch Test Solution.—To 100 Cc. of freshly-prepared starch test solution (see No. 109) add 5 Gm. of zinc chloride (*Zinci Chloridum, U. S. P.*) and 3 Gm. of zinc iodide (*Zinci Iodidum, U. S. P.*). Preserve the colorless solution carefully in small, dark amber-colored and well-stoppered vials.

III. VOLUMETRIC SOLUTIONS.

Note.—Since most of the volumetric instruments (burettes, pipettes, mixing cylinders, flasks, etc.) which are for sale in the market are graduated to hold the number of cubic centimeters indicated by weighing into them the corresponding number of grammes of water at the temperature of 15.556° C. (60° F.), or 15° C. (59° F.), it is necessary not to deviate materially from this temperature in making the volumetric solutions, or in using them in testing.

All measuring vessels employed for volumetric determinations should agree among themselves in accuracy of graduation.

All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should, prior to use, be rinsed with a small quantity of the solution they are to contain.

Volumetric solutions are designated as normal ($\frac{N}{1}$) when they contain in 1 liter the molecular weight of the active reagent, expressed in grammes, and reduced to the valency corresponding to 1 atom of replaceable hydrogen, or its equivalent.

Thus, hydrochloric acid ($HCl = 36.37$), having but 1 H atom replaceable by a basic element, has 36.37 Gm. of HCl in 1000 Cc. of the normal volumetric solution; while sulphuric acid ($H_2SO_4 = 97.82$) having 2 replaceable H atoms, contains only one-half this number, or 48.91 Gm. of H_2SO_4 in 1000 Cc. of its normal solution. Potassium hydrate ($KOH=55.99$) has but 1 K to replace 1 H in acids, hence its normal solution contains 55.99 Gm. of KOH in 1 liter. Two molecules of potassium permanganate ($2KMnO_4=315.34$), in oxidation, give off 5 atoms of O, which are equivalent to 10 atoms of H; hence its normal solution should contain $\frac{315.34}{10}$ or 31.534 Gm. in 1 liter.

Solutions containing in 1 liter one-tenth of the quantity of the active reagent in the normal solution are called decinormal ($\frac{N}{10}$); those containing one-hundredth, centinormal ($\frac{N}{100}$); those containing twice the amount, double-normal ($\frac{2}{N}$); half the amount, seminormal ($\frac{N}{2}$).

Solutions containing quantities of the active reagent having *no* simple relation to the molecular weight are called empirical.

In the following list full decimals are given, which, however (especially when delicate balances and weights are not at hand), are in practice frequently abbreviated or rounded off, as, for instance, oxalic acid: 62.85 Gm. to 63 Gm.

When weighing out portions of a substance which is to be tested volumetrically, it will, in most cases, be advantageous to weigh out such a multiple of the amount required, as will suffice for several repetitions of the test, and will, at the same time, bring the amount to be weighed out as near to a whole number of grammes as possible.

117. Alkaline Cupric Tartrate Volumetric Solution (Fehling's Solution).—*A. The Copper Solution.*—Dissolve 34.64 Gm. of carefully selected, small crystals of pure cupric sulphate, showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of water to make the solution measure, at or near 15° C. (59° F.), exactly 500 Cc. Keep this solution in small, well-stoppered bottles.

B. The Rochelle Salt Solution.—Dissolve 173 Gm. of potassium and sodium tartrate (*Potassii et Sodii Tartras, U. S. P.*), and 125 Gm. of potassium hydrate (*Potassa, U. S. P.*), in a sufficient quantity of water to make the solution measure, at or near 15° C. (59° F.), exactly 500 Cc. Keep the solution in small, rubber-stoppered bottles. For use, mix exactly equal volumes of the two solutions at the time required.

One cubic centimeter of the mixed solution is the equivalent of:

	Gramme.
Cupric sulphate, crystallized, $CuSO_4+5H_2O$	0.03464
Cupric tartrate, $CuC_4H_4O_6+3H_2O$	0.03685
Glucose, anhydrous, $C_6H_{12}O_6$	0.00500

118. Decinormal Bromine Volumetric Solution (Koppeschaar's Solution) ($Br=79.76$; 7.976 Gm. in 1 liter. $NaBrO_3=150.64$.—$NaBr=102.76$. $KBrO_3=166.67$.—$KBr=118.79$).—Dissolve 3 Gm. of sodium bromate and 50 Gm. of sodium bromide (or 3.2 Gm. of potassium bromate and 50 Gm. of potassium bromide) in enough water to make, at or near 15° C. (59° F.), 900 Cc. Of this solution transfer 20 Cc., by means of a pipette, into a bottle having a capacity of about 250 Cc., provided with a glass stopper; add 75 Cc. of water, next 5 Cc. of pure hydrochloric acid, and immediately insert the stopper. Shake the bottle a few times, then remove the stopper just sufficiently to quickly introduce 5 Cc. of potassium iodide T.S., taking care that no bromine vapor escape, and immediately stopper the bottle. Agitate the bottle thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water so that the washings flow into the bottle, and then add from a burette decinormal sodium hyposulphite V.S. until the iodine tint is exactly discharged, using toward the end a few drops of starch T.S. as indicator. Note the number of cubic centimeters of the sodium hyposulphite V.S. thus consumed, and then dilute the bromine solution so that equal volumes of it and of decinormal sodium hyposulphite V.S. will exactly correspond to each other under the conditions mentioned above.

Example.—Assuming that the 20 Cc. of the bromine solution have required 25.2 Cc. of the hyposulphite to completely discharge the iodine tint, the bromine solution must be diluted in the proportion of 20 to 25.2. Thus, if 850 Cc. of it are remaining, they must be diluted with water to measure 1071 Cc.

After the solution is thus diluted, a new trial should be made in the manner above described, in which 25 Cc. of the decinormal sodium hyposulphite V.S. should exactly discharge the tint of the iodine liberated by the bromine set free from the 25 Cc. of bromine solution. Keep the solution in dark amber-colored glass-stoppered bottles.

One cubic centimeter of decinormal bromine solution V.S. is the equivalent of:

	Gramme.
Bromine, Br	0.007976
Carbolic acid, C_6H_5OH	0.001563

The following article is tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.
Acidum carbolicum	0.039	24	96 of pure phenol.

119. Normal Hydrochloric Acid (HCl=36.37; 36.37 Gm. in 1 liter).—Mix 130 Cc. of hydrochloric acid of specific gravity 1.163 with enough water to make it measure, at or near 15° C. (59° F.), 1000 Cc. Of this liquid (which is still too concentrated) carefully measure 10 Cc. into a flask, add a few drops of phenolphtalein T.S., and gradually add, from a burette, potassium hydrate V.S., until the red tint produced by it no longer disappears on vigorous shaking, but is not deeper than pale pink. Note the number of cubic centimeters of potassium hydrate V.S. consumed, and then dilute the acid solution so that equal volumes of this and of the potassium hydrate V.S. neutralize each other.

Example.—Assuming that 10 Cc. of the acid solution first prepared required exactly 11 Cc. of potassium hydrate V.S., each 10 Cc. of the former must be diluted to 11 Cc., or the whole of the remaining acid solution in the same proportion. Thus, if 950 Cc. are remaining, 95 Cc. of water must be added. After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of potassium hydrate V.S. If necessary, a new adjustment should then be made to render the correspondence perfect.

One cubic centimeter of normal hydrochloric acid is the equivalent of:

	Gramme.
Hydrochloric acid, absolute, HCl	0.03637

Note.—Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (see below, No. 134), and may be employed, if more convenient, for the same purposes.

120. Decinormal Iodine Volumetric Solution (I=126.53; 12.653 Gm.† in 1 liter).—Dissolve 12.653 Gm.† of pure iodine (see below) in a solution of 18 Gm. of pure potassium iodide in 300 Cc. of water. Then add enough water to make the solution measure, at or near 15° C. (59° F.), exactly 1000 Cc. Transfer the solution to small, glass-stoppered vials, which should be kept in a dark place.

Preparation of Pure Iodine.—Heat powdered iodine in a porcelain dish placed over a boiling water-bath, and stir it constantly with a glass rod, so that the adhering moisture, together with any cyanogen iodide and most of the iodine bromide and chloride that may be present, may be vaporized. After 20 minutes transfer the iodine to a porcelain or other non-metallic mortar, and triturate it with about 5 per cent of its weight of pure, dry potassium iodide, so as to decompose any remaining iodine, bromide and chloride. Then return the mass to the dish, cover it with a clean glass funnel, and heat the dish on a sand-bath. Detach the sublimed, pure iodine, and keep it in well-stoppered bottles, in a cool place.

One cubic centimeter of decinormal iodine V.S. is the equivalent of:

	Gramme.
Iodine, I	0.012653
Arsenic trioxide (arsenous acid), As_2O_3	0.004942
Potassium sulphite, crystallized, $K_2SO_3 \cdot 2H_2O$	0.009692
Sodium bisulphite, $NaHSO_3$	0.005193
Sodium hyposulphite (thiosulphate) crystals, $Na_2S_2O_3 \cdot 5H_2O$	0.024764
Sodium sulphite, crystallized, $Na_2SO_3 \cdot 7H_2O$	0.012579

Antimony and potassium tartrate, cryst., $2K(SbO)C_4H_4O_6 \cdot H_2O$	0.016560

---

† Instead of taking 12.653 Gm., this figure is often rounded off to 12.6 [illegible] delicate [illegible] have also the exact amount above directed [illegible] the

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.
Acidum arsenosum	0.1	20.0	98.8 of As_2O_3.
Acidum sulphurosum	2.0	40.0	6.4 of SO_2.
Antimonii et potassii tartras (cryst.)	0.331	20.0	100 of pure salt.
Liquor acidi arsenosi	24.7 Cc.	49.4 to 50	1 of As_2O_3.
Liquor potassii arsenitis	24.7 Cc.	49.4 to 50	1 of As_2O_3.
Sodii bisulphis	0.26	45.0	90 of pure salt.
Sodii hyposulphis	0.25	9.9	98.1 of cryst. salt.
Sodii sulphis	0.63	48.0	96 of cryst. salt.

121. Decinormal Mercuric Potassium Iodide Volumetric Solution (**Mayer's Solution**) ($HgI_2+2KI=783.98$; 39.2 Gm. in 1 liter).—Dissolve 13.546 Gm. of pure mercuric chloride in 600 Cc. of water, and 49.8 Gm. of pure potassium iodide in 100 Cc. of water. Mix the two solutions, and then add enough water to make the mixture measure, at or near 15° C. (59° F.), exactly 1000 Cc.

One cubic centimeter of decinormal mercuric potassium iodide V.S. is the equivalent of:

	Gramme.
Mercuric potassium iodide, HgI_2+2KI	0.0392

122. Normal Oxalic Acid Volumetric Solution ($H_2C_2O_4+2H_2O=125.7$; 62.85 Gm.† in 1 liter).—Dissolve 62.85 Gm.† of pure oxalic acid (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 Cc.

Pure Oxalic Acid, crystallized, is in form of colorless, transparent, clinorhombic crystals, which, on ignition upon platinum foil, leave no residue. One part of it is completely soluble in 14 parts of water at 15° C. (59° F.). Oxalic acid which leaves a residue on ignition, or on solution in water, must be purified, which may be done as follows: To 1 part of the acid add 10 parts of cold water, and shake until the latter is saturated. Filter off the solution from the undissolved crystals, evaporate the filtrate to about three-fourths of its volume, and set it aside so that the fixed salts which it contains may crystallize out. Carefully decant the liquid from the crystals, concentrate it by evaporation, and set it aside to crystallize, stirring occasionally to prevent the formation of large crystals which might enclose moisture. Drain the crystals in a funnel, dry them carefully on blotting paper, and preserve them in well-stoppered bottles.

Note.—Normal oxalic acid volumetric solution is in every respect equivalent in neutralizing power to *Normal Sulphuric Acid* (No. 134), or *Normal Hydrochloric Acid* (No. 119), and may be employed, if more convenient, for the same purposes. The solution, however, has a tendency to crystallize at the point of the burette.

One cubic centimeter of normal oxalic acid V.S. is the equivalent of:

	Gramme.
Oxalic acid, crystallized, $H_2C_2O_4+2H_2O$	0.06285
Ammonia gas, NH_3	0.01701
Sodium hydrate, NaOH	0.03996
Potassium hydrate, KOH	0.05599
Potassium permanganate, $KMnO_4$	0.03153

†This is frequently rounded off to 63 Gm., when a delicate balance and exact weights are not at hand.

123. Decinormal Oxalic Volumetric Solution ($H_2C_2O_4+2H_2O=125.7$; 6.285 Gm.† in 1 liter).—Dissolve 6.285 Gm.† of pure oxalic acid (see under No. 122) in enough water to make, at or near 15° C. (59° F.), exactly 1000 Cc.

One cubic centimeter of decinormal oxalic acid V.S. is the equivalent of:

	Gramme.
Oxalic acid, crystallized, $H_2C_2O_4+2H_2O$	0.006285
Ammonia gas, NH_3	0.001701
Calcium hydrate, $Ca(OH)_2$	0.003691
Potassium hydrate, KOH	0.005599
Potassium permanganate, $KMnO_4$	0.0031534
Sodium hydrate, NaOH	0.003996

†Generally rounded off to 6.3 Gm., when a delicate balance and exact weights are not available.

The following articles are tested with this solution:

	Gm. taken	Cc. required.	Per cent of strength indicated.
Liquor calcis	50.0	20.0	0.14 of $Ca(OH)_2$.
Potassii iodidum (alkalinity, K_2CO_3)	1.0	0.05	0.034 of alkali.
Potassii permanganas	0.1	31.3	98.70 of pure salt.

124. Decinormal Potassium Bichromate Volumetric Solution ($K_2Cr_2O_7$ 293.78; 4.896 Gm.† in 1 liter).—Dissolve 4.896 Gm.† of pure potassium dichromate (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 Cc.

Pure potassium dichromate for use in volumetric analysis, besides responding to the tests given in the text of the Pharmacopœia (under *Potassii Bichromas*), must conform to the following tests. In a solution of 0.5 Gm. of the salt in 10 Cc. of water, rendered acid by 0.5 Cc. of nitric acid, no visible change should be produced either by barium chloride T.S. (absence of sulphate), or by silver nitrate T.S. (absence of chloride). In a mixture of 10 Cc. of the aqueous solution (1 in 20) with 1 Cc. of ammonia water, no precipitate should be produced by ammonium oxalate T.S. (absence of calcium).

When used with phenolphtalein as indicator, to neutralize alkalies, the volumetric solution of potassium dichromate is decinormal when it contains 14.689 Gm. in 1 liter. It is then the exact equivalent of any decinormal acid, corresponding to the amounts of alkalies quoted, for instance, under *Decinormal Oxalic Acid* V.S. (No. 123).

When used as an oxidizing agent to convert ferrous into ferric salts, or to liberate iodine from potassium iodide, the solution just mentioned (containing 14.689 Gm. in 1 liter) has the effect of a $\frac{3N}{10}$ volumetric solution, and a solution of one-third of this strength, containing 4.896 Gm. in 1 liter, has the value of a decinormal solution, and is the equivalent of equal volumes of decinormal potassium permanganate V.S., or, in the case of iodine liberated from potassium iodide, it is the equivalent of equal volumes of decinormal sodium hyposulphite V.S. For titrating iron in *ferrous* compounds, it is used in the following manner. Introduce the aqueous solution of the ferrous salt into a flask, and if it is not already acid, render it so with sulphuric acid. Now add, gradually, decinormal potassium dichromate V.S. from a burette, until a drop taken out upon a white surface no longer shows a blue color with a drop of freshly-prepared potassium ferricyanide T.S.

Decinormal potassium dichromate V.S. may also be used, in conjunction with potassium iodide (from which it liberates iodine) and sulphuric acid, for adjusting the titer of sodium hyposulphite (thiosulphate) V.S. and, by its means, that of the iodine V.S.

One cubic centimeter of decinormal potassium dichromate V.S. is the equivalent of:

	Gramme
Potassium dichromate, $K_2Cr_2O_7$	0.004896
Iron, in ferrous compounds	0.005588
Ferrous carbonate, $FeCO_3$	0.01157
Ferrous sulphate, anhydrous, $FeSO_4$	0.015170
Ferrous sulphate, crystallized, $FeSO_4 + 7H_2O$	0.027742
Ferrous sulphate, dried, $2FeSO_4 + 3H_2O$	0.017864
Potassium hydrate, KOH	0.001866
Sodium hyposulphite (thiosulphate), $Na_2S_2O_3 + 5H_2O$	0.024764

The following articles may be tested with this solution:

	Gm. taken	Cc. required	Per cent of strength indicated
Ferri carbonas saccharatus	1.116	15	7.5 of iron
Ferri sulphas	1.3871	50	100 of pure salt.
Ferri sulphas granulatus	1.3871	50	100 of pure salt

†Generally rounded off to 4.9 Gm. when a delicate balance and exact weights are not available.

125. Normal Potassium Hydrate Volumetric Solution (KOH 55.99; 55.99 Gm.† in 1 liter).—Dissolve 75 Gm. of potassium hydrate (*Potassa, U.S.P.*) in enough water to make, at or near 15° C. (59° F.), about 1050 Cc., and fill a burette with a portion of this liquid.

†This figure is frequently rounded off to 56 Gm.

Put 0.6285 Gm.[†] of pure oxalic acid (see No. 122) into a flask of the capacity of about 100 Cc., and dissolve it with about 10 Cc. of water. Add a few drops of phenolphtalein T.S., and then carefully add, from the burette, the potassium hydrate solution, frequently agitating the flask, and regulating the flow to drops toward the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of cubic centimeters of the potassium hydrate solution consumed, and then dilute the remainder of the solution so that exactly 10 Cc. of the diluted liquid shall be required to neutralize 0.6285 Gm.[†] of oxalic acid.

Example.—Assuming that 8.0 Cc. of the stronger solution of potassium hydrate first prepared has been consumed in the trial, then each 8.0 Cc. must be diluted to 10 Cc., or the whole of the remaining solution in the same proportion. Thus, if 1000 Cc. should be still remaining, this must be diluted with water to 1250 Cc.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 10 Cc. of the diluted solution should exactly neutralize 0.6285 Gm.[†] of oxalic acid. If necessary, a new adjustment should then be made to render the correspondence perfect.

Note.—Solutions of caustic alkalies are very prone to absorb carbon dioxide from the atmosphere, and thereby become liable to occasion errors when used with litmus T.S. or phenolphtalein T.S. as indicator (methyl orange T.S. is not affected by the presence of carbonic acid). Hence the volumetric solutions should be preserved in small vials provided with well-fitting corks or rubber stoppers, or better still, they should have tubes filled with a mixture of soda and lime attached to their stoppers, so as to absorb the carbon dioxide and prevent its access to the solution.

In place of potassium hydrate V.S., sodium hydrate V.S. (see No. 132) may be used, in the same manner and in the same quantity. Potassium hydrate V.S., however, is preferable, since it foams less, and attacks glass more slowly and less energetically.

One cubic centimeter of normal potassium hydrate V.S. is the equivalent of:

	Gramme.
Potassium hydrate, KOH	0.05599
Sodium hydrate, NaOH	0.03996
Ammonia gas, NH_3	0.01701
Ammonium chloride, NH_4Cl	0.05338
Acetic acid, absolute, $HC_2H_3O_2$	0.05986
Citric acid, crystallized, $H_3C_6H_5O_7+H_2O$	0.06983
Hydrobromic acid, absolute, HBr	0.08076
Hydrochloric acid, absolute, HCl	0.03637
Hydriodic acid, absolute, HI	0.12753
Hypophosphorous acid, HPH_2O_2	0.06588
Lactic acid, absolute, $HC_3H_5O_3$	0.08979
Nitric acid, absolute, HNO_3	0.06289
Oxalic acid, crystallized, $H_2C_2O_4+2H_2O$	0.06285
Phosphoric acid, H_3PO_4 (to form K_2HPO_4; with phenolphtalein)	0.0489
Phosphoric acid, H_3PO_4 (to form KH_2PO_4; with methyl orange)	0.0978
Potassium dichromate, $K_2Cr_2O_7$.	0.14689
Sulphuric acid, absolute, H_2SO_4	0.04891
Tartaric acid, crystallized, $H_2C_4H_4O_6$	0.07482

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.
Acidum aceticum	6.0	36.0	36 of absolute acid.
Acidum aceticum dilutum	24.0	24.0	6 of absolute acid.
Acidum aceticum glaciale	3.0	49.5	99 of absolute acid.
Acidum citricum	3.5	50.0	100 of crystall. acid.
Acidum hydrobromicum dilutum	8.08	10.0	10 of absolute acid.
Acidum hydrochloricum	3.64	31.9	31.9 of absolute acid.
Acidum hydrochloricum dilutum	3.64	10.0	10 of absolute acid.
Acidum hypophosphorosum dilutum	6.6	*10.0	*10 of absolute acid.

[†] This figure may be rounded off to 0.63 Gm., if a delicate balance and exact weights are not available.

	Gm. taken.	Cc. required	Per cent of strength indicated.
Acidum lacticum	4.50	37.5	75 of absolute acid.
Acidum nitricum	3.145	34.0	68 of absolute acid.
Acidum nitricum dilutum	6.29	10.0	10 of absolute acid.
Acidum phosphoricum	0.978	17.0	85 of absolute acid.
Acidum phosphoricum dilutum	4.89	10.0	10 of absolute acid.
Acidum sulphuricum	0.49	9.25	92.5 of absolute acid.
Acidum sulphuricum aromaticum	4.89	*18.5	*18.5 of absolute acid.
Acidum sulphuricum dilutum	4.89	10.0	10 of absolute acid.
Acidum tartaricum	3.75	50.0	100 of crystall. acid.
Vinum album Vinum rubrum	50.0	3.0 to 5.2	0.45 to 0.78 of acid assumed to be tartaric.

126. Centinormal Potassium Hydrate Volumetric Solution (KOH = 55.99; 0.5599 Gm. in 1 liter).—Dilute 10 Cc. of normal potassium hydrate volumetric solution with enough distilled water to make 1000 Cc.

One cubic centimeter of centinormal potassium hydrate V.S. is the equivalent of:

	Gramme.
Potassium hydrate, KOH	0.0005599
Sulphuric acid, H_2SO_4	0.0004891
Combined alkaloids of nux vomica*	0.00364

*Assumed to consist of equal parts of strychnine and brucine.—Centinormal potassium hydrate V.S. (in place of which centinormal sodium hydrate V.S., prepared in the same manner, may be employed) is used in the assay of extract of nux vomica, to neutralize the excess of decinormal sulphuric acid employed.

127. Decinormal Potassium Permanganate Volumetric Solution ($2KMnO_4$=315.34; 3.1534 Gm.† in 1 liter).—1. Place 3.5 Gm. of pure, crystallized potassium permanganate in a flask, add 1000 Cc. of boiling water, and boil until the crystals are dissolved. Close the flask, and set it aside for 2 days, so that any suspended matters may deposit. This is the *stronger solution*. Prepare another, *weaker solution*, in the same manner, using 6.6 Gm. of the salt and 2200 Cc. of water, and set this also aside for 2 days. After the lapse of this time, pour off the clear portion of each solution into separate vessels provided with glass stoppers, and then proceed to test each separately.

Introduce into a flask 10 Cc. of decinormal oxalic acid V.S., add 1 Cc. of pure, concentrated sulphuric acid, and, before this mixture cools, gradually add from a burette small quantities of the weaker permanganate solution, shaking the flask after each addition and reducing the flow to drops toward the end of the operation. When the last drop of the permanganate solution added is no longer decolorized but imparts a pinkish tint to the liquid, note the number of cubic centimeters consumed. In the same manner ascertain the titer of the stronger solution, and likewise note down the number of cubic centimeters of the latter consumed. Finally mix the two solutions in such proportions that 50 Cc. of the mixture will exactly correspond to an equal volume of decinormal oxalic acid V.S.

Note.—To obtain the accurate proportions for mixing the two solutions, deduct 10 from the number of cubic centimeters of the weaker solution required to decompose 10 Cc. of decinormal oxalic acid V.S. With this difference multiply the number of cubic centimeters of the stronger solution required for the same purpose. The product shows the number of cubic centimeters of the *stronger solution* needed for the mixture.

Next deduct the number of cubic centimeters of the stronger solution required to decompose 10 Cc. of decinormal oxalic acid V.S. from 10, and with the difference multiply the number of cubic centimeters of the weaker solution required for the same purpose. The product shows the number of cubic centimeters of the *weaker solution* needed for the mixture.

Or, designating by S the number of cubic centimeters of the stronger solution, and by W the number of cubic centimeters of the weaker solution required

---

†This quantity is never directly weighed, but adjusted either by oxalic acid or by iron. In calculations it is often abbreviated.

to decompose 10 Cc. of decinormal oxalic acid V.S., the following formula will give the proportions in which the solutions must be mixed:

Stronger Solution: Weaker Solution:

$$(W-10)S \quad + \quad (10-S)W$$

Example.—Assuming that 9 Cc. of the stronger (S) and 10.5 of the weaker (W) solution had been required, then, substituting these values in the above given formula, we obtain:

$$(10.5-10)9+(10-9)10.5$$
$$\text{or, } 4.5 \quad +\text{or, } 10.5$$

making 15 Cc. of final solution.

The bulk of the two solutions is now mixed in the same proportion, 450 Cc. of the stronger and 1050 Cc. of the weaker, or 900 Cc. of the stronger and 2100 Cc. of the weaker solution.

After the mixture is thus prepared, a new trial should be made, when 10 Cc. of the solution should exactly decompose 10 Cc. of the decinormal oxalic acid V.S. If necessary, a new adjustment should be made to render the correspondence perfect.

This solution should be kept in small, dark amber-colored and glass-stoppered bottles (or in bottles provided with tubes, especially designed for the purpose). Thus prepared, this solution will hold its titer for months; yet it should be tested occasionally, and, when it is found reduced, the liquid should be brought back to normal strength by the addition of such an amount of the stronger solution as may be determined in the manner above described.

II. When potassium permanganate V.S. is to be prepared for immediate use, this may be done in the following manner: Dissolve 3.5 Gm. of pure, crystallized potassium permanganate in 1000 Cc. of pure water, recently boiled and cooled. Introduce 10 Cc. of decinormal oxalic acid V.S. into a beaker, add 1 Cc. of pure concentrated sulphuric acid, and proceed as directed above for the weaker permanganate solution. Note the number of cubic centimeters of the solution consumed, and then dilute the remainder with pure water recently boiled and cooled, until 50 Cc. will exactly correspond to 50 Cc. of decinormal oxalic acid V.S.

Example.—Assuming that 9.1 Cc. of the permanganate solution first prepared had been required to produce a permanent pink tint, then every 9.1 Cc. of the solution must be diluted to 10 Cc., or the whole of the remaining solution in the same proportion. A new trial should then be made to verify the agreement.

Note.—Potassium permanganate V.S. thus prepared is liable to deteriorate more readily and quickly than that prepared by the method first given (under I.). It can not be safely trusted without verification each time it is to be used.

One cubic centimeter of decinormal potassium permanganate V.S. is the equivalent of:

	Gramme.
Potassium permanganate, $KMnO_4$	0.0031534
Barium dioxide, BaO_2	0.008441
Calcium hypophosphite, $Ca(PH_2O_2)_2$	0.0021209
Ferric hypophosphite, $Fe_2(PH_2O_2)_6$	0.0020877
Iron, in ferrous compounds, Fe	0.005588
Ferrous carbonate, $FeCO_3$	0.011573
Ferrous oxide, FeO	0.007195
Ferrous sulphate, anhydrous, $FeSO_4$	0.015170
Ferrous sulphate, crystals, $FeSO_4+7H_2O$	0.027742
Ferrous sulphate, dried, $2FeSO_4+3H_2O$	0.017864
Hydrogen dioxide, H_2O_2	0.001696
Hypophosphorous acid, HPH_2O_2	0.001647
Oxalic acid, crystallized, $H_2C_2O_4+2H_2O$	0.006285
Oxygen, O	0.000798
Potassium hypophosphite, KPH_2O_2	0.002598
Sodium hypophosphite, $NaPH_2O_2+H_2O$	0.002646

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.	
Acidum hypophosphorosum dilutum	0.5	*30.3	*10	of absolute acid
Aqua hydrogenii dioxidi	1.7 Cc.	*30.0	* 3	of H_2O_2.
Barii dioxidum	0.422	40.0	80	of pure BaO_2.
Calcii hypophosphis	0.1	47.0	99.68	of pure salt.
Ferri carbonas saccharatus	1.16	*15.0	*15	of $FeCO_3$.

	Gm taken.	Cc. required.	Per cent of strength indicated.
Ferri hypophosphis	0.1	47.0	98.1 of pure salt.
Ferri sulphas	1.39	50.0	100 of pure salt.
Ferri sulphas granulatus	1.39	50.0	100 of pure salt.
Ferrum reductum	0.056	8.0	80 of iron as metal.
Potassii hypophosphis	0.1	38.0	98.7 of pure salt.
Sodii hypophosphis	0.1	37.0	97.9 of pure salt.

128. Centinormal Potassium Permanganate Volumetric Solution ($2KMnO_4=315.34$; 0.31534 Gm. in 1 liter).—Dilute 10 Cc. of the decinormal potassium permanganate V.S., after having ascertained that it possesses its exact titer, with enough distilled water strictly complying with the tests given in the text of the Pharmacopœia for *Aqua Destillata*, to make 100 Cc. This solution should be freshly made when required.

One cubic centimeter of centinormal potassium permanganate V.S. is the equivalent of:

	Gramme.
Potassium permanganate, $KMnO_4$	0.00031534
Oxalic acid, crystallized, $H_2C_2O_4+2H_2O$	0.0006285
Oxygen (derived from the permanganate) available for oxidation	0.0000798

129. Decinormal Potassium Sulphocyanate Volumetric Solution (Volhard's Solution) ($KSCN=96.99$; 9.699 Gm. in 1 liter).—Dissolve 10 Gm. of crystals of pure potassium sulphocyanate in 1000 Cc. of water.

This solution is yet too concentrated, and has to be adjusted so as to correspond in strength exactly with decinormal silver nitrate V.S. For this purpose, introduce into a flask 10 Cc. of decinormal silver nitrate V.S., together with 0.5 Cc. of ferric ammonium sulphate T.S., and 5 Cc. of diluted nitric acid. To this mixture add, from a burette, in small portions at a time, the sulphocyanate solution. At first a white precipitate of silver sulphocyanate appears, then every drop falling from the burette is surrounded by a deep brownish-red color of ferric sulphocyanate which disappears on vigorous shaking of the flask as long as any of the silver nitrate remains unchanged. When all the silver has been converted into sulphocyanate, a single additional drop of the potassium sulphocyanate solution produces a brownish-red color which no longer disappears on shaking, but communicates a perceptible pale-brownish or reddish tint to the contents of the flask. Note the number of cubic centimeters of the potassium sulphocyanate solution used, and dilute the whole of the remaining solution so that equal volumes of this and of the decinormal silver nitrate V.S. will be required to produce the permanent brownish or reddish tint. The same depth of pale-brownish or reddish tint to which the volumetric solution is adjusted must be attained when the solution is used for volumetric assays.)

After the dilution, a new trial should be made, in which 50 Cc. of decinormal silver nitrate V.S., 2.5 Cc. of ferric ammonium sulphate T.S., and 25 Cc. of diluted nitric acid are used, and there should be required exactly 50 Cc. of the sulphocyanate solution to produce the same depth of a permanent pale-brownish or reddish tint. If necessary, a new adjustment should be made, to render the correspondence perfect.

One cubic centimeter of decinormal potassium sulphocyanate V.S. is the equivalent of:

	Gramme.
Potassium sulphocyanate, KSCN	0.009699
Silver, Ag	0.010766
Silver nitrate, $AgNO_3$	0.016955

The following articles are tested with this solution:

Ferri iodidum saccharatum Syrupus ferri iodidi	Determined by residual titration with decinormal silver nitrate V.S., and decinormal potassium sulphocyanate V.S.

130. Decinormal Silver Nitrate Volumetric Solution ($AgNO_3=169.55$; 16.955 Gm.† in 1 liter).—Dissolve 16.955 Gm.† of pure silver nitrate in enough water to make, at or near 15° C. (59° F.), exactly 1000 Cc. Keep the solution in small, dark amber-colored, glass-stoppered vials, carefully protected from dust.

---

†Frequently rounded off to 16.96 Gm., when a delicate balance and exact weights are not available.

Note.—Titration by decinormal silver nitrate V.S. may be managed in various ways, adapted to the special preparation to be tested:

a. In most cases it is directed by the *U. S. P.* to be used in presence of a small quantity of potassium chromate T.S., which serves to indicate the end of the reaction by the appearance of the red color of silver chromate.

b. In some cases (potassium cyanide, hydrocyanic acid) it is added until the first appearance of a permanent precipitate.

c. It may be used in *all* cases without indicator by observing the exact point when no further precipitate occurs. This may be practised in the case of ferrous iodide, where the addition of potassium chromate would be improper, but it consumes much time in waiting for the precipitate to subside so as to render the liquid sufficiently clear to recognize whether a further precipitate is produced by addition of the silver solution.

d. It may be added in definite amount, known to be in excess of the quantity required, and the excess of the decinormal silver solution measured back by the addition of decinormal potassium sulphocyanate V.S. (residual titration).

One cubic centimeter of decinormal silver nitrate V.S. is the equivalent of:

	Gramme.
Silver nitrate, $AgNO_3$	0.016955

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.	
Acidum hydrocyanicum dilutum	1.35	10.0	2	of absolute acid.
Ammonii bromidum	0.3	30.9	99	of pure salt.
Calcii bromidum	0.25	25.0	99.7	of pure salt.
†Ferri iodidum saccharatum	1.55	*20.0	*20	of iodide.
Lithii bromidum	0.3	35.3	98	of pure salt.
Potassii bromidum	0.5	42.85	97	of pure salt.
Potassii cyanidum (to first precip.)	0.65	45.0	90	of pure salt.
Potassii iodidum	0.5	30.25	99.5	of pure salt.
Sodii bromidum	0.3	29.8	97.29	of pure salt.
Sodii chloridum	0.195	33.4	99.9	of pure salt.
Sodii iodidum	0.5	34.5 to 33.4	*98	of pure salt.
Strontii bromidum (dry)	0.3	24.6	98	of pure salt.
Strontii iodidum (dry)	0.3	18.0	98	of pure salt.
Syrupus acidi hydriodici	32.0	*25.0	* 1	of HI.
†Syrupus ferri iodidi	1.55	*10.0	*10	of FeI_2.
Zinci bromidum	0.3	26.7	99.95	of pure salt.
Zinci chloridum	0.3	44.1	99.84	of pure salt.
Zinci iodidum	0.5	31.0	98.62	of pure salt.

Note.—The articles marked with † are determined by residual titration with decinormal silver nitrate V.S. and decinormal potassium sulphocyanate V.S.

131. Decinormal Sodium Chloride Volumetric Solution ($NaCl—58.37$; 5.837 Gm.† in 1 liter).—Dissolve 5.837 Gm.† of pure sodium chloride (see below) in enough water to make, at or near 15° C. (59° F.), exactly 1000 Cc. Pure sodium chloride may be prepared by passing a current of dry hydrochloric acid gas into a saturated aqueous solution of the purest commercial sodium chloride, separating the crystalline precipitate, and drying it at a temperature sufficiently high to expel all traces of free acid. In place of this, transparent crystals of pure rock-salt may be employed.

One cubic centimeter of decinormal sodium chloride V.S. is the equivalent of:

	Gramme.
Sodium chloride, $NaCl$	0.005837
Silver, Ag	0.010766
Silver nitrate, $AgNO_3$	0.016955
Silver oxide, Ag_2O	0.011564

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.
Argenti nitras	0.34	20.0	100 of silver nitrate.
Argenti nitras dilutus	1.0	19.5	33.14 of silver nitrate.
Argenti nitras fusus	0.34	19.0	95 of silver nitrate.

†Frequently rounded off to 5.84 Gm., when a delicate balance and exact weights are not available.

132. Normal Sodium Hydrate Volumetric Solution ($NaOH—39.96$; 39.96 Gm.† in 1 liter).—Dissolve 54 Gm. of sodium hydrate (*Soda, U. S. P.*) in enough water to make, at or near 15° C. (59° F.), about 1050 Cc., and fill a burette with a portion of this liquid. Put 0.6285 Gm.‡ of pure oxalic acid (see under No. 122) into a flask of the capacity of about 100 Cc., and dissolve it with about 10 Cc. of water. Add a few drops of phenolphtalein T.S., and then carefully add, from the burette, the sodium hydrate solution, frequently agitating the flask, and regulating the flow to drops toward the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of cubic centimeters of the sodium hydrate solution consumed, and then dilute the remainder of it so that exactly 10 Cc. of the diluted liquid will be required to neutralize 0.6285 Gm.‡ of oxalic acid.

Example.—Assuming that 7.8 Cc. of the stronger solution of sodium hydrate first prepared had been consumed in the trial, then each 7.8 Cc. must be diluted to 10 Cc., or the whole of the remaining solution in the same proportion. Thus, if 980 Cc. should be still remaining, this must be diluted with water to 1258 Cc. After the liquid is thus diluted, a new trial should be made in the manner above described, in which 10 Cc. of the diluted solution should exactly neutralize 0.6285 Gm. of oxalic acid. If necessary, a new adjustment should then be made to render the correspondence perfect.

Note.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air, as are prescribed for normal potassium hydrate V.S. (see No. 125).

This solution may be employed in place of the normal potassium hydrate V.S., volume for volume.

†Frequently rounded off to 40 Gm.
‡This may be rounded off to 0.63 Gm., when a delicate balance and exact weights are not available.

133. Decinormal Sodium Hyposulphite Volumetric Solution ($Na_2S_2O_3+5H_2O=247.64$; 24.764 Gm. in 1 liter).—Dissolve 30 Gm. of selected crystals of sodium hyposulphite (sodium thiosulphate) in enough water to make, at or near 15° C. (59° F.), 1100 Cc. Of this solution transfer 10 Cc. into a flask, add a few drops of starch T.S., and then gradually add, from a burette, decinormal iodine V.S., in small portions at a time, shaking the flask after each addition, and regulating the flow to drops toward the end of the operation. As soon as the color produced by the influx of the iodine solution no longer disappears on shaking, but is not deeper than very pale blue, note the number of cubic centimeters of the iodine solution consumed. Then dilute the sodium hyposulphite solution so that equal volumes of it and of decinormal iodine V.S. will exactly correspond to each other under the conditions mentioned above.

Example.—Assuming that 10 Cc. of the stronger sodium hyposulphite solution first prepared had required 10.7 Cc. of decinormal iodine V.S. to produce a faint reaction with starch, the hyposulphite solution must be diluted in the proportion of 10 Cc. to 10.7 Cc., or 1000 Cc. to 1070 Cc.

After the solution is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the decinormal sodium hyposulphite V.S. should require exactly 50 Cc. of decinormal iodine V.S. to produce a faint reaction with starch. If necessary, a new adjustment should then be made to render the correspondence perfect.

Keep the solution in small, dark amber-colored, glass-stoppered bottles, carefully protected from dust.

Note.—When this solution is to be used, fill a burette with it, place the liquid to be tested either for the free iodine it already contains, or for that which it liberates from an excess of potassium iodide added to it, into a flask, and gradually add small portions of the solution from the burette, shaking after each addition, and regulating the flow to drops toward the end of the operation, until the brown color of the iodine has nearly disappeared. Now add a few drops of starch T.S., which will produce a blue color, and then continue to add the hyposulphite solution in drops until the blue tint is exactly discharged.

One cubic centimeter of decinormal sodium hyposulphite V.S. is the equivalent of:

	Gramme.
Sodium hyposulphite (thiosulphate), $Na_2S_2O_3+5H_2O$	0.024764
Bromine, Br	0.007976
Chlorine, Cl	0.003537
Iodine, I	0.012653
Iron, Fe, in ferric salts	0.005588

The following articles are tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength indicated.	
Aqua chlori	17.7	20.0	0.4	of chlorine.
Calx chlorata	0.354	35.0	35	of chlorine.

Ferri et strychninæ citras	0.56	*16.0	*16	of iron.
Ferri phosphas solubilis	0.56	*12.0	*12	of iron.
Ferri pyrophosphas solubilis	0.56	*10.0	*10	of iron.
Ferri valerianas	0.56	15.0 to 20.0	15 to 20	of iron.
Ferrum reductum	0.056	8.0	80	of iron.
Iodum	0.32	25.0	98.85	of iodine.
Liquor ferri acetatis	1.12	*15.0	* 7.5	of iron.
Liquor ferri chloridi	1.12	*26.0	*13	of iron.
Liquor ferri citratis	1.12	*15.0	* 7.5	of iron.
Liquor ferri nitratis	1.12	* 2.8	* 1.4	of iron.
Liquor ferri subsulphatis	1.12	*27.2	*13.6	of iron.
Liquor ferri tersulphatis	1.12	*16.0	* 8	of iron.
Liquor iodi compositus	12.66	49.3 to 50	5	of iodine.
Liquor sodæ chloratæ	6.7	50.0	2.6	of chlorine.
Tinctura ferri chloridi	1.12	* 9.4	* 4.7	of iron.
Tinctura iodi	6.3 Cc.	*35.0	* 7 Gm.	of I in 100 Cc.

134. Normal Sulphuric Acid (H_2SO_4=97.82; 48.91 Gm. in 1 liter).—Carefully mix 30 Cc. of pure, concentrated sulphuric acid (of specific gravity 1.835) with enough water to make about 1050 Cc., and allow the liquid to cool to about 15° C. (59° F.). Place 10 Cc. of this liquid (which is yet too concentrated) into a flask, add a few drops of phenolphtalein T.S., and afterward, from a burette, normal potassium hydrate V.S., shaking after each addition, and regulating the flow to drops toward the end of the operation, until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of cubic centimeters of potassium hydrate consumed. Then dilute the sulphuric acid solution so that equal volumes of this and of normal potassium hydrate V.S. exactly neutralize each other.

Example.—Assuming that 10 Cc. of the acid solution first prepared had required exactly 11.2 Cc. of normal potassium hydrate V.S., each 10 Cc. of the former must be diluted to 11.2 Cc., or each 1000 Cc. to 1120 Cc.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of potassium hydrate V.S. If necessary, a new adjustment should be made to render the correspondence perfect.

Note.—It is recommended that, in alkalimetric determinations, when an acid of normal strength is required, normal sulphuric acid be employed, in place of normal oxalic acid V.S. (see note under No. 122).

One cubic centimeter of normal sulphuric acid is the equivalent of:

	Gramme
Sulphuric acid, absolute, H_2SO_4	0.04891
Ammonia gas, NH_3	0.01701
Ammonium carbonate, $(NH_4)_2CO_3$	0.42035

135. Decinormal Sulphuric Acid (H_2SO_4=97.82; 4.891 Gm. in 1 liter).—Dilute 10 Cc. of normal sulphuric acid with enough water to make 100 Cc.

One cubic centimeter of decinormal sulphuric acid is the equivalent of:

	Gramme.
Sulphuric acid, absolute, H_2SO_4	0.004891
Combined alkaloids of nux vomica, assumed to consist of equal parts of strychnine and brucine	0.0364
Potassium hydrate, KOH	0.005599

The following article is tested with this solution:

	Gm. taken.	Cc. required.	Per cent of strength required.
Extractum nucis vomicæ	0.4	†1.65	15 of total alkaloids.

†To be determined to at least 2 decimals by titrating the uncombined acid with centinormal potassium hydrate V.S.

GASOMETRIC ESTIMATIONS.

(U. S. P.)

In certain cases the Pharmacopœia directs the strength of a product or chemical substance to be determined by the volume of some gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the nitrometer in the following manner:

Arrange a nitrometer consisting of a measuring tube (graduated for at least 50 Cc.), and connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, by suitable clamps attached to a stand, that either tube may be readily and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and fix the equilibrium tube at a low level. Having ascertained that the stop-cock is closed air-tight, and having, if necessary, wiped out the graduated funnel tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it by the prescribed quantities of the several reagents (potassium iodide T.S., and normal sulphuric acid). When the reaction, which takes place at once, moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents, without permitting any gas to pass into the open tube. When the reaction has completely ceased, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be at or near 25° C. (77° F.). Then adjust the two tubes so that the liquid columns are at exactly the same level, and read off the volume of gas in the measuring tube. Multiply this figure by the weight of the substance yielding 1 Cc. of nitrogen dioxide (see below). The result will be the weight of the pure substance (nitrite) contained in the amount taken for the assay.

For pharmacopœial purposes the determination will be sufficiently exact if the evolved gas be measured at or near 25° C. (77° F.). If it be desired to ascertain the volume which the gas would occupy at any other temperature between 0° C. and 40° C. (32° to 104° F.), this may be done with the aid of the table below printed.

Example.—Assuming that the volume of gas read off was 44.5 Cc. at 27° C. (80.6° F.), and that it be desired to ascertain the corresponding volume at 0° C. (32° F.), barometric pressure not being taken into consideration, then the 44.5 Cc. must be reduced in the proportion of 1.098901 to 1; or 44.5 must be divided by 1.098901. The result will be 40.5 Cc.

The following table shows the expansion which 1 Cc. of a gas will undergo when it is raised from 0° C. (32° F.) to 40° C. (104° F.):

EXPANSION OF 1 Cc. OF A GAS, BETWEEN 0° AND 40° C.

°C.	Cc.	°C.	Cc.	°C.	Cc.
0	1.000000	14	1.051282	28	1.102564
1	1.003663	15	1.054945	29	1.106227
2	1.007326	16	1.058608	30	1.109890
3	1.010989	17	1.062271	31	1.113553
4	1.014652	18	1.065934	32	1.117216
5	1.018315	19	1.069597	33	1.120879
6	1.021978	20	1.073260	34	1.124542
7	1.025641	21	1.076923	35	1.128205
8	1.029304	22	1.080586	36	1.131868
9	1.032967	23	1.084249	37	1.135531
10	1.036630	24	1.087912	38	1.139194
11	1.040293	25	1.091575	39	1.142857
12	1.043956	26	1.095238	40	1.146520
13	1.047619	27	1.098901		

136. Estimation of Nitrogen Dioxide.—

$$NO = 29.97;\ 1 \text{ liter} \begin{cases} \text{at } 0° \text{ C. and 760 Mm.—1.3423 Gm.} \\ \text{at } 25° \text{ C. and 760 Mm.—1.2297 Gm.} \end{cases}$$

One cubic centimeter of nitrogen dioxide is the equivalent of:

	At 0° C. and 760 Mm. Gramme.	At 25° C. and 760 Mm. Gramme.
Nitrogen dioxide, $NO=29.97$	0.0013423	0.0012297
Amyl nitrite, $C_5H_{11}NO_2=116.78$	0.0052305	0.0047923
Ethyl nitrite, $C_2H_5NO_2=74.87$	0.0033529	0.0030716
Sodium nitrite, $NaNO_2=68.93$	0.0030873	0.0028283

The following articles are tested gasometrically by the volume of nitrogen dioxide evolved and measured at or near 25° C. (77° F.):

	Amount taken.	Volume of NO.	Strength indicated.
Amyl nitris	0.26 Gm.†	40 Cc.	*80% of pure amyl nitrite.
Sodii nitris	0.15 Gm.	50 Cc.	97.6% of pure salt.
Spiritus ætheris nitrosi (fresh)	5 Cc.	55 Cc.	* 4% of pure ethyl nitrite.

†This quantity will, theoretically, yield a little more than 40 Cc. of the gas, but there will be a slight loss, as the gas is somewhat soluble in the liquid.

ALKALOIDAL ASSAY BY IMMISCIBLE SOLVENTS.

(U. S. P.)

It is a property of many alkaloids that they are soluble in certain liquids in which their salts are insoluble, while in other liquids the case is reversed. When such liquids are not miscible, the conditions are favorable to what has been called the "shaking-out" process of separation. In many cases the extraction or separation may be effected by shaking together the concentrated aqueous extract, to which a suitable alkaline precipitant has been added, and some solvent, such as chloroform, ether, benzin, benzol, amyl alcohol, etc. The precipitated alkaloid is thus washed out of the aqueous solution, and is dissolved by the chloroform or other immiscible liquid employed. From the solution of the alkaloid thus obtained, the latter may again be abstracted by a dilute acid. In this Pharmacopœia the only liquid which is directed as solvent for alkaloids in such assays is *chloroform.* The extraction is directed to be performed in a glass separator or separatory funnel, which consists of an elongated (globular, cylindrical, or conical) glass-vessel, provided with a well-fitting stopper and an outlet-tube containing a well-ground glass stop-cock.

When the solution of an alkaloid, suitably prepared, is introduced into this vessel, and chloroform subsequently added, the latter, owing to its higher specific gravity, will form the lower layer. If the two layers are violently shaken together, there will often result an emulsion, which will separate only slowly, and often imperfectly. This is particularly liable to happen when the aqueous liquid containing the alkaloid either in suspension or in solution is strongly alkaline, and when it has a high specific gravity. To avoid the formation of an emulsion, the extraction should be accomplished rather by rapid rotation and frequent inversion of the separator than by violent shaking. When an emulsion has formed, its separation may be promoted by the addition of more of the solvent, preferably somewhat heated, aided, if necessary, by the external application of a gentle heat (the stopper being removed for the time being), or by the introduction of a small quantity of alcohol or of hot water. The separation of the two layers may also be promoted by stirring the lower, chloroformic layer with a glass rod and detaching from the walls of the separator the adhering drops of emulsion.*

On withdrawing the chloroform solution of an alkaloid from the separator, a small amount of the solution will generally be retained in the outlet-tube by capillary attraction. If this were lost, the results of the assay would be seriously vitiated. To avoid this loss, several successive, small portions of chloroform should be poured into the separator without agitation, and drawn off through the stop-cock to wash out the outlet-tube.

Another source of loss is the pressure sometimes generated in the separator by the rise of temperature caused when an alkaline and an acid liquid are shaken together. On loosening the stopper, the liquid which adheres to the juncture of the latter with the neck is liable to be ejected. This is best avoided by mixing the liquids at first by rotation (avoiding contact of the contents with the stopper), and allowing them to become cold before stoppering the separator.

The same precautions should be observed when an alkali carbonate has been used, in place of a caustic alkali, for setting free the alkaloid. In this case the liquids should be cautiously and gradually mixed by rotation, and the separator should be left unstoppered until gas is no longer given off.

If a regular glass separator is not available, an ordinary burette, stoppered with a sound cork, may be employed in its place. In this case the quantities of the alkaloidal solution and of the volatile solvent must be adjusted to the size of the burette.

DETERMINATION OF THE OPTICAL ROTATION OF ORGANIC SUBSTANCES.

(U. S. P.)

Many organic substances either liquid by nature or in solution in suitable solvents, when examined in a specially constructed polarizing apparatus or polaristrobometer, exhibit the property of circular polarization, or, in other words, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextro-rotatory" or "dextrogyrate," and when rotating to the left, as "lævo-rotatory" or "lævogyrate." Substances which do not possess this property of optical rotation are termed "optically inactive."

Among the substances recognized by this Pharmacopœia, there are several, particularly certain essential or volatile oils, and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for this purpose vary somewhat in their construction. Those which are most generally adapted for the examination of the substances mentioned above are the polaristrobometer of Wild, in which the optical activity of the substance is manifested by the appearance or disappearance of dark, parallel stripes, or the so-called "half-shadow" instrument of Laurent, in which the two sides of the field of vision are capable of becoming unequally illuminated. Both of the instruments permit the angle of rotation to be read off in degrees or fractions of a degree of a circle.

---

*In our experience, the breaking of emulsions may be facilitated considerably by placing a pellet of absorbent cotton, of suitable size, into the emulsified fluid, and repeatedly pressing the cotton against the walls of the separator by means of a glass rod.

These optical determinations are best made in a dark room, and by means of homogeneous or monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is important that the observations should be made with tubes of a definite length, such as 100, 50, or 25 Mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the extent of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1. and in a tube having a length of 1 decimeter (100 Mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[\alpha]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number.

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

I. For liquid substances $[\alpha]_D = \frac{100 \times \alpha}{L \times d}$

II. For solutions of solids

$$\left\{ \begin{array}{l} [\alpha]_D = \dfrac{10000 \times \alpha}{L \times p \times d} \\ \text{or} \quad [\alpha]_D = \dfrac{10000 \times \alpha}{L \times c} \end{array} \right.$$

For calculating these formulas the determination of the following factors is necessary:

α = the angle of rotation of the liquid or solid observed with sodium light.
L = the length of the tube in millimeters.
d = the density or specific gravity of the active liquid.
p = the amount of active substance in 100 parts by weight of the solution.
c = the number of grammes of active substance in 100 cubic centimeters of the solution.

EXPLANATION

OF THE

PRINCIPAL ABBREVIATIONS

OCCURRING IN

PHARMACEUTICAL FORMULAE.

[Revised from the earlier editions of this Dispensatory.]

R., Recipe—Take.
F. S. A., Fiat secundum artem—Let it be made or prepared according to the rules of the art.
M., Misce—Mix.
M. S. D., Misce, signa, da—Mix the medicine, and deliver it afterward, with the requisite instruction, to the patient (or nurse) in writing.
M. F. P., Misce fiat pulvis—Mix to form a powder.
M. F. Mist., Misce fiat mistura—Mix to form a liquid mixture.
M. F. Pil., Misce fiant pilulæ—Mix to form pills.
Div., Divide—Divide.
Sol., Solve—Dissolve.
Fasc. j., Fasciculus—An armful.
Man. j., Manipulus—A handful, a gripe.
Pugil. j., Pugillus—A pinch.
Cyath. j., Cyathus—A glassful.
Cochl. j., Cochlear or Cochleare—A spoonful.
Gutt., Gutta—Drop.
No. 1, 2, 3, etc.—The number of pieces or parts, etc., written j, ij, iij, iv, v.
Ana, or āā—Of each.
P. Ae., Partes æquales—Equal parts.
Q. S., Quantum sufficit.
Q L., Quantum libet—As much as you like.
Q. V., Quantum volueris—As much as you like.
℔., Libra—A pound.
℥., Uncia—An ounce.
ʒ., Drachma—A drachm or dram.
℈., Scrupulus—A scruple.
Gr., Granum—A grain.
Pil., Pilula—A pill.
Pot., Potio—A potion.
Pulv., Pulvis—A powder. Pulvis factis, powdered.
Tinc., Tinctura—A tincture.
Ext., Extractum—An extract.
Chart., Chartula—A small paper.
Collyr., Collyrium—An eye-water.
Collutor., Collutorium—A mouth wash.
Cong.. Congius—A gallon.
O. Oct., Octarius—A pint.
f℥., Fluiduncia—A fluid ounce.
fʒ., Fluidrachma—A fluid drachm.
♏., or Min., Minimum—A minim.
Decoct., Decoctio, Decoctum—A decoction.
Garg., Gargarisma—A gargle.
Haust., Haustus—A draught.
Infus., Infusum—An infusion.
Mass., Massa—A mass.
Mist., Mistura—A mixture.
Ss., Semis—A half.
Zz., Zingiber—Ginger.

A VOCABULARY

OF THE WORDS MOST FREQUENTLY OCCURRING IN THE PRESCRIPTIONS OF PHYSICIANS.

A, āā, or ana, of each ingredient; more properly expressed by the genitive case plural (singulorum) of each; for instance:

R—Aquæ cinnamon, tinct. rhei, āā ʒij, means:
Take of cinnamon-water, and tincture of rhubarb, of each 2 drachms.

Abdom., Abdomen, the belly. Gen.—inis, of the belly. Dat. —ini, to the belly

Abs. febr., absente febre, while the fever is off.

Acc., Accuratè (adverb), accurately. Accuratè pensi, Acc. pen., weighed with the utmost exactness. Accuratè misceantur, Acc. mis., let them be mixed very completely.

Acid., Aciditas, sharpness. Ad. grat. acid., Ad gratam aciditatem, make it just acid enough to be palatable, and not too sour. To an agreeable sourness.

Acm., Acme, the height of a fever or any other disease.

Ad, to. Ad duas vices, at twice taking.

Add., Adde, add., let it or them be added. Addantur, let them be added. Addendus, to be added. Addendo, adding.

Ad lib., Ad libitum, at pleasure, as you like.

Ad recid. præc., Ad recidivium præcavendum, to prevent a relapse.

Admov., Admoveatur, let there be applied—antur, plural, when more than one is to be applied.

Adst. feb., Adstante febre, while the fever is on.

Æger, a sick person, a patient. Ægra, a female patient.

Agg. feb., Aggrediente febre, when the fever is coming on.

Aggressus, an attack. Aggressus febris, the attack of a fever.

Agit. vas., Agitato vasè, shaking the vial.

Albus, white. Alb., or Album.

Aliquant., Aliquantillum, a very little.

Aliquot, some. Aliquoties, sometimes.

Alt., Alter, altera, alterum, the other.

Altern., Alternus, alternate. Altern. hor., Alternis horis, every second hour. Altern. dieb., Alternis diebus, every alternate day.

Aluta, leather. Extende super alutam mollem, E. S. A. M., spread on soft leather, or A. M. E. S.

Alv., Alvus, the belly, the bowels. Adstrictâ alvo, when costive.

Amp., Amplus, large. Coch. amp. Cochleare amplum, a tablespoonful.

A. M., Ante meridiem, before noon. Antemeridianus, in the forenoon, any time before twelve o'clock at noon.

Antè, before. Ut antè, as before.

Apparatus, any sort of a preparation, instruments, or, in short, everything that is requisite to be had in readiness for performing any sort of operation. Also, the more delicate term for a bladder and pipe for clysters.

Aper., Aperiens, opening, gently purging.

Applic., Applicetur, let there be applied.

Aq., Aqua, water. Aquæ, of water. Aq. bull., Aqua bulliens, boiling water. Aq. ferv., Aqua fervens, hot water. Aq. dest., Aqua destillata, distilled water. Aq. font., Aqua fontana, spring water. Aq. marin., Aqua marina, sea or salt water. Aq. niv., Aqua nivalis, snow water. Aq. pluv., Aqua pluvialis, rain water. Aq. pur., Aqua pura, pure water.

Armatus. armed. Fistula armata, an apparatus for clysters; a pipe and bladder.

Auris, the ear. Auri, to the ear. Aures, ears. Auribus, to the ears.

Aut, or.

Bacc., Baccæ, berries.

Baln. mar., Balneum mariæ, a salt water bath. Baln. tep., Balneum tepidum, a lukewarm bath. Baln. vap., Balneum vaporis, a vapor bath. Baln. frigid., Balneum frigidum, a cold bath. Baln. cal., Balneum calidum, hot bath. Baln. ar., Balneum arenæ, sand bath.

Ben., Benè, well. Benè misceatur, B. M., let it be well mixed.

Bib., Bibat, let him drink.

Bidu., Biduum, two days. O. B. V. T., Omni biduò vel triduò, every two or three days.

Bih., Bihorium, the space of two hours. Om. Bih., Omni bihorio, every two hours.

Bis, twice: bis terve, twice or thrice.

Bis in d., Bis in dies, twice a day.

Bol., Bolus, a ball, a pill, a morsel, a dose.

Bullio, to boil: bulliens, boiling. Aq. bull., Aquæ bullientis, of boiling water.

Bull., Bulliant, let them boil.

Calef., Calefactus, made warm.

Cap., Capiat, let (the patient) take. Capt. cochl. iij magn., Capiat cochlearia tria magna, three tablespoonfuls to be taken.

Cat., Cataplasm, a poultice.

Cath., Catharticus, purging, cathartic.

Caut., Cautè, cautiously.

Cerevisia, beer. Cerevisia Londinensis, porter. Cerevisia Lagenaria, bottled porter or stout.

Chart., Charta, paper. Charta Cærulea, blue paper. Chartula, a little piece of paper. Cola trans chartam, filter through paper.

Cib., Cibus, food.

Circa, about. Circiter, about.

Cit., Citò, soon, quickly. Citissimè (the superlative degree), as quick as possible

Clausus, clausa, clausum, covered. Vase clauso, in a covered vessel.

Co., coch., Cochleare, a spoonful. Cochlearia, spoonfuls. Coch. magnum, amplum, a tablespoonful. Co. infantulorum, coch. medium, child's spoonful, a dessertspoonful. Co. parvum, a teaspoonful.

Coctio, a boiling. Sub. fin. coct., Sub finem coctionis, toward the end of the boiling; when almost boiled.

Cæruleus, blue. Charta cærulea, blue paper. Unguentum cæruleum, mercurial ointment.

Col., Cola (imperat. of Colo), strain, to filter.

Colatus, strained, filtered. Colato liquori, to the strained liquor.

Colatura, a straining, Colaturæ, to the strained liquor.

Coletur, let it be strained. Colentur, let them be strained.

Collum, a neck.

Comp., Compositus, compounded.

Conf., Confectio, confection.

Cons., Conserva, conserve (imperat.).

Consp., Conspergo, to sprinkle. Consp. pulv. cinnam., Conspergatur pulvere cinnamomi, sprinkle with (or roll in) powdered cinnamon; usually applied to pills.

Cont., Continuo, to continue. Cont. rem., Continuantur remedia, go on with the same medicines as last prescribed.

Contundo, to bruise. Contus., Contusus, bruised.

Contusio, a bruise, a contusion.

Coq., Coque, boil. Coque parùm, boil a little while.

Coquantur, let them be boiled.

Cor, the heart. Scrob. cord., Scrobiculus cordis, the pit of the stomach.

Cort., Cortex, the bark.

Coxa, Coxendix, the hip.

Cras, to-morrow. C. m., Cras mane, early to-morrow morning. C. M. S., cras mane sumendus, to be taken early to-morrow morning. C. V., Cras vespere, to-morrow evening. C. N., Cras nocte, to-morrow night.

Crastinus (adj.), of to-morrow. In usum crastinum, for to-morrow's use.

Cribrum, a sieve. Trans cribrum, through a sieve.

Cuj., Cujus, of which. Cuj. cap., or sum., Cujus capiat, or sumat, of which (the patient is to) take.

Cum, with.

Cyath., Cyathus, a cup. Cyath. vinar., Cyathus vinarius, a wineglass. Cyathus theæ, a teacupful. Cyatho theæ, in a cup of tea.

D. Dos., Dosis, a dose.

Da, give. Detur, dentur (plural), let be given.

De, of. De quo, or quâ, of which. De die, in a day.

Deauratus, gilt. Deaur. pil., Deaurentur pilulæ, let the pills be gilt.

Debilitas, weakness.

Debitus, due. Ad. deb. spiss. Ad. debitam spissitudinem, to a proper degree of thickness, as to consistence.

Decoct., Decoctio, decoction.

Dec., Decanta, pour off.

Decem, ten. Decimus, the tenth.

Decubitus, lying down. Horâ decubitûs, at bedtime.

Deglutio, to swallow. Deglutiatur, is swallowed—etur, let be swallowed.

Dein, deinde, then; afterward.

Dejectio, a depositing, or putting down, also a going to stool; as, post duas dejectiones alvi, after two motions.

Dejicio, to deposit. Donec alvus bis dejecerit, until the patient shall have had two stools.

Det., Detur, let it be given.

Dexter, the right. Manus dextra, the right hand. Auri dextro, to the right ear.

Dictus, spoken of, said.

Dies, a day. Die, in a day; bis die, twice a day. Diebus, in days; tertiis diebus, every third day. Alternis diebus, every alternate day. De d. in d., de die in diem, from day to day.

Dil., Dilutum, diluted.

Dim., Dimidium, the half. Dimidius, a, um (adjective), half.

D. P., Directione propria, with its proper direction.

Diu, a long time. Tere diu, rub for a long time.

Diut., Diuturnus, long-continued. Diuturnâ trituratione, D. trit., by long-continued rubbing, or grinding in the mortar. Diuturna coctione, by long boiling.

Div., Divido, divide.

Dolens, pained. Parti dolenti, to the pained part.

Dolor. pain. Dolores, pains. Doloris, of the pain.

Donec, until. Donec liquescat, till it melts. Donec alv. bis dej., Donec alvus bis dejecerit, until the bowels have been twice moved.

Dr., Drm., Drachma, a drachm.

Dum, whilst.

Dur. dol., Durante dolore, while the pain continues.

Eadem, eandem, the same. Eodem, in the same.

Effervescentia, the effervescence.

Effervescit, effervesces; donec effervescat, until it effervesces.

Effund., Effunde, pour out.

Ejusdem, of the same, the genitive case of idem.

Elect., Electuarium, an electuary.

Emp., Emplastrum, a plaster.

Enema, a clyster. Enemata, clysters.

Erit, shall be.

Evanesco, evanui, to disappear. Evan., Evanuerit, shall have disappeared.

Exhib., exhibe, Exhibeatur, give. Exhibendus, to be given.

Extendo, to extend, also to spread. Ext. sup. alut., Extende super alutam, spread it on leather.

Exten., Extensus, a, um, spread.

Ex., Ext., Extractum, an extract.

F., Ft., Fiat, let there be made.

Fac, make. Fac in pilulas xij, make into 12 pills.

Farina, flour. Farina seminis lini, linseed meal.

Febris, a fever. Febre durante, while the fever is on.

Femoribus, to the thighs. Femoribus internis, to the inner sides of the thighs.

Femur, a thigh.

Fervens, boiling. Fervidus, fervida, hot.

Ferventis, of boiling. ℞ aq. ferventis, take of boiling water.

Fiat, let be made, make (the singular number). Fiant, make (plural).

Filt., Filtra, filter.

Finis, the conclusion. Sub finem coctionis, when almost boiled enough.

Flo., Flors., Flores, flowers.

F., Fl., Fluidum. Fluid, liquid.

Fontana, fountain. Aqua fontana, spring water.

Formula, prescription.

Fotus, a fomentation.

Fruct., Fructus, fruit.

Frust., frustillatim, in small pieces.

Fuerit, shall have been; as, donec alvus soluta fuerit, until a motion is (or shall have been) procured.

Garg., Gargarisma, a gargle.

Gelatina, jelly. Gelatina ribesiorum, currant jelly. Gelatina quavis, in any sort of jelly.

Globulus, a little ball. Globuli Gascoigni, Gascoign's ball. Don. glob. evan., Donec globuli evanuerint, until the globules (of quicksilver) shall have totally disappeared (so that they can not be seen even with a microscope).

Grad., Gradatim, by slow degrees.

Gr., Grana, grains.

Gratus, grata, gratum, agreeable, pleasant. Ad gratum, aciditatem, so as to make it pleasantly acid without being too sour. In quovis grato vehiculo, in any agreeable vehicle.

Gutta, a drop. Gtt., Guttæ, drops. Guttas, drops.

Guttatim, drop by drop.

Hac, this. Hac nocte, this night. Hanc, this. Sumat hanc, let him take this.

Hactenus, hitherto, heretofore, up to the present day.

Harum, of these. Harum pilularum sumat tres, of these pills let him or her take 3.

Haust., Haustus, a draught.

H. P. N., Haustus purgans noster, a formula of purging draught made according to a practitioner's own private Pharmacopœia, and is prepared so as to keep a long time without spoiling, that we may not have the trouble of preparing it every time a draught is wanted. Mitt. H. P. N. ℥ij ad ij Vices C. M. S. Mitte Haustus purgantis nostri uncias duas ad duas Vices cras mane sumendus; send two ounces of our purging draught, to be taken to-morrow morning, at twice, that is, half at first, and the remaining half in an hour if the first does not operate.

Hebdomada, a week.

Heri, yesterday. Ut heri, as yesterday.

Hesternus, of yesterday. Hesterna nocte, last night.

Hirud., Hirudo, a leech. Hirudines, leeches.

His, in these, to these. His adde, add to these.

Hora, an hour. Horæ, of an hour. Horæ (plural), hours.

H. S. (horâ somni), at the hour of rest.

H. S. S. (horâ somni sumendus), to be taken at bedtime. Horâ decubitus, at the hour of going to rest, bedtime

Horâ vespertinâ, in the evening.

Horæ [illegible], horæ quadrante, quarter of an hour.

Horæ unius spatio, in the space of one hour.

Horis intermediis, at intermediate hours, when two medicines are to be taken. Horis intermediis, means that one is to be given exactly at midtime from the other (suppose a draught is ordered to be taken every six hours), and a powder horis intermediis, that is, every six hours intermediately, then a draught will be taken at six o'clock and at twelve and a powder at three and at nine.

Hujusmodi, of this sort, like these.

Idem, eadem, the same. Ejusdem, of the same, the genitive case of Idem.

Idoneus, proper, appropriate.

Imponatur (sing.), let there be put on—nantur (plural).

Impr., Imprimis, first.

In, in. In die, in a day.

Ind., Indiès (an adverb), every day, daily (from day to day).

Indicaverit, shows, indicates.

Infunde, infundatur, infuse.

Infus., Infusio, infusum, an infusion.

Infus. panis tostus, toast-bread water.

Inject., Injectio, injection.

Inter, between.

Injiciatur, let it be thrown in, thrown up. Injiciatur enema, let a clyster be administered.

Injiciendus, injiciendum, to be administered.

Inquietudo, restlessness. Urgente inquietudine, if restless.

Instar (an adverb), as big as. Sumat molem instar nucis moschatæ, the bigness of a nutmeg to be taken.

Intermedius, intermediate.

Internis, the inner side.

Jam, already. Jampridem, jamdudum, some time ago, heretofore.

Jugulum, the throat.

Jusculum, broth. Jusculum ovillum, mutton broth. Jus. bovinum, beef tea.

Juxta, near to.

Lac, milk. Lactis, of milk. Lacte, in milk.

Læv., Lævigatus, levigated.

Lana, flannel. Lana nova, new flannel.

Languor, faintness, lowness. In lang., In languoribus, in the fainting fits, when low and faint.

Latus, the side. Lateris, of the side. Lateri, to the side. Latus dolens, the pained side. Lateri dolenti, to the pained side.

Latus, lata, latum (adjective), broad.

Lectus, a bed. In lecto, in bed.

Liber, a book.

Libet (a verb impersonal), it pleases. Ad libitum, just as you please.

Libra, a pound. Libris, libras, pounds.

Linteum, lint; also linen.

Liquesco, to liquefy, to melt. Donec liquescat, till it melts.

Liquid., Liquidus, liquid. Sedes liquidæ, loose stools. In quovis liquido, in any liquid.

Liq., Liquor, liquor.

Londinensis, of London. Pharmacopœia Londinensis, the London Dispensatory.

Lot., Lotio, lotion.

Lumborum, of the loins.

Mac., Macera, macerate.

Mag., Magnus, magna, magnum, large. Magnum cochleare, a tablespoonful.

Major, greater, larger. Cochlearia duo majora, two tablespoonfuls.

Malleolus, the ankle. Malleolus internus, the inner ankle.

Manè, in the morning. Manè primo; valde manè, very early in the morning.

Manus, a hand. Manu calefacta, with a warm hand.

Mass., Massa, a mass. M. P., Massa pilularis, a mass fit for forming into pills.

Matutinus, in the morning or forenoon.

Maximè, chiefly.

Maximus, the greatest. Maximâ curâ. witn the greatest care.

Medioc., Mediocris, middle-sized. Pilulæ mediocres, middle-sized pills. Cochleare mediocre, a dessertspoonful, a papspoonful, or a child's spoonful. Mediocris also means indifferent, as to quality.

Medius, middle. Media nocte, in the middle of the night.

Melior, melius, better.

Mic. pan., Mica panis, crumb of bread.

Minatur, minaretur, threatens. Minante, threatening.

Minimus, very small. Coch. min., Cochleare minimum, a teaspoonful.

Minutum,* a minute.

M., Misce, mix. Bene misceatur, let it be well mixed.

Mist., Mistura, mixtura, a mixture.

Mitigatio, mitigation, alleviation. Donec doloris mitigatio sit, until the pain is easier.

Mitigatus, a, um, mitigated, lessened.

Mitt., Mittatur (singular), let it be sent. Mittantur (plural), let them be sent.

Mittatur sanguis, take blood away; *i. e.*, bleed the patient.

Mitte, send.

Modicus, middle-sized.

Modus, a manner. Modo præscripto, in the manner directed.

Moles, a mass, a lump, a piece. Sumat molem instar nucis moschatæ, let him (or her take the bigness or size of a nutmeg.

Molestus, troublesome. Molesto, to trouble, to be troublesome. Molestante dolore, when the pain is troublesome. Molestante tussi, when the cough is troublesome.

Mollis, molle, soft.

Mora, delay. Sine morâ, without delay.

---

*The word minutum, for a minute, is very barbarous Latin: we believe there is no such word: but the right Latin for a minute, Sexagesima pars horæ, is as long and tiresome to write as "Semivitreous oxide of lead," for the simple word "Litharge."—*Griffith.*

Mos, moris, manner. More solito, in the usual manner, also, in the same manner as I am in the habit of prescribing it to other people.

Morta., Mortarium, a mortar. Mortario aheneo, in the brass mortar. Mortario marmoreo, in the marble mortar. Mort. vitreo, in the glass mortar. Mort. lapideo, in the stone mortar.

Mucil., mucilago, mucilage.

Narthecium, a gallipot.

Nates, the buttocks.

Ne, lest, also, do not; as ne tradas sine nummo, N. T. S. N., do not deliver the medicine without the money.

Nec., necnon, also.

Ni, nisi, unless.

Nig., Niger, nigra, nigrum, black.

Nihil, nothing.

Nim., Nimis, nimium, too much.

Nisus, an endeavor, an attempt, a straining, a motion, a straining to vomit, or go to stool.

N., Nocte, at night. Noctes, nights. N. man., Nocte maneque, night and morning. Alt. noct., Alternis noctibus, every second night.

Nodulus, a little knot. Nodulo ligati, tied up in a piece of clean rag.

Nomen, nominis, a name. Signetur nomine proprio, S. N. P., write its common name upon the label.

Non., Nonus, the ninth.

Nov., novem, nine.

Novis., Novissimè, very lately, the last of all.

Novus, nova, novum, new.

Nucha, the nape of the neck. Nuchæ, to the nape.

Nuper, lately. Nuperrime, very lately.

N. M., Nux moschata, a nutmeg. Sumat magnitudinem nucis moschatæ, take the bigness of a nutmeg.

Numeri. Numbers.

1. or j. unus, una, unum, one.
unius, of one.
2. ij. duo, duæ, two.
duorum, of two.
duobus, in two, to two.
3. iij. tres, tria, three.
tribus, in three, to three.
trium, of three.
ter, three times.
4. iv. quatuor, four.
quartus, a, um, fourth.
quater, four times.
5. v. quinque, five.
quintus, fifth.
6. vj. sex, six.
sextus, sixth.
7. or vij. septem, seven.
septimus, seventh.
septimana, or
7 mana, a week.
8. viij. octo, eight.
octavus, eighth.
9. ix. novem, nine.
nonus, ninth.
10. x. decem, ten.
decimus, tenth.
11. xj. undecim, eleven.
12. xij. duodecim, twelve.
20. xx. viginti, twenty.
24. xxiv. viginti quatuor, twenty-four.

Obst., Obstante, hindering, preventing.

Occ., Occasio, occasion, opportunity.

O. Oct., Octarius, a pint.

Octavus, eighth. Octavo quaque horâ, every eighth hour.

Octo, eight.

Ol. Lini, S. I., Oleum lini sine igne, cold-drawn linseed oil.

O. O. O., Oleum olivæ optimum, best olive oil.

Olim, some time ago.

Olla, a pot, a gallipot.

Omnis, all. Omni mane, every morning. Omni horâ, every hour. Omni bihorio, every two hours. Omni nocte, every night. Omni ¼ horâ, Omni quadrante horâ, every quarter of an hour. Tere omnia, rub all together. Omn. alt. hor. omnibus alternis horis, every other hour.

Omninò, quite, wholly, entirely.

Optimè, very well, as well as possible.

Opt., Optimus, ma, mum, best.

Opus, need, occasion. Si opus sit, or fuerit, if it be necessary.

Ovil. jusc., Ovillum jusculum, mutton broth.

Ovum, an egg. Vitell. ovi, the yelk of an egg. Ovorum, of eggs.

Panis biscoctus, biscuit. Panis nauticus, sea biscuit. Panis tostus, toast bread. Infus. panis tostus, toast-bread water. Panis triticeus, wheat bread.

Pannus, a rag. Pannus linteus, a linen rag. Pannus laneus, Pannus è lanâ, a piece of flannel.

Paroxysmus, a paroxysm, a fit, a convulsion fit.

Pars, a part. Partes, parts. Parti dolenti, to the pained part.

Part. aff. Partem affectam, to the part affected.

P. Æ. Partes æquales, equal parts.

Partitus, parted. Part. vic., Partitis vicibus, means that you are not to give a medicine all at once, but divide the dose according to the directions most commonly previously given; for example, if a purging or emetic draught, half or a third (as the case may be) to be taken at first, and the other half or third at a certain distance of time, if the former quantity be not found sufficient to produce the desired effect.

Parum, a little. Parumper, a little.

Parv., Parvus, little. Coch. parv., Cochleare parvum, a teaspoonful.

Pauculum, pauxillum, paululum, a little.

Pect., Pectus, the breast. Pectoris, of the breast.

Pediluvium, a bath for the feet.

Pensus, weighed. Accuratè pensi, weighed exactly.

Per, by, or through.

Peractus, Perf., Perfectus, completed, perfected, quite done. gone through with; as, Peracta operatione emetici, after the emetic has quite done operating.

Perfric., Perfricetur, let it be rubbed. Perfricandus, to be rubbed.

Perg., Pergo, to go on with. Perg. in us. med., Pergat in usu medicinarum, he may continue the medicines as before.

Perpetuus, perpetual. Fiat perpetuum, keep it open (when it refers to a blister).

Ph., Pharmacopœia, a Pharmacopœia, or Dispensatory.

Ph. D., Pharmacopœia Dublinensis, Dublin Pharmacopœia.

Ph. E., Pharmacopœia Edinensis, Edinburgh Pharmacopœia.

Ph. L., Pharmacopœia Londinensis, London Pharmacopœia.

Ph. U. S., Pharmacopœia, United States Pharmacopœia, U. S. P.

Pil., Pilulæ, pills.

Pluvialis, also pluviatilis aqua, rain water.

Poculum, a cup.

Pollex, the thumb. Pollex pedis, the great toe.

Pomeridianus, postmeridianus, in the evening or afternoon, time of the day.

Pomum, an apple. Pomi, of an apple.

P. M., post meridiem, after noon, in the afternoon, after twelve o'clock at noon.

P. R. N., Pro re natà, occasionally, according as circumstances may occur, according as the symptoms may require.

Pond., Pondere, by weight.

Pone, behind.

Porro, moreover.

Post, after. Postea, tnen, afterward.

Post sing. sed. liq., Post singulas sedes liquidas, after every loose stool.

Postul., Postulet, postulent, may require, demand.

Pot., Potus, drink, beverage of any kind.

Præc., Præcipue, especially.

Præp., Præparatus, prepared. Pr., Preparatio, preparation, or prescription.

Præparo, to prepare. Præp., Præparentur, let them be prepared.

Prim., Primus, ma, mum, the first. Primò, first of all. Primo mane, very early in the morning.

Prior, prius, the former. the first.

Prius, Priusquam, before that.

Pro, for. Pro re natâ, P. R. N., occasionally, according to the nature of the case, etc. Pro ratione, according to, or in proportion to; as pro ratione ætatis, according to the age of the patient, pro. rat. æt.

Pro pot. ord., Pro potu ordinario, for a common drink.

Prop., Proprius, a, um, proper. S. N. P., Signetur nomine proprio, mark it with its proper direction.

Prox. luc., Proxima luce, the day before.

Pruritus, an itching. Pruriens, itching. Dolichos pruriens, cowhage.

Psora, the itch.

Pug., Pugillus, a handful; a pinch-dose.

Pulp., Pulpa, the pulp.

Pulv., Pulvis, a powder. Pulveres, powders. Pulveribus, in powders.

Pulvis subtilissimus, the very finest powder. Pulv. subt.

Pur., Purificatus, a, um, purified.

Pyx., Pyxis, pyxidis, a pill-box, or lozenge-box.

Quac., quacum, with which.

Quad., Quadrans, quadrantis, quadrante, quarter. Omni quadrante horá, every quarter of an hour.

Quadruplicata, four times as much.

Quamp., Quamprimum, as soon as possible, without the least delay.

Quâqua, every. Quaq., Quaque, every one. Quàvis (fem.), with any.

Quartus, a, um, the fourth.

Quater, four times. Quatuor, four. Quarta pars, a fourth part.

—que (at the end of any Latin word), and.

Quem, quam, quod, which (the accusative case).

Qui, quæ, quod, which (the nominative case).

Quib., Quibus, to which, with which.

Quibusdam, to or with some. Cum guttis quibusdam, with a few drops.

Quiescat, goes to rest, is easier.

Quilibet, quælibet, quodlibet, gen. Cujuslibet, abl. Quolibet, any.

Quinq., Quinque, five. Quintus, a, um, the fifth. Quinquies, five times.

Quinquina (cinchona), Peruvian bark.

Quisq., Quisque, every one.

Q. P., Quantem plácet, as much as you please.

Q. Q. H., Quaque quarta hora, every four hours; or Quadrihoris.

Q. S. q. s., Quantum sufficiat, as much as may be sufficient.

Quor., Quorum, quarum, of which. Quos, quas, which. Quocum, quacum, with whic

Quovis, with any.

Rad., Radix, the root.

Ras., Rasuræ, shavings.

Ratio, a reason, also a proportion. Pro ratione ætatis, according to the age of the patient. Pro ratione doloris, according to the urgency of the pain.

Raucedo, hoarseness.

Recipe, take. Recipe (taken substantively), a prescription.

Red., Redactus, a, um, reduced. Red. in pulv., Redactus in pulverem, reduced to powder; or, in pulv. redact.

Red., Redigatur, let it be reduced. Redig. in pulv., Redigatur in pulverem, let it be reduced to powder.

Redigo, to reduce. Red., Redige, reduce. Redigatur, it may be reduced.

Refr., Refrixerit, the subjunctive perfect of refrigesco, to cool.

Regio, a region (an anatomical term for certain parts of the body); as, regio epigastrica, the epigastric region; regio lumborum, the region of the loins; appl. emplastr. regioni umbilicali, applicetur emplastrum, etc., let a plaster be applied to the umbilical region, or parts in the neighborhood of the navel. Reg. hep., Regio hepatis, region of the liver.

Reliq., Reliquus, a, um, the rest, the remaining part.

Rem., Remedium, a remedy. Cont. rem., Continuantur remedia, go on with the same remedies as before.

Repet., Repetatur, let it be repeated, repeat.

Repet., Repetendus, to be repeated.

Resp., Respondeo, responderit, shall have answered. Donec alvus ad sedes ij vel iij responderit, until two or three stools shall have been procured.

Retin., Retinendus, to be retained or kept.

Ribes, currants. Gelatina ribesiorum, currant jelly.

Ruber, rubra, rubrum, red.

Rubus idæus, raspberry.

S., Signa, write.

S. V. R., spiritus vini (or vinosus) rectificatus, rectified spirit of wine, alcohol.

S. V., Ten., or tenuis, proof-spirit.

Sacch. alb., Saccharum album, white sugar.

Sæpe, often; sæpius, oftener; sæpisme, very often.

Sal., Salt.

Salt., Saltem, at least.

Sang., Sanguis, blood,—inis, of blood. Sang. miss., Sanguinis missura, bloodletting.

Saph. ven., Saphena vena, the ankle vein.

Scapula, the shoulder blade. Inter scapulas, betweeen the shoulders.

Scil., Scilicet, to wit, namely.

Scrob. cord., Scrobiculus cordis, the pit of the stomach.

Sec., Secundus, a, um (adjective), second.

S. A., Secundum artem, according to art; that is, you are to use your own ingenuity to do it in the most proper and scientific way.

Sed, but.

Sedes, a stool—plural, stools.

Semel, once.

Sem., Semen, seed. Semina, seeds.

Ss., semis, Semi-, half. Semihora, half an hour. Semidrachma, half a drachm.

Semper, always.

Septem, seven.

Sept., Septimana, a week, seven days. Septimus, seventh.

Seq., Sequens, following. Seq. luce, sequens luce, the following day.

Serum is also the watery part of the blood which separates from the red part, or crassamentum, on standing until cold.

Serum lactis, whey. In sero lactis vinoso, in wine whey.

Serv., serva, keep or preserve.

Sesq., Sesqui, one and a half; as sesqhr., sesquihora, an hour and a half. Sesquiuncia, or sescuncia, an ounce and a half. Sesquidrachma, a drachm and a half. Remember well to attend to the difference between semi and sesqui, for many young men, by not knowing that sesqui means one and a half, but confounding it with semi, have made bad mistakes.

Sex, six. Sextus, sixth.

Si, if. Sive, or, whether.

Si N. V., Si non valet, if it does not answer.

S. O. S., Si op. sit, Si opus sit, if there be occasion.

Si V. P., Si vir. perm., Si vires permittant, if the strength allow.

Signatura, a label or direction.

Sig., Signetur, let it be marked, directed, written upon.

S. N. P., Signetur nomine proprio, mark it with the name it is usually known by.

Simul, together; as, terantur simul, let them be rubbed together. Simul ac, at the same time that.

Sine, without. Sine morâ, without delay.

Singultus, hiccup.

Singulus, a, um, each; in singulis, in each; Sing., singulorum, of each.

Sin., Sinister, tra, trum, the left. Aur. sin., Auri sinistro, to the left ear.

Sitis, thirst; si sitiat, if thirsty.

Soli., Solitus, accustomed.

Solus, alone, only.

Solutus, a, um, dissolved, also loosened; donec alvus soluta fuerit, until a stool is procured. Solu., Solutio, solution.

Solve, dissolve.

Som., Somnus, sleep. Hora somni, at bedtime.

Spina, the spine, the backbone; also, a thorn.

Spt., Spiritus, spirit. Spt. rect., Spiritus rectificatus, rectified spirits, alcohol.

Spissus, thick. Spissitudo, consistence of thickness.

Sq., Squama, æ, a scale.

Statim, directly, immediately.

St., Stent, let them stand. St., Stet, let it stand.

Sternutatorius pulvis, sneezing powder, snuff.

Stupa, tow.

Sub, subter, under. Sub fin. coct., Sub finem coctionis, when the boiling is almost finished. Sub prefixed to a word, implies diminution, or a process not completed; also, in many words has the same signification as the termination ish in English words, as subniger, blackish, not quite black; subtepidus, lukewarm. The same meaning prevails when applied to terms of chemistry, as subcarbonas, subsulphas, etc.

Subactus, a, um, subdued, dissolved.

Subige, dissolve it, make it unite. Subdue quicksilver with lard or balsam of sulphur.

Subinde, frequently, now and then.

Subitus, a, um, Subitaneus, sudden. Subito (adverb), suddenly.

Subtep., Subtepidus, a little warm, lukewarm.

Subt., Subtilis, subtle, reduced to fine powder. Pulv. subtilissimus, the very finest powder.

Succ., Succus, juice.

Succ. pom. ferment., Succus pomi fermentatus, cider.

Sudor, sweet.

Sumat, let him take. Sum., Sumatur, sumantur, let it (them) be taken, take. Sum., Sumendus, to be taken.

Sum. tal., Sumat talem, let the patient take one like this.

Superbibo, to drink after taking anything; as, chamomile tea or warm water after an emetic; or a cup of water, or any liquid medicine, to wash down a dose of any sort of pills.

Superinfundo, to pour upon.

Supra, above. Supradictus, above mentioned.

Syncope, a fainting fit.

Syr., Syrupus, syrup.

Tabel., Tabellæ, tabulæ, lozenges.

Tactus, the touch.

Tænia, the tapeworm.

Talis, such. Sumat talem, let him take such a one as this.

Talus, the ankle.

Tam, so. Tamen, yet.

Temperies, temperamentum, temperament, degree of heat.

Tempora, the temples. Temporibus, to the temples. Temp. dext., Tempori dextro, to the right temple. Tempori sinistro, to the left temple.

Tempus, temporis, time.

Tenacitus, tenacity. Ad debitam tenacitatem, to a proper degree of tenacity or consistence.

Teneo, to hold. Tenendus, to be held.

Tenuis, weak, thin, small, slender.

Tepef., Tepefactus, warmed, made warm.

Ter, three times, thrice. Ter quaterve, three or four times.

Teres, teretis, round, taper; also, teres is a name for the long and round worm infesting the human body, viz., vermis teres.

Tergum, the back. A tergo, behind.

Tero, to rub. Tere (imperative), rub. Terendus, to be rubbed. Terantur, let them be rubbed.

Tertius, tertia, tertium, the third.

Testacea, the prepared powders made of oyster shells, egg shells, crabs' claws, etc.

Thorax, the chest. Thoracis, of the chest.

Thus, frankincense.

Tinea capitis, scald head.

Torref., Torrefactus, toasted.

Tres, tria, three; tribus, in three, to three.

Triduum, three days.

Trituratio, a grinding. Trituratus, triturated, ground. Tritus, ground. Trituratur exactissime minutes decem, Trit. ex. min. dec., T. E. M. D., let it be triturated exactly ten minutes. Trituratur intime commisceantur, Trit. int. com., triturate intimately or accurately together. Trit., Tritura, triturate.

T. O., Tinctura Opii, what is commonly called Laudanum.

T. O. C., Tinctura Opii Camphorata, Camphorated Tincture of Opium, formerly called Paregoric Elixir. This tincture is also called (since the London Pharmacopœia, edit. 1809) Tinctura Camphoræ Composita.

Trans, through. Cola trans chartam, filter through filtering paper.

Tussis, a cough. Tuss. mol., Tussi molestante, when the cough is troublesome.

Ultimus, ultima, um, the last. Ult. pr., Ultimó præscriptus, which was last prescribed.

Umbilicus, the navel.

Unà (an adverb), together.

Uncia, an ounce. Unciam cum semisse, an ounce and a half (accus.).

Undecim, eleven.

Unus, una, unum, one. Unius, of one. Uni, to one.

Urg. tuss., Urgente tussi, when the cough is troublesome.

Urgeo, to urge, to oppress, to be troublesome, or painful.

Usque ad, up to, as far as.

Usus, use. Pergat in usu remediorum, continue the use of the medicine as before.

Ut, as, that, so that; in the same manner as.

Utatur, let him make use of.

Utend., Utendus, to be used.

Uterque, utraque, utrumque, both. Utriusque, of both. Utrique, to both, to either. Admoveantur hirudines ij tempori utrique, apply two leeches to each temple.

Utriuslibet, of whichever of the two, or more, the patient likes best.

Vacc., Vaccinatio, the act of inoculating for the cowpock.

Vaccinum lac, cow's milk.

Valde, very, very much.

Valeo, to avail; si non valeat, if it does not answer.

Varicella, the chicken-pox.

Variolæ, the smallpox.

Variolæ vaccinæ, the cowpock.

Vas, a vessel. Vasis, of a vessel. Vase clauso, in a covered vessel. Agitato vase, shaking the vessel. Vas vit., vas vitreum, a glass vessel.

Ve, vel, or, either; —ve is never at the beginning but the end of a word.

Vehiculum, a vehicle; that is, whatever liquid, or any other eatable or drinkable we take a medicine in, as barley water, whey, jelly, or panada, etc.

Vena, vein. Vena saphena, the ankle vein.

Venæsectio, bleeding. Fiat venæsectio, bleed him.

Vent., Ventriculus, the stomach.

Vertebræ, the joints of the neck, back or loins; the vertebræ altogether form that column of bones which is called the spine.

Verus, true, real, genuine.

V. S., Venæs., venæsectio, bloodletting.

V. S. B., Venæsectio brachii, bleeding in the arm. Fiat venæsectio in venâ saphena, bleed the patient in the ankle vein; or it may be understood, to bleed wherever you can find the best vein, at the top of the foot, to get blood from.

Vesp., Vespere, in the evening.

Vespertinus, in the evening; as, horâ VI^{a}, vespertina, at six o'clock in the evening.

Vice, in the room of. Vices, turns. Ad duas vices sumendus, to be taken at twice; that is, half to be taken at first, and the other half in some time after. Ad secundam vicem, for the second time.

Vicibus partitis. See Partitus, in P.

Viginti, twenty. Vicesimus, vigesimus, the twentieth.

Vinosus, vinarius, of wine. Cyathus vinarius, a wineglass.

Vires, strength. Si vires permittant, if the strength will bear it.

Vitellus, the yelk of an egg.

V. O. S., Vitello Ovi Solutum, dissolved in the yelk of an egg.

Vitrum, a glass. Vitreus, made of glass.

Vix, scarcely, hardly. Ut vix sentiatur, so that it can scarcely be perceivable.

Vomitio, a vomiting. Vomitione urgente, when the vomiting is troublesome.

Vultus, the countenance.

COMPARISON

OF THE

DIFFERENT THERMOMETRIC SCALES.

The thermometer used in this country is usually that of Fahrenheit. In this instrument the range between the freezing and boiling points of water is divided into 180°, and as the greatest possible degree of cold was supposed to be that produced by mixing snow and salt together, it was made the zero. Hence, the freezing point became 32°, and the boiling point 212°.

The Centigrade thermometer places the zero at the freezing point of water, and divides the range between the freezing and boiling points into 100°. This scale has long been used in Sweden, under the title of Celsius's thermometer, and is generally adopted on the continent.

Réaumur's thermometer, which was formerly used in France, divides the space between the freezing and boiling points of water into 80°, and places the zero at the freezing point. It is now little employed.

Le Lisle's thermometer is used in Russia. The graduation begins at the boiling point, and increases toward the freezing point. The boiling point is marked 0°, and the freezing point 150°.

To convert the degrees of Centigrade into those of Fahrenheit, multiply by 9, divide by 5, and add 32.

To convert the degrees of Centigrade into those of Réaumur, multiply by 4, and divide by 5.

To convert the degrees of Fahrenheit into those of Centigrade, deduct 32, multiply by 5, and divide by 9.

To convert the degrees of Fahrenheit into those of Réaumur, deduct 32, divide by 9, and multiply by 4.

To convert the degrees of Réaumur into those of Centigrade, multiply by 5, and divide by 4.

To convert the degrees of Réaumur into those of Fahrenheit, multiply by 9, divide by 4, and add 32.

EXAMPLES:

$$20^\circ\text{ C.}=\frac{20\times 9}{5}+32=68^\circ\text{ F.}$$

$$20^\circ\text{ C.}=\frac{20\times 4}{5}=16^\circ\text{ R.}$$

$$-14^\circ\text{ C.}=\frac{(-14)\times 9}{5}+32=\frac{-126}{5}+32=+6\tfrac{4}{5}^\circ\text{ F.}$$

$$-24^\circ\text{ R.}=\frac{(-24)\times 5}{4}=\frac{-120}{4}=-30^\circ\text{ C.}$$

$$275^\circ\text{ F.}=\frac{275-32}{9}\times 5=27\times 5=135^\circ\text{ C.}$$

$$-26^\circ\text{ F.}=\frac{-26-32}{9}\times 5=\frac{-58}{9}\times 5=-32\tfrac{2}{9}^\circ\text{ C., etc.}$$

TABLES OF WEIGHTS AND MEASURES.

"All weights and measures used in this country are now derived from the United States National Prototype Standards of the Meter and the Kilogramme, made of platinum-iridium, received by the United States Government from The International Bureau of Weights and Measures in 1890, and placed in the custody of the Office of Standard Weights and Measures at Washington. The value of the

United States National Prototype Standard Meter is identical with that of the International Standard Meter derived from the Mètre des Archives; and the United States National Prototype Standard Kilogramme, like the International Standard Kilogramme, is derived from the Kilogramme des Archives" —(*U. S. P.*).

"The actual liter is the volume of one kilogramme of pure water at the temperature of its maximum density, *in vacuo*. Theoretically the liter is equal to one cubic decimeter, or 1000 cubic centimeters. The United States *yard* is defined to be equal to $\frac{360000}{393700}$ meter; the commercial *pound* (Avoirdupois) is defined as being equal to $\frac{700000000}{1543235639}$ kilogramme; and the liquid *gallon* is the volume of 3785.434 grammes (58418.1444 grains) of water at the temperature of its maximum density, weighed *in vacuo**" —(*U. S. P.*).

"The weights and measures *referred to by physicians in prescribing, and used by pharmacists in dispensing medicines*, are, in the United States, the Apothecaries' Weights and Fluid Measures, and those of the Metric System."

"The Apothecaries' Weights and Fluid Measures used in the United States are the same as those used in England prior to 1825, the weights being originally derived from the Old English Troy Weight, and the Fluid Measures from the Wine Measure" —(*U. S. P.*).

"The Apothecaries' grain is identical in value with the Troy grain, the American commercial grain, and the grain of the British Imperial System"— (*U. S. P.*).

All merchandise sold by weight, except the precious metals and precious stones, is now bought and sold by Avoirdupois weight in all English-speaking countries. Precious metals and jewelry are sold by Troy weight; the latter is also in use in the British and United States Mints. Avoirdupois weight is also called Imperial weight in Great Britain. The term "pound," used in the present *Dispensatory*, refers to "avoirdupois," unless stated otherwise. O. Oldberg's *Manual of Weights and Measures*, 2d ed., 1887, Chicago, was freely consulted in the compilation of the subjoined tables; however, the figures below given are revised, as far as possible, according to the standards laid down in the *U. S. P.*, 1890, and the *Br. Pharm.*, 1898.

TROY WEIGHT.

Pound	Ounces.	Pennyweights.	Grains.	Grammes.	
1	12	240	5760	373.241664	0.822856 pound (av.).
	1	20	480	31.103472	1.097143 ounces (av.).
		1	24	1.5551736	24 grains (av.).
			1	0.0647989	1 grain (av.).

APOTHECARIES' WEIGHT.

Differs from the Troy System by the adoption of drachms and scruples, and the nonrecognition of pennyweights.

Pound.	Ounces.	Drachms.	Scruples.	Grains.	Grammes.	
℔ 1	12	96	288	5760	373.241664	0.822856 lb. (av.)=1 lb. (troy).
	℥ 1	8	24	480	31.103472	1.097143 ozs. (av.) = 1 oz. (troy).
		ʒ 1	3	60	3.887934	2.194286 drachms (av.).
			℈ 1	20	1.295978	20 grains (av.).
				gr 1	0.0647989	1 grain (av.) = 1 grain (troy).

AVOIRDUPOIS WEIGHT.

Ton	Hundredweights.	Stones.	Pounds (av.).	Ounces.	Drachms.	Grains.	Grammes.	
1	20	160	2240					
	1	8	112					
		1	14					
			1	16	256	7000	453.5924277	1.215278 lb. (troy).
				1	16	437.5	28.349527	0.911458 oz. (troy).
					1	27.34375	1.771845	1.13932 dwt. (troy).
						1	0.0647989	1 grain (troy).

---

* While the liquid gallon of the United States is designed to be a volume of 231 cubic inches, it is determined or adjusted by weight on the assumption that 252.892 grains of water, at its maximum density, weighed *in vacuo*, measure one cubic inch. If the theoretical kilogramme (the weight of one cubic decimeter of water at its maximum density, *in vacuo*) and the actual International Standard Kilogramme (the equivalent of which in terms of English weight is 15432.35639 grains) are identical values, then, as 39.370 inches equal one meter, the weight of a cubic inch of water at its maximum density, *in vacuo*, is 252.892 grains, and from this value the weight of 231 cubic inches of water at its maximum density, *in vacuo*, is found. These values are those employed by the Office of Standard Weights and Measures of the United States" —(*U. S. P.*).

WINE MEASURE, APOTHECARIES', OR U. S. LIQUID MEASURE.

Is now used in the United States exclusively.

Gallon.	Quarts	Pints.	Gills.	U. S. Fluid ounces.	U. S. Fluid drachms.	Minims.	Corresponding weight of water at 4° C. in grains.	Cubic inches.	Cubic centimeters.	Imperial measure.
1	4	8	32	128	1024	61440	58418.1444	231	3785.434	0.83321 gal.
	1	2	8	32	256	15360	14604.5361	57.750	946.3585	0.83321 qt.
		1	4	16	128	7680	7302.268	28.875	473.17925	0.83321 pt.
			1	4	32	1920	1825.567	7.21875	118.2948	0.83321 gill.
				1	8	480	456.392	1.8047	29.5737	1.04151 fl. ozs.
					1	60	57.0489	0.2256	3.696	1.04151 fl. drs.
						1	0.9508	0.00376	0.0616	1.04151 mins.
								1	16.387	

IMPERIAL MEASURES AND WEIGHTS.

The fluid measures of this system are not used in the United States; the weights are Avoirdupois.

Bushel.	Pecks.	Gallons	Pottles.	Quarts.	Pints.	Gills.	Fluid ounces.	Fluid drachms.	Minims.	Cubic inches.	Metric.	Corresponding weight of water at 16⅔° C. (62° F.).	U. S. Liquid measure.
1	4	8	16	32	64	256	1280	10240	614400	2217.920	36.3677048 liters.

(For detailed tables, giving the equivalents of Metric weights and measures [from 1000 Gm. and Cc. downward], with the Avoirdupois and Troy systems, see *U. S. P.*, 1890.)

By means of the foregoing tables, the measures and weights of one system may be converted into their equivalents in other systems. Each table contains the factor necessary in calculating the conversion—for example, to convert Troy ounces into Avoirdupois ounces, multiply by 1.097143, or, approximately, add one-tenth.

To convert Imperial fluid ounces, fluid drachms, and minims, approximately. into the corresponding Wine (U. S.) measures, deduct 4 per cent; in the reversed case, add 4 per cent.

To convert grains, approximately, into grammes, multiply by 0.065; or divide by 15.4; more precisely, multiply by 0.0647989 (see table). To convert grammes, approximately, into grains, multiply by 15.4.

To convert inches, approximately, into millimeters, multiply by 25; or, more precisely, by 25.39977 (see table); to convert millimeters into inches, divide by this number.

The following is a brief abstract of the foregoing tables:

1 grain (troy)	=	1	grain (av.)	=	0.0648	gramme =64.8 milligrammes.
1 ounce (troy)	=	480	grains	=	31.1	grammes.
1 ounce (av.)	=	437.5	grains	=	28.35	grammes.
1 pound (troy)	=	7000	grains	=	373.24	grammes.
1 pound (av.)	=	5760	grains	=	453.59	grammes.
1 gallon (U. S.)	=	231	cubic in.	=	3.785	liters.
1 gallon (Imp.)	=	277.2	cubic in.	=	10 lbs. (av.) = 70000 grs. = 4.543 liters.	
1 fluid ounce (U. S.)	=	480	minims (U.S.)	=	29.574	cubic centimeters.
1 fluid ounce (Imp.)	=	480	minims (Imp.)	=	28.41	cubic centimeters.
1 foot	=	12	inches	=	30.48	centimeters.
1 inch	=	12	lines	=	25.4	millimeters.
1 liter	=	0.264	gallon (U.S.)	=	0.220	gallon (Imp.).
1 gramme	=	15.43	grains.			
1 kilogramme	=	2	pounds (Met.)	=	1000	grammes = 2.20 pounds (av.).
1 pound (Metric)	=	500	grammes	=	1.10	pounds (av.).

APPROXIMATE MEASUREMENTS.

A teacup contains about 3½ or 4 fluid ounces; a wineglass contains about 1½ or 2 fluid ounces; a tablespoon about 3½ or 4 fluid drachms; and a teaspoon about 50 minims or 1 fluid drachm. But these are very uncertain methods of measuring, especially where accuracy is required.

Drops are frequently supposed to be equal to minims, but this is not the case; 1 drop of some fluid substances will exceed 1 minim, while that of others will fall considerably below it. The same fluid may vary in the size of its drops, according to the size or form of the edge of the vessel from which it is dropped.

TABLE OF PROPORTIONATE DOSES

AT DIFFERENT AGES.

(GAUBIUS' TABLE.)

			Examples.	
Under ½ year	1-15th	of a full dose,	or 4	grains.
Under 1 year	1-12th	of a full dose,	or 5	grains.
Under 2 years.	1-8th	of a full dose,	or 7½	grains.
Under 3 years	1-6th	of a full dose,	or 10	grains.
Under 4 years	1-5th	of a full dose,	or 12	grains.
Under 7 years	1-3d	of a full dose,	or 20	grains.
Under 14 years	1-half	of a full dose,	or 30	grains.
Under 20 years	2-3ds	of a full dose,	or 40	grains.
Under 21 years	the full dose,		or 1	drachm.
Under 63 years	11-12ths	of a full dose,	or 55	grains.
Under 77 years	5-6ths	of a full dose,	or 50	grains.
Under 100 years	2-3ds	of a full dose,	or 40	grains.

The following is the more simple rule of Dr. Young:

"For children under 12 years, the dose of most medicines must be diminished in the proportion of the age to the age increased by 12. Thus, at 2 years, the dose will be $\frac{1}{7}$ of that for adults, viz: $\frac{2}{2+12}=\frac{1}{7}$. At 21 the full dose may be given."

To the above rule there are certain exceptions; thus castor oil requires to be given in larger proportionate doses, while opium and narcotics generally should be administered in smaller proportionate quantities.

Sex, temperament, and *idiosyncrasy* have also a modifying effect upon the dose, and they should always be kept in view in the administration of medicines. Females usually require smaller doses than males; and persons of sanguine temperament bear depletory medicines better than the phlegmatic.

TO DIVIDE MEDICINES INTO FRACTIONS OF A GRAIN.

1. Divide 1 grain of strychnine into doses of $\frac{16}{25}$ each.

Take of starch (or other inert or insoluble powder), 24 grains; strychnine, 1 grain; mix, and triturate thoroughly together, and then weigh out 16 grains of the mixture, which will be equal to $\frac{16}{25}$ grain of strychnine. Or, for a solution, take of distilled water, 49 minims; nitric or phosphoric acid, 1 minim; strychnine, 1 grain. Mix. When the strychnine is dissolved, 32 minims of the solution will be equal to $\frac{32}{50}$ or $\frac{16}{25}$ grain of the alkaloid.

2. Required a dose of an alkaloid, $\frac{8}{15}$ grain.

Take of starch (or other inert powder), 14 grains; of the alkaloid, 1 grain; mix, and triturate thoroughly together. Eight grains of the mixture will equal $\frac{8}{15}$ grain of the alkaloid. Or, for a tincture, take of alcohol, 30 minims; of the alkaloid, 1 grain; mix, and dissolve the alkaloid. Sixteen minims of the solution will be equal to $\frac{16}{30}$ of $\frac{8}{15}$ grain of the alkaloid. Or, for a solution, take of distilled water, 150 minims; of the alkaloid, 1 grain. Mix. Eighty minims of this solution is equal to $\frac{80}{150}$ or $\frac{8}{15}$ grain of the solution.

3. Required $\frac{7}{16}$ grain of chloride of gold and soda to add to 1 fluid ounce of water.

Take of chloride of gold and sodium, 1 grain; starch (or finely-powdered pumice stone, sand, or emery, etc.), 15 grains; mix, triturate well together, and then weigh out 7 grains, equal to $\frac{7}{16}$ of the gold salt, and add it to the water, which will dissolve this salt, but not the emery, or pumice, etc.

N. B.—The balance of the triturated medicine, not employed, should be kept for future use in a small vial, with the proportions of medicine and inert powder labeled upon it. In all cases where solutions or tinctures are to be made, and it is not desirable to have other matters to enter therein, triturate with some insoluble material, and when the solution is made, filter. Powdered emery, pumice-stone, sand, etc., may be used when the article is to be dissolved in water; and if in alcohol or ether, powdered starch, gum Arabic, tragacanth, or sugar of milk, etc.

4. Dissolve $10\frac{4}{15}$ grains of atropine in 1 pint of alcohol.

First, weigh out 10 grains of atropine and add it to the alcohol.

Second, triturate 1 grain of atropine with 14 grains of powdered pumice stone, and of this mixture add 4 grains to the alcohol, making $10\frac{4}{15}$ grains of atropine that have been added to the fluid. Filter, if required.

TABLE FOR DETERMINING WHAT QUANTITY OF MEDICINE, AT A GIVEN DOSE, IS REQUIRED TO ENTER INTO THE FORMATION OF A DEFINITE NUMBER OF PILLS OR POWDERS.

EXAMPLE.—I. How much will it require to make 48 pills or powders of podophyllin, at ¼-grain dose: quinine, at ½-grain dose; citrate of iron, at 1-grain dose; and cimicifugin, at 1-grain dose?

Answer: Podophyllin, (dose, ¼ grain)=grains, 12
Quinine, (dose, ½ grain)=grains, 24
Citrate of Iron, (dose, 1 grain)=grains, 48
Cimicifugin, (dose, 1 grain)=grains, 48

II. How many doses will 3 grains of strychnine make at 1/20 grain for a dose? Answer: 60.

Trace along the line from 1/20, the size of the dose, until 3 grains is reached, and, on looking at the top of the column in which it is placed, the answer 60 will be found.

TABLE OF DOSES IN SOLUTION.

Table for determining the quantity of a medicinal agent required to enter into a definite amount of fluid, which is to be administered in certain doses, each dose holding a given quantity of said agent.

QUANTITY OF MEDICINE REQUIRED IN FLUID.

EXPLANATION.

The preceding table is designed to facilitate the determination of how much medicine, in a given dose, must be added to a required quantity of fluid, so that this fluid may be prescribed in doses of a certain amount. (1) The *given dose of the medicine* will be found in the first column, at the left of the brackets, or, in other words, the *quantity* of the *medicinal agent* required to be taken with each dose of the mixture or solution into which it enters; (2) the *dose of the fluid solution* of this medicine will be found in the first column, inclosed within the brackets, or in other words, the *size* of the dose of the *mixture* or *solution* prescribed; (3) the quantity of *fluid required* or *prescribed* to form the solution will be found at the heads of the other columns; and (4) the *quantity of the medicine which must be added* to the required or prescribed amount of fluid will be found in the column under the head of such amount. Thus:

I. It is desired to give 4 fluid ounces of liquid to a patient, to be taken in ½-fluid-drachm doses, each dose to contain strychnine, $\frac{1}{30}$ grain; quinine, ½ grain; morphine, ⅛ grain. How much of each of these alkaloids must be added to the 4 fluid ounces prescribed? As already explained, find the given dose of the strychnine, $\frac{1}{30}$ grain, and opposite to it, inclosed within the bracket, find the dose of the fluid solution, viz., ½ fluid drachm; from which follow out the line until the column under 4 fluid ounces has been reached, when it will be found that $2\frac{2}{15}$ grains of strychnine will be required. Again, find the given dose of the quinine, grain ½, and inclosed within its brackets also find the dose of the fluid solution, viz., ½ fluid drachm; from this, trace along the line as before, and in the column under 4 fluid ounces the quantity of fluid prescribed, will be found the required amount of quinine, viz., 32 grains. For the morphine, find the given dose, grain ⅛, then the ½ fluid drachm inclosed in its bracket, and tracing along, as before, the quantity of this alkaloid required will be found, 8 grains.

II. It is desired to prescribe 2 ounces of fluid to be taken in doses of 10 minims, each dose to contain $\frac{1}{50}$ grain of an alkaloid; how much of the alkaloid must be contained in the 2 fluid ounces? As $\frac{1}{50}$ grain is not in the table, find $\frac{1}{25}$ grain, and on the 10 minims line under 4 fluid ounces will be found $7\frac{17}{25}$ grains, or the quantity required, were the given dose of the alkaloid $\frac{1}{25}$ for 4 fluid ounces; one-half of which will be the amount of the alkaloid, at $\frac{1}{25}$-grain dose, for 2 fluid ounces, viz., $3\frac{21}{25}$ grains; and one-half of this again will be the quantity of the alkaloid, at $\frac{1}{50}$-grain dose, for 2 fluid ounces, viz., $1\frac{23}{25}$.

III. It is desired to add 2 grains of veratrine to a fluid, to be administered in 20 minim doses, each dose to contain $\frac{1}{25}$ grain of veratrine. How much of the fluid will be required for the 2 grains? Find the given dose, $\frac{1}{25}$ grain, and the dose of the fluid, 20 minims; follow this line until the amount nearest to 2 grains is found, which in the present instance will be $3\frac{21}{25}$ grains, in the column under 4 fluid ounces; $3\frac{21}{25}$ grains is $1\frac{21}{25}$ grains more than 2 grains, or an excess of $\frac{46}{25}$ grains=46 doses. By the following table it will be seen that 4 fluid ounces contain 96 doses of 20 minims each; subtract from this the excess of 46 doses, and

50 doses remain for the 2 grains, and as each dose is to consist of 20 minims of the solution, 50 doses will be=1000 minims=16 drachms and 40 minims of fluid. The same result may be obtained as follows: One dose is to contain $\frac{1}{25}$ grain, therefore 2 grains will give $\frac{50}{25}$, or 50 doses, which being multiplied by the number of minims required for each dose (20), will give 1000 minims=16 drachms and 40 minims.

IV. How much fluid will be required for 12 grains of morphine; the fluid to be given in 20-minim doses, each containing ½ grain of morphine? Answer: 1 ounce.

V. I have 1 ounce of iodide of ammonium which I desire to give in solution in doses of 1 teaspoonful containing 2 grains each; how much water will the ounce of iodide require?

Find the given dose of the iodide, *i. e.*, 2 grains, and the line containing the dose of the fluid, *i. e.*, 1 drachm; follow this line along until the column containing 1 ounce, or 8 drachms, is found, and at the top of this column will be found the required answer, viz., 30 ounces of fluid.

TABLE FOR DETERMINING THE NUMBER OF DOSES THERE ARE IN A DEFINITE AMOUNT OF FLUID MEDICINE, WHEN GIVEN IN A CERTAIN DOSE.

NUMBER OF DOSES IN

SIZE OF DOSE.	℥ 1	℥ 4	℥ 8	1 Pint.	℥ 20	℥ 24	℥ 30	2 Pints.

Ounces 2		2	4	8	10	12	15	16

How many doses of 15 minims, each, are there in 24 ounces of fluid?

By following the dose (15 minims), in the first line along, until the column under 24 ounces is reached, the answer will be found, viz.: 768 doses.

How many drachm doses are there in 30 ounces of fluid? Answer: 240.

TABLE FOR DETERMINING HOW MUCH FLUID MEDICINE MUST BE GIVEN TO A PATIENT TO LAST FOR A DEFINITE LENGTH OF TIME, WHEN TAKEN IN A CERTAIN DOSE, WHICH IS TO BE REPEATED THREE TIMES EVERY DAY.

Thus, 8 drops of a fluid, repeated 3 times a day, will require 1½ ounces to last a month. The small figures to the right of the drachms signify minims.

N. B.—A drop here is considered equal to a minim.

Size of Dose 3 times a day.	Quantity required for 2 weeks or 15 days.			Quantity required for 1 month.			Quantity required for 6 weeks.			Quantity required for 2 months.			Quantity required for 10 weeks.			Quantity required for 3 months.

EXAMPLE.

It is desired to give a patient enough fluid to last 6 weeks, to be taken in teaspoonful doses 3 times a day, each dose to contain 1 grain of quinine and ⅓ grain of morphine. What quantity of fluid must be given, and what proportions of quinine and morphine must it contain?

By the above table, a teaspoonful or drachm dose, given 3 times a day, will require 1 pint and 7 drachms of fluid to last for 6 weeks. Now, by referring to table on page 2161, on a line with the given dose, 1 grain, it will be found that for drachm doses 1 pint will require 2 drachms and 8 grains of the medicine, while 8 drachms or 1 ounce will require 8 grains, making 2 drachms and 16 grains; but as only 7 drachms are required, or 1 drachm less than the ounce, the amount of the dose for the superfluous drachm, which contains 1 grain, must be deducted, making 2 drachms and 15 grains of quinine. Again, by referring to the given dose, ⅓ grain, in same table, and following the line of drachm doses, it will be found that 1 pint will require 42⅔ grains, while 8 drachms will require 2⅔ grains, making in all 45⅓ grains; from which deduct the superfluous drachm, which contains ⅓ grain, and the result will be 45 grains of morphine.

TABLE OF ATOMIC WEIGHTS.

For further tables, giving specific gravity and percentage of solutions of Acetic, Hydrobromic, Hydrochloric, Nitric, Phosphoric, and Sulphuric Acids, as well as of Ammonia Water, **Potassium Hydrate**, and **Sodium Hydrate**, see *United States Pharmacopœia.*

SHOW COLORS FOR DRUGGISTS' SHOP WINDOWS.

BLUE.

No. 1.—Sulphate of copper, ℥j; sulphuric acid, ℥ss; water, ℥x.

No. 2.—Ammonio-sulphate of copper, ammonio-nitrate of nickel (see No. 5), and water.

No. 3.—Prussian blue, gr. x; oxalic acid, gr. xx; water, ℥xvj.

No. 4.—Dissolve nickel in diluted sulphuric acid, add ammonia in excess, and dilute with water.

No. 5.—Dissolve nickel in diluted nitric acid, add ammonia in excess, and dilute with water.

No. 6.—To the green color made by formula No. 8 under that color, add sufficient aqua ammoniæ to make it blue.

No. 7.—Dissolve sulphate of indigo in water.

GREEN.

No. 1.—Sulphate of copper, ℥ij; chloride of sodium, ℥iv; water, ℥xx.

No. 2.—Dissolve ℥j of nickel in ℥vj of nitric acid, and add Ov of water.

No. 3.—Dissolve nickel in dilute sulphuric acid, and dilute with water.

No. 4.—Dissolve sulphate of copper in water, and add bichromate of potassium until the required color is produced.

No. 5.—Dissolve ammonio-sulphate of copper in water, and add bichromate of potassium until the required color is produced.

No. 6.—Dissolve sulphate of copper in water, and add nitric acid until the required color is produced.

No. 7.—Dissolve verdigris in acetic acid, and dilute with water.

No. 8.—Dissolve a copper cent in nitric acid, and add enough of the solution to water or proof-spirit to give it the right shade.

No. 9.—Add distilled water and sulphate of copper to a strong decoction of turmeric.

LILAC.

No. 1.—Dissolve zaffre (impure oxide of cobalt) in hydrochloric acid, filter and add carbonate of ammonium in excess; to this add ammonio-sulphate of copper until the required color is produced.

No. 2.—Dissolve zaffre in hydrochloric acid, filter, and add carbonate of ammonium in excess; to this add ammonio-nitrate of nickel (see *Blue* No. 5) until the required tint is produced.

ORANGE.

No. 1.—Dissolve bichromate of potassium in water until the required tint is produced.

No. 2.—The same as No. 1, but adding some oil of vitriol, or hydrochloric acid.

PINK

No. 1.—Dissolve ℥ij of zaffre in ℥vj of hydrochloric acid, filter, add solution of carbonate of ammonium in excess; then add fl℥j of liquor potassæ, and dilute with water to produce the required color.

No. 2.—Nitrate of cobalt may be used, with carbonate of ammonium, in the same way as the preceding.

PURPLE.

No. 1.—Sulphate of copper, ℥j; carbonate of ammonium, ℥jss; water, Oijss.

No. 2.—The last color, with a small quantity of the *Pink* No. 1.

No. 3.—Dissolve permanganate of potassa in water.

No. 4.—Dissolve verdigris 2 drachms, and aqua ammoniæ 4 fluid ounces, in 1½ pints of water.

No. 5.—Acetate of lead, 1 ounce; powdered cochineal, 1 scruple; water, a sufficient quantity until the required tint is produced.

YELLOW.

No. 1.—Bichromate of potassium, ʒvj; carbonate of potassium, ʒiv; water, ℥xvj.

No. 2.—Add a sufficient quantity of tincture of iodine to alcohol or proof-spirit to make a bright straw color.

No. 3.—Dissolve iron in hydrochloric acid, and dilute with water.

No. 4.—Dissolve Indian yellow in water.

No. 5.—Pour boiling water on powdered turmeric, and filter. A small quantity of any alkaline solution converts it into a *brown* color.

VIOLET.

Ammonio-sulphate of copper, diluted with water, and enough of the pink color No. 1 to produce the required tint.

RED.

No. 1.—Macerate powdered cochineal in spirit of hartshorn, and dilute it with water.

No. 2.—Dissolve carmine in solution of ammonia, and dilute it with water.

No. 3.—Wash the best madder two or three times with cold water, then macerate it in solution of carbonate of ammonium, filter the solution, and dilute it with water

No. 4.—Dissolve madder lake in solution of carbonate of ammonium.

No. 5.—Add a sufficient quantity of tincture of iodine to alcohol or proof-spirit, to produce the desired color. Should it fade renew the color by adding more tincture of iodine.

No. 6.—Dissolve carmine in water to which a little chloride of tin has been added.

No. 7.—To a solution of sal ammoniac add a sufficient quantity of cochineal.

No. 8.—Boil a red beet in water, dilute it to the required tint, and brighten it with a little acetic acid.

N. B.—Alcohol answers better for colors than water or proof-spirit, as there is seldom any precipitate or decomposition; beside, as it does not freeze in winter, there is no breaking of the show-bottles, which is apt to ensue when water is used. Many show colors can now be made also from aniline dyes, by dissolving them in water or alcohol.

GENERAL INDEX
