KING'S
AMERICAN DISPENSATORY

BY

HARVEY WICKES FELTER, M. D.

ADJUNCT PROFESSOR OF CHEMISTRY, PHARMACY, AND TOXICOLOGY, AND PROFESSOR OF ANATOMY, IN
THE ECLECTIC MEDICAL INSTITUTE, CINCINNATI, OHIO; EDITOR OF LOCKE'S SYLLABUS
OF MATERIA MEDICA AND THERAPEUTICS; EX-PRESIDENT OF THE OHIO
STATE ECLECTIC MEDICAL ASSOCIATION, ETC., ETC., ETC.

AND

JOHN URI LLOYD, PHR M., PH. D.

PROFESSOR OF CHEMISTRY, PHARMACY, AND TOXICOLOGY, IN THE ECLECTIC MEDICAL INSTITUTE,
CINCINNATI, OHIO; FORMERLY PROFESSOR OF CHEMISTRY AND PHARMACY IN THE CINCINNATI
COLLEGE OF PHARMACY; EX-PRESIDENT OF THE AMERICAN PHARMACEUTICAL
ASSOCIATION; AUTHOR OF THE CHEMISTRY OF MEDICINES; DRUGS AND
MEDICINES OF NORTH AMERICA; A STUDY IN PHARMACY;
ETIDORHPA, ETC., ETC., ETC.

ENTIRELY REWRITTEN AND ENLARGED.

NINETEENTH EDITION. THIRD REVISION.

IN TWO VOLUMES.

VOL. II.

CINCINNATI:
THE OHIO VALLEY COMPANY,
317–321 RACE STREET.
1905.

AUTHORIZATION.

Resolution passed by the National Eclectic Medical Association at the annual meeting, in Cleveland, Ohio, June 19, 1879:

Resolved, That this Association adopt THE AMERICAN DISPENSATORY as its STANDARD AUTHORITY.

ALEXANDER WILDER, M. D., *Secretary*.

"AUTHORITY to use for comment the *Pharmacopœia of the United States of America* (1890), Seventh Decennial Revision, has been granted by the Committee of Revision and Publication."

AUTHORITY to print selections from the *National Formulary*, has been granted by the Council of the American Pharmaceutical Association.

COPYRIGHTS.

PRINTED AND BOUND
BY
THE OHIO VALLEY COMPANY,
CINCINNATI.

LIST OF ILLUSTRATIONS.

ABBREVIATIONS.

Endeavor has been made to extend full credit in the text by means of abbreviations, most of which are self-explanatory. The following selective list may assist some readers:

GALANGA.—GALANGAL.

The rhizome of *Alpinia officinarum*, Hance.

Nat. Ord.—Scitamineæ (Zingiberaceæ).

COMMON NAMES: *Colic root, East India root, Galangal.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 271.

Botanical Source and History.—The plant that yields galangal was described by Mr. H. F. Hance, in the *Journal of the Linnæan Society* (1871). The plant was obtained from Hainan, an island directly south of China, but it also doubtless grows on the adjacent mainland, as the root is largely exported from Shanghai and other China ports. The galangal of commerce is known as *Lesser galangal;* another variety known as *Greater galangal*, is rarely found in the market. It is the product of *Alpinia Galanga*, Willdenow, (*Maranta Galanga*, Linné), and grows in Java. The name *galangal* is said to be derived from the Arabic *Khanlanjan*, which, in turn, is perhaps the perversion of a Chinese word, signifying mild ginger. Galangal has long been an article of commerce with the Eastern nations, and has been known in Northern Europe since the twelfth century (Hance). The stem is from 2 to 4 feet high, erect, and bears a close resemblance to the common cultivated canna, or shot plant. The parallel-veined leaf blades are about a foot long, 2 to 4 inches wide, smooth, entire, and sharply acuminate. They are attached at the base to a scarious, margined sheath, which clasps the stem. The flowers are borne in a terminal dense spike; they consist of a short, tubular, superior calyx, a white corolla, with 3 lobes, a large ovate labellum marked with red veins, a single anther-bearing stamen, and a pistil with an inferior ovary and a slender style (Bentley and Trimen, *Med. Plants*).

Fig. 116.

Root of Alpinia officinarum.

Description.—The rhizome, as found in market, is in sections of from 1 inch to 4 inches in length, and of a reddish-brown color, as though covered with rust. The cut ends are usually rounding, while the edges expand outwardly and turn back. Each fragment has, generally, one or more short branches, and it is evident that the roots are taken from the ground in masses, and chopped into pieces. Encircling them at intervals of from ¼ to ½ inch apart, are corrugated rings of a light color consisting of adhering bases of leaf sheaths. The roots are stout, and break with a granular fracture presenting a brownish-gray color, interspersed throughout which are small ligneous fibers. These fibers project a short distance beyond one surface of the root, thus leaving depressions on the opposite side, resembling pin-holes; the center of the root, for about one-fourth to one-third of its diameter, consists of a bundle of these fibers. Galangal reminds us of ginger, and imparts a pungent taste and an aromatic odor, very similar to that article. In this country, galangal has not come into use among physicians, but has been sold extensively by street-corner venders under such names as "colic root," "the wonderful East India root," etc., and was asserted by them to be a certain cure for toothache, headache, etc.

Chemical Composition.—The constituents of galangal are similar to those of ginger. A volatile oil is obtained by distilling the root with water, which possesses a camphoraceous smell resembling that of cajeput oil. This is due, according to Schimmel & Co. (1890), to the presence of appreciable amounts of *cineol.* It is soluble in alcohol, and is lighter than water. A soft resin, having a pungent taste, is extracted by ether, and also a peculiar, crystalline substance, named by Brandes (1839), *kæmpferid*. Jahns (1881) differentiated the kæmpferid of Brandes into three compounds, all forming yellow crystals, viz., *kæmpferid* ($C_{16}H_{12}O_6$), fusing at 222° C. (431.6° F.), almost insoluble in water, and soluble with difficulty in alcohol; *galangin* ($C_{15}H_{10}O_5$), fusing at 214° C. (417.2° F.), soluble in 34 parts of absolute and 68 parts of 90 per cent alcohol; and *alpinin* ($C_{17}H_{12}O_6$), fusing at 173° C. (343.4° F.).

Kæmpferid, by oxidation with nitric acid, forms *anisic acid* ($C_6H_4[OCH_3]COOH$), oxalic acid and other products. *Galangin* similarly yields benzoic and oxalic acids (*Amer. Jour. Pharm.*, 1882, p. 288). Kostanecki and Harry M. Gordin

(*Dissert.*, 1897), showed *kæmpferid* to be a flavonol derivative and established its exact graphic formula. Probably galangin is similarly constituted. Thresh (*Pharm. Jour. Trans.*, Vol. XV., 1884, p. 234), announced the presence of a pungent principle, which he designated *galangol*, and gave the tabulated results of a complete analysis of the root, which shows as much as 23.7 per cent of starch.

Action, Medical Uses, and Dosage.—Galangal is a stimulating aromatic, and has been successfully employed to aid the digestive process, preventing fermentation and removing *flatus*. It will be found especially useful in some forms of *dyspepsia*, preventing vomiting or sickness of the stomach, and facilitating digestion. It may be used in all cases in which a stimulating aromatic is indicated. It has some reputation as a remedy for *perineal relaxation* with *hemorrhoids*, and for a *lax* and *pendulous abdomen*. Its best form of administration is in tincture, the dose of which is from ½ to 1 fluid drachm. The powder may be given in doses of 15 to 20 grains; from 30 to 60 grains may be given in infusion. It is rarely prescribed at the present day.

GALBANUM.—GALBANUM.

The gum-resin of *Ferula galbaniflua*, Boissier and Buhse; *Ferula rubricaulis*, Boissier; and probably from other related species.

Nat. Ord.—Umbelliferæ.

SYNONYM: *Gummi-resina galbanum.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 128.

Botanical Source.—*Ferula galbaniflua* is a north Persian plant having a solid, tall stem about 4 or 5 feet high. The leaves are grayish-tomentose, the radical ones being triangular in outline, and decompound-pinnate, pinnatifid, the sections being linear-obtuse. The radical leaves are large and the stem leaves small. The fruit is thin and flat, winged near the face, has slender, prominent ribs, and in the grooves presents single oil-tubes. Sometimes two narrow tubes are present. The commissure has no tubes.

Ferula rubricaulis is a south Persian plant, probably growing to some extent in northern Persia also. It has been classed with the preceding by some botanists, while others accord to it a separate place. It differs chiefly in the greater width of the leaf segments, and in having more numerous and narrower oil-tubes.

History and Description.—The plant from which the gum-resin *Galbanum* is obtained, is not definitely known. The *British Pharmacopœia* (1898) mentions the above-named species and refers to the probability of other species of *Ferula* yielding it. That the *Ferula galbaniflua* is believed to yield it is due to the statement of F. A. Buhse, a German resident of Persia, who relates that in 1848 (see Flückiger, 1891), he was informed that the product spontaneously exudes from the plant in question, and was told by the natives that it was the source of galbanum. Galbanum is imported from the Levant, and from India in cases and chests. It is generally met with in lumps, consisting of large, irregular masses of a brownish or dark-brownish color, and composed of agglutinated tears, some few of which, when broken, are somewhat translucent; they have a waxy density, but become soft and sticky at a temperature of 35° to 37.7° C. (95° to 100° F.), are not pulverizable unless in very cold weather, have a strong, unpleasant odor, and a hot, somewhat acrid, and amarous taste. Occasionally, galbanum is met with in the form of oval, globular, or irregular tears. On account of the impurities it contains, it should be melted and strained previous to employing it. When the color of galbanum is dark-brown or blackish, and when it contains an admixture of sand, straw, chips of wood, and other foreign matters, the article should be rejected as being inferior. The specific gravity of galbanum is 1.212. Galbanum is partially dissolved by water, vinegar, or wine, forming therewith an emulsion. Alcohol dissolves about three-fifths of it, the residue being gum and impurities. Diluted alcohol is its best solvent.

Chemical Composition.—According to Pelletier, galbanum contains 6 per cent volatile oil, 67 per cent resin, 19 per cent gum, and 8 per cent foreign matter (H. and H.). The *volatile oil* consists mainly of a hydrocarbon of the terpene series, $C_{10}H_{16}$. According to Mössmer its boiling point is between 160° and 165° C.

(320° and 329° F.). It is dextro-rotatory, colorless, has a specific gravity of 0.884, and forms crystals with gaseous hydrochloric acid. Probably other hydrocarbons are also present. The yellow-brown *resin* of galbanum may be obtained (Flückiger, *Pharmacognosie*, 1891, p. 65), by extracting galbanum with alcohol and distilling off the solvent. The residual resin is also soluble in carbon disulphide in commercial but not quite in absolute ether, and in caustic soda. Upon destructive distillation galbanum resin yields an aqueous fraction containing fatty acids, and a thick blue oil of the composition $C_{20}H_{30}O$, or more probably $C_{10}H_{16}O$, after removing therefrom a hydrocarbon $C_{10}H_{16}$ (Kachler, 1871). The blue oil boils at 289° C. (552.2° F.), and holds in solution or suspension a crystalline body which Sommer (1859) named *umbelliferon*. This substance is a common constituent of the products of the dry distillation of such gum-resins as asafœtida, sagapenum and opopanax, and those derived from *Imperatoria Ostruthium*, *Angelica Archangelica*, etc., all being umbelliferous plants, hence the name. An occurrence exceptional to this rule was observed in the non-umbelliferous plant, *Daphne Mezereum* (Zwenger, 1854).

Umbelliferon may be abstracted from the blue oil by means of boiling water, or by slightly alkaline water. It may also be obtained from galbanum resin direct by heating it with hydrochloric acid to 100° C. (212° F.), abstracting with chloroform and evaporating the solvent. *Umbelliferon* ($C_9H_6O_3$), is closely related to *coumarin*, being *para-oxycoumarin*. It is hardly soluble in cold, soluble in 100 parts of boiling water, little soluble in ether, soluble in alcohol. It melts at 224° C. (435.2° F.), developing thereby an aromatic smell. In aqueous solution it exhibits a bluish fluorescence markedly increased by alkalies. Its solution in concentrated sulphuric acid is likewise beautifully fluorescent. When boiled with caustic potash umbelliferon is decomposed into *resorcin* (*meta-dioxy-benzene*) ($C_6H_4[OH]_2$), and formic and carbonic acids. *Resorcin* is likewise formed when galbanum resin is fused with caustic potash, and was discovered by this reaction in 1866, by Hlasiwetz and Barth. It enters into the composition of many dyestuffs, especially fluoresceine (which see), and has been produced since on the manufacturing scale. When boiled with nitric acid, galbanum resin yields *trinitroresorcin* or *styphnic acid* ($C_6H[NO_2]_3[OH]_2$). Galbanum gum may be obtained by exhausting the drug with alcohol, and extracting the residue with water. The aqueous solution is optically inactive (Hirschsohn), and is precipitated by basic, but not by neutral acetate of lead.

A distinctive test for galbanum is as follows: Extract its resin by means of carbon disulphide, dissolve it in alcohol, and gently warm with hydrochloric acid of sp. gr. 1.15. The mixture then assumes a beautiful blue color which is evanescent. Galbanum resin, when in prolonged contact (for several hours) with hydrochloric acid of sp. gr. 1.12 or higher, imparts to the latter, especially upon warming, a beautiful red color (Flückiger, *Pharmacognosie*, 1891).

Action, Medical Uses, and Dosage.—The effects of galbanum are similar to those of asafœtida and ammoniac, being weaker than the former, but stronger than the latter. Upon the unbroken skin it produces papules, while it causes ulceration if the skin be broken. It controls *excessive catarrhal discharges*, and causes some arterial tension and cerebral fullness. It has been used in *hysteria*, *chronic rheumatism*, *suppressed menstruation*, *leucorrhœa* and *chronic mucous affections of the air passages;* and may be given in doses of from 10 grains to ½ drachm, in pill form, or in emulsion. Externally, a plaster is sometimes employed, as a mild stimulant and resolvent to *indolent tumors;* and the tincture has been efficient in *scrofulous ophthalmia*, or *irritability* or *weakness of the eyes.*

Related Gum-resins and Drugs.—SAGAPENUM (or *Serapinum* of mediæval times). Sagapenum is imported from the Levant. It is the solidified juice of an unknown plant, probably a *Ferula*, of Persian origin. It is commonly in tears agglutinated together, of a brownish-yellow color, a hot and bitter taste, often alliaceous odor, softens between the fingers, is sparingly soluble in water, not completely soluble in alcohol, and when distilled with water it yields a pale-yellow, very fluid volatile oil, lighter than water, of a strong, alliaceous smell, and a bitter, acrid taste, it is readily soluble in ether and alcohol, and is speedily changed to a transparent resin on exposure to the air. According to Hager (*Handbuch der Pharm. Praxis*, 1886), sagapenum consists of about 50 per cent resin, 30 per cent gum, 5 to 10 per cent volatile oil, and 5 to 8 per cent impurities. Flückiger (*Pharmacographia*), states that sagapenum contains *umbelliferon* but no sulphur, and that it is remarkable for the permanent, intense blue color it assumes in the cold when a very small piece is placed in hydrochloric acid (density 1.13). Sagapenum possesses medicinal properties similar to ammoniac and asafœtida; but is not so powerful as the last of these. It is sometimes added to discutient plasters as a stimulating ingredient. The dose is from 10 grains to ½ drachm.

OPOPANAX.—The gum-resin of *Opopanax Chironium*, Koch (*Pastinaca Opopanax*, Linné). *Nat. Ord.*—Umbelliferæ. This plant, called *Rough parsnip*, is indigenous to the south of Europe. On wounding the stalk-base, or the root, a yellowish lactescent juice exudes and concretes. This is opopanax. The best grade is that which occurs in irregularly angular pieces, or subglobular tears, varying in size, and of a reddish or yellowish brown color. It readily fractures, displaying a waxy interior, and often exhibits imbedded fragments of vegetable tissues. Its odor is strong and disagreeable, and its taste acrid, bitter and balsamic. When warmed it becomes soft, exhaling an onion-like odor. It burns with a bright, non-sooty flame. The poorer qualities are not so bitter as good opopanax, and come in masses larger than a walnut. A specimen of false opopanax has been observed in commerce by J. H. Marais (see *Amer. Jour. Pharm.*, 1875, p. 39), consisting entirely of gum myrrh, which it resembles in appearance. Myrrh changes to a rose color with the vapors of nitric acid, while gum opopanax is not altered by the same treatment. It forms a yellow emulsion with water. Besides vegetable impurities it contains starch (4.2 per cent), wax, volatile oil, resin (42 per cent), and gum (33.4 per cent (Pelletier, *Bull. de Pharm.*, 1812, p. 51). It is seldom used in medicine now, but in olden times was one of the gum-resins thought to be applicable to almost all ills, hence the name *opopanax*, meaning the "all-healing juice." In later times it was used in plasters, and internally in *bronchitis* with abundant expectoration, *asthma*, *hysteria*, *hypochondriasis*, *amenorrhœa*, etc. Dose, from 15 to 30 grains.

Herniaria glabra.—About 1885 a demand was made in this city for Herniaria glabra, the drug being introduced by a specialist for whom the writer procured a supply in England. The remedy is still employed by physicians, several claiming to derive good results from the fluid extract. This is a very old remedy, popular with the early herbalists of England. *Herniarine*, the crystallizable body obtained from this plant has been shown to be *methyl-umbelliferon* ($C_{10}H_8O_3$). *Paronychine*, an alkaloid, has been found in small amounts in the plant by Schneegans (*Amer. Jour. Pharm.*, 1890, p. 488). About the only use the plant now has is in *catarrhal affections of the bladder*. J. H. Schröder (1693) and Samuel Dale (*Pharmacologia*, 7th ed., 1751) refer to the plant as being principally employed to cure *hernia* (hence its name) and to increase the flow of urine. It was also said to increase the flow of bile, and was employed for the cure of *jaundice* and excess of mucus in the stomach (probably *gastric catarrh*). Internally and externally it was praised in *snake-bites*, and the powdered plant was employed to kill maggots upon unhealthy *sores* of horses. It was reputed to "crush" and expel *calculi* from the kidneys and bladder, assisting in their expulsion by carrying with them an enveloping coating of mucus. Its general properties were said to be cooling and drying, and the plant was popularly known as *Breast wort* and *Knot weed*.

GALEGA.—GOAT'S RUE.

The herb of *Galega officinalis*, Linné.
Nat. Ord.—Leguminosæ.
COMMON NAME: *Goat's rue.*

Botanical Source and History.—This is an herbaceous plant, native of southern Europe. It has an erect, perennial, glabrous stem, about 3 feet high, and is found growing mostly in sandy soil. The leaves are alternate, oddly pinnate, and furnished at the base with lanceolate stipules. The leaflets are smooth, lanceolate, and terminate in a mucronate point. The flowers appear in June and July, are blue, and borne in loose, axillary racemes longer than the leaves. The calyx has 5 narrow, equal lobes. The corolla is papilionaceous with an obtuse keel. The stamens are united in one set; the filament of the tenth, however, is distinct for about one-half its length. The fruit is a dry, round, smooth, many-seeded legume.

Tephrosia virginiana, Persoon (see *Tephrosia*), a plant formerly referred to the genus Galega, is a native of the United States, and the root, which is slender and very tough, is reputed to be an anthelmintic. We can not find that either of the aforenamed plants have been examined chemically.

Action, Medical Uses, and Dosage.—Galega has a disagreeably bitter taste, and upon being chewed, imparts a dark-yellowish color to the saliva. Various properties were attributed to it in former times, in which it was considerably employed as a vermifuge, as a stimulant to the nervous system, as a diuretic and tonic in *typhoid conditions*, and is also stated to have been of service in the *plague*, as well as to stimulate the lactiferous vessels to an increased secretion during the period of lactation. It is seldom, if ever, prescribed in practice.

GALIUM.—CLEAVERS.

The herb of *Galium aparine*, Linné, and other species of Galium.

Nat. Ord.—Rubiaceæ.

COMMON NAMES: *Cleavers*, *Goose-grass*, *Catch-weed*, *Bedstraw*, etc.

Botanical Source.—*Galium aparine* is an annual, succulent plant, with a weak, procumbent, quadrangular, retrorsely-prickled stem, which grows from 2 to 6 feet long, and is hairy at the joints. The leaves are 1 or 2 inches in length, 2 or 3 lines in width, verticillate in sixes, sevens, or eights; linear-oblanceolate, nearly sessile, mucronate, tapering to the base, and rough on the margins and midvein; the peduncles are axillary and 1 or 2-flowered; the flowers white, small, numerous and scattered. Calyx 4-toothed, corolla rotate and 4-parted, stamens 4 and short, styles 2. The fruit is large and bristly, with hooked prickles (W.—G.).

History, Description, and Chemical Composition.—This plant is common to Europe and the United States, growing in cultivated grounds, moist thickets, and along banks of rivers, and flowering from June to September. Its root consists of a few hair-like fibers, of a reddish color. There are several species of Galium, all of which possess similar medicinal virtues, as *Galium asprellum*, Michaux, *Rough* or *Pointed cleavers*, which differs from the above in having its leaves in whorls of 4 or 6, and smaller, its fruit smooth, its stem less in length, and is perennial; *Galium verum*, Linné, or *Yellow bedstraw*, with an erect stem, leaves in whorls of 8, root long, perennial, fibrous, flowers densely paniculate, yellow, and terminal; *Galium trifidum*, Linné, or *Small cleavers*, with a perennial root, decumbent stem, herb smaller than the others, leaves in fours or fives, and white flowers; *Galium triflorum*, Michaux, or *Sweet-scented bedstraw* contains *coumarin* ($C_9H_6O_2$), an odorous principle found also in tonka beans, melilotus and other plants; the *Galium tinctorium*, a variety of the G. trifidum, having a stouter and a nearly smooth stem, leaves of the branches in fours, of the stem in sixes; peduncles 2 to 3-flowered; parts of the flowers usually in fours; *G. lanceolatum*, Torrey, and *G. circæzans*, Michaux, are sometimes known as *Wild licorice* on account of their taste.

In a green state these plants have an unpleasant odor, but are inodorous when dried, with an acidulous, astringent, and bitter taste. Cold or warm water extracts the virtues of the plants; boiling destroys them. The roots dye a permanent red, and the bones of the animals who eat the plant are said to be colored, similar to that caused by madder. The flowers are said to curdle milk, but this is not a constant effect. Analysis has detected in *G. verum* and *G. aparine rubichloric acid*, *galitannic acid*, citric acid, starch, chlorophyll, etc, *G. aparine* contains more citric acid than *G. verum*, while the latter holds the most galitannic acid. Oxalic acid may be present.

Action, Medical Uses, and Dosage.—A most valuable refrigerant and diuretic, and will be found very beneficial in many diseases of the urinary organs, as *suppression of urine*, *calculous affections*, *inflammation of the kidneys* and *bladder*, and in the scalding of urine in *gonorrhœa*. It is contraindicated in diseases of a passive character, on account of its refrigerant and sedative effects on the system, but may be used freely in *fevers* and all *acute diseases*. It has been recommended in *scorbutic* and *nervous affections*, but can not be depended upon. *Growths* or deposits of a nodular character in the skin or mucous membranes are regarded as indications for its use. An infusion may be made by macerating 1½ ounces of the herb in a pint of warm water for 2 hours, of which from 2 to 4 fluid ounces may be given 3 or 4 times a day, when cold. It may be sweetened with sugar or honey. Equal parts of cleavers, maiden-hair, and elder-blows, macerated in warm water for 2 or 3 hours, and drank freely, when cold, form an excellent drink in *acute erysipelas*, *scarlatina*, and other *exanthematous diseases*, in their inflammatory stages. The infusion made with cold water is also considered very beneficial in removing *freckles* from the face, likewise *lepra*, and several other *cutaneous eruptions;* the diseased parts must be washed with it several times a day, and continued for 2 or 3 months in case of freckles. It has also been found useful in many cutaneous diseases, as *psoriasis*, *eczema*, *lichen*, *cancer*, and *scrofula*, and is more particularly useful in these diseases when they are combined with a strumous diathesis. The infusion may be prepared and administered as above mentioned. Of specific galium the dose is from 5 to 60 drops.

Galium tinctorium is said to be nervine, antispasmodic, expectorant, and diaphoretic. It has been used successfully in *asthma*, *cough*, and *chronic bronchitis*, and appears to exert an influence principally upon the respiratory organs. The plant has a pungent, aromatic, pleasant, persistent taste. A strong decoction of the herb may be given in doses of from 1 to 4 fluid ounces, and repeated 2 or 3 times a day, according to circumstances. The root of this plant is said to dye a permanent red.

Specific Indications and Uses.—Dysuria, painful micturition; renal and cystic irritation with burning; diuretic for inflammatory states of the urinary tract, and for febrile conditions; "nodulated growths or deposits in skin or mucous membranes" (Scudder).

GALLA.—NUTGALL.

"An excrescence on *Quercus lusitanica*, Lamarck (*Quercus infectoria*, Olivier), caused by the punctures and deposited ova of *Cynips Gallæ tinctoriæ*, Olivier. *Class:* Insecta. *Order:* Hymenoptera"—(*U. S. P.*).

Nat. Ord.—Cupuliferæ.

SYNONYMS: *Galls*, *Galla tinctoria*, *Galla halepense*, *Galla levantica*, *Galla quercina*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 249.

Botanical Source.—*Quercus lusitanica* (*Quercus infectoria*), is a small shrub, or tree, from 4 to 6 feet in height. The stems are crooked; the leaves borne on short petioles, 1 to 1½ inches long, oblong, with a few coarse mucronate teeth on each side, bluntly mucronate, rounded and rather unequal at the base, smooth, bright-green, and shining on the upper side. The fruit or acorns are solitary, long, and obtuse; the cup is scaly and hemispherical (L).

History.—Dyer's oak, or gall oak, is indigenous to the country from the Bosporus to Syria, and from the Archipelago to the frontier of Persia. It furnishes the *gall-nuts* or *galls* of commerce. These are produced by the puncture of the foliaceous or cortical parts of the tree by an insect, for the deposition of its eggs. The insect producing the galls of commerce is the *Cynips Gallæ tinctoriæ*, Olivier (*Cynips quercusfolii*, of Linnæus, or *Diplolepsis Gallæ tinctoriæ*, of Geoffroy). After the female has made a puncture, she deposits her eggs therein; in consequence of the irritation thus caused, an excrescence is soon formed, from the concretion of the morbid secretion which subsequently ensues, and which is called galls. The larva of the insect is soon developed from the egg, changing first into the pupa and then into the imago. Toward the end of July, the young insect, having passed through all its stages of transformation into the state of fly, perforates its prison and escapes. The best galls are those which are gathered about the middle of July, just before the escape of the insect. These are bluish-black, heavy, not yet perforated, and constitute the commercial *black*, *blue*, or *green galls*. Those galls from which the insect has escaped are commonly larger, lighter colored, perforated, and less astringent; they are called *white galls*, and command a lesser price in commerce (P.—*Ed.*).

Galls are chiefly imported from the Levant, *i. e.*, Syria and Turkey, though some valuable grades (rhus galls) are brought in smaller quantity from several other countries, *e. g.*, China and Japan (see below). The *Aleppo* or *Syrian galls* are blue or black; *Sorian galls* are small and blackish, and the radiation of the interior is absent; and the *Smyrna galls* are grayish or olive-gray green intermingled with *white galls*. European countries also furnish oak galls, *e. g.*, England, Germany, Italy, but these are decidedly inferior in the amount of tannin they contain. For an interesting monograph on various species of galls, including American oak galls, see C. Hartwich, *Arch. der Pharm.*, 1883, pp. 819 to 881.

Description and Chemical Composition.—Galls are described by the *U. S. P.* as follows: "Subglobular, 1 or 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ inch) in diameter, more or less tuberculated above, otherwise smooth, heavy, hard; often with a circular hole near the middle, communicating with the central cavity; blackish olive-green or blackish-gray; fracture granular, grayish; in the center a cavity containing either the partly developed insect, or pulverulent remains left by it; nearly inodorous, taste strongly astringent. Light, spongy, and whitish-colored nutgall should be rejected"—(*U. S. P.*). Water is the best solvent of galls, and proof-spirit the next; pure alcohol or ether acts more feebly upon them. The chemical reactions of galls in decoction or tincture, are similar to those named for *tannic acid* or *tannin* (gallotannic acid, which see), as this substance exists in galls in large proportions. A number of analyses of galls from various sources are recorded in "*The Tannins*" (1892) by the late Prof. Henry Trimble. The amount of tannin varied from 24 per cent in European galls (German, English, Italian), to 61 per cent in Aleppo galls, and 69 per cent or more in Chinese galls.

H. K. Bowman (*Amer. Jour. Pharm.*, 1869) obtained from selected oak galls 80 per cent of tannin; from white galls about 30 per cent; and from good commercial powdered galls 52 per cent.

Prof. Trimble (*Amer. Jour. Pharm.*, 1890, p. 563) found in two species of galls, both from *Quercus alba*, growing in the vicinity of Philadelphia, from 32 to about 35 per cent of tannin, and 1.11 and 1.71 per cent of ash, referred to dried substance. Moisture was 46 and 73 per cent. Trimble observed that galls, when allowed to air-dry slowly, will deteriorate in tannin strength, hence must be rapidly dried at 100° C. (212° F.) in order to destroy the insect in whose development the tannic acid seems to be consumed. Gallic acid is present in galls in small amounts (about 1.5 per cent).

Action, Medical Uses, and Dosage.—Galls are astringent, and were used in all cases where astringents are indicated, as in *chronic dysentery*, *diarrhœa*, *passive hemorrhages*, and in cases of *poisoning by strychnine*, *veratrine*, and other *vegetable alkaloids*, with which it forms tannates possessing less activity than the other salts of these bases. Boiled in milk the decoction is used for the *diarrhœa of children*. As a local application, the infusion is employed as an injection in *gleet*, *leucorrhœa*, *prolapsus ani*, or for a gargle in *indolent ulceration of the fauces*, *relaxed uvula*, and the *chronic stage of mercurial action on the mouth*. The addition of alum is said to render it more beneficial. Dose of the powder, from 5 to 20 grains; of the tincture, ½ to 1 fluid drachm; of the infusion, from ½ to 1 fluid ounce. Gallic and tannic acids have now supplanted it as a medicine.

Related Galls and Drugs.—GALLÆ CHINENSES SEU JAPONICÆ. *Chinese and Japanese galls.* This important variety of galls, containing 70 per cent of gallotannic, or common tannic acid, is derived from the *Rhus semialata*, Murray, being produced upon the leaf or leafstalk through the agency of the *Aphis chinensis*, Bell, which punctures the part. These galls are hollow, light, very irregular in shape, more or less lobed, and have numerous protuberances. Their shell is thin, horny and translucent, brittle, and breaks with a smooth, glistening fracture. These galls are attenuated toward the base and inflated at the other extremity. The shell is of a red-brown color, densely covered with a velvety gray downy pubescence. The interior of the gall contains a number of dead insects. The Japanese galls are similar but more slender, and have more lobes. Their pubescence is denser than that of the Chinese variety, and of a pale brown color. The Japanese galls are thought to be derived from *Rhus japonica*, Siebold.

TAMARISK GALLS.—Product of *Tamarix orientalis*, Forskal. South and southwest Asia. These are knotty, subglobular, and from ⅛ to ½ inch in thickness. They yield tannin to the extent of 40 to 50 per cent. *Tamarisk africana*, Poiret, of northern Africa, yields a similar gall, while the bark and leaves of the *Tamarisk gallica*, Linné, are used as astringents in Europe.

AMERICAN NUTGALLS.—Several species of Quercus, especially *Quercus alba*, Linné, yield inferior light, spongy galls, which contain comparatively little tannin. Forty per cent of tannin is said to be yielded, however, by a Texan species, the *Quercus virens*, Aiton (see Trimble, *The Tannins*). The *Quercus lobata*, Engelmann, furnishes *California oak-galls*, rich in tannin.

VALLONEA (*Valonia*), *Acorn cups.*—Several varieties of acorn cups, including many of our indigenous products, are astringent. Those of *Quercus Robur*, Linné, furnish *Hungaria valonia*, while the *Oriental valonia* is the product of several species of Quercus from southwestern Asia and southeast Europe, especially Greece and Asia Minor, such as *Quercus Vallonea*, Kotschy, *Quercus Ægilops*, Linné, and others.

BASSORA GALLS contain on an average 27 per cent of tannin. They are ground and subsequently pressed into rectangular cakes. Persia and Asia Minor produce them, and they are employed in tanning.

NANCE BARK.—Probably from *Malpighia glabra*. Contains over 26 per cent of tannin Holberg, *Amer. Jour. Pharm.*, Vol. XVI . Considerably employed by the Mexicans in tanning.

BEDEGUAR.—An excrescence, known as *Fungus rosarum*, produced by the puncture of insects (*Cynips*) upon the *Eglantine* or *Sweet briar* and other species of the rose family. It is roundish or irregular, about an inch through, and made up of cavities, each containing a larva. It is feebly astringent and almost odorless. It was formerly regarded anthelmintic, lithontriptic and diuretic, being given in doses of from 10 to 40 grains.

GARCINIA.—MANGOSTEEN.

The fruit of *Garcinia mangostana*, Linné, and other species of *Garcinia*.

Nat. Ord.—Guttiferæ.

COMMON NAMES: *Mangosteen*, *Mangostan*.

ILLUSTRATIONS: *Botanical Magazine t.*, 1847. Of *G. indica*, Bentley and Trimen, *Med. Plants*, 32.

Botanical Source, Description, and History.—The tree furnishing the mangosteen is large and handsome, having elliptic, oblong or oblong-lanceolate, deep-green glossy leaves. The bark of the tree is bitter and exceedingly astringent. The fruit is brownish or brownish-gray, marbled with yellow, and is crowned by the 4-parted, sessile stigma. There are from 6 to 8 seeds, and the pulp is juicy, white, and delicious in taste and odor. It is about the size of an orange.

Garcinia pedunculata, Roxburgh, yields a yellow fruit having an acidulous taste. It is of an inferior quality.

Garcinia Kydia, Roxburgh, yields a small fruit of a deep-yellow color. It is of better quality than the preceding variety.

Garcinia indica, Choisy (*Garcinia purpurea*, Roxburgh; *Brindonia indica*, Du-Petit-Thouars).—The fruit of this species is of a dull or purplish-red or purple color, having also a purple, acid pulp. The pulp, dried in the sunlight and slightly salted, is a commercial article, and when fresh the fruit is used in a currie in India, where a purple syrup, for use in bilious affections, is also prepared from it. The juice is occasionally used as mordant for dyeing purposes. The fruit, seeds and bark are all employed in India (Dymock, *Mat. Med.*, *Western India*). The seeds, when bruised and boiled with water, yield the *concrete oil of mangosteen*, known as *kokam* or *kokum butter*. It is hard and friable at all ordinary temperatures, has a crystalline structure, and comes pressed in the form of hand-molded, egg-shaped cakes. It has a greenish-white or yellowish color, and produces the unctuous touch of spermaceti. The fat, as found in market, must be strained before being employed in pharmaceutical operations. This removes particles of seed, fruit, etc., with which it is usually mixed. This butter is sometimes used for cooking purposes in India, but is more valuable in the preparation of *ointment of nitrate of mercury*, for, when added to lard, it gives it a good consistence for hot climates (Dymock, *Mat. Med.*, *Western India*).

Garcinia mangostana is found in the Malay islands. It was grown in the gardens of the Duke of Northumberland in 1855, and produced both blossom and fruit (see illustration in *Bot. Mag. t.*, 1847). The fruit of this tree is the famous *mangostan* or *mangosteen*, said to be among the most luscious of tropical fruits. Its rind is about the fourth of an inch in thickness, contains a very astringent juice, from which, during wet weather, a yellow gum exudes, which is a variety of gamboge. The Chinese use the bark of the tree to produce a black dye, and it is also used in dysentery.

Chemical Composition.—The bitter and astringent rind of the fruit of Garcinia mangostana, according to W. Schmid, contains tannin, resin, and crystallizable *mangostine* ($C_{20}H_{22}O_5$), forming golden-yellow, tasteless scales, melting at 190° C. (374° F.), readily soluble in alcohol or ether, insoluble in water. Basic lead acetate precipitates it from its alcoholic solution. Its solution in alkalies reduces gold and silver solutions. The acidity of the fruit is due to malic acid. The resinous exudation of the trunk of the tree was investigated, in 1858, by N. Reitler in Wittstein's laboratory (*Vierteljahresschr. f. prakt. Pharm.*, Vol. VII, p. 170), and found to consist of 88 per cent of resin, soluble in alcohol and in ether. Ammonia differentiates it into a soluble and an insoluble resin.

Kokum butter exists in the seeds of *Garcinia purpurea* to the extent of 30 per cent, and consists chiefly of tristearin and the glycerides of oleic and myristic acids (*Jahresb. der Pharm.*, 1896, p. 71).

Action, Medical Uses, and Dosage.—The rind of the fruit is highly recommended for *dysentery*, and has been extensively employed in India for that disease. A few years ago the rind was introduced into Europe by Gruppe, of Manila, who prepared an extract which was administered in the Vienna hospitals, as an astringent, with success in *catarrhal conditions of the throat*, *bladder*, *urethra*, and *uterus*, etc. The dose of the solid extract is 1 grain, repeated 6 or 8 times per day, in pill form, or rubbed up with syrup.

Related Products.—KOLA BITTER or MALE KOLA. These seeds have a coffee-like, astringent and bitter taste. They are produced by the *Garcinia Kola*, Heckel, of western Africa (see *Kola*).

MAMMEE APPLE.—A subglobular, brownish-yellow fruit, about the size of a large orange, the pulp of which is yellow and aromatic, and the rind coriaceous and bitter. The seeds are 3 or 4 and rough. It is the product of the West Indian *Mammea americana*, Linné, *Nat. Ord.*—Guttiferæ. Another fruit is also known in the West Indies as *mammee.* It is the rusty-brown, oblong-ovoid berry of *Lucuma mammosa*, Jussieu, of the *Nat. Ord.*—Sapotaceæ. It has one large polished seed of a yellow-brown color. The pulp of the fruit is sweet and mucilaginous, and of a yellowish or reddish color.

GAULTHERIA.—WINTERGREEN.

The leaves of *Gaultheria procumbens*, Linné (*Gaultiera repens*, Rafinesque; *Gaultheria humilis*, Salisbury).

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Wintergreen*, *Mountain tea*, *Deerberry*, *Teaberry*, *Boxberry*, and improperly as *Partridgeberry* and *Checkerberry*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 164; Bigelow, *Medical Botany*, 22.

Botanical Source.—Gaultheria procumbens is a native, suffruticose plant, with a woody, horizontal root or rhizome, often ¼ of an inch in thickness. The stems are several, ascending about 3 inches from the rhizome, round and downy. The leaves are alternate, evergreen, scattered, near the extremities of the branches, coriaceous, shining, oval or obovate, acute at both ends, revolute at the edge, furnished with a few small serratures, each terminating in a bristle. The flowers are few, drooping, axillary, white, on round, downy stalks. Bracts 2, concave and cordate. The calyx is white, cleft into 5 roundish, acute segments. The corolla is urceolate, 5-angled, contracted at the mouth; the limb divided into 5 short, reflexed segments. Stamens 10, rose colored; filaments white, hairy, bent toward the corolla; anthers oblong, orange colored, ending in 2 double horns, bursting outwardly for their whole length above the filaments; pollen white. The ovary is roundish, depressed, and 5-angled, resting on a reddish, 10-toothed, glandular disk; style erect and straight; stigma simple. The fruit is a small, 5-celled, many-seeded capsule, invested with the calyx, which becomes large, round and fleshy, having the appearance of a bright scarlet berry.—(L.)

Fig. 117.

Gaultheria procumbens.

History, Description, and Chemical Composition.—This plant is a native of the United States, growing from Maine to Florida, and westward to Pennsylvania and Kentucky, in cool, damp woods, sandy soils, and on mountains, flowering from June to October. It does not grow in alluvial soil, nor in limestone countries. The leaves are medicinal, yet the whole plant may be used; the leaves have a peculiar fragrance and an agreeable, characteristic flavor, with a slight astringency; the berries possess a similar flavor with sweetness, and are eaten by many; some wild animals, as deer, partridges, etc., use it for food. Water, by infusion, and alcohol extract the virtues of the plant. The leaves contain an odorous volatile oil, which may be obtained in the same manner as oil of peppermint. The specific gravity of the oil is 1.173 at 10° C. (50° F.). It is colorless at first, but subsequently becomes more or less of a pinkish color, has a hot and aromatic taste, possesses acid properties, and is soluble in alcohol or ether (see *Oleum Gaultheriæ*).

Mr. J. Oxley, in 1872, found the leaves to contain glucose, chlorophyll, gum, tannic acid, a body analogous to gallic acid, but not yielding pyrogallic acid upon heating, and principles found also in uva ursi and chimaphila, viz.: *Arbutin*, *ericolin* and *urson*. A quantitative proximate analysis of the leaves made by F. W. Droelle (*Amer. Jour. Pharm.*, 1887, p. 289) largely confirmed these results.

Volatile oil was found to the extent of ½ per cent. Gaultheria procumbens was ascertained by Prof. Power and N. C. Werbke to be free from *andromedotoxin*, a neutral poisonous principle present in several plants of the natural order Ericaceæ (see *Amer. Jour. Pharm.*, 1889, p. 361).

Action, Medical Uses, and Dosage.—Wintergreen possesses stimulant, aromatic, and astringent properties. It is used in infusion as an astringent in *chronic mucous discharges*, as a diuretic in *dysuria*, as an emmenagogue, as a stimulant in cases of *debility*, and is said to augment the flow from the lactiferous vessels of nursing women, but this is doubtful. It is also recommended as a valuable remedy for *articular* and *muscular rheumatism.* The infusion and the essence both relieve *irritation of the urethra* and *bladder*, and are adapted to the incipient stages of *renal inflammation. Tubal nephritis* is alleged to have been arrested by it even when examination has revealed in the urine the presence of blood corpuscles and tube casts (Webster). Scudder recommends it in *spermatorrhœa* with increased sexual excitement, and as a sedative in *irritation* and *inflammation of the urethra, prostate gland* and *bladder.* The volatile oil (see *Oleum Gaultheriæ*), or its tincture, is used to render syrups and other preparations more agreeable. The oil allays the pain of *carious teeth*, and large doses of it administered internally have caused death by producing inflammation of the stomach; the essence of wintergreen is a carminative, and is sometimes used in the *flatulent colic* of infants. An infusion of the leaves or whole plant (℥j to water Oj) may be drunk freely. Dose of essence, 1 to 30 drops; of specific gaultheria, 1 to 20 drops.

Specific Indications and Uses.—Cystic and prostatic irritation, undue sexual excitement, renal inflammation (early stage).

Related Species.—*Gaultheria hispidula*, or *Cancer wintergreen*, is supposed to be efficient in removing the carcinomatous taint from the system; used also in *scrofula* and *prolapsus uteri.*

Melastoma Ackermanni.—Colombia. Yields an oil probably identical with oil of wintergreen (methyl salicylate). Used provincially as an anti-neuralgic.

GELATINA.—GELATIN.

Purified glue prepared by boiling gelatinous animal tissues in water, evaporating and drying the product in the air. Carefully selected fresh bones are preferred.

Synonyms: *Gelatine, Artifical isinglass, Glutin.*

Source and History.—Gelatin is found in abundance in various animal substances, especially in the skin, cartilages, tendons, membranes and bones. The common gelatin of commerce, called *glue*, is made from trimmings and scraps of skins, ears, bones and hoofs of animals. It may be obtained by boiling these animal parts in water, straining the decoction, and evaporating it until it forms a jelly on cooling. This is divided into thin slices of various sizes, which are allowed to dry in the open air. The purest variety of gelatin is obtained from the air bladder of fishes—*e. g.*, the sturgeon and codfish—and is named isinglass (see *Ichthyocolla*). The gelatin used for culinary and pharmaceutical purposes, in photography, etc., usually called *gelatin* proper, is carefully prepared from the bones of animals from which the fat is previously removed and the earthy matter dissolved out by means of hydrochloric acid. (For a detailed description of the processes of manufacture involved, see Prof. S. P. Sadtler, *Ind. Org. Chem.*, 1895, p. 334.) Gelatin may also be obtained from the vegetable kingdom, viz.: From certain species of sea weeds in Asiatic waters (see, for example, *Agar Agar*).

Description and Chemical Composition.—Glue (*Colla*). Glue of good quality is firm and friable, not easily pulverized, of a light-brown color, and translucent. On the addition of water it becomes soft and swells up, but does not dissolve except the water be hot or boiling. When dissolved in hot water, it is much in use for uniting wood and various other substances together, but is too impure for internal employment or for a chemical test. Addition of acetic acid, or boiling with dilute nitric acid, has the effect of destroying the gelatinizing power of gelatin, while its adhesive properties are fully retained. A cement or liquid glue is thus obtained, which does not require the aid of heat to render it fit for use. A strong, liquid glue, very convenient for a number of objects, and even for porcelain, glass, and pearl, and which is preferable to that made with vinegar or nitric acid, is prepared as follows: To 3 parts of strong glue well bruised add 8 parts of water, and allow them to remain in contact for several hours; then add ½ a part of hydrochloric acid, and ¾ of a part of sulphate of zinc. Expose the whole for 10 or 12 hours to a temperature of 80° to 90° C. (176° to 194° F.).

GELATIN appears in commerce in thin, rectangular, transparent sheets, variously marked by impressions received from the nets upon which the moist jelly is spread in order to dry. It also occurs in smooth, transparent pieces, or in thicker, opaque, porous pieces. It is not so thick as pieces of glue. Gelatin comes also in shreds and is often artificially colored. After digestion in hot water it should develop no odor nor should it change color. Dried gelatin, when dissolved in 100 parts of hot water, solidifies in the form of a tremulous jelly upon cooling. Prolonged boiling of the aqueous solution causes it to lose its gelatinizing properties.

Gelatin differs from albuminous bodies in not coagulating in aqueous solution on boiling, nor being precipitated by nitric acid or potassium ferrocyanide. Its aqueous solution is precipitated, however, by alcohol and by tannic acid. Upon the latter reaction depends the conversion of hide into leather in the process of tanning. Two proximate principles may be distinguished in various forms of gelatin: *Glutin*, or gelatin proper, which is the gelatinous principle of tendons, hides, and the larger bones; and *chondrin*, which occurs mostly in the cartilages of the ribs and joints and the young bones while yet soft (S. P. Sadtler). *Glutin* has all the aforenamed properties of gelatin, and has a greater adhesive power than chondrin, swelling up in cold and dissolving in hot water, forming a jelly upon cooling. When boiled with diluted sulphuric acid or alkali, *glycocoll* ($C_2H_5NO_2$) and *leucin* ($C_6H_{13}NO_2$) are chiefly produced. The former substance is not formed with chondrin. Dry distillation yields bases of the fatty and the *pyridine* series. *Chondrin* is precipitated by alum, lead acetates and metallic salts, not by corrosive sublimate, while *glutin* is precipitated by corrosive sublimate, but not by lead acetates, nor by alum or ferric chloride T.S.

Action and Medical Uses.—Gelatin probably does not affect the growth of the bodily structures. In the form of jellies it has been used during convalescence, but the nutrition derived from these preparations is believed to be due to the sugar, etc., usually employed in preparing them. Gelatin may act as a protective in rectal enemas, in the treatment of *skin affections*, and in cases of *poisoning by corrosive substances.* Medicated gelatin (see *Gelanthum*) is now used to some extent in the treatment of *skin diseases*, particularly those of an *eczematous type*, and in the treatment of *catarrhal affections of the nasal passages.*

Gelatin has been introduced here, in consequence of its application in pharmacy, for the purpose of promoting certain useful indications. Several remedial agents of a valuable character, are unfortunately so repulsive to the palate as to produce nausea and vomiting whenever swallowed, and, as in many instances, it is almost impossible to dispense with them, an important object is to prepare them so that they may reach the stomach without offending the organs of taste. This has been effected by inclosing the medicine in a case or cover of gelatin, forming what are called *gelatin capsules*, invented in France by M. Mothe. There are several methods at the present day for making these capsules; thus the end of an iron rod is made bulbous or egg-shaped, and is highly polished; being slightly oiled it is dipped into a hot, concentrated solution of 3 parts of pure gelatin, ½ part of sugar, and 6 parts of water. A number of rods are generally used. The rods are then rotated to spread the solution evenly over the mold or bulb, and placed, bulb upward, on a board perforated for the purpose; when cool and dry they may be removed by giving to the capsule or bulb a pulling and gently twisting motion. These are then filled with the medicine, and the orifice closed over with more of the gelatin solution. Sometimes animal membrane, or fine skin, distended with mercury, is used instead of the iron bulb. (For a detailed method of preparing gelatin capsules, see standard works on pharmacy and *Amer. Jour. Pharm.*, Vol. IX, p. 20). In this way capsules may be made to contain from 10 to 20 grains of liquid. Since the foregoing appeared in former editions of this Dispensatory, commercial empty capsules of all sizes have become a standard article of commerce. When received into the stomach the gelatin is dissolved, allowing the medicine to accomplish its therapeutical influences. If *soft capsules* are demanded a little glycerin added to the gelatin will make the product elastic. Capsules are now largely employed for dispensing quinine and similar medicines of unpleasant taste. These capsules are oblong, rounded and closed at one end, and cut off and open at the other end. It is only necessary to introduce the powder and slip a second capsule over the open end of the filled one. *Folding* or *devorative capsules* are thin films of gelatin designed to be used like powder-papers, except that after folding upon the powder the edges are made to adhere by moistening them. When ready to be taken the whole capsule (and powder) is dipped in water until softened, and then swallowed. *Medicinal pearls* of gelatin, combined with sugar, acacia and honey, are also employed to enclose ether and similar fluids. Gelatin (3 parts) and glycerin (7 parts) is sometimes used as a basis for *bougies* and rectal and vaginal *medicated suppositories.* Gelatin is also used for making *court-plaster*, *hectographs*, for *coating pills*, and for estimating the amount of tannin contained in a drug or preparation.

A good paste is made by dissolving best white glue, 3 ounces (av.); refined sugar, 1½ ounces; water, 10 fluid ounces, or a sufficient quantity, together by the aid of a water-bath, and, while warm, apply it by means of a suitable brush to the reverse side of the labels while uncut or in sheets. After being dried and moderately pressed they are ready for cutting. Thick paper and not sized will require less water than when thin and well sized, and in all cases it should be quickly and evenly applied. It can only be used while warm. It does not penetrate the paper and disfigure the labels, is very adhesive, never loosens from glass and leaves no disagreeable impression in the mouth after being moistened with saliva.

GELATINUM CHONDRI (N. F.)—IRISH MOSS GELATIN.

Preparation.—*Formulary number*, 184: "Irish moss, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water a sufficient quantity. Wash the Irish moss with cold water, then place it in a suitable vessel, and add fifty thousand cubic centimeters (50,000 Cc.) [about 106 pints] of hot water, and heat it on a boiling water-bath for 15 minutes, frequently stirring. Strain the decoction, while hot, through a strong muslin strainer; return the strained, mucilaginous liquid to the water-bath, evaporate it to a semi-fluid consistence, then transfer it to shallow, flat-bottomed trays, and evaporate it at a temperature not exceeding 90° C. (194° F.), so that the gelatin may become detached in scales. *Note.*—Irish moss gelatin thus prepared furnishes a mucilage of Irish moss which is opaque, like that made directly from the moss itself. It may be prepared so as to yield a transparent mucilage by following the plan pointed out in the *Note to Mucilago Chondri* (F. 275)"—(*Nat. Form.*).

Action and Medical Uses.—(See *Chondrus.*)

GELSEMIUM (U. S. P.)—GELSEMIUM.

The rhizome and roots of *Gelsemium sempervirens* (Linné), Persoon. (*Gelsemium nitidum*, Michaux; *Gelsemium lucidum*, Poiret; *Bignonia sempervirens*, Linné; *Anonymos sempervirens*, Walter; and *Lisianthus sempervirens*, Miller).

Nat. Ord.—Loganiaceæ.

COMMON NAMES: *Yellow jasmine, Yellow jessamine, Wild woodbine, Carolina jasmin* or *jessamine.*

ILLUSTRATIONS: Johnson, *Med. Bot. of N. A.*, Plate 7; Meehan, *Native Flowers and Ferns*, I, 9; Bentley and Trimen, *Med. Plants*, 181; Millspaugh's *Amer. Med. Plants*, Plate 130.

Botanical Source.—The Yellow jasmine is a handsome climber growing along banks and in lowlands and woods. The stem is smooth and twining; the leaves opposite, entire, ovate, or lanceovate, nearly evergreen, being dark-green, smooth, and shining on top; paler beneath. The flowers are in axillary clusters, showy, and of deep-yellow color, and emit an agreeable, but rather narcotic odor.

The calyx is 5-parted and very small, with acute, lanceovate lobes. The corolla is ¾ to 1½ inches long, with 5-lobed margin; stamens 5, half as long as the corolla, and inserted on it. The style is longer than the stamens, and supports two 2-parted stigmas. The fruit is an elliptical pod, 2-celled, 2-valved, and many-seeded. The seeds are flat, and attached to the margins of the valves. Owing to its evergreen leaves, fragrant flowers, and the shade it affords, it is extensively cultivated in the gardens of the South for ornamentation.

Fig. 118.

Gelsemium sempervirens.

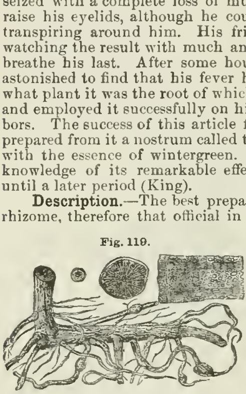
History.—This strikingly beautiful climber, peculiar to our southern cities, furnishes one of the most valued and universally used Eclectic remedies. It is a twining vine, flourishing in great profusion from Virginia to Florida, hanging in festoons from the neighboring trees and shrubs, sometimes growing to the height of 50 feet. The average height, however, is from 20 to 30 feet. The plant blooms in early spring—in Florida during March, and in Mississippi and Tennessee in May and June. During the flowering period it perfumes the air with a delightful fragrance similar to that of the true jasmine. When the vine is abundant, the odor of the flowers is said to be almost overpowering. Gelsemium is known by several popular names, as Yellow jessamine, Yellow jasmin, Carolina jessamine, Carolina jasmin, and Wild woodbine. The name gelsemium was given it by Jussieu, and is derived from the Italian *gelsomina*, meaning jasmine. The plant, however, resembles the true jasmine only in its fragrance, and belongs to an entirely different natural order. Mr. E. M. Holmes (*Pharm. Jour. Trans.*, 1875, p. 481) states that it is rather unfortunate that it should often be called the Yellow jessamine in America, since there is a true jessamine (*Jasminum fruticans*, Linné) with yellow flowers, which is often found in cultivation. If the name jessamine be applied to *Gelsemium sempervirens* at all, it should be carefully distinguished as the *Carolina jessamine* (see also Dr. A. R. L. Dohme, in *Drug. Circ.*, 1897, p. 179). Gelsemium was formerly known botanically as *Bignonia sempervirens* of Linnæus, and the *Gelsemium nitidum* of Michaux and Pursh. The name *gelsemium*, as used exclusively by Eclectics, arose from a typographical error, and was widely copied in various writings, and accepted as authority before the mistake was discovered (see Prof. J. U. Lloyd, in *Ec. Med. Jour.*, for March, 1892).

While gelsemium is one of our best remedies, yet, like iris, phytolacca, and other plants, it suffers from worthless representatives on the market. These preparations, made from old, dried material, will fail to fulfil the expectations of he who administers them for the specific effect. Specific gelsemium, the preparation employed by Eclectic physicians almost exclusively, fully represents the plant. Prof. J. U. Lloyd informs me that, in the preparation of specific gelsemium, the green root only is used. It is gathered in February or in early spring, cut into small pieces, put in barrels, and to the contents of each barrel is added 10 gallons of alcohol. In this condition it is shipped from the Carolinas (where it is gathered) to Cincinnati. On arrival, it is dumped into the drug mill and ground, alcohol and all, and from this material the specific medicine is made. He further states that, in one season, when the winter was uncommonly mild, the continuous growth of the plant caused a large amount of albuminous material to form in the root, and that preparations manufactured from such a product threw down an unsightly albuminous precipitate, which, though it did not impair the therapeutic value of the preparation, rendered it unsalable.

This plant was brought into notice, as far as we can learn, in the following manner: A planter of Mississippi, whose name we have forgotten, while laboring under a severe attack of bilious fever, which resisted all the usual remedies, sent a servant into his garden to procure a certain medicinal root, and prepare an infusion of it for him to drink. The servant, by mistake, collected another root, and gave an infusion of it to his master, who, shortly after swallowing some of it, was seized with a complete loss of muscular power, unable to move a limb, or even raise his eyelids, although he could hear, and was cognizant of circumstances transpiring around him. His friends, greatly alarmed, collected around him, watching the result with much anxiety, and expecting every minute to see him breathe his last. After some hours, he gradually recovered himself, and was astonished to find that his fever had left him. Ascertaining from his servant what plant it was the root of which acted in this manner, he collected some of it, and employed it successfully on his own plantation, as well as among his neighbors. The success of this article finally reached the ear of some physician, who prepared from it a nostrum called the "Electrical Febrifuge," which was disguised with the essence of wintergreen. This plant was the Yellow jessamine, and a knowledge of its remarkable effects was not communicated to the profession until a later period (King).

Description.—The best preparations of gelsemium are made from the green rhizome, therefore that official in the *U. S. P.* is not adapted to the uses of the Eclectic pharmacist and doctor. That work simply states the "*rhizome and roots*," without specifying whether green or dried, hence it is to be inferred that the dried root is the one intended. For the sake of completeness we give the official description:

Fig. 119.



Rhizome of Gelsemium sempervirens.

"Cylindrical, long, or cut in sections, mostly from 5 to 15 Mm. ($\frac{1}{5}$ to $\frac{3}{5}$ inch), and occasionally 3 Cm. ($\frac{1}{5}$ inch) thick, the roots much thinner; externally light yellowish-brown, with purplish-brown, longitudinal lines; tough; fracture splintery, bark thin, with silky bast-fibres, closely adhering to the pale-yellowish, porous wood, which has fine, medullary rays, and in the rhizome a thin pith, odor aromatic, heavy; taste bitter"—(*U. S. P.*). Gelsemium yields its virtues to water or alcohol. The rhizome is several feet in length (roots in Fig. 119 are cut off), with scattered fibers, and is from 2 to 3 lines in diameter to nearly 2 inches. The internal part is woody, and of a light-yellowish color; the external part, or bark, in which the medicinal virtues are said principally to reside, is of a light snuff-color, and from $\frac{1}{2}$ to 3 lines in thickness. The root of this plant has been said to contain a resin which is poisonous in very small doses, and a tincture, made by digesting it in undiluted alcohol, is stated to have proved fatal. This statement is denied, and upon good grounds, for, were it true, death would necessarily follow the use of the tincture made with undiluted alcohol, in consequence of the presence of this resin, which would still be taken up by alcohol in a proportion corresponding to the alcoholic strength of the solvent. Again, it has been asserted, that the deaths, which have occurred where the article was used, were owing, not to the gelsemium, but to the presence of another very poisonous root, somewhat resembling it, which was carelessly or ignorantly collected and mixed with it. Others again, state that they have given large doses without any serious consequences, and, in one case, 6 fluid drachms of the tincture were swallowed by a lad of 20 years of age, without any permanent injury. Notwithstanding these statements, death has followed the employment of what was supposed to be the tincture of gelsemium, in a few instances, and further investigations are required to determine its probable cause, and whether this agent will produce any fatal results in large medicinal doses. Yellow jessamine may be administered in decoction, infusion, or tincture.

Dr. Hiram H. Hill, formerly of the late firm of F. D. Hill & Co., of Cincinnati, has collected many hundred pounds of the gelsemium root in the South. I am indebted to him for the following statement of it: "The length of the gelsemium root, in clay soil, is from 3 to 10 feet, and on the Magnolia ridges, and along small streams, I have traced some roots to the extent of 30 feet, although the average length is about 15 feet. Like the roots of many other vines, it is branching, with scattered fibers, and runs horizontally near the surface of the ground, sometimes merely under the leaves, for several feet. When first pulled up it is very yellow, and has a peculiar odor like that of the tincture, with a bitter, rather pleasant taste to most persons, at least people were constantly tasting or chewing it, while I was collecting it. The vine is of a green color, and always runs to the top of the tree or bush on which it fastens, then branches out, covering the topmost branches with its thick foliage. I have seen it on trees that were 50 feet in height, and the size of the vine was the same near the top as at the ground; its general length is from 20 to 30 feet. The bark of the vine is full of a silk-like fiber, which is not found in other vines that I have seen. On old vines, the leaves are about 1½ inches in length, of a dark-green color, lance-shaped, and on short foot-stalks; on young vines or shoots they are longer, and are 4 or 5 inches apart, while on the old ones they are very close and always opposite. The flowers are funnel-shaped and yellow. The vine, the root of which is sometimes gathered by mistake for the gelsemium, resembles it very much in appearance, though it is of a lighter color, and the outer bark is covered with white specks or marks somewhat similar to those on young cherry or peach limbs, and the lower parts of the old vines become rough, and have small tendrils that fasten upon the bark of trees, and which are never seen on the gelsemium. The bark of the vine is also more brittle, and the leaves are always on long foot-stalks, which are opposite, at the end of which are two opposite leaves, almost exactly resembling the leaf of the *Aristolochia Serpentaria*. The root is almost white, very tough, brittle when dry, not so fibrous as the true root, straight, about the same length of the medicinal root, and has a slightly bitter, disagreeable, nauseating taste. I never saw any of the flowers, though they are said to resemble the others in shape, but are pale, dirty-white, with a slight unpleasant odor, by no means like that peculiar to gelsemium. The vine is called *White poison vine* and *White jessamine*" (King).

Chemical Composition.—Mr. Henry Kollock, in 1855 (*Amer. Jour. Pharm*,. Vol. XXVII, p. 197), found, beside the usual constituents of plant roots, a volatile oil, a dry, acrid resin (the *gelsemin* of the older Eclectics, see later), and a bitter, crystalline, alkaloidal substance which he named *gelseminia*. Prof. Maisch and C. L. Eberle (*Amer. Jour. Pharm.*, 1869, p. 35) again obtained this alkaloid; the latter stated its being absent from the wood of the root, which was later confirmed by Gerrard. In 1870 (*Amer. Jour. Pharm.*, p. 1), Prof. Th. G. Wormley, examining a fluid extract of the root, discovered therein a crystallizable acid, which he called *gelseminic* (or *gelsemic*) *acid*, and which is remarkable for the beautiful blue fluorescence exhibited by solutions of the acids in aqua ammoniæ or other alkalies, even when highly diluted. Chas. A. Robbins, in Prof. Sonnenschein's laboratory (*Amer. Jour. Pharm.*, 1876, p. 191), found gelsemic acid to be non-nitrogenous, and pronounced it to be identical with *æsculin*, the characteristic glucosid of horse chestnut bark. Prof. Wormley (*Amer. Jour. Pharm.*, 1882, p. 337) and recently, Prof. V. Coblentz (*Proc. Amer. Pharm. Assoc.*, 1897, p. 225) proved, however, that gelsemic acid and *æsculin* presented some striking differences in solubilities, etc., and could not, therefore, be identical. In this connection, it may be said that, 15 years ago, Prof. F. A. Flückiger, from gelsemic acid made for him by J. U. Lloyd, and æsculin made by himself, established that they presented certain differences. He communicated his results by letter to Mr. Lloyd, but they were not published to our knowledge. More recently, Prof. E. Schmidt (*Archiv der Pharm.*, 1898, p. 324) has clearly proved the identity of gelsemic acid with the known substance *beta-methyl-æsculetin* ($C_{10}H_8O_4$). In harmony with this result are the researches of Prof. Coblentz, who gave experimental proof of the fact that gelsemic acid contains two hydroxyl groups, which agrees with the constitution of that substance identified by Prof. Schmidt. More doubt exists with regard to the alkaloidal principle, owing to the difficulty of obtaining it in crystallized form. Sonnenschein and Robbins (1876) gave it the formula $C_{11}H_{19}NO_2$, while A. W. Gerrard (*Amer. Jour. Pharm.*, 1893, p. 256), evidently obtaining it in much purer form (from the purified hydrochloride), finds $C_{12}H_{14}NO_2$. L. Spiegel's results

(1893) agree with the latter formula. Finally, Mr. F. A. Thompson (laboratory of Parke, Davis & Co.) (*Pharm. Era*, 1887, p. 3) believes that, besides this alkaloid, which he calls *gelsemine*, there exists another in gelsemium root, which he calls *gelsiminine;* its hydrochloride is more easily soluble in water than that of the first alkaloid. Gelsemine is believed to act as a paralyzing, gelseminine as a tetanizing, medium. A. R. Cushny (*Ber. d. Deutsch. Chem. Ges.*, 1893, p. 1725) corroborates the existence of the two alkaloids mentioned.

Wormley (*Amer. Jour. Pharm.*, 1877, p. 150) gives the following directions for obtaining from the fluid extract of gelsemium root the alkaloid, *gelseminine* (*gelsemine*), and *gelsemic acid:* Acidulate the fluid extract with acetic acid; add this slowly to 8 times its bulk of water, filter from the resins, concentrate the filtrate on the water-bath to somewhat less than the original volume; then abstract gelsemic acid by ether, and, subsequently, the gelsemine by ether or chloroform, after rendering the fluid alkaline with sodium carbonate. In fluid extracts, prepared in the quantity of 480 grains of root to the ounce, Prof. Wormley obtained a yield of 0.2 per cent of gelsemine and 0.4 per cent of gelsemic acid.

Comparative analyses of the rhizome, root, and stem of gelsemium, carried out in the laboratory of Prof. L. E. Sayre (*Amer. Jour. Pharm.*, 1897, p. 234), showed the total absence of the alkaloid and the acid in the stem, while the rhizome contained 0.2 per cent of alkaloid and 0.37 per cent of gelsemic acid, and the root 0.17 per cent of alkaloid and 0.3 per cent of gelsemic acid. The alkaloid, *gelseminine* (*gelsemine* of Thompson), is described by Wormley as a colorless, odorless, intensely bitter, basic principle, and was obtained by A. W. Gerrard in crystalline form. When pure, it exhibits no color reaction with sulphuric and nitric acids, as claimed by Sonnenschein. It is sparingly soluble in water, freely soluble in acids, in chloroform and ether (1 in 25). Its nitrate crystallizes best of all its salts (Spiegel, *Amer. Jour. Pharm.*, 1893, p. 381).

Gelsemic acid (*beta-methyl-æsculetin* of E. Schmidt), according to Prof. Wormley, is a colorless, odorless, nearly tasteless, crystallizable acid, readily dissolving in alkalies with beautiful blue fluorescence; sparingly soluble in cold water (1 in 1000), more easily soluble in hot water; also soluble in chloroform, ether, and alcohol. Its salts formed with heavy metals are soluble, with difficulty, in water.

GELSEMIN, the so-called concentration (resinoid), should not be employed for at least two reasons. First, it is of uncertain strength and quality. Secondly, its name being so similar, both in spelling and sound, to that of the alkaloid, *gelsemine*, that, through mistake, the latter agent might be supplied and serious results follow. Death has resulted from such a mistake, consequently it should be discarded, especially as it is not equal in therapeutic power to the fluid preparations of gelsemium. It may be of interest to state that nearly all of the so-called concentrations (excepting podophyllin) of the earlier Eclectics have been discarded by the Eclectics of the present day, and are now used almost exclusively by the regular school, and especially by European physicians; also, by that class who believe that *all* the virtues of a remedy reside in concentrations and alkaloidal principles. Clinical experience proves that such preparations do not fulfil the indications as do the fluid preparations containing all the soluble medicinal ingredients of the plant.

Action, Medical Uses, and Dosage.—Gelsemium powerfully impresses the nervous system, though in man it never produces convulsions. Convulsions may occur in the lower animals. Small (medicinal) doses relax the muscles, especially the levator palpebræ, and allay nervous irritation. A pleasant or languid sense of ease and relaxation is usually experienced, accompanied in the case of larger doses by a tendency of the lower jaws to drop, and a difficulty in managing the eyelids. Sometimes sensation is lost first; again, and usually, muscular paralysis is the first to take place. The continued administration of it effects the brain (indirectly), spinal centers, and medulla, causing marked feebleness of muscular movements, confusion of vision, and vertigo. Large doses paralyze the spinal cord and cause almost complete loss of muscular power. Reflex action is depressed with the loss of muscular power, and these and the lack of sensibility, which usually takes place, are due to its action upon the spinal marrow. Consciousness may be lost, but it is usually retained even when toxic doses have been taken. When fatal, however, dissolution is usually preceded by loss of consciousness. The characteristic toxic symptoms are palpebral relaxation, disturbance of the ocular muscles, the dropping of the lower jaw, and the profound prostration and muscular relaxation. The pupil dilates, there is drooping of the eyelids (ptosis), and double vision (diplopia). Applied locally to the eye, it dilates the pupils and interferes with the action of the muscles of accommodation. The pulse is slowed to 30 or 40 beats, and there is a marked decrease in temperature. Respiration is at first quickened, then slowed, breathing becomes shallow, and the action upon the heart appears to depend upon the effect upon respiration. As a rule, the mental faculties are not directly affected by it, unless it be due to accumulation of carbon dioxide, the result of respiratory paresis. Occasionally, death results from overdoses, and, when it does so occur, is due to asphyxia. Persons are reported to have been poisoned by eating honey gathered by the bees from gelsemium flowers.

Gelsemium is said to increase the tetanizing power of strychnine. The postmortem appearances after death from gelsemium present nothing specially characteristic. Twelve minims of the fluid extract have been asserted to have killed a boy of 3 years, yet recoveries have taken place from much larger doses. Death from gelsemium usually takes place in from 1 to 8 hours. (For report of two fatal cases, see Taylor's *Med. Jurisp.*, 1892, p. 164.)

In poisoning by gelsemium or its alkaloid, gelsemine, evacuate the stomach by emetics or stomach pump, administer, hypodermatically, morphine and atropine, use friction, internal stimulation, hot drinks, external heat, etc. Tannin and the alkalies and their carbonates are reputed chemically antagonistic. Artificial respiration should be resorted to, and the heart should be sustained by digitalis and similar agents. As but few cases of poisoning by gelsemium have occurred, the antidotal treatment is as yet not well established.

Therapeutically, gelsemium acts upon the cerebro-spinal nerve centers, diminishing the blood supply to them, as in determination of the blood to the head and spine, thereby preventing spasmodic action. Consequently, in *determination of the blood to the brain and spinal cord* and their appendages, or in *inflammatory conditions of the cerebro-spinal system*, the drug would be clearly indicated. It is never the remedy for congestion. Prof. Scudder has pointed out as the specific indications for it: "The flushed face, bright eye, contracted pupils, increased heat of head, great restlessness, and excitation." With these may be associated a general headache. Bearing these indications in mind, the drug will be found useful in the diseased conditions named in this article. Gelsemium was first employed in febrile diseases, as *bilious, remittent, typhoid and malarial fevers*. In these conditions, it was found to have such a marked antipyretic action that it rapidly rose in favor among the earlier Eclectics. More pronounced effects were looked for by the Eclectic fathers than are now known to be most desirable. They regarded it as the only agent ever yet discovered capable of subduing in from 2 to 20 hours, and without the least possible injury to the patient, the most formidable and most complicated, as well as the most simple *fevers* incident to our country and climate, quieting all nervous irritability and excitement, equalizing the circulation, promoting perspiration, and rectifying the various secretions, without causing nausea, vomiting, or purging. They also believed it adapted to any stage of the disease, while the majority of those who now employ it believe it best adapted to the earlier stages of fevers, and seldom of marked value, if not harmful, in the advanced stages, or after the period of excitation has passed. It may follow any preceding treatment with safety. It is best suited to sthenic cases with determination of blood to nerve centers. It is to its controlling influence over nerve irritation that its antipyretic action is mainly due. As soon as its physiological effects are observed, the remedy should be discontinued, lest the relaxation may be too great for the system to recover from. A writer observes that his experience in the treatment of fevers, with this agent, inclines him to believe that when given in doses sufficiently large to produce its full and complete constitutional effects, it impairs the tonicity of the muscular fibers of the heart (which are always weakened in those fevers), and thus retards or prolongs convalescence. Gelsemium is a remedy for elevation of temperature, whether from cold, or due to graver affections, as the fevers above noticed, or whether due to *pneumonia, pleurisy*, or even *puerperal fever*, in which it is often of marked value. Chilly sensations upon moving the body are indications for it, and are usually followed by the high temperature and the stage of excitation, in which the drug has earned its reputation.

Gelsemium possesses a most perfect control over the nervous system, removing nervous irritability more completely than any other known agent. Such agents as passiflora increase its efficiency in this direction. Prof. W. E. Bloyer (*E. M. J.*, 1894, p. 532) writes: "There is a species of *nervousness* that gelsemium always overcomes. The patient says that he is 'nervous.' He is grouchy, touchy, every impulse and feeling, whether painful or pleasant, is magnified or accelerated, and the contracted pupil is not always specially noticeable. If the patient be nervous and without fever or inflammation, give him pulsatilla; with these, give specific gelsemium."

By allaying nervous excitement and restoring the secretions it prepares the system for quinine, for quinine is very frequently associated with gelsemium in the treatment of various conditions. In the *fevers* and *inflammations of children* this irritation is often marked, and frequently results in *convulsions*. These cases are promptly relieved by gelsemium, which, as an antispasmodic, is second to no other drug. Its power is well displayed in *convulsions from dentition*, and in like conditions from *inflammatory states of the digestive tract*, as *enteritis*, *gastro-enteritis*, especially in *bowel troubles of the second summer*, as *cholera infantum*, *diarrhœa*, and *dysentery*. Its powerful antispasmodic action makes it especially applicable to hysterical females. In *hysteria*, begin with 1 drop and increase until the muscles relax and diplopia results. In *convulsions*, with cramping rigidity of the muscles, give gelsemium until its physiological effects are produced. *Neuralgia*, with powerful nervous twitching, is relieved by it. *Toothache*, from peridental inflammation, is relieved by it as well as that form of toothache frequently accompanying pregnancy. It is a good agent in *facial neuralgia* from nerve excitation and darting pain, from cold, or from dental caries. Administer in drop doses. *Insomnia* is often relieved by gelsemium. It is prominent as a remedy for *pain*, though the specific indication (nervous tension) should be present or the remedy will be likely to fail. There must also be evidence of increased circulation—hyperemia of the part. In *headache*, with active circulation, and especially from *eye strain*, in *migraine*, in *nervous headache*, and in *myalgia*, administer small doses. It also benefits *bilious headache* and *tic-douloureux*. For *ovarian neuralgia* full doses are necessary. It benefits *intercostal neuralgia* and *sciatica*. It relieves the tenesmus of *dysentery* and other *spasmodic conditions of the bowels*. It is a valuable agent in *chorea*, and it has been used with marked success in *epilepsy* and *tetanus*, its effects in the latter affection having been very favorable. In *spasmodic conditions of the urinary tract* it is frequently indicated. It produces relaxation during the passage of *renal calculi*. Scanty flow of urine, with irritation of urinary passages, calls for gelsemium. It should generally, unless specially contraindicated, be given previously to or with the indicated diuretic, when *urinal suppression* is due to renal or cystic irritation (not congestion). It is *the* remedy for *dysuria* from *spasmodic urethral stricture*. Hot applications to the loins and back aid its action. It acts promptly in the *retention of urine* in the hysterical woman. It is a good remedy in *gonorrhœa*, and some cases of *spermatorrhœa* in plethoric subjects have been cured by it, though as a rule it is far less serviceable than other agents in nocturnal emissions. One of its early uses was for gonorrhœa, for which it was thought to be almost specific. For the early inflammatory stages of this affection, with tendency to *chordee*, no agent is more prompt than gelsemium. It is frequently given with aconite and cannabis indica for this purpose. Gelsemium quickly relieves the tenesmic pain, ischuria, etc., of *irritative catarrhal conditions of the bladder*. *Inflammation of the kidneys, bladder* or *urethra*, are relieved by gelsemium. In *puerperal convulsions* it has probably been used oftener than any other remedy, excepting morphine and chloroform.

In the pelvic disorders of women it is a favorite remedy. With the usual indications it subdues *ovaritis*, *metritis*, and *salpingitis*. Severe *dysmenorrhœa* with colicky pains, and *uterine colic* are promptly relieved by large doses of it. *Rigid os uteri*, with thin, unyielding edges, and a dryness of the parts, is relaxed by gelsemium. In fact, it relaxes all sphincters. By rectifying such complications it facilitates *labor*. Free doses should be administered. Gelsemium, alone or combined with pulsatilla, is invaluable to overcome the marked restlessness evinced by some parturients, and gelsemium will often retard a labor that has begun before the parts are ready for the ordeal, particularly when the woman is excessively excitable and nervous, and the pains are spurious, or at least jerky and ineffectual. The *nervous tension* following accouchement is quickly relieved by this drug. *After-pains* are controlled by it, and it is serviceable in some forms of *leucorrhœa*.

By blunting peripheral sensibility it allays the itching of *eczema*, and locally applied (diluted) is serviceable in *prurigo*. *Delirium tremens*, *mania*, and *paralysis* have been treated successfully with this drug. It has also been employed to some extent as a mydriatic in eye practice. Prof. King derived considerable advantage from gelsemium in *conjunctivitis*, *muscular asthenopia*, *iritis*, and in *tinnitus aurium*, administered in small doses every 3 or 4 hours; being extremely careful not to carry the influence of the agent to depression or relaxation. Dr. J. Parrish, of Philadelphia, derived the greatest benefit from the administration of this drug, in cases of *habitual drunkards* and *opium eaters*. *Gastro-intestinal irritation* and *irritative dyspepsia*, with feeling of rawness, heat, and pain, with a sensation of knotty contraction in the stomach, call for gelsemium. In the *exanthemata* this remedy is often indicated by the great heat and restlessness. It is nearly always called for in *cerebro-spinal meningitis*. In the recent epidemics of *influenza* (*la grippe*) probably no one remedy was more extensively used, or oftener indicated. Where there were persistent high temperature and headache, with great excitability, it acted promptly and kindly. Gelsemium has been used quite extensively in *whooping-cough*, *spasmodic cough*, *spasm of the glottis*, *asthma*, and the *cough of hysteria*. In *excessive action of the heart*, especially in hysterial subjects, it is often serviceable. Gelsemium has also proved beneficial in *vertigo*, *hemorrhages*, *ague-cake*, *gout* and *rheumatism*, in the latter disease aiding some of the antirheumatic remedies. *Bronchitis*, *laryngitis* and *albuminuria* have also been successfully treated with gelsemium. Externally, gelsemium will be found of service in *neuralgic* and *rheumatic pains*. The usual prescription is from 5 to 15 drops of specific gelsemium in 4 ounces of water. Dose, a teaspoonful. For the larger doses begin with 1 drop, and administer cautiously until the physiological effects are apparent. Dose of specific gelsemium, $\frac{1}{10}$ drop to 10 drops.

Specific Indications and Uses.—Gelsemium is indicated by bright eyes, contracted pupils, flushed face, great heat, and restlessness; mental irritability; insomnia, with excitation; pain over the whole head; dysuria, with scanty secretion of urine; irritation of the urinary tract; pinched, contracted tissues; thin, dry, unyielding os uteri, with dry vaginal walls; arterial throbbing and exalted sensibility; chilly sensations upon motion; hyperemia; and convulsions.

GENISTA.—GENISTA.

The young branches and leaves of *Genista tinctoria*, Linné.

Nat. Ord.—Leguminosæ.

Common Names: *Dyer's green-weed*, *Wood-waxen*, *Green weed*, *Dyer's broom*, *Dyer's weed*.

Botanical Source and History.—This plant is an erect shrub, about a foot high, and is a native of Central Europe. It is quite common in poor soil throughout England, and has been naturalized, and grows abundantly, in a few localities of the eastern United States. The stem is short, woody, and sends up numerous erect branches. The leaves are simple, a character distinguishing the plant from most of the native leguminous plants. They are narrowly lanceolate, acute, entire, sessile, alternate, and attached to the stem at an acute angle. The flowers are numerous, bright yellow, and are borne in terminal, showy racemes. The calyx is 2-lipped, with a deeply 2-lobed upper, and a 3-lobed lower lip. The corolla is papilionaceous, and the 10 stamens are united into a complete tube at the base. The fruit is a flat, several-seeded pod.

There are three English species of Genista, two unarmed; *G. tinctoria*, with smooth, and *G. pilosa*, with hairy, leaves. The armed species, *G. anglica*, has sharp, simple thorns. The leaves of *G. purgans*, a native of France, are used as a cathartic.

Little is known of the chemical history of the several species of *Genista*. Dr. Plugge (*Jahresb. der Pharm.*, 1895, p. 134), investigating the occurrence of the alkaloid *cytisine* in various species of Papilionaceæ, found *Genista tinctoria* and *G. pilosa* to be free from this substance. Genista tinctoria has been in some little repute as a medicine since the day of Culpepper. The flowers yield an inferior yellow dye. The dried plant possesses scarcely any taste. It must not be confused with *Broom tops* (*Scoparius*).

Action, Medical Uses, and Dosage.—Both the flowers and the seeds have been employed in medicine, in *dropsical affections*, and with considerable efficacy. Sixty grains of the powdered seeds produce active catharsis, and even emesis, and is the dose generally advised in *dropsy*. An infusion of the flowers has been advantageously employed in *gout* and *rheumatism*, and is also stated to have been successful in several cases of *albuminuria*, in doses of 2 tablespoonfuls every 1 or 2 hours. Probably a tincture would be found more available. Formerly this plant had an unmerited reputation for the prevention, as well as the cure, of *hydrophobia*.

Specific Indications and Uses.—"Ascites, and œdema with cutaneous disease, or erosion of the skin with exudation" (Scudder, *Spec. Med.*).

GENTIANA (U. S. P.)—GENTIAN.

"The root of *Gentiana lutea*, Linné"—(*U. S. P.*).

Nat. Ord.—Gentianeæ.

COMMON NAMES: *Gentian, Gentian-root.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 182.

Botanical Source.—This plant has a long, thick, cylindrical, wrinkled, ringed, forked, perennial root, brown externally, and yellow within. The stem is 3 or 4 feet high, hollow, stout, and erect. The radical leaves are ovate-oblong, 5-nerved, and 2 or 3 inches broad; those on the stem sessile, ovate, and acute; those next the flowers cordate, amplexicaul, and concave; all are a pale, bright-green. The flowers are large, bright-yellow, in many-flowered whorls, and peduncled; the calyx is monophyllous, of a papery texture, semitransparent, 3 or 4-cleft, with short, lanceolate, unequal segments. The corolla is rotate, with a very short tube, 5 or 6 green glands at the base, 5 or 6-parted, with oblong, acute, narrow, veiny lobes; the stamens, 5 or 6 in number, are not so long as the corolla; the anthers are subulate, somewhat united, becoming distinct; the ovary conical; the stigmas sessile and revolute; the capsule stalked, oblong, 2-valved, and 1-celled, and the seeds are many and flattened, with thin, brownish edges (L.).

Fig. 120.

Gentiana lutea.

History and Description.—This plant is common to the central and southern parts of Europe, especially the Pyrenees, Alps, etc., being found from 3,000 to 5,000 feet above the level of the sea. Its root affords the medicinal portion, and is brought to this market from Havre, Marseilles, etc. The *U. S. P.* describes it as follows:

"In nearly cylindrical pieces or longitudinal slices, about 25 Mm. (1 inch) thick, the upper portion closely annulate, the lower portion longitudinally wrinkled; externally deep yellowish-brown; internally lighter; somewhat flexible and tough when damp; rather brittle when dry; fracture uneven; the bark rather thick; separated from the somewhat spongy meditullium by a black cambium line; odor peculiar, faint, more prominent when moistened; taste sweetish and persistently bitter"—(*U. S. P.*).

The root imparts its virtues readily to cold or hot water, alcohol, or sulphuric ether. A liquor prepared from it in some parts of Switzerland is much prized as a stomachic; it is made by macerating the root in cold water, adding some sugar, yeast, and distilling after vinous fermentation has occurred. Flückiger (*Pharmacognosie*, 1891), states that as a consequence of this use, the plant has almost disappeared from some parts of Switzerland.

Chemical Composition.—The following three proximate principles are the characteristic constituents of gentian root: *Gentiopikrin*, of Kromayer (1862), to which the root owes its bitterness; *gentisin*, of Hlasiwetz and Habermann (1875), a yellow, tasteless substance, whose reactions with ferric chloride seem to have been mistaken for those of tannin (see Maisch, *Amer. Jour. Pharm.*, 1876, p. 486, and 1880, p. 1); and *gentianose*, of Arthur Meyer (1882), a crystallizable, fermentable sugar, not reducing Fehling's solution, and which occurs in the fresh root only. The root also contains a volatile oil to which its odor is due; fatty and resinous matter, uncrystallizable sugar, large quantities of mucilage, about 8 per cent of ash, but no starch. Drying the root seems to have the effect of increasing the resinous matter (Flückiger, *Pharmacognosie*, 1891).

GENTIOPIKRIN ($C_{20}H_{30}O_{12}$), first obtained pure by Kromayer (*Arch. der Pharm.*, 1862, Vol. CLX, p. 27), was previously described as *gentianin* by Henry and Caventou (1821), and later differentiated by Trommsdorff, Leconte, and Dulk into the bitter *gentianin* and the non-bitter acid *gentisin* or *gentisic acid*.

Gentiopikrin is completely abstracted from aqueous solution by animal charcoal; on this principle its purification was affected. It crystallizes in needles of bitter taste, soluble in water and alcohol, insoluble in pure ether. It is a glucosid, being decomposed by diluted acids into sugar and amorphous, yellow-brown, bitter *gentiogenin* ($C_{14}H_{16}O_5$). Kromayer obtained from 6 pounds of fresh root only 4 grammes of crystallized gentiopikrin. Flückinger (1891) records that alcoholic tinctures of gentian root lose their bitterness upon standing, crystallized dextrose being deposited (Crawfurd and Wittstein). Alkali likewise destroys the bitterness of the tincture.

GENTISIN ($C_{14}H_{10}O_5$), of Hlasiwetz and Habermann (*Jaresb. der Pharm.*, 1874, p. 309), forms yellow, tasteless needles, nearly insoluble in water and ether, crystallizable from alcohol. The researches of Kostanecki and his pupils (*Ber. d. Deutsch. Chem. Ges. Ref.*, 1891 and 1894) have shown that this substance is a *trioxyxanthone* belonging to the same class of substances as *chrysin*, *quercetin*, *fisetin*, and other vegetable dyes. Fusing with caustic potash splits gentisin into acetic acid, phloroglucin, and oxysalicylic acid ($C_9H_6O_4$), an isomer of protocatechuic acid: it was probably the *gentisic* or *gentianic acid* of older authors. In 1894, Kostanecki and Tambor succeeded in effecting the complete chemical synthesis of gentisin (which is *methyl-gentiseïn*, Kostanecki, 1891); *gentiseïn* ($C_{13}H_8O_5+H_2O$) being the intermediary product (*Ber. d Deutsch. Chem. Ges. Ref.*, 1894, p. 190). G. W. Kennedy (*Amer. Jour. Pharm.*, 1881, p. 280), found *gentiopikrin* and *gentisin* also in the root of *Frasera Walteri* (which see).

Action, Medical Uses, and Dosage.—A powerful tonic, improves the appetite, strengthens digestion, gives more force to the circulation, and slightly elevates the heat of the body. When taken in large doses it is apt to oppress the stomach, irritate the bowels, and even produces nausea and vomiting, as well as fullness of pulse and headache. Its administration is contraindicated where gastric irritability or inflammation are present. Used in cases of *debility* and *exhaustion*, and in all cases where a tonic is required, as *dyspepsia*, *gout*, *amenorrhœa*, *hysteria*, *scrofula*, *intermittents*, *diarrhœa*, *worms*, etc. A tincture made by percolation of 1 part of podophyllum and 5 parts of gentian, diluted alcohol being the menstruum, was prized by Prof. Scudder as one of the most efficient remedies for "*atony of the stomach and bowels* with feeble or slow digestion" (*Spec. Med.*). Gentian is valuable to relieve irritation and increase the appetite, after protracted fevers, where the powers of life are depressed and recovery depends upon ability to assimilate food. Dose of the powder, from 10 to 30 grains; of the extract, from 1 to 10 grains; of infusion, 1 or 2 fluid ounces; of tincture, 1 or 2 fluid drachms; of specific gentiana, 5 to 40 drops.

Dr. Küchenmeister believes that impure and uncrystallized gentianin (see previous editions of the *Amer. Disp.*) is the most valuable substitute for quinine, acting as rapidly and as efficaciously on the spleen, in doses of from 15 to 30 grains twice a day.

Specific Indications and Uses.—"Sense of depression referred to epigastric region, and associated with sense of physical and mental weariness" (Scudder, *List of Specific Indications*).

Related Species.—*Gentiana Catesbæi*, Walter (*Gentiana Saponaria*, Linné), *Blue* or *American gentian*, has a perennial, branching, somewhat fleshy root, with a simple, erect, rough stem, 8 to 10 inches in height. Leaves opposite, ovate or lanceolate, slightly 3-veined, acute, rough on the margin. Flowers large, blue, crowded, subsessile, axillary, and terminal. Calyx divided into 4 or 5 linear-lanceolate segments longer than the tube. Corolla large, blue, ventricose, plaited; its border divided into 10 segments, the outer 5 roundish and more or less acute, the inner 5 bifid and imbricate. Stamens 5, with dilated filaments and sagittate anthers. Ovary oblong-lanceolate, compressed, supported by a sort of pedicel. Style none; stigmas 2, oblong, reflexed. Capsule oblong, acuminate, 1-celled, 2-valved (L.—B.). It grows in the grassy swamps and meadows of North and South Carolina, flowering from September to December. The root is about ⅓ inch in thickness and 3 inches long, having a vivid, yellow, epidermal covering, under which is a whitish, spongy, cortical layer enclosing a thin column of woody tissue. Its bitterness is less pronounced than that of the official drug. It is little inferior to the foreign gentian, and may be used as a substitute for it in all cases, in the same doses and preparations. Alcohol and boiling water extract its virtues. Probably the *Gentiana Andrewsii*, Grisebach, or *Closed blue gentian*, the *Gentiana puberula*, Michaux, and the *Gentiana crinita*, Frœlich, or *Blue fringed gentian*, possess analogous medicinal virtues. Maisch believed the two first-mentioned to be collected indiscriminately with the *Gentiana Catesbæi*, of Walter, The same author also found the root of *Gentiana crinita*, Frœlich, and of *G. Catesbæi*, Walter. to be free from tannin (*Amer. Jour. Pharm.*, 1876, p. 487).

The following European species are sometimes gathered and used like gentian:

Gentiana purpurea, Linné. South and Central Europe, in Alpine meadows. Differs from gentian root only in having a peculiarly branched top, and being of a more pronounced bitter. Flowers yellow-purple.

Gentiana punctata, Linné. South and Central Europe, Alpine districts. Resembles preceding. Flowers yellow and dotted with purple.

Gentiana pannonica, Scopoli. Austrian mountain districts. Root smaller than that of *G. purpurea*, but similar in other respects. Flowers deep-purple.

GENTIANA OCHROLEUCA.—OCHROLEUCOUS GENTIAN.

The root and tops of *Gentiana ochroleuca*, Frœlich.

Nat. Ord.—Gentianeæ.

Common Names: *Marsh gentian*, *Yellowish-white gentian*, *Straw-colored gentian*, *Sampson snakeroot*, etc.

Botanical Source.—This plant has a stout, ascending stem, mostly smooth, from 1 to 2 inches in height. The leaves are from 2 to 4 inches long, ¾ of an inch to 1½ inch wide, obovate-oblong, sessile or amplexicaul, margin slightly scabrous, narrowed at the base, the lowest broadly ovate and obtuse, the uppermost somewhat lanceolate. The flowers are straw-colored, 2 inches long, ¾ of an inch thick, disposed in a dense, terminal cyme, often also in axillary cymes. The calyx is 5-cleft, the lobes unequal, linear, longer than the tube, and shorter than the corolla. The corolla is clavate, connivent or slightly expanding at the top, ochroleucous or straw-colored, with green veins and lilac-purple stripes internally; the lobes are ovate and obtuse; the folds entire, acute, and short. Anthers separate. The capsule or pod is included in the persistent corolla. The seeds are entirely wingless (W.—G.).

History.—This plant is found growing in dry grounds, especially through the middle and low country of the southern states, flowering in September and October. Said likewise to inhabit Canada, and the western states, but this must be rare. The root is the medicinal part, and the tops are also often employed. They are bitter to the taste, and probably possess the medicinal properties, in a greater or less degree, of the other plants of the same family. Alcohol or boiling water extracts their virtues. None of the American Gentians seem to have been satisfactorily analyzed.

Action, Medical Uses, and Dosage.—Bitter tonic, anthelmintic, and astringent. Formerly much used in *dyspepsia*, *intermittents*, *dysentery*, and all *diseases of periodicity*. To 2 ounces of the tops and roots, pour on 1½ pints of boiling water, and when nearly cold, add ½ pint of brandy. Dose, from ½ to 4 fluid ounces, every ½ hour, gradually increased as the stomach can bear it, at the same time lengthening the intervals between the doses. Also used for *bites of snakes*, and in *typhus fever*, *pneumonia*, etc. This is a valuable agent, and deserves greater attention from the profession than it has received. It will be found very useful as a tonic to all enfeebled mucous tissues, and especially when there is more or less mucous discharge, as in *chronic catarrhal affections*, *mucous diarrhœa*, etc.

GENTIANA QUINQUEFLORA.—FIVE-FLOWERED GENTIAN.

The root of *Gentiana quinqueflora*, Lamarck.

Nat. Ord.—Gentianeæ.

COMMON NAMES: *Five-flowered gentian*, *Gall-weed.*

ILLUSTRATION: *Botanical Magazine*, Plate 3496.

Botanical Source.—This is an annual plant, found in woodland pastures and other open situations in the eastern section of the United States. The stem is smooth, erect, 4-angled, and from 1 to 2 feet high. The leaves are opposite, entire, sessile, slightly cordate, clasping the stem at the base, and acute at the apex. They are about 1 inch long, and have from 3 to 5 veins proceeding from the base. The flowers, which appear late in the summer, and open only in sunshine, are of a bright-blue color, and erect. They are borne on loose panicles. in axillary and terminal clusters of 3 to 5, on pedicels shorter than the flowers. The calyx is about one-quarter the length of the corolla, and is deeply 5-parted, having very narrow, linear lobes. The corolla is smaller than in the other native species of Gentiana, being slightly less than an inch in length. It is narrowly bell-shaped, and has 5 acute, short lobes. The stamens are 5, and attached to the corolla tubes; they have versatile anthers, which are introrse when the flower expands, but at length turn away from the pistil. The pistil consists of a 1-celled ovary, supported on a slender stipe, and bears 2 distinct, sessile stigmas. The fruit is a dry capsule, opening by 2 valves, and filled with very numerous small seeds. The plant above described is the form of Gentiana quinqueflora occurring in the eastern section of the United States. A western variety (var. *occidentalis*, Gray) differs in being more robust, and in having the calyx-lobes half the length of the corolla. It occurs in the prairies of Illinois, and throughout the neighboring states, and southwardly.

History and Description.—This plant was recommended as a substitute for quinine, the root being employed. As found in the market, under the above name, it is about the size of senega, has the general appearance of this root, excepting the angled form and ridge. It has a smooth bark, which is light-yellow externally, and white within. It breaks with a clear fracture and is hard and woody. The taste is very bitter, resembling the Apocynums rather than *Gentiana lutea.* It has never been chemically examined. The plant grows in woods and pastures, flowering in September and October, and is found from Vermont to Pennsylvania.

Action, Medical Uses, and Dosage.—Gentiana quinqueflora, Five-flowered gentian, sometimes called Gall-weed, on account of its intense bitterness, has been found of much service in *headache*, *liver affections*, *jaundice*, etc., and is greatly superior in its action to the official root. This is certainly a valuable tonic and cholagogue, and deserves further investigation. It is regarded a valuable agent in *chronic gastro-intestinal atony.* Dose of a saturated tincture of the recent root, from 5 to 40 drops.

GERANIUM (U. S. P.)—GERANIUM.

"The rhizome of *Geranium maculatum*, Linné"—(*U. S. P.*).

Nat. Ord.—Geraniaceæ.

COMMON NAMES: *Cranesbill*, *Wild cranesbill*, *Crowfoot*, *Spotted geranium*, *Alum-root*, etc.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 42; Johnson's *Med. Bot. of N. A.*, Plate 4.

Botanical Source.—Geranium has a perennial, horizontal, thick, rough and knobby root, with many small fibers. The stems are grayish-green, erect, round, clothed with reflexed hairs, angular, dichotomous, and 1 or 2 feet high. The leaves are spreading, hairy, palmate, with 3, 5, or 7 deeply cleft lobes, 2 leaves at each fork; lobes cuneiform, entire at the base, and incisely serrate above. The radical leaves are on long petioles, erect and terete; leaves at the top opposite, subsessile, those at the middle of the stem opposite, petiolate, and generally reflexed. Stipules linear or lanceolate. The flowers are large, generally purple, mostly in pairs, on unequal pedicles, sometimes umbelled at the ends of the peduncles. Peduncles long, round, hairy, tumid at the base, and at the forks of the stems 2-flowered. The calyx consists of 5 obovate, ribbed, mucronate sepals, the outermost hairy. The petals are 5, obovate, entire, light purple, and marked with green at the base. The stamens are erect or curving outward, alternately longer, furnished at the base with glands, terminated by oblong, convex, deciduous, purple anthers. Ovary ovate; style straight, as long as the stamens; stigmas 5, at first erect, and afterward recurved. The capsules are 5, together, and each 1-seeded (L.—W.).

Fig. 121.

Geranium maculatum.

History and Description.—Geranium is a native of this country, growing in nearly all parts of it in low grounds, open woods, etc., flowering from April to June. There are several varieties of this species which are probably equivalent in medicinal virtues to the *G. maculatum.* The dried root is the official part. It is officially described as follows: "Of horizontal growth, cylindrical, 5 to 7 Cm. (2 to 3 inches) long; about 1 Cm. ($\frac{2}{5}$ inch) thick; rather sharply tuberculated, longitudinally wrinkled, dark-brown; fracture short, pale reddish-brown; bark thin; wood-wedges yellowish, small, forming a circle near the cambium line; medullary rays broad; central pith large; roots thin, fragile; inodorous; taste strongly astringent (*U. S. P.*).

Chemical Composition.—Geranium was analyzed, in 1829, by Dr. Staples, who found it to contain a large quantity of gallic acid, tannic acid, mucilage, red coloring matter, principally in the external covering of the root, a small amount of resin, and a crystallizable vegetable substance (*Jour. Phil. Col. Pharm.*, Vol. I, p. 171). The Messrs. Tilden have more recently made a quantitative analysis of the root, and found it to contain a resin soluble in alcohol, a resin soluble in ether, an oleoresin soluble only in ether, tannin, gallic acid, gum, pectin, starch, sugar, albumen, lignin, chlorophyll, etc. (*Pharm. Jour.*, 1863, Vol. V., p. 22). H. K. Bowman, in 1869, found in the root of Geranium maculatum about 13 and 17 per cent, and Chas. F. Kramer, in 1882, about 17 per cent of tannin; while Henry J. Mayers, who made a complete analysis of the root (*Amer. Jour. Pharm.*, 1889, p. 238), obtained only 4.28 per cent, with much decomposed tannin (phlobaphene); from another specimen he obtained about 11.5 per cent. He also confirmed the presence of gallic acid. More recently (*Bull. Kew. Gardens*, 1896, No. 109, p. 30) Henry R. Procter found as high as 25.7 per cent tannin. These contradictory results are sufficiently explained by the researches of Prof. Trimble and Mr. J. C. Peacock (*Amer. Jour. Pharm.*, 1891, p. 265). In these experiments moisture and tannin were determined in samples which were obtained from 14 collections systematically extending over a period of two years. The principal result of this work may be summarized as follows:

I. Root collected in January had 11.72 per cent tannin, calculated on absolutely dry drug. The amount rose to 27.85 per cent in spring, just before bloom, and fell to 9.72 per cent in October.

II. The tannin obtained yields pyrogallol, upon heating, hence is related to gallotannic acid.

III. The tannin obtained is a glucosid; when heated with 2 per cent hydrochloric acid it easily decomposes into gallic acid, glucose, and *geranium red*, a phlobaphene, which also forms as a red-brown precipitate when a 1 per cent solution of the tannin is allowed to stand.

IV. No gallic acid is present in the fresh root, nor in the decoction made therefrom; only after the rhizome is dried is gallic acid present, due to the decomposition of the tannin.

Action, Medical Uses, and Dosage.—Geranium is a powerful astringent. Used in infusion with milk in the second stage of *dysentery*, *diarrhœa*, and *cholera* *infantum.* In bowel disorders it is the chronic or subacute states in which it is applicable, and especially where the discharges are abundant and debilitating. The relaxation of membranes following the inflammatory stage is an indication for its use. In dysentery it is not adapted to the first and acute stage, but should be used, atter a laxative, as magnesium sulphate, where the disease tends to chronicity. The infusion or the specific geranium in milk may be employed. Both internally and externally it may be used wherever astringents are indicated, in *hemorrhages, indolent ulcers, aphthous sore mouth, ophthalmia, leucorrhœa, gleet, hematuria, menorrhagia, diabetes,* and all excessive *chronic mucous discharges;* also, to cure *mercurial salivation. Relaxation of the uvula* may be benefited by gargling with a decoction of the root, as well as *aphthous ulceration of the mouth and throat. Chronic pharyngeal catarrh* has been cured with it, while recently an old-school authority claims for it restorative properties in *incipient pulmonary consumption.* From its freedom from any nauseous or unpleasant qualities, it is well adapted to infants and persons with fastidious stomachs. In cases of *bleeding piles,* a strong decoction of the root may be injected into the rectum, and should be retained as long as possible. Hemorrhoids are said to be cured by adding of the root in fine powder, 2 ounces, to tobacco ointment, 7 ounces, and apply to the parts, 3 or 4 times a day. Troublesome *epistaxis, bleeding from wounds* or small vessels, and from the extraction of teeth, may be checked effectually by applying the powder to the bleeding orifice, and, if possible, covering with a compress of cotton. With Aletris farinosa in decoction, and taken internally, it has proved of superior efficiency in *diabetes,* and in *Bright's disease of the kidney.* A mixture or solution of 2 parts of hydrochlorate of berberine and 1 part of extract of geranium, will be found of unrivaled efficiency in all *chronic mucous diseases,* as in *gleet, leucorrhœa, ophthalmia, gastric affections, catarrh,* and *ulceration of the bladder,* etc., etc. A decoction of 2 parts of geranium and one of sanguinaria forms an excellent injection for *gleet* and *leucorrhœa.* Dose of the powder, from 20 to 30 grains; of the decoction, from 1 to 2 fluid ounces; of specific geranium, 5 to 30 drops.

Specific Indications and Uses.—Relaxed mucous tissues, with profuse, debilitating discharges; chronic diarrhœa, with mucous discharges; chronic dysentery; diarrhœa, with constant desire to evacuate the bowels; passive hemorrhages.

Related Species.—*Geranium Robertianum,* Linné, or *Herb Robert,* grows wild both in Europe and in the United States, but is rare in this country; and Pursh states that the American plant is destitute of the heavy smell by which the European is so well known, though the two agree in all other respects. It has a tapering root, with several round, leafy, branched, reddish, brittle, succulent, and diffuse stems, hairy, chiefly on one side (L.—W.). The plant flowers from May to September, and has a strong, unpleasant smell. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. A bitter principle and tannin are among its constituents. It has been used internally in *intermittent fever, consumption, hemorrhages, nephritic complaints, jaundice,* etc., and has been employed as a gargle in *affections of the throat,* and applied externally as a resolvent to *swollen breasts* and other *tumors.*

Erodium cicutarium, L'Héritier (*Geranium cicutarium,* Linné), *Storksbill.*—Southern Europe and common in Western United States, though scarce in Atlantic states. A valuable nutritious forage plant, and, though neither a clover nor a grass, is known as *Alfilaria* (from Spanish *alfilerilla,* signifying *pin;* hence pin-weed), *Pin-clover, Pin-grass,* and *Filaree.* Cold weather does not kill it and it is the only green vegetable substance available for stock in dry seasons. It is said to impart a fine flavor to butter and milk (see *Agr. Grasses and Forage Plants of U. S.,* by Vasey, 1889). Diuretic for *dropsy.*

Erodium moschatum, Aiton.—Mediterranean Europe, north and south Africa, and California. Valuable forage plant in dry seasons. It has the odor of musk. Therapeutically it is diaphoretic. Other astringents are:

Vinca major, Greater periwinkle; Vinca minor, Lesser periwinkle.—England. Reputed useful in *menorrhagia* and other *hemorrhagic states.*

Oroxylum indicum.—East India. Bark contains an acrid substance and a yellow crystalline principle. *oroxylin* (*Pharm. Jour. Trans.,* 1890, Vol. XXI, p. 257). Bark a powerful sudorific, astringent and tonic. Employed in *diarrhœa.*

Raimbaultii combretum.—Africa. Contains an abundance of tannin. Employed by the Africans in *hematuric bilious fever.*

GERARDIA.—BUSHY GERARDIA.

The herb of *Gerardia pedicularia,* Linné (*Dasystoma pedicularia,* Bentham).

Nat. Ord.—Scrophulariaceæ.

COMMON NAMES: *Bushy gerardia, Lousewort, Fever weed, American fox-glove.*

Botanical Source.—This is a perennial plant, whose stem is tall and bushy, with a scattered woolly pubescence, 2 or 3 feet in height, and brachiate-panicled. The leaves are numerous, opposite, ovate-lanceolate or oblong, pinnatifid, the segments being doubly cut-dentate. The flowers are large, yellow, axillary, trumpet-shaped, opposite, and pediceled; the pedicels are longer than the calyx. Calyx 5-cleft, cut-dentate, segments as long as the hairy tube. Corolla yellow, an inch or more in length, subcampanulate, unequally 5-lobed, segments mostly rounded, spreading, leaf-like, and woolly inside. Capsule 2-celled, dehiscent at the top (L.—W.).

History.—This is a most elegant plant, found growing in dry copses, pine ridges, and barren woods and mountains from Canada to Georgia and Kentucky, and flowering in August and September. The whole plant is used. Water or spirit extracts its virtues. It has not been analyzed. There are several varieties of the species, which probably possess analogous virtues.

Action, Medical Uses, and Dosage.—Diaphoretic, antiseptic, and sedative. Used principally in *febrile* and *inflammatory diseases;* a warm infusion produces a free and copious perspiration in a short time. Dose of the infusion, from 1 to 3 fluid ounces.

GEUM.—GEUM.

The rhizome and rootlets of *Geum rivale*, Linné, and *Geum virginianum*, Linné. *Nat. Ord.*—Rosaceæ.

Common Names: (1) *Water avens*, *Purple avens;* (2) *Virginia geum*, *Throat-root*, *Chocolate-root*.

Botanical Source.—*Geum rivale*, likewise known as *Purple avens*, is a perennial, hairy, deep-green herb, with a creeping, blackish, somewhat woody root, running deep into the ground, with numerous fibers. The stems are 1 or 2 feet high, nearly simple, erect, and slightly paniculate at top. The radical leaves are nearly lyrate, uninterruptedly pinnate, with large terminal leaflets on long hairy petioles, rounded, lobed, and crenate-dentate, and from 4 to 6 inches long. The cauline leaves are few, subsessile, from 1 to 3 inches long, and divided into 3 serrate, pointed lobes; the stipules are ovate, acute, cut, and purplish, The flowers are few, sub-globose, nodding, yellowish-purple, on axillary and terminal peduncles. The calyx is inferior, erect, purplish-brown, with 10 lanceolate, pointed segments, 5 alternately smaller than the others; petals 5, as long as the erect calyx segments, broad-obcordate, clawed, purplish-yellow, and veined. The seeds are oval, bearded, and hooked at the end (L.—W.—G.).

Geum virginianum, Linné, also known as *Throat-root*, *Chocolate-root*, etc., is also perennial, with a small, brownish, horizontal, crooked root. The stem is simple or branched, smoothish above, pubescent below, and 2 or 3 feet high. The radical leaves are pinnate, lyrate, or simple and rounded, with appendaged petioles from 6 to 8 inches long; the cauline leaves 3 or 5-lobed, softly pubescent; all the leaves are unequally and incisely dentate. The flowers are rather small, white, erect, and borne on long, diverging peduncles; the calyx is 5-cleft, with 5 smaller and exterior, alternate bracteoles; the petals 5, about the length of the calyx; the stamens numerous; filaments slender, anthers yellowish and round. The styles are many, persistent, mostly jointed, geniculate, bearded, and hooked after the upper joint falls away. The fruit is an achenia, aggregated on a dry receptacle caudate with the style (W.—G.).

History and Description.—*Geum rivale* is common to Europe and this country, and is found growing in woods, wet meadows, and along streams, especially in the northern and middle states, and flowering in June and July. The American species differs from the European (*Geum urbanum*, Linne), in having the petals more orbicular on their free margin, the flowers of less size, and its leaves with deeper incisions. The fresh root is aromatic.

Geum virginianum is found in hedges and thickets, and in moist places in most parts of the United States, flowering from June to August. These plants, with some other varieties, have long been used in domestic practice. The whole herb contains medicinal properties, but the medicinal and most efficient portion is the root. The dried root of the *G. rivale* is scaly, jointed, tapering, hard, brittle.

easily pulverized, of a reddish or purplish color, and inodorous; that of the *G. virginianum*, is brown, crooked, tuberculated, and brittle; both are white internally, and of a bitterish, astringent taste. Boiling water or alcohol extracts their virtues, the solution becoming reddish. They have not been analyzed, but probably contain tannic acid, bitter extractive, gum, resin, etc. A weak decoction of the root of *G. rivale* is sometimes used by invalids as a substitute for tea and coffee. Its constituents are probably the same as those of Avens (*Geum urbanum*, Linné) (see *Related Species*).

Action, Medical Uses, and Dosage.—Tonic and astringent. Useful in all cases where there is an enfeebled state of mucous tissues, or morbid secretions therefrom. Large doses may cause emesis. Used in numerous diseases, as *passive* and *chronic hemorrhages*, *chronic diarrhœa* and *dysentery*, *leucorrhœa*, *dyspepsia*, *phthisis*, *congestions of the abdominal viscera*, *intermittents*, *aphthous ulcerations*, etc. Dose of the powder, from 20 to 30 grains; of the decoction, from 1 to 2 fluid ounces, 3 or 4 times a day. *Geum urbanum*, or *European avens*, possesses similar properties (see below).

Specific Indications and Uses.—(*Geum rivale*). "Tearing, spasmodic, abdominal pains recurring upon taking food or exercise" (Scudder).

Related Species.—*Geum album*, Gmelin; *White geum*. United States. Flowers in May and August. Used in *headaches* and *irritable conditions of the stomach* (*Amer. Jour. Pharm.*, 1883).

Geum urbanum, Linné; *Avens*, *European avens*. Europe, growing in woodlands and shady situations, and has yellow flowers. The rhizome of this plant is hard, dark-brown, tuberculated at top, short (1 or 2 inches long and from ¼ to ½ inch thick), and has the summit beset with hairy, reddish-brown leaf scales. The fresh rhizome resembles cloves in odor, hence has been called *radix caryophyllata*. Internally the rhizome is whitish, surrounding a central red portion. It has many fibrous roots of a lighter brown hue. It imparts a red color to both water and alcohol. Buchner analysed it in 1844, and found a considerable amount of tannin and an amorphous and neutral yellow mass, to which he gave the name *geum bitter*. He also confirmed the observation of Trommsdorff as to the presence of a greenish-yellow volatile oil (0.04 per cent), and found that it has a clove-like odor (*Rep. d. Pharm.*, 1844, Vol. LXXXV, p. 168 to 201).

Avens is an astringent tonic considerably employed in European practice, where it is used in *intermittents*, *dysentery* and *diarrhœa*, *passive hemorrhages*, and *leucorrhœa*. It is apt to derange the stomach and induce emesis if given too freely. The dose of the powder is from 20 to 60 grains, but the decoction, made by boiling 1 ounce of avens in 1 pint of water, is preferable. The dose is 1 or 2 fluid ounces

GILLENIA.—INDIAN PHYSIC.

The bark of the rhizome of *Gillenia trifoliata*, Moench (*Spiræa trifoliata*, Linné), and *Gillenia stipulacea*, Nuttall (*Spiræa stipulata*, Willdenow).

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Indian physic*, *American ipecac*, *Indian hippo*, and sometimes *Bowman's root*.

Botanical Source.—Indian physic is an indigenous, perennial herb, with an irregular, brownish, somewhat tuberous caudex, from which radiate many long, knotted, delicate fibers. The stems are several, from the same root, about 2 or 3 feet in height, erect, slender, flexuose, smooth, branched above, and of a reddish or brownish color. The leaves are alternate, trifoliate, subsessile, furnished with small linear-lanceolate and slightly-toothed stipules at the base; the leaflets are lanceolate, acuminate, sharply and unequally toothed, the upper ones often single, the lower broader at the end, but acuminately terminated. The flowers are white, with a reddish tinge, borne in terminal, loose panicles, few in number, scattered, on long peduncles, occasionally furnished with minute, lanceolate bracts. The calyx is subcampanulate or tubular, terminating in 5 sharp, reflexed teeth. Petals 5, the 2 upper ones separated from the three lower, white with a reddish tinge on the edge, lanceolate, unguiculate, contracted and approximated at base and 3 times as long as the calyx. The stamens are about 20, in a double series within the calyx, with short filaments, and small, yellow anthers. Styles 5, with obtuse stigmas. Capsules 5, connate at base, oblong, acuminate, diverging, gibbous without, sharp-edged within, 2-valved, 1-celled, and 1 or 2-seeded. The seeds are oblong, brown, and bitter (L.—B.).

History.—The plant *Gillenia trifoliata*, sometimes called *Bowman's root*, is found growing from Canada to Florida, in rich woods, light, gravelly soils, and in moist and shady situations; it is more common in the Atlantic States than the Western. It blossoms from May to August. The root is the medicinal part, and must be collected in autumn. As met with in commerce it is a dry, tuberculated root, 3 or 4 lines in diameter, corrugated lengthwise, and of a reddish-brown color externally; it is composed of a light-colored, ligneous, internal substance, and an easily removed, dense, friable, brownish bark, which is readily reduced to a powder, having a similar color. It is nearly odorless, and has a nauseous, amarous taste, and yields its properties to alcohol or water at 100° C. (212° F.). The bark is the active portion, the internal woody substance being nearly inert. The root of *G. stipulacea* is larger, tuberculated, and the rootlets present an annulated appearance due to constrictions passing part way around the rootlet, forming semicircular depressions.

Gillenia stipulacea, Nuttall, also called *Bowman's root*, which is found on the western side of the Allegheny Mountains, growing through Ohio, Indiana, Illinois, Missouri, and southward, flowering at the same time as the above, possesses similar properties, but is more efficient in the same doses. It may be distinguished by its drab-colored and branching stems, its greater size, its large, clasping, ovate-cordate, leafy, gashed, and serrated stipules, its lower leaves being of a reddish-brown color at the tips; the stipules are leafy, ovate, doubly incised and clasping; and the flowers are fewer, smaller, on slender peduncles, hanging in loose panicles. It is seldom met with in limestone or alluvial soils. (For an interesting article on the nomenclature of Gillenia, see *Amer. Jour. Pharm.*, 1898, p. 501.)

Chemical Composition.—According to Mr. Shreeve, gillenia contains starch, gum-resin, wax, a fatty matter, a red coloring substance, a volatile coloring matter, and a peculiar principle soluble in alcohol and diluted acids, but insoluble in water or ether (*Amer. Jour. Pharm.*, Vol. I, p. 28). Mr. W. B. Stanhope procured *gillenin* from Gillenia trifoliata by making an alcoholic extract of the powdered bark, evaporating to dryness, treating with water, macerating the resinous and bitter residue with diluted sulphuric acid for 10 days, filtering, evaporating with excess of magnesia, extracting with alcohol and allowing the solvent to evaporate spontaneously. The gillenin thus obtained was permanent in the air, very bitter, soluble in water, alcohol, ether, and diluted acids, neutral, giving a fine green color with chromic acid, and blood-red with strong nitric acid. Tannic acid produced no effect, but caustic potash, subacetate of lead, and tartar emetic threw down white precipitates. In doses of ½ grain it produced emesis, with considerable vertigo (*Amer. Jour. Pharm.*, 1856, p. 200). Mr. Frank W. White (*Amer. Jour. Pharm.*, 1892, p. 121), found the active principle of Gillenia trifoliata to be a glucosid, obtainable by agitating the aqueous solution of the alcoholic extract with chloroform.

In *Gillenia stipulacea* Mr. Gordon L. Curry found two glucosids which he obtained from the ether extract of an aqueous infusion. One, which he named *gillein*, was obtainable in feathery crystals, easily gives off sugar, is soluble in water, alcohol, and diluted acids, and causes nausea in the dose of ¼ grain. The other glucosid, called *gilléenin*, is amorphous, much more stable, soluble in water, but sparingly soluble in alcohol and ether. Neither of these substances gives the reactions of Stanhope's *gillenin*. Sugar, gum, and tannin were also found (*Amer. Jour. Pharm.*, 1892, p. 513). Both this root and that of the Gillenia trifoliata were formerly official in the *U. S. P.*

Action, Medical Uses, and Dosage.—The root-bark of these plants is emetic, cathartic, sudorific, expectorant, and tonic. In their action, they resemble ipecacuanha. Like the latter, their dust will provoke irritation of the throat and breathing organs. They have been recommended in *amenorrhœa*, *rheumatism*, *dropsy*, *habitual costiveness*, *dyspepsia*, *worms*, and in *intermittents*. As an emetic and cathartic, from 20 to 35 grains is a dose, which, when vomiting is required, may be repeated at intervals of 20 minutes. It may be used in all diseases where emetics are indicated, as a safe and efficient agent. In *dyspepsia*, accompanied with a torpid condition of the stomach, from 2 to 4 grains forms an excellent tonic. As a sudorific, 6 grains may be given in some cold water, and repeated at intervals of 2 or 3 hours, or it may be given in combination with a small portion of opium. Large and oft-repeated doses of the infusion cause severe vomiting and purging.

GLECHOMA.—GROUND IVY.

The plant *Glechoma hederacea*, Linné (*Nepeta Glechoma*, Bentham
Nat. Ord.—Labiatæ.

COMMON NAMES: *Ground ivy, Cat-foot, Gill-go-over-the-ground.*

ILLUSTRATION: Johnson's *Med. Bot. of N. A.*, Fig. 145, p. 213.

Botanical Source and Description.—This plant, the *Glechoma hederacea* of Linnæus, is a perennial, gray, hairy herb, with a prostrate, creeping stem, radicating at base, square, and from a few inches to 1 or 2 feet long. The leaves are petiolate, opposite, roundish, cordate-reniform, crenate, hairy, and glaucous on both sides, though often purplish beneath. The floral leaves are of the same form. The flowers are bluish-purple, about 3 together in axillary whorls. The corolla is about 3 times as long as the calyx, with a variegated throat. The calyx is long, curved, villous, the limb oblique, the teeth lanceolate-subulate, the upper being the largest. The bracts are scarcely as long as the pedicel. The 2 anthers of each pair of stamens meet with their 2 divaricate cells, forming the appearance of a cross (L.—W.—G.).

History and Chemical Composition.—This plant is common to Europe and the United States, where it is found growing in shady places, waste grounds, dry ditches, fences and hedges, and on the sides of moist meadows, flowering in May and August. The leaves are the parts used, and yield their virtues, by infusion, to boiling water. They have an unpleasant odor, and a harsh, bitterish, slightly aromatic taste. This plant was found by Mr. Charles A. Ridgway to contain an essential oil (0.06 per cent), fat, resin, gum, wax, sugar, tannic acid, about 16 per cent of ash, etc., and an acrid, fatty substance (0.96 per cent) (*Amer. Jour. Pharm.*, 1892, p. 66).

Action, Medical Uses, and Dosage.—Ground ivy is stimulant, tonic, and pectoral, and has been recommended in *diseases of the lungs* and *kidneys*, *asthma*, *jaundice*, *hypochondria*, and *monomania*. An infusion of the leaves is highly recommended in *lead colic*, and it is stated that painters who make use of it often are never troubled with that affliction. The fresh juice snuffed up the nose is said to cure *headache*. Dose of the powdered leaves, from ½ to 1 drachm; of the infusion, 1 or 2 fluid ounces. A tincture of the fresh plant, prepared with 98 per cent alcohol, may be given in doses of 1 to 15 drops.

GLYCERINUM (U. S. P.)—GLYCERIN.

FORMULA: $C_3H_5(OH)_3$. MOLECULAR WEIGHT: 91.79.

"A liquid obtained by the decomposition of vegetable or animal fats or fixed oils, and containing not less than 95 per cent of absolute glycerin ($C_3H_5[OH]_3$ 91.79)"—(*U. S. P.*).

SYNONYMS: *Glycerina* (*U. S. P.*, 1870), *Glycerine*, *Glycerol*, *Propenyl alcohol.*

History and Preparation.—Glycerin was discovered, in 1779, by Scheele in the saponification products of olive oil by means of litharge, and later recognized by him as a common constituent of other oils and fats, and therefore named the "sweet principle of fats." Chevreul gave it the name *glycerin*, and cleared up the nature of its combination in the fats. Glycerin, or *glycerol*, as it is now preferably called to indicate its alcohol character, is a trihydric alcohol ($C_3H_5[OH]_3$), containing the trivalent radical "glyceryl" (C_3H_5). It exists in oils and fats, combined with palmitic, stearic, and oleic acids in the form of glycerylesters of these acids (*tripalmitin*, *tristearin*, *triolein;* also see under *Adeps*). In some oils and fats it is combined partially with other acids—*e. g.*, in butter—wherein 5 per cent of the total fat is glyceryl-tributyrate, or *tributyrin;* in cod-liver oil it is said to exist in part combined with acetic acid, as glyceryl triacetate, or *triacetin*, etc. Glycerin also exists in the yolk of eggs and the human brain in the form of *phospho-glyceric acid*. Pasteur's researches have also established its occurrence as a regular constituent among the products of fermentation (see *Alcohol*).

On a small scale glycerin may be obtained in the process which led to its discovery, viz., that of making lead plaster (see *Emplastrum Plumbi* The late

Mr. Robert Shoemaker prepared by this method probably the first commercial glycerin in the United States, in 1848, at $4.00 a pound (*Amer. Jour. Pharm.*, 1879, p. 289). The article became official in the *U. S. P.*, in 1850.

Large quantities of glycerin are now obtained as a by-product in the manufacture of soaps and candles. This was formerly thrown away as useless. The principle involved is simply that of splitting the fat into its constituents (*fatty acid* and *glycerin*) by adding the elements of water (see *Emplastrum Plumbi*). The process of saponification is being carried out in several different ways: (1) With *alkalies;* the fatty acids thereby combine with alkali and form soap (see *Sapo*); the glycerin in diluted form is contained in the aqueous layer below the soap. (2) With *milk of lime* (old process of Campbell Morfit, see this *Dispensatory*, previous revision), or with *milk of lime* and *water* in closed vessels under a pressure of 10 atmospheres and a temperature of 172° C. (242.6° F.) (Milly's Autoclave Process, see Prof. S. P. Sadtler, *Handbook of Indust. Org. Chem.*, 1895, p. 56). The glycerin water separates from the layer of lime soap and fatty acids; glycerin is obtained therefrom best by evaporation *in vacuo.* (3) With *superheated steam* ("aqueous saponification") and subsequent redistillation of the raw glycerin. This method was introduced, in 1855, by Messrs. Wilson and Paine, and marked a great step forward in the problem of obtaining a pure article. In saponifying the fats with superheated steam, the temperature must not exceed 300° C. (572° F.), or else decomposition products will be formed. Both the fatty acid and the glycerin distill over. In redistilling the raw glycerin by superheated steam, the liquid is heated to about 180° C. (356° F.), and the steam has a temperature of about 110° C. (230° F.). For details regarding the manufacture of glycerin, consult the various works on chemical technology.

Description.—Glycerin is officially described as follows; "A clear, colorless, liquid, of a thick, syrupy consistence, oily to the touch, odorless, very sweet and slightly warm to the taste. When exposed to the air, it slowly abstracts moisture. Specific gravity, not less than 1.250 at 15° C. (59° F.). Soluble, in all proportions, in water or alcohol, also soluble in a mixture of 3 parts of alcohol and 1 part of ether, but insoluble in ether, chloroform, carbon disulphide, benzin, benzol, and fixed or volatile oils. Glycerin is slowly volatilized from an aqueous solution, at or above 100° C. (212° F.), with the vapor of water. Heated by itself to a higher temperature, it yields acrid decomposition products, boils at a temperature at or above 165° C. (329° F.), and is finally entirely decomposed and dissipated"—(*U. S. P.*). The exceedingly irritating decomposition products are chiefly due to the formation of *acrolein* (*allyl aldehyde*, $C_2H_3.CHO$), which is also formed when fats are burned, or when glycerin is heated with strong sulphuric acid. Yet Prof. Trimble has demonstrated (*Amer. Jour. Pharm.*, 1885, p. 275) the propriety of the use of the vapors of pure glycerin for inhalations, the details being as follows: When 50 grammes of pure glycerin were slowly heated in an open capsule, vaporization became abundant at 130° C. (266° F.). At 264° C. (497.2° F.), slight boiling was perceptible, but very little was left, and the dense vapors formed had a purely sweet taste, absolutely free from any irritating quality. Pure glycerin, when heated to 150° C. (302° F.) in an open crucible, can be ignited, and burns with a blue flame. Glycerin of only 90 per cent can be burned with the aid of a wick, like alcohol, in a spirit lamp. Absolute glycerin has the specific gravity of 1.266 at 15° C. (59° F.), and boils at 290° C. (554° F.), while 95 per cent glycerin has a specific gravity of 1.2526 and boils at 164° C. (327.2° F.) (Gerlach). At one time crystallized glycerin, from a Vienna manufacturer, was brought to London, requiring the knife and hammer to break it. It resembled rock-candy (sugar), being in white, octahedral crystals, with considerable refractive power, and, when melted, the liquid glycerin presented all its usual properties, but could not be again reduced to the crystalline condition. It seems that prolonged exposure to a temperature of 0° C. (32° F.) will bring about crystallization, and contact with a crystal already formed will promote this process. The crystals, while hard and gritty, are very hygroscopic. More recently, some specimens, after being melted, were found by Prof. Trimble to have a high specific gravity (1.2618) (see Wallace Procter, in *Amer. Jour. Pharm.*, 1885, p. 273).

Glycerin dissolves many vegetable exudations and resinous substances. It does not dissolve sugar or gum, but readily mixes with syrups and mucilages.

It is insoluble in fatty matter, and can only be incorporated with it mechanically, to effect which it is necessary that the fat should have a soft consistence, which may be imparted to it by combination with oil of sweet almonds, or some other fixed oil. Glycerin mixes with acetic acid; moistens bodies without rendering them greasy, does not become rancid, and is easily charged with the aroma of volatile oils.

The solubilities of certain substances in glycerin (Klever) as taken from *Chemiker Kalender*, 1897, are as follows: One hundred parts (by weight) of glycerin dissolve at 15.5° C. (60° F.):

	PARTS.		PARTS.
Alum	40	Phosphorus	0.20
Ammonium carbonate	20	Potassium arsenate	50
Ammonium chloride	20	Potassium bromide	25
Arsenic trioxide	20	Potassium chlorate	3.5
Arsenic pentoxide	20	Potassium cyanide	32
Atropine	3	Potassium iodide	40
Atropine sulphate	33	Quinine	0.5
Barium chloride	10	Quinine tartrate	0.25
Benzoic acid	10	Sodium arsenate	50
Boric acid	10	Sodium biborate	60
Brucine	2.2	Sodium bicarbonate	8
Calcium sulphide	5	Sodium carbonate	98
Cinchonine	0.5	Sodium chlorate	20
Cinchonine sulphate	6.7	Strychnine	0.25
Cupric acetate	10	Strychnine nitrate	4
Cupric sulphate	30	Strychnine sulphate	22.50
Iodine	1.9	Sulphur	0.10
Lead acetate	20	Tannic acid	50
Mercuric chloride (corr. subl.	7.5	Tartar emetic	5.5
Mercuric cyanide	27	Urea	50
Morphine	0.45	Veratrine	1
Morphine acetate	20	Zinc chloride	50
Morphine chloride	20	Zinc iodide	40
Oxalic acid	15	Zinc sulphate	35

Glycerin dissolves the vegetable acids, aloes, some resinous substances, the deliquescent salts, the sulphates of potassium, sodium, and copper, the nitrates of potassium and silver, the alkaline chlorides, caustic potash, caustic soda, baryta, strontia, bromine, iodine, and even oxide of lead, and one-fifth part of arsenous acid. It dissolves about 1 per cent of its weight of calcium sulphate, and 2 per cent of chloride of lead. It dissolves the salts of morphine, sulphate of quinine, and, when triturated with these, or with the salts of strychnine, veratrine, brucine, and other vegetable alkaloids, forms a medicinal cerate very useful for frictions and embrocations. It also dissolves sulphides of potassium, of calcium, and of iodine, iodides of sulphur, of potassium, and of mercury, and some chlorides. It promotes the solution of borax in tincture of myrrh, no water being required; added to tincture of kino it retards gelatinization. The vegetable extracts are soluble in it, some of the solutions, as of extract of belladonna, forming useful external applications. Being possessed of strong antiseptic properties, it preserves animal and vegetable substances; meat has been immersed in glycerin for several months and preserved its freshness. It dissolves the carbonate of iron immediately on its formation, giving a deep-green solution. Like sugar it arrests the conversion of the ferrous into ferric salts, and has kept iodide of iron for years without change. It may be used in the preparation of spirits (*essences*) of cloves, cinnamon, etc., for syrups of phosphate of iron, bromide of iron, and iodide of quinine, for preserving fresh lemon juice, and for preserving the soft consistence of pill masses and confections. Thus it is seen that the solvent powers of glycerin, both diluted and undiluted, are very extensive and important.

By oxidation with cold nitric acid, glycerin yields *glyceric acid* ($CH_2OH.CH.OH.COOH$) and a variety of other acids. Potassium permanganate in alkaline solution produces oxalic acid. Upon the latter reaction is based a quantitative determination of glycerin by Benedict and Zsigmondy, a process also indicated by Wm. Fox and J. A. Wanklyn (see *Amer. Jour. Pharm.*, 1886, p. 248). Another method for the quantitative determination of glycerin, by L. Legler and O. Hehner (*Amer. Jour. Pharm.*, 1887, p. 464, from *The Analyst*, Jan. and Feb., 1887).

is based on the fact that glycerin can be completely oxidized to carbonic acid and water by being heated with sulphuric acid and potassium bichromate. Sulphuric acid combines with glycerin to form an ester glycerylsulphuric acid $(SO_4H.C_3H_5[OH]_2)$. Likewise glycerin combines with phosphoric acid to form a similarly constituted compound $(PO_4H_2.C_3H_5[OH]_2)$. Nitroglycerin is a highly explosive compound that is made by methods safe only on a manufacturing scale and in the hands of qualified men (see *Spiritus Glonoini*). Glycerin liberates from borax half its quantity of boric acid; thus if blue litmus solution is added to separate quantities of neutral glycerin and borax solution, when mixed, a red color results. W. R. Dunstan (*Amer. Jour. Pharm.*, 1883, pp. 447–456) has shown that the red color turns blue upon warming, and reappears on cooling. Again, when adding glycerin to a mixture of molecular quantities of bicarbonate of sodium and borax, the boric acid liberated by the glycerin will expel with effervescence half of the carbonic acid in the bicarbonate, and monocarbonate will remain (with reference to this reaction, see also Mr. L. F. Kebler, *Amer. Jour. Pharm.*, 1894, p. 428).

Glycerin is capable of undergoing fermentation under certain conditions. A. Fitz (1877) obtained, by the action of a certain class of fungi, called *Schizomycetes*, from glycerin diluted with twenty times its bulk of water, large quantities of normal butylalcohol and normal butyric acid; also ethyl alcohol, capronic acid, hydrogen, and carbonic acid. Freund has also shown that *trimethyleneglycol* $(C_3H_8O_2)$ is one of the principal products formed. This substance has more recently been demonstrated by A. A. Noyes and W. H. Watkins (*Amer. Jour. Pharm.*, 1895, p. 633), to occur as a troublesome by-product in the manufacture of glycerin from fats that have undergone spontaneous saponification and subsequent fermentation.

Tests and Uses.—For medicinal purposes, glycerin only should be used that has been purified by distillation; an impure glycerin when applied to wounds or ulcers is very apt to cause a burning sensation, and a papular eruption on the skin; when pure it is unirritating. Formerly its impurities were more numerous than now, owing to the imperfect method of its manufacture. The process of purifying glycerin by distillation has reduced the proportion of ash considerably, which in pure distilled glycerin does not exceed 0.2 per cent, while undistilled glycerin from soap lyes may have from 7 to 14 per cent of ash. Impurities liable to occur in glycerin are: water, volatile fatty acids (*e. g.*, formic and butyric acids), added sugar or glucose, empyreumatic substances, oxalic acid, chlorides, sulphates of calcium, magnesium, and heavy metals, as iron, lead, zinc, etc. Siebold (1889) observed the presence of arsenic in glycerin (in one instance, 0.04 per cent), an impurity due to the employment, during manufacture, of sulphuric acid containing it. When present in glycerin, arsenic is exceedingly difficult to remove; it is claimed that agitating with recently precipitated ferric hydrate will remove this contamination (*Amer. Jour. Pharm.*, 1890, p. 523) The presence of iron in glycerin, due, according to Hanssmann (*Amer. Jour. Pharm.*, 1895, p. 84) to its being kept in tinned iron cans, disturbs the color of pharmaceutical preparations in which glycerin is combined with tannin, or phenols, or salicylic acid. Another impurity occasionally occurring in commercial glycerin is the *trimethyleneglycol* before mentioned. Glycerin, beside answering to the official description given before, should conform to the following tests of the *U. S. P.*: "If a fused bead of borax, on a loop of platinum wire, be moistened with glycerin, and then held in the non-luminous flame, the latter will be transiently tinted deep green. An aqueous solution of glycerin is neutral to litmus paper. When a small portion of glycerin is heated to boiling in an open porcelain or platinum capsule, and then gently ignited, it should burn and vaporize so as to leave not more than a dark stain (absence of dextrin and sugar), which would leave a bulky, difficultly combustible, charred mass); and on full combustion no residue whatever should be left (absence of fixed impurities). If 5 Cc. of glycerin be mixed with 50 Cc of water and 10 drops of hydrochloric acid in a small flask, and heated for half an hour on a boiling water-bath, then 10 Cc. of the hot liquid mixed with 2 Cc. of sodium hydrate T.S. and 1 Cc. of alkaline cupric tartrate V.S., no yellowish-red cloudiness or precipitate should appear within six hours (absence of sugars). On gently warming a mixture of equal volumes of glycerin and of concentrated sulphuric acid in a test-tube, the liquid should not acquire a dark color (absence of readily carbonizable impurities). On gradually heating 5 Cc. of glycerin with 3 Cc. of diluted sulphuric acid in a test-tube, short of boiling, no offensive or acidulous odor should be evolved (absence of fatty acids, etc.). No color, cloudiness or precipitate should appear when separate portions of its aqueous solution (1 in 10) are treated with hydrogen sulphide or ammonium sulphide T.S. (absence of metals), barium chloride T.S. (sulphuric acid), calcium chloride T.S. (oxalic acid), or ammonium oxalate T.S. (calcium salts). If a mixture of 2 Cc. of glycerin with 10 Cc. of water, contained in a perfectly clean, glass-stoppered cylinder, be heated for five minutes in a water-bath at a temperature of 60° to 65° C. (140° to 149° F.), then mixed with 10 drops of silver nitrate T.S., and the cylinder set aside, well stoppered, in diffused daylight, no change of transparency or color should occur in the mixture within five minutes (absence of chlorides, and limit of impurities having reducing properties)"—(*U. S. P.*). The presence of butyric acid may be detected, according to the *British Pharmacopœia* (1898), by adding a mixture of equal volumes of alcohol (90 per cent) and diluted sulphuric acid, and gently heating, whereupon the pineapple odor of butyric ether is at once developed. As pure glycerin does not polarize transmitted light, the presence of sugar may be easily recognized also by optical methods. The *British Pharmacopœia* (1898) fixes the limit of arsenic in glycerin by the following test: "2 Cc. diluted with 5 Cc. of a mixture of 1 part of hydrochloric acid and 7 parts of water, 1 Gm. of pure zinc being added, and the whole placed in a long test-tube, the mouth of which is covered by a piece of filter paper moistened with a drop or two of test solution of mercuric chloride, and dried, should not afford a yellow stain on the paper, even after 15 minutes (limit of arsenium)"— *Br. Ph.*, 1898). (Also see article on arsenic in glycerin, by A. C. Langmuir, *Jour. Amer. Chem. Soc.*, 1899, p. 133.) The most extensive use of glycerin, in the industries and arts, is in the manufacture of nitroglycerin; large quantities are also used in the making of cosmetics, and for filling wet-process gas meters to prevent the containing fluid from freezing in winter and evaporating in summer. It is also employed as a food preservative, and for the treatment of wine, vinegar and beer (this process being called *scheelizing*), and in addition to its use in pharmacy and medicine, it is also employed for many practical purposes in the mechanical arts.

Action, Medical Uses, and Dosage.—Stimulant, antiseptic, laxative and demulcent. Pure glycerin abstracts water from the tissues, leaving them hard and irritated, and if of the skin liable to crack; impure glycerin, besides acting in the same manner, is more of an irritant on account of traces of sulphuric and nitric acids as well as certain organic acids, and other deleterious substances contained in it. In view of these facts only the purest glycerin should be used, and that should be mixed with a certain amount of water or rose-water before using. Glycerin may be used in *prurigo*, *psoriasis*, *impetigo*, *lichen*, *lepra*, *pityriasis*, *herpes exedens*, and some *syphilitic* and *strumous affections*. M. Fonssagrives considers its usefulness in *parasitical cutaneous affections* to be due to its antiseptic, antiputrid, and antiparasitical properties. Glycerin has been used in the place of cod-liver oil, to improve nutrition in convalescence from exhausting diseases, and in asthenic conditions generally. It is also used as a solvent of many alkaloids, extracts, salts, acids, etc., etc., especially for local application to *inflamed*, *ulcerated* or *suppurating parts;* also, as stated above, to several cutaneous maladies. Pure glycerin has been recommended for *diabetic patients* by Drs. Pavy and Abbot Smith, as a substitute for cane sugar, honey, molasses, etc., sweetening tea, coffee, various drinks, cakes, etc., with it. It is generally regarded as a non-nutritious substance at the present day, and has lost prestige as a food in *phthisis* and *diabetes*, and other *exhausting diseases*. It can not compare with cod-liver oil for this purpose, though there is some good evidence that it lessens, and in some instances checks, the excretion of sugar in *saccharine diabetes*. Large amounts of glycerin act not unlike alcohol, producing intoxication and the same gastric effects. From one-third to one-twelfth of glycerin may be added to washes or cataplasms, to render them soothing, and to keep the latter moist for some time. It acts as an emollient and soothing application, absorbing moisture from the air, and preventing the parts to which it is applied from becoming too dry.

A very small amount added to a few grains of borax and rose-water, furnishes one of the most elegant and efficient washes for *chapped hands, face, lips, or nipples*. A small quantity of glycerin added to pills or extracts, will preserve them from becoming hard and moldy. Vaccine virus may be preserved by mixing it with glycerin. It has been highly recommended for *deafness* in which there is a partial or total absence of ceruminous secretion, by protecting the tympanum, and gradually restoring the parts to their natural condition; it is likewise said to cause hearing in cases where the tympanum is thickened and indurated, or where it is in an unsound state or destroyed by ulceration; but in this last case it is not permanent; and when there is a hardness of the cerumen, and induration of the tympanum, it has proved successful. The plan is to moisten wool with the glycerin, pure or diluted with water, and pass it into the ear. In fact water and glycerin, or glycerin alone, are the best solvents for impacted and *hardened cerumen*, and by softening the mass with either, it may be readily removed by syringing carefully with warm water. An efficient lotion for dressing the parts after the removal of the impacted mass, is the following: ℞ Colorless hydrastis (Lloyd's), ʒj; glycerin, gtt. xx; distillate of hamamelis, q. s. fl℥ss. Mix. Sig. Apply warm to the parts by means of cotton. The bland and unirritating character of pure glycerin, in the presence of a little water, its permanence when exposed to the atmosphere (except its absorption of moisture), and the completeness with which it shields the parts covered by it, render it susceptible of many important applications. Mr. J. H. Ecky has given a formula for the preparation of a glycerin ointment, especially useful for *chapped hands, lips, excoriations of the skin*, etc. It will also serve as a medium for applying powders, etc., to *ulcers, cutaneous affections*, or other difficulties, by combining them with it, in the desired proportions. The formula is as follows: Melt together spermaceti half an ounce, and white wax 1 drachm, with oil of almonds 2 fluid ounces, at a moderate heat; put these into a Wedgewood mortar, add glycerin 1 fluid ounce, and rub together until well mixed and cold. An excellent lotion for cracked hands, and especially for those who work in water, is the following: ℞ Carbolic acid (liquefied by warmth), gtt. v; tincture of arnica, fl℥ss; glycerin, fl℥ss; rose-water (or water or distillate of hamamelis), q. s. fl℥vj. Mix. Sig. Wash the hands thoroughly with asepsin soap and warm water, rinse them, and apply the lotion while the hands are still wet.

A *Glycerin Balsam* for chapped lips and hands is made by melting together 1 ounce, each, of white wax and spermaceti, then stirring in half a pound of sweet almond oil and 2 ounces of glycerin, and when nearly cold, half a drachm of attar of roses. Mr. Wilson recommends glycerin as an injection into the bladder to dissolve *calculous deposits*, especially urea, and phosphate of calcium; also to be used as a substitute for syrups in preserving fruits; mixed with alcohol or pyroxylic spirit as an economical fuel for spirit-lamps; and as a remedy in *diseases of the mucous membrane of the stomach*. Dr. Wm. Bayes advises a solution of tannic acid in pure glycerin as a local application to *local hemorrhages*, by a sponge or brush, also to the vaginal, uterine, urethral, rectal, or nasal membranes, where a strong and non-irritant astringent lotion is desired. Glycerin dissolves nearly its own weight of tannic acid; the solution should be recently prepared and be kept in the dark, else it will decompose (see *Glycerites*). On account of its affinity for the water of the tissues, glycerin may be used as an astringent. It has thus been employed to dry and constringe *wounds*, lessening the tendency to the formation of pus, and a cotton pledget first dipped in hot water, squeezed, and saturated with glycerin, applied to fresh wounds, is said to cause union by first intention. Glycerin is an efficient astringent for *leucorrhœa*. *Otorrhœa, ozæna*, and other *catarrhal discharges* may be lessened by the local use of glycerin. *Abscesses, boils, carbuncles*, and *local œdemas*, as of the prepuce, may be treated with it. A mixture of glycerin and water is in common use to relieve *dryness of the mouth* induced by febrile and other states. Internally administered, glycerin is somewhat laxative, and cures of *chronic constipation* and *hemorrhoids*, both blind and bleeding, have been accredited to its use. When used by rectal injection, or by means of the glycerin suppository, it certainly is a very efficient remedy for *habitual costiveness*, provided the fecal mass be located in the rectum, and there is no lesion of the parts. If the parts be sound and the glycerin pure, no smarting or pain is likely to follow its use. It may be employed even with very young infants, and a few injections will generally break up the constipation habit. Occasionally irritation of the rectum has followed in infants, but such instances are rare, and probably due to an unhealthy condition of the rectum or to the use of an impure glycerin. The amount to be used is from ½ to 1 drachm. A small glass syringe may be employed. Added to washes and ointments for *skin diseases*, glycerin aids in allaying itching, when present. One of the best applications for *tibial ulcerations* is the following: ℞ Glycerin, ℥j; carbolic acid (melted by warmth), gr. iij; aqua pura, q. s. Oj. Mix. Sig. Bathe the part two or three times a day, and keep the part wetted by laying upon it a cloth saturated with the solution.

Dr. Goddard has given a formula for a very adhesive *glycerin paste*, suitable for fixing paper labels to glass and other surfaces, and which keeps well; it is to dissolve 1 ounce of gum Arabic in 2 fluid ounces of boiling water, add 2 fluid drachms of glycerin, and strain if necessary. This forms a valuable paste for druggists, chemists, and others. A *glycerin jelly* is prepared by intimately mixing half a drachm of soft soap with 2 fluid drachms of pure honey, then gradually adding 5 ounces of clear olive oil, stirring without intermission until all the oil is taken up. Care must be taken not to add the oil too fast. Or it may be prepared by rubbing and mixing well together half an ounce of powdered gum Arabic, and 4 ounces of simple syrup, then add the yolks of 3 eggs, and when well mixed, add gradually 4 ounces of olive oil, and 2 ounces of glycerin, previously mixed together. The ordinary dose of glycerin is 1 drachm, though from 2 to 4 drachms night and morning may be used.

Related Preparation.—GLYCONES, prepared by Eli Lilly & Co., Indianapolis, Ind., are rectal suppositories containing 95 per cent of pure glycerin, covered with an easily removable coating which is impervious and unchangeable, preserving the suppositories in all climates. They are designed to overcome *constipation*, and quickly and easily produce rectal evacuation.

GLYCERITA.—GLYCERITES.

SYNONYMS: *Glycerina* (*Br.*), *Glycerines* (*Br.*), *Glycerata*, *Glyceroles*, *Glycerolata*, *Glycerols*, *Glycerates*, *Glycemates*.

By this class of preparations is generally understood solutions of medicinal substances in glycerin, although in certain instances the various Pharmacopœias deviate to an extent. The term Glycerita as here applied to fluid glycerines, or solutions of agents in glycerin, is preferable to the ordinary names, "*glyceroles*," "*glycerates*," or "*glycemates*," etc., and includes all fluid preparations of the kind referred to, whether for internal administration or local application. Many solutions of glycerin or glycerin and water, are apt upon standing to develop microscopic cryptogams, unless a certain proportion of alcohol is added to the solutions. On this account, it is better to prepare many members of this class of solutions in small quantity at a time, and only as they are wanted (see *Lotions* and *Plasma*).

Related Preparation. GLYCELÆUM. This was introduced, in 1867, by T. B. Groves. Take almond meal (fine), ½ ounce; glycerin, 1 ounce; olive oil, 3 ounces. Triturate the meal with the glycerin and gradually incorporate the oil with the mixture. This semi-gelatinous, pasty mass may be made into emulsions by gradually adding water to it. Powders may also be incorporated with it. Oleoresins and essential oils may be employed as substitutes, wholly or in part.

GLYCERITUM ACIDI CARBOLICI (U. S. P.)—GLYCERITE OF CARBOLIC ACID.

SYNONYMS: *Glycerin of carbolic acid*, *Glycerole of carbolic acid*.

Preparation.—"Carbolic acid, twenty grammes (20 Gm.) [309 grs.]; glycerin, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Weigh the carbolic acid and glycerin, successively, into a tared capsule, and stir them together until the acid is dissolved. Then transfer the solution to a bottle."—*U. S. P.*

Action and Medical Uses.—This has been beneficially employed as a local application in several forms of *cutaneous disease*, attended with intense itching, *prurigo*, *psoriasis*, etc.; likewise in parasitical affections of the skin, as *tinea*, *pityriasis*, *itch*, etc.

This preparation may be used of full strength in the preparation of carbolic acid plaster, but when designed for local applications, it should be still further diluted with glycerin. A solution of the above has been advised as a dressing to *gangrenous wounds* in preference to a solution of permanganate of potassium (Maissonneuve). Solutions of various strengths have been used in various *cutaneous affections*, *cancerous* and other *fetid ulcerations*.

GLYCERITUM ACIDI GALLICI.—GLYCERITE OF GALLIC ACID.

Synonym: *Glycerin of gallic acid.*

Preparation.—Take of gallic acid, 1 troy ounce; glycerin, 4 fluid ounces. Powder the gallic acid in a mortar, then gradually add the glycerin, rubbing the mixture constantly, until an even mixture is effected. Transfer this to a porcelain evaporating dish, and warm gently upon a water-bath, stirring constantly until the acid dissolves. This preparation should not be heated above the boiling point of water, 100° C. (212° F.), lest poisonous pyrogallol be formed (T. E. Thorpe).

Action, Medical Uses, and Dosage.—This preparation has been taken internally, instead of gallic acid in substance, in the several varieties of disease in which this acid is indicated, and is supposed to be more promptly absorbed when used in this form. Useful in *inflammatory affections of mucous surfaces*, as of the fauces, nasal membrane, ear, vagina, etc. It is to be applied locally, either as a wash, gargle, or injection. Its dose is from 10 minims to 1 fluid drachm. Externally it has been applied to the scalp, in cases of *alopecia*.

GLYCERITUM ACIDI SALICYLICI.—GLYCERITE OF SALICYLIC ACID.

Synonym: *Glycerin of salicylic acid.*

Preparation.—Take of salicylic acid (made from wintergreen oil), borax (in fine powder), each, 60 grains; glycerin, 2 fluid ounces. Triturate the acid with the borax, in a mortar, until thoroughly mixed; then add the glycerin, and rub until a clear solution is obtained.

Action, Medical Uses, and Dosage.—(See *Acidum Salicylicum.*) This preparation will be found very useful in all maladies in which salicylic acid is indicated. It may be used internally as well as externally, and constitutes a useful local application in several *diseases of the mouth and pharnyx*, in *gangrenous ulcers*, *leucorrhœa*, *offensive discharges*, *pediculi*, *pruritis*, etc. The dose internally is from ½ to 2 fluid drachms.

GLYCERITUM ACIDI TANNICI (U. S. P.)—GLYCERITE OF TANNIC ACID.

Synonyms: *Glycerin of tannin*, *Glycerole of tannin.*

Preparation.—"Tannic acid, twenty grammes (20 Gm.) [309 grs.]; glycerin, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Weigh the tannic acid and glycerin, successively, into a tared porcelain capsule, avoiding contact with metallic utensils, and apply the heat of a water-bath, until the acid is completely dissolved. Then transfer the solution to a bottle"—(*U. S. P.*).

Action and Medical Uses.—This forms a useful local application in *bleeding* from *cuts*, *leech bites*, *epistaxis*, *sore nipples*, *anal fissure*, *chronic coryza*, *spongy gums*, *vaginal leucorrhœa*, and *chronic mucous inflammations*, in which the mucous membrane is relaxed. It will be found an excellent local application in gleet, the *nasal* *discharges* following the *exanthematous affections, otorrhœa* in children, *granular ophthalmia, ozæna*, etc. It is contraindicated in active inflammations, which should be allayed previous to its use (see *Acidum Tannicum*). Chronic diseases of the skin, as *eczema, impetigo, tinea, lichen*, etc., have also been greatly benefited by its application.

GLYCERITUM ALOES.—GLYCERITE OF ALOES.

SYNONYMS: *Glycerinum aloes, Glycerin of aloes, Glycerole of aloes.*

Preparation.—Take of finely powdered socotrine aloes, 4 drachms; glycerin, 4 troy ounces: triturate the aloes with the glycerin in a glass or porcelain mortar, transfer to a bottle and agitate well together. If the aloes is not entirely dissolved digest the mixture for 15 minutes in a water-bath and strain. This forms a syrupy liquid of a bright mahogany color.

Action and Medical Uses.—This is recommended as a local application in *lichen agrius*, and *eczematous affections*.

GLYCERITUM ALUMINIS.—GLYCERITE OF ALUM.

SYNONYM: *Glycerin of alum.*

Preparation.—Alum, 1 ounce; glycerin, 5 fluid ounces; place ingredients in a porcelain vessel, stir them together, and heat gently until solution is accomplished. Set the solution aside, and when all particles have settled pour off the clear liquid.

Action and Medical Uses.—This is to be used for the same purposes as alum (see *Alumen*). It is more irritating than glycerite of tannin, but has the advantage of being stainless.

GLYCERITUM AMYLI (U. S. P.)—GLYCERITE OF STARCH.

SYNONYMS: *Glycerin of starch, Plasma, Glycamyl.*

Preparation.—"Starch, ten grammes (10 Gm.) [154 grs.]; water, ten cubic centimeters (10 Cc.) [162 ♏]; glycerin, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]. To the starch, contained in a porcelain capsule, add the water and glycerin, and stir until a homogeneous mixture is produced. Then apply a heat gradually raised to 140° C. (284° F.), and not exceeding 144° C. (291.2° F.), stirring constantly, until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers"—(*U. S. P.*).

This preparation, if exposed to the atmosphere, readily absorbs moisture, hence it should be kept in closely-stoppered bottles. According to Willmott the substitution of water in place of one-third of the glycerin used will prevent this change.

Action and Medical Uses.—Glycerite of starch forms a bland preparation, very useful in cases in which it is desired to apply mild, non-irritating dressings, as in the burning heat of *eczema*, in *excoriated surfaces*, in *erythema*, and in several other *irritated* or *inflamed conditions of the skin*. It likewise forms a vehicle for the application of other agents with which it may be mixed.

GLYCERITUM BISMUTHI (N. F.)—GLYCERITE OF BISMUTH.

SYNONYMS: *Liquor bismuthi concentratus, Concentrated solution of bismuth.*

Preparation.—"Bismuth and ammonium citrate, two hundred and seventy-five grammes (275 Gm.) [9 ozs. av., 307 grs.]; stronger water of ammonia (*U. S. P.*), a sufficient quantity; glycerin, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the bismuth and ammonium citrate with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water and two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of glycerin, and add to it gradually just enough stronger water of ammonia to dissolve the salt, and to produce a neutral solution. Then add the remainder of the glycerin and enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and filter. Each fluid drachm contains 16 grains of bismuth and ammonium citrate. *Note.*—If glycerite of bismuth should at any time deposit a precipitate, this may be redissolved by the addition of just sufficient stronger water of ammonia"—(*Nat. Form.*).

Action and Medical Uses.—Useful as a local application in *eczema, excoriations, chaps of the lips and hands*, in *gonorrhœa, vaginitis, chronic granular conjunctivitis, ciliary* and *glandular blepharitis*, etc. It should always be well shaken just previous to using it.

GLYCERITUM BOROGLYCERINI (U. S. P.)—GLYCERITE OF BOROGLYCERIN.

Synonyms: *Glycerite of glyceryl borate, Solution of boroglyceride.*

Preparation.—"Boric acid, in fine powder, three hundred and ten grammes (310 Gm.) [10 ozs. av., 409 grs.]; glycerin, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Heat four hundred and sixty grammes (460 Gm.) [1 lb. av., 99 grs.] of glycerin, in a tared porcelain capsule, to a temperature not exceeding 150° C. (302° F.), and add the boric acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has been reduced to the weight of five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.], add to it five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.] of glycerin, mix thoroughly, and transfer it to suitable vessels"—(*U. S. P.*).

This may also be made quickly by dissolving boroglyceride (1 ounce, av.) in glycerin (1 ounce, av.) by gently heating the mixture.

Description and Uses.—This preparation is colorless, thick, viscid and sweet. It is antiseptic and possesses marked preservative qualities.

Boroglycerinum (N. F.), *Boroglycerin, Glyceryl borate, Boroglyceride.*—"Boric acid, in powder, six hundred and twenty grammes (620 Gm.) [1 lb. av., 5 ozs., 381 grs.]; glycerin, nine hundred and twenty grammes (920 Gm.) [2 lbs. av,, 198 grs.]. Heat the glycerin in a tared porcelain capsule to a temperature not exceeding 150° C. (302° F.), and add the boric acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has become reduced to a weight of one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], pour it out on a flat surface previously coated with a very small quantity of petrolatum, let it cool, cut it into pieces and transfer them immediately to bottles or jars, which should be well-stoppered. *Note.*—The official glycerite of boroglycerin may be made from this by adding an equal weight of glycerin to the finished boroglycerin while it is still warm"—(*Nat. Form.*).

GLYCERITUM HYDRASTIS (U. S. P.)—GLYCERITE OF HYDRASTIS.

Preparation.—"Hydrastis, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; alcohol, water, each a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Moisten the hydrastis with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the hydrastis is practically exhausted. To the percolate add two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water, and then drive off the alcohol by evaporation or distillation. After the alcohol is driven off, add enough water to the residue to make it measure five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏], and set it aside for 24 hours. Then filter, pass enough water through the filter to make the filtrate measure five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏], add the glycerin, and mix thoroughly"—(*U. S. P.*).

History.—This preparation was first elaborated by Prof. J. U. Lloyd, in response to a call from Dr. L. E. Wickens, of Holly, Michigan. It came into extended use, and the published formula has now found its way into the *National Formulary* and *United States Pharmacopœia*. Owing to the yellow color it has fallen into general disfavor.

Action and Medical Uses.—(Those of *Hydrastis*.) Dose, ½ to 1 fluid drachm.

GLYCERITUM IODINII COMPOSITUM.—COMPOUND GLYCERITE OF IODINE.

SYNONYMS: *Glycerinum iodinii compositum, Compound glycerin of iodine, Glycerole of iodine.*

Preparation.—Take of iodine, 1 drachm; iodide of potassium, 1 drachm; glycerin, 4 drachms; thoroughly triturate in a glass mortar the iodide of potassium and glycerin together, then gradually add the iodine, and continue the trituration until it is all dissolved, and keep the mixture in a well-closed vessel.

Action and Medical Uses.—This is a somewhat caustic preparation, very useful as a local application to *ulceration of the os uteri, non-vascular goitre, scrofulous ulcers*, as well as those from *constitutional syphilis*. It should be applied by means of a hair pencil, or lamp-wick porte-caustic.

GLYCERITUM KINO.—GLYCERITE OF KINO.

SYNONYMS: *Glycerinum kino, Glycerin of kino, Glycerole of kino.*

Preparation.—Take of powdered kino, 4 drachms; glycerin, 2 fluid ounces. Triturate thoroughly together in a Wedgewood mortar, and transfer to a vial.

Action and Medical Uses.—This forms a permanent solution, not giving any deposit, and should be employed as a substitute for the tincture of kino.

GLYCERITUM PEPSINI (N. F.)—GLYCERITE OF PEPSIN.

Preparation.—*Formulary number*, 187: "Pepsin (*U. S. P.*), eighty-five grammes (85 Gm.) [3 ozs., av.]; hydrochloric acid (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; glycerin, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the pepsin with four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of water and the hydrochloric acid, and agitate until solution has been effected. Then incorporate the purified talcum with the liquid, filter, returning the first portions of the filtrate until it runs through clear, and pass enough water through the filter to make the filtrate measure five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]. To this add the glycerin, and mix. Each fluid drachm represents 5 grains of pepsin (*U. S. P.*). *Note.*—For filtering the aqueous solution of pepsin first obtained by the above formula, as well as for filtering other liquids of a viscid character, a filter paper of loose texture (preferably that known as "Textile Filtering Paper"), or a layer of absorbent cotton placed in a funnel, or percolator, should be employed"—(*Nat. Form.*).

Action and Medical Uses.—(Those of *Pepsin*.)

GLYCERITUM PICIS.—GLYCERITE OF TAR.

SYNONYMS: *Glycerin of tar, Glycerole of tar.*

Preparation.—Take of tar, 1 troy ounce; glycerite of starch, 8 troy ounces. Transfer the tar to a mortar, and gradually add the glycerite of starch, stirring constantly until an even mixture results (*New Remedies*, 1879, p. 200). It is advisable to previously warm the glycerite of starch.

Action and Medical Uses.—This preparation forms a very useful local application in *lichen*, *prurigo*, *pityriasis*, *psoriasis*, *lepra*, *herpes*, *erythema*, *eczema*, *tinea*, *pruritis*, and *alopecia;* also in *indolent* and *gangrenous ulcers.* It may be rubbed upon the affected part, or be spread on a piece of linen and thus applied. It is very apt to afford more or less relief, even when it does not remove the disease. Do not confound this valuable tar compound for external use with the following liquid to be taken internally:

Related Preparation.—GLYCERITUM PICIS LIQUIDÆ. A good formula, with its uses, is as follows: Take of tar, strained, 1 troy ounce; carbonate of magnesium, rubbed to powder on a sieve, 3 troy ounces; alcohol, 2 fluid ounces; glycerin, 4 fluid ounces; water, a sufficient quantity. Mix the alcohol and glycerin with 10 fluid ounces of water. Rub the tar in a mortar with the carbonate of magnesium added gradually, until a smooth pulverulent mixture is obtained, then, add gradually, in small portions at a time, with thorough trituration continued for 15 or 20 minutes, 6 fluid ounces of the mixture of alcohol, glycerin, and water, and strain with strong pressure; return the residue to the mortar, and repeat the trituration as before, with 5 fluid ounces more of the same liquid, and again strain and express; again treat the dregs in the same manner with the remainder of the fluid mixture, and after expression, reduce the residue by trituration to a uniform condition, and finally pack firmly in a glass funnel, prepared for percolation, and pour upon it the expressed liquors, previously mixed, and when the mixture has all passed from the surface, continue the percolation with water until 1 pint of liquid has been obtained.

This is an elegant and palatable preparation of tar, of a beautiful rich reddish-brown color at first, but losing its transparency from a deposition of resinous matter, which does not, however, affect the medicinal virtues of the preparation in the least. If glycerin be substituted for the alcohol, in its preparation, the solution is nearly as strong as when alcohol is employed and deposits less resin. Glycerin appears to be a good solvent of the medicinal properties of tar, and possessing demulcent, alterative, and nutrient properties, serves as a valuable adjunct to the latter therapeutically.

Glycerin solution of tar is very valuable in *chronic cough*, *chronic laryngeal*, *bronchial* and *pulmonary affections*, and, being free from sugar, it is less liable to offend the stomach and disturb the digestive functions of patients requiring its long-continued use. It may be associated with the fluid extracts of wild cherry bark, blood-root, etc., to suit the views of the prescribing physician. The dose is from 2 to 4 fluid drachms, 3 or 4 times a day, which will represent from about 7½ to 15 grains of tar (J. B. Moore, *Amer. Jour. Pharm.*, 1869, p. 115)

GLYCERITUM POTASSII CHLORAS.—GLYCERITE OF POTASSIUM CHLORATE.

SYNONYMS: *Glycerinum potassii chloras*, *Glycerin solution of chlorate of potassium*, *Glycerole of chlorate of potassium.*

Preparation.—Take of chlorate of potassium, in powder, 1 drachm; glycerin, 10 drachms. Place the two articles in a vial, and agitate until the chlorate is all dissolved.

Action and Medical Uses.—This has been found valuable as a disinfectant and dressing for *ill-conditioned wounds* and *ulcers*, and as a local application to enfeebled and ulcerated mucous surfaces, as in *aphthous affections of the mouth*, *leucorrhœa*, *gonorrhœa* in females, *nasal ulcerations*, etc.

GLYCERITUM QUININÆ SULPHAS.—GLYCERITE OF QUININE SULPHATE.

SYNONYMS: *Glycerinum quininæ sulphas*, *Glycerin of sulphate of quinine*, *Glycerole of quinine.*

Preparation.—Take of sulphate of quinine, 24 grains; glycerin, 2 fluid ounces. Triturate the quinine with the glycerin, in a glass mortar, until it is dissolved, and transfer to a vial.

Action and Medical Uses.—This forms an elegant preparation, containing 1½ grains of sulphate of quinine to the fluid drachm. It may be used both internally and externally in all cases where quinine is indicated

GLYCERITUM SAPONIS.—GLYCERITE OF SOAP.

Preparation.—Take neutral cocoanut-oil-soda soap (or tallow-soda soap), 1 part; glycerin (sp. gr., 1.250), 4 parts. The soap must be exactly neutral and dried at 100° C. (212° F.). Dissolve the soap in the glycerin on a water-bath, and while still hot filter the solution.

Description and Uses.—This process yields a hygroscopic, odorless, light-yellow mass, having elasticity. The heat of the body is sufficient to liquify it. This has been proposed by Hebra as an ointment base, the desired medicinal agents being added to it (*Proc. Amer. Pharm. Assoc.*, 1891).

GLYCERITUM SODII BORATIS.—GLYCERITE OF BORATE OF SODIUM.

SYNONYMS: *Glycerite of borax, Glycerin of borax.*

Preparation.—Take of crystallized borate of sodium (borax), 1 troy ounce; glycerin, 8 fluid ounces. Rub the borax in a mortar until it is finely powdered, then gradually add the glycerin and rub together until the borax is dissolved. The *Glycerinum Boracis* of the *Br. Pharm.* contains powdered borax, 1 ounce (av.); glycerin, 4 fluid ounces; and distilled water, 2 fluid ounces.

Action and Medical Uses.—This preparation is employed, locally, in *aphthæ*, *thrush*, and other forms of *stomatitis*, in *fissured* and *ulcerated nipples*, in *eczema*, *lichen*, *intertrigo*, in *parasitic cutaneous diseases*, and especially in *pityriasis of the scalp*. It is also useful in *aphthous* and *ulcerative conditions of the vulva*. It most generally relieves the burning and itching attending many *cutaneous maladies*.

GLYCERITUM TRAGACANTHÆ (N. F.)—GLYCERITE OF TRAGACANTH.

Preparation.—*Formulary number*, 189: "Tragacanth, in fine powder, one hundred and twenty-five grammes (125 Gm.) [4 oz. av., 179 grs.]; glycerin, seven hundred and seventy-five cubic centimeters (775 Cc.) [26 fl℥, 99 ♏]; water, one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl℥, 123 ♏]. Triturate the tragacanth with the glycerin in a mortar, add the water, and continue the trituration, until a homogeneous, thick paste results."

Note.—"The *Glycerinum Tragacanthæ* of the *Br. Pharm.* (1885) is prepared by mixing 3 troy ounces of tragacanth with 12 fluid ounces of glycerin in a mortar, adding 2 fluid ounces of water, and triturating until a translucent, homogeneous jelly is formed.

"*Mucilago Tragacanthæ* of the *U. S. P.* (1890) is made by mixing 18 grammes of glycerin with 75 cubic centimeters of water, heating the mixture to boiling, adding 6 grammes of tragacanth, macerating for 24 hours, and then adding water to make 100 grammes, heating it to a uniform consistence, and straining.

"*Unguentum Glycerini* of the *Ger. Pharm.* is prepared by triturating 1 part of powdered tragacanth with 5 parts (by weight) of alcohol (of about 91 per cent), then adding 50 parts of glycerin, and heating on a steam-bath"—(*Nat. Form.*).

Uses.—This jelly-like mass is used chiefly as a pill excipient.

GLYCERITUM VITELLI.—GLYCERITE OF YOLK OF EGG.

SYNONYMS: *Glyconin, Glyconinum.*

Preparation.—"Fresh yolk of egg, forty-five grammes (45 Gm.) [1 oz. av., 257 grs.]; glycerin, fifty-five grammes (55 Gm.) [1 oz. av., 411 grs.]: to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub the yolk of egg, in a mortar, with the glycerin, gradually added, until they are thoroughly mixed. Then transfer the mixture to a bottle"—(*U. S. P.*)

This preparation is of a honey-like consistence and is of value as an emulsifying agent for cod-liver and other oils. If kept from contact with the air, so that it can not absorb moisture, it keeps unaltered for a great length of time.

Action and Medical Uses.—Protective and emollient. Useful in *burns, erysipelas, erythema*, and other *cutaneous irritations* for which glycerite of starch is employed. It is inferior to that agent for most purposes.

GLYCYRRHIZA (U. S. P.)—GLYCYRRHIZA.

"The root of *Glycyrrhiza glabra*, Linné, and of the variety *glandulifera* (Waldstein et Kittaibel) Regel et Herder" (*U. S. P.*) (*Liquiritia officinalis*, Mœnch).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Liquorice-root, Spanish licorice-root, Licorice-root, Radix glycyrrhizæ hispanicæ.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 74.

Botanical Source.—The liquorice-plant has a perennial, cylindrical root, running to a considerable length and depth, grayish-brown externally, yellow internally, succulent, tough, flexible, rapid in growth, and provided with scattered fibers. The stems are erect, herbaceous, smooth, striated, with few branches, of a dull, glaucous-gray color, growing 2 or 3 feet in height. The leaves are alternate and unequally pinnate; the leaflets generally about 13, oval, entire, obtuse, slightly emarginate, viscid, and 1 terminal; the stipules are inconspicuous. The flowers are small, bluish or purplish, in axillary, erect spikes, shorter than the leaves, and borne on long peduncles. Calyx persistent, tubular, bilabiate, and 5-cleft. The corolla is a straight, ovate-lanceolate vexillum; the keel is biparted, acute and straight. Stamens diadelphous; anthers simple and rounded; style filiform; and stigma blunt. The legumes are oblong, compressed, 1-celled, and 1 to 4-seeded; the seeds are small and reniform (L.—Wi.).

The variety *glandulifera* differs in not being smooth like the preceding, but in partaking more or less of a pubescent character, the leaves (beneath) and stem being glandular-pubescent, while the pods are glandular and prickly.

History.—This plant inhabits southern Europe, and some parts of Asia, and is cultivated in England, Germany, France, and in the United States to some extent. The so-called *Russian liquorice* (that produced by the variety *glandulifera*) grows from Hungary and Turkey into western Asia. Liquorice root is imported chiefly from Spain and Sicily. Commercially considered there are 5 grades, viz.: *Italian*, the best and sweetest, *Spanish* or *Common liquorice root*, *Syrian*, *Turkish* and *Russian*, the bitterest. These grades are preferred in the order named.

Fig. 123.

Glycyrrhiza glabra.

Description.—"In long, cylindrical pieces, from 5 to 25 Mm. (⅕ to 1 inch) thick, longitudinally wrinkled, externally grayish-brown, warty; internally tawny-yellow; pliable, tough; fracture coarsely fibrous; bark rather thick; wood porous, but dense, in narrow wedges; medullary rays linear; taste sweet, somewhat acrid. The underground stem, which is often present, has the same appearance, but contains a thin pith. The drug derived from the variety *glandulifera* (so-called Russian liquorice) consists usually of roots and root-branches, 1 to 4 Cm. (⅖ to 1 inch) thick, 15 to 30 Cm. (6 to 12 inches) long, frequently deprived of the corky layer, the wood rather soft, and usually more or less cleft"—(*U. S. P.*). Liquorice root has a faint odor and is so dense as to sink in water. It must be kept in a dry place. Those roots are to be preferred which are not worm-eaten or decayed, and whose surfaces of fracture are bright yellow.

Chemical Composition.—The characteristic constituent of the root is *glycyrrhizin*, so named by Robiquet (1809) on account of its sweet taste. There are furthermore present, fatty and resinous matter (0.8 per cent), small amounts of gum, albuminous substances, tannin, starch, yellow coloring matter, a bitter principle (*glycyramarin*), and *asparagin* (Plisson, 1828), a substance already recognized by Robiquet, who named it *agédoïte*. Sestini (1878) found from 2 to 4 per cent of this principle present in liquorice root.

Glycyrrhizin was obtained by Gorup-Besanez by making a cold infusion of the root, and heating the solution to boiling, filtering, evaporating to a smaller bulk, and precipitating with sulphuric acid. The yellow flakes thus obtained are washed with water and further purified by means of ether-alcohol (Husemann and Hilger). Z. Roussin (1875) and Habermann (1879) showed that the sweet principle, glycyrrhizin, is the acid ammonium salt of a peculiar nitrogenous tribasic acid, called *glycyrrhizic acid* (often termed glycyrrhizin), to which Habermann assigned the formula $C_{44}H_{63}NO_{18}$. The acid potassium salt of this acid is remarkable for its intensely sweet taste. The free acid, prepared from the lead salt, forms a brown, gelatinous mass, soluble in hot water, and having a bitter-sweet taste and acid reaction. It decomposes carbonates, swells up in cold water, is easily soluble in glacial acetic acid, but not in alcohol or ether.

Habermann (1880) found that by boiling with diluted sulphuric acid, it splits into *glycyrretin* ($C_{32}H_{47}NO_4$), a white, tasteless powder, insoluble in water, alkali and ether, soluble in alcohol; and *parasaccharic acid* ($C_6H_{10}O_8$), which reduces Fehling's solution. Gorup-Besanez believed that dextrose was formed in this reaction. Habermann obtained the *acid ammonium glycyrrhizinate* (glycyrrhizin proper) by crystallizing the commercial liquorice extract from glacial acetic acid, and subsequent recrystallization. In the purest state it forms yellow crystals of sweet taste, little soluble in cold water. When dissolved in hot water and then cooled, a stiff jelly is formed. This salt is hardly soluble in alcohol or ether. The amount of glycyrrhizic acid contained in liquorice root is varying. Sestini (1878) obtained 3.3 per cent from air-dried root; H. J. Möller, in 1880, obtained 7.5 per cent from Russian root (Flückiger, 1891). Mr. L. McCullough (*Amer. Jour. Pharm.*, 1890, p. 389), found 7.18 per cent. In *commercial liquorice extract* glycyrrhizin was found by Kremel (*Archiv der Pharm.*, 1889, p. 511) to vary from 5.8 to 11.9 per cent. Peltz (*Pharm. Zschr. f. Russland*, 1876, p. 257) records the results of 10 analyses of commercial extracts of liquorice root. Glycyrrhizin was found to vary from 1.33 to 18.14 per cent, starch from 1.33 to 35 per cent. Sestini (1878) found water, 48.7; glycyrrhizin, 3.27; carbohydrates, 29.62; asparagin, 1.25; ash, 2.08. (For methods of valuation of commercial liquorice extracts, see Flückiger, *Pharmacognosie*, 3d ed., 1891, and Alfred Mellor, *Amer. Jour. Pharm.*, 1898, p. 136.) Glycyrrhizin is stated (Flückiger) to occur in other plants, *e. g.*, *Abrus precatorius* (Berzelius), *Astragalus glycyphyllos*, *Polypodium vulgare* (Guignet, 1885), *Myrrhis odorata* (Schroeder, 1885), *Gulielma speciosa*, Martius, and *Monesia bark* (Peckolt, *Pharm. Rundschau*, 1888, pp. 31, 203, 206), but these statements, according to Flückiger, require verification.

Action, Medical Uses, and Dosage.—Liquorice root is emollient, demulcent, and nutritive. It acts upon mucous surfaces, lessening irritation, and is consequently useful in *coughs*, *catarrhs*, *irritation of the urinary organs*, and *pain of the intestines in diarrhœa*. It is commonly administered in decoction, sometimes alone, at other times with the addition of other agents, and which is the preferable mode of using it. As a general rule, the acrid bark should be removed previous to forming a decoction. When boiled for some time the water becomes impregnated with its acrid resin; hence, in preparing a decoction for the purpose of sweetening diet drinks, or covering the taste of nauseous drugs, it should not be boiled over 5 minutes. The efficiency of the root in *old bronchial affections* may be due to this acrid resin. The powdered root is also employed to give the proper solidity to pills, and to prevent their adhesion; the extract for imparting the proper viscidity to them. The extract, in the form of lozenge, held in the mouth until it has dissolved, is a very popular and efficient remedy in *coughs* and *pectoral affections*. An excellent troche or lozenge, very useful in ordinary cough, may be made by combining together 6 parts of refined liquorice, 2 parts of benzoic acid, 4 parts of pulverized alum, and ½ a part of pulverized opium. Dissolve the liquorice in water, and evaporate to the proper consistence, then add the powders with a few drops of oil of anise, and divide it into 3 or 6-grain lozenges. The bitterness of quinine, quassia, aloes, and the acrid taste of senega, guaiacum, mezereon and ammonium chloride are masked by liquorice.

Related Species. *Glycyrrhiza lepidota*, which grows in Missouri, possesses the taste of liquorice to a considerable degree. McCullough (*Amer. Jour. Pharm.*, 1890, p. 389) found it to contain over 6 (6.39) per cent of *glycyrrhizin*.

Ononis spinosa, Linné, *Rest-harrow.*—Europe, in sandy situations. The root of this plant is about 2 feet in length, and from less than ½ to nearly 1 inch in thickness. It is tough, curved, or twisted, and flattened, deeply rugose, and covered with a thin, deep grayish-brown bark. It is whitish internally. This has a mucilaginous taste, at first sweetish, then bitter and disagreeable, and on the whole somewhat resembles that of liquorice root. Reinsch (1842 obtained therefrom crystals of *ononin* ($C_{30}H_{34}O_{13}$), tasteless and colorless, and recognized by Hlasiwetz (1855) to be a glucosid. Another constituent, *ononid* ($C_{18}H_{22}O_8$, Hlasiwetz), discovered by Reinsch, much resembles glycyrrhizin in its chemical behavior. Hlasiwetz also isolated from Reinsch's impure ononin a waxy substance which he called *onocerin.* This body was recently found by H. Thoms (*Archiv. der Pharm.*, 1897, p. 28) to be a secondary alcohol ($C_{26}H_{42}[OH]_2$), for which he proposes the altered name *onocol.* It seems closely related to *phytosterin* (*vegetable cholesterin*).

Aqueous or acetous decoctions of this root are reputed diuretic and lithontriptic, other properties also being ascribed to it. Its principal use is as a diuretic for *dropsy*, for which it is a popular remedy in France. Other conditions in which it has been employed are as a wash for *ulcers*, *toothache*, *hemorrhoids*, *scalp eruptions*, *hydrocele*, *enlarged glands*, and internally in *jaundice*, *gout*, and *rheumatism*, usually combined, in the two latter diseases, with renal depurants. The decoction is made with from 1 to 2 ounces of ononis root to water, 1 pint, the dose of which is a wineglassful several times a day. From 3 to 5 grains of *ononin* produced a prolonged irritation and sense of rawness in the mouth and throat (Schroff).

GLYCYRRHIZINUM AMMONIATUM (U. S. P.)—AMMONIATED GLYCYRRHIZIN.

Preparation.—"Glycyrrhiza, in No. 20 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; water, ammonia water, sulphuric acid, each, a sufficient quantity. Mix four hundred and seventy-five cubic centimeters (475 Cc.) [16 fl℥, 30 ♏] of water with twenty-five cubic centimeters (25 Cc.) [406 ♏] of ammonia water, and, having moistened the powder with the mixture, macerate for 24 hours. Then pack it moderately in a conical glass percolator, and gradually pour water upon it until five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of percolate are obtained. Add sulphuric acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer. wash it with cold water until the washings no longer have an acid reaction, redissolve it in water with the aid of ammonia water, filter, if necessary, and again add sulphuric acid so long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of ammonia water previously diluted with an equal volume of water, and spread the clear solution upon plates of glass, so that, when dry, the product may be obtained in scales"—(*U. S. P.*).

Description and Chemical Composition.—"Dark-brown or brownish-red scales, without odor, and having a very sweet taste. Readily soluble in water and in alcohol. The aqueous solution, when heated with potassium or sodium hydrate T.S., evolves ammoniacal vapors. If the aqueous solution be supersaturated with an acid, there will be produced a precipitate (glycyrrhizin) which, when dissolved in hot water, forms a jelly on cooling. This substance, after being washed with diluted alcohol, and dried, appears as an amorphous, yellow powder, having a strong, bitter-sweet taste, and an acid reaction. Upon incineration, ammoniated glycyrrhizin should not leave more than a trace of ash"—(*U. S. P.*). This product consists largely of ammonium glycyrrhizate ($[NH_4]C_{44}H_{62}NO_{18}$) and glycyramarin ($C_{36}H_{57}NO_{13}$), a bitter glucosid, dissolving in ether-alcohol (see *Glycyrrhiza*). This preparation is used mainly for masking the bitterness of quinine salts. It produces with these substances, when in solution, precipitates which contain the quinine. Hence, care must be taken to shake the vial before taking a dose.

GNAPHALIUM.—WHITE BALSAM.

The herb of *Gnaphalium polycephalum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Indian posy*, *Sweet-scented life-everlasting*, *Old field balsam.*

Botanical Source.—This plant is indigenous, herbaceous, and annual, with an erect, whitish, woolly, and much-branched stem, from 1 to 2 feet in height The leaves are alternate, sessile, linear-lanceolate, acute, entire, scabrous above. and whitish tomentose beneath. The flowers are tubular and yellow, borne in heads clustered at the summit of the panicled-corymbose branches, ovate-conical before expansion, then obovate. The involucre is imbricate, with whitish, ovate, and oblong, rather obtuse scales. Florets of ray, subulate—of disk, entire. The receptacle is flat and naked, the pappus pilose and scabrous capillary (W.—G.).

History.—White balsam is found in Canada and various parts of the United States, growing in old fields and on dry, barren lands, and bearing whitish-yellow flowers in July and August. The leaves have a pleasant, aromatic smell, and a slightly bitter and astringent, but rather agreeable taste. They yield their properties to water. No analysis has been made of them. The *Antennaria Margaritacea*, R. Brown, formerly *Gnaphalium Margaritaceum*, Linne, or pearl-flowered life-everlasting, a perennial plant, possesses similar properties to the above (see *Antennaria*).

Action, Medical Uses, and Dosage.—Astringent. The leaves and blossoms chewed, and the juice swallowed, have proved beneficial in *ulcerations of the mouth* and *throat*. A warm infusion (℥ss to water Oj), may be used in *fevers* to produce diaphoresis, and is of service in *quinsy*, *pulmonary complaints*, *leucorrhœa*, etc.; it may be used internally and as a local application. Likewise used as an infusion in *diseases of the bowels*, and *hemorrhages*, and applied in fomentations to *bruises*, *indolent tumors*, and other local affections. Prof. Scudder suggests investigation to determine its influence upon the reproductive and urinary stuctures, in *acute* and *chronic ulcerations*, and in *digestive disorders*. The fresh juice is reputed an aphrodisiac.

GOODYERA.—NET-LEAF PLANTAIN.

The leaves of *Goodyera pubescens*, Robert Brown.

Nat. Ord.—Orchidaceæ.

Common Names: *Net-leaf plantain*, *Scrofula weed*, *Adder's violet*, *Rattlesnake-leaf*.

Botanical Source.—This plant has a perennial root, from which arises an erect, sheathed, and pubescent scape, from 8 to 12 inches in height. The leaves are radical, ovate, dark-green, conspicuously reticulated, blotched above with white, about 2 inches in length, and contracted at base into winged petioles scarcely half as long. The flowers are white, numerous, pubescent, and borne in a crowded, terminal, oblong, cylindric spike. Lip ovate, acuminate, saccate, and inflated. Petals ovate. The *Goodyera repens*, R. Brown, is a reduced variety of the above, the scape being from 6 to 8 feet in height; leaves less conspicuously reticulated, flowers being on a somewhat unilateral spike, more or less spiral; in other respects about the same as the preceding (W.—G.).

Fig. 123.

Goodyera pubescens.

History.—This herb grows in various parts of the United States, in rich woods, and under evergreens, and is common southward, while the *G. repens* is more common northward and on mountains. It bears white or yellowish-white flowers in July and August. The leaves are the parts employed, and yield their virtues to boiling water. No analysis has been made of them.

Action, Medical Uses, and Dosage.—Net-leaf plantain is anti-scrofulous, and is reputed to have cured severe cases of *scrofula*. The fresh leaves are steeped in milk and applied as a poultice to *scrofulous ulcers*, or the bruised leaves may be laid on them, and in either case they must be renewed every 3 hours; at the same time a warm infusion must be taken as freely as the stomach will allow. Used as an injection into the vagina, and at the same time exhibited internally, the infusion has proved beneficial in *leucorrhœa*, recent *prolapsus uteri*, and as a wash in *scrofulous ophthalmia*.

GOSSYPIUM PURIFICATUM (U. S. P.)—PURIFIED COTTON.

"The hairs of the seed of *Gossypium herbaceum*, Linné, and of other species of *Gossypium* (*Nat. Ord.*—Malvaceæ), freed from adhering impurities and deprived of fatty matter"—(*U. S. P.*).

SYNONYMS: *Gossypium* (*Pharm.*, 1880), *Absorbent cotton*, *Bombyx*, *Lana gossypii*, *Lanugo gossypii*, *Pili gossypii*, *Cotton wool.*

Source and Preparation.—Purified cotton is now made on an enormous scale by manufacturers whose processes, being private and of great personal value, should not be published in justice to the owners. All the absorbent cotton of commerce is purchased by pharmacists and other consumers, none being made on a small scale. It may be prepared from raw cotton by "*mercerizing*" the latter, that is, by boiling with weak solutions of alkalies. By union with the fatty material of the cotton a soap is formed which is removed by repeatedly washing the cotton with water. F. L. Slocum's process (*Amer. Jour. Pharm.*, 1881, p. 53), is as follows: Carded cotton is boiled for one-half hour in diluted solution (5 per cent) of caustic potash (or caustic soda). The soap formed is thoroughly washed out, the cotton expressed and placed for 15 or 20 minutes in a diluted solution (5 per cent) of chlorinated lime. It is then washed with water, dipped into water made slightly acid with hydrochloric acid, and again thoroughly washed with water. The cotton is then expressed and again boiled for 15 or 20 minutes with the diluted (5 per cent) alkali (hydroxide of potassium or sodium), washed again with water, next with acidulated water, and lastly with water. The cotton is then expressed and dried rapidly. It requires two boilings with alkalies to completely remove the fats. Mr. Slocum defines absorbent cotton to be cotton entirely freed from all matter (grease), that will obstruct capillary attraction. It is on record that in order to meet a popular demand for pure whiteness and a peculiar "feel" in purified cotton, the latter, after being freed from fatty and resinous matter, has been covered again with a trace of free fatty acid by passing it through a (diluted) soap solution, and an acid solution afterward (*Amer. Jour. Pharm.*, 1891, p. 189).

Description.—Cotton is tasteless, odorless, highly combustible, and according to Thompson, is not soluble in alcohol, water, ether, oils, or vegetable acids; weak alkaline liquids have no perceptible action on it, but when very strong they dissolve it by the aid of heat. Tannic acid forms a brown or yellow compound with it; nitric acid decomposes it when assisted with heat, oxalic acid being formed; sulphuric acid dissolves it. The strong mineral acids generally decompose it. Gun-cotton (*Pyroxylin*) a nitro-compound of an explosive character, is prepared from it by means of nitric acid (see *Collodium* and *Pyroxylinum*).

Purified cotton is almost pure cellulose. It is officially described as follows:

"White, soft, fine filaments, appearing under the microscope as hollow, flattened and twisted bands, spirally striate, and slightly thickened at the edges; inodorous and tasteless; insoluble in ordinary solvents, but soluble in copper ammonium sulphate solution. Purified cotton should be perfectly free from all visible impurities, and, on combustion, should not leave more than 0.8 per cent of ash. When purified cotton, previously compressed in the hand, is thrown on the surface of cold water, it should readily absorb the latter and sink, and the water should not acquire either an acid or an alkaline reaction (evidence of proper purification)"—(*U. S. P.*).

Action and Medical and Surgical Uses.—Externally, cotton is used as a local application in *erysipelas*, *erythema*, *fresh burns*, *wounds*, *severe bruises* or *contusions*. in *rheumatic pains*, and has been successfully employed in dressing *blisters*. In *burns* and *blisters*, it quickly allays pain, but care must be taken that the cotton does not harden and adhere firmly to the part over which it is applied, as it will then cause irritation the same as any other foreign body; this may usually be avoided by first applying some simple oleaginous substance over the surface which is to come in contact with the burn or ulcer. Cotton is supposed to prove efficient by excluding the air from the parts over which it is applied, and also by imbibing the secretions. As an application after surgical operations it is unsurpassed, and by taking up the discharges prevents purulent absorption. It is often medicated with boracic acid, carbolic acid, etc., for this purpose. Pessaries and tampons are often prepared with cotton, but should be frequently removed lest they become foul from absorption of the discharges. Surgeons make extensive use of absorbent cotton to clean surfaces and cavities, and it is specially applicable for use in the nasal and aural passages, both for cleansing purposes and for the introduction of medicaments. For packing wounds and cavities and similar surgical uses some of the forms of gauze are preferred.

Cotton Preparations.—Gossypium stypticum (N. F.), *Styptic cotton. Formulary number,* 190: "Purified cotton (*U. S. P.*), solution of chloride of iron (*U. S. P.*), glycerin, water, of each a sufficient quantity. Mix the liquids in the proportion of five (5) parts of the iron solution, one (1) part of glycerin, and four (4) parts of water, in such quantities that the purified cotton shall be completely immersed in the liquid when gently pressed. Allow the cotton to remain in the liquid 1 hour, then remove it, press it until it has been brought to twice its original weight, spread it out in thin layers, in a warm place, protected from dust and light, and when it is sufficiently dry, transfer it to well-closed receptacles"—*Nat. Form.*).

Hemostatic cotton is prepared by impregnating absorbent cotton with solution of subsulphate of iron or mixture of alum and chloride of iron.

Salicylic cotton or *Salicylated cotton*, contains from 5 to 10 per cent of the salicylic acid. Cotton is also impregnated with other substances, as benzoic acid (benzoic cotton), iodoform (iodoform cotton), chlorine (chlorinated cotton), boracic acid (borated cotton), etc.

GOSSYPII RADICIS CORTEX (U. S. P.)—COTTON ROOT BARK.

"The bark of the root of *Gossypium herbaceum*, Linné, and of other species of *Gossypium*"—(*U. S. P.*).

Nat. Ord.—Malvaceæ.

Illustration: Bentley and Trimen, *Med. Plants*, 37.

Botanical Source.—*Gossypium herbaceum* is a biennial or triennial herb with a fusiform root, giving off small radicles, and a round, pubescent, branching stem, about 5 feet high. The leaves are hoary, palmate, with 5 sublanceolate, rather acute lobes, 3 large, 2 small, lateral, and a single gland on the midvein below, ½ an inch from the base. The stipules are falcate-lanceolate. The flowers are yellow; the calyx cup-shaped, obtusely 5-toothed, surrounded by an involucel of 3 united and cordate leaves, deeply and incisely toothed. The petals are 5 in number and deciduous, with a purple spot near the base. Style simple, marked with 3 or 5 furrows toward the apex. Stigmas 3 or 5. Capsules 3 or 5-celled, 3 or 5-valved, and loculicidal; the seeds, 3 or 5, are involved in cotton, somewhat plano-convex and reniform (W.—R.—W.).

Gossypium barbadense, Linné, or *Sea Island cotton plant*, is a larger plant than the preceding; leaves 5-lobed, with 3 glands beneath, upper ones 3-lobed; cotton white and seeds black. It is likewise biennial or triennial (W.).

History.—Cotton is an Asiatic plant, but is extensively cultivated in India, Syria, Asia Minor, the Mediterranean, and America. Cultivation has considerably changed the plant so as to render it difficult for botanists to correctly describe the originals. Several species have been named by authors, which Swartz and Macfayden believe to be mere varieties of one species; while Wight, Arnold, and Hamilton believe that there are but two distinct species, the *G. album*, whose seeds are white, and which furnishes, according to A. W. Chapman, the *upland* or *short-staple* cotton, and the *G. nigrum*, whose seeds are black, and which furnishes *long-staple* or *Sea Island cotton* of the United States. *G. barbadense* yields true Sea Island cotton. The various cotton plants differ considerably in the form of the leaf and its gland, the height of the plant, the hue of the petals, and the elongation and delicacy of the cotton. The plant can not be profitably cultivated north of the Ohio River, or above that latitude. The leaves are very mucilaginous, and have been used in cases where mucilage is required. A fixed oil is contained in the seeds, which may be procured by pressure; it is a drying oil. The part used in medicine is the inner bark of the root, and the white, downy substance contained in the matured capsule, and known as "cotton." When examined microscopically, the filaments constituting cotton are seen to consist of distinct, flat, narrow ribbons or tubular hairs, with occasional appearances of joints, indicated by lines at right angles to the side of the tube.

The *U. S. P.* thus describes cotton root: "In thin, flexible bands or quilled pieces; outer surface brownish-yellow, with slight, longitudinal ridges or meshes, small, black, circular dots, or short, transverse lines, and dull, brownish-orange patches, from the abrasion of the thin cork; inner surface whitish, of a silky lustre, finely striate; bast fibers long, tough, and separable into papery layers; inodorous; taste very slightly acrid and faintly astringent"—(*U. S. P.*).

Chemical Composition.—Prof. E. S. Wayne (*Amer. Jour. Pharm.*, 1872, p. 289) regards the red resin so frequently precipitated in fluid extracts of gossypium as being produced by chemical change from a chromogene substance existing in all parts of the plant. It has acid properties, dissolves in alkali and forms colored precipitates with solutions of metallic salts, and is, therefore, called *gossypic acid*. About 8 per cent of the acid resin was found by Wm. C. Staehle (1875) in the powdered bark. It was soluble in alcohol, chloroform, ether, and somewhat less in benzol. Charles C. Drueding (*Amer. Jour. Pharm.*, 1877) removed from the red coloring matter a yellow principle by means of boiling benzin. He also finds in the root fixed oil, gum, sugar, tannin, and chlorophyll. Walter A. Taylor (*Amer. Jour. Pharm.*, 1876, p. 402) observes that fresh root yields with strong alcohol a tincture of pale yellow color, which turns red upon prolonged standing, yet without precipitating. A weaker alcohol solution exhibits the same change in color, but precipitates. Old root yields to strong alcohol at once a deep-red solution, which does not precipitate upon standing.

Action, Medical Uses, and Dosage.—The bark of the recent root of the cotton plant is emmenagogue, parturient, and abortive. It is said to promote uterine contraction with as much efficiency and more safety than ergot, and was used by the slaves of the South for inducing abortion, which it effected without any apparent detriment to the general system. It is adapted to cases of *uterine inertia*, and, while acting after the manner of ergot, is a much feebler though less dangerous drug. Four ounces of the inner root-bark may be boiled in a quart of water down to a pint, the dose of which is 1 or 2 fluid ounces every 20 or 30 minutes. The hydro-alcoholic extract, as well as the decoction and specific gossypium, form excellent emmenagogues, and may be used in *chlorosis*, *amenorrhœa*, *dysmenorrhœa*, etc. It is very doubtful whether this will ever take the place of other more certain parturients. In my own practice, it failed in producing any influence upon the uterus during parturition in about one-half the cases in which it has been used, owing, probably, to its not being fresh enough. It operated exceedingly well in the first cases in which it was exhibited (J. King). The old root-bark is valueless as a medicine. The fluid extract is less efficient than the decoction, and fluid preparations are valueless after they begin to gelatinize, and deposit the so-called "*red tannates*" (see *Fluid Extract of Gossypium*). Enthusiastic reports of its efficiency in *hysteria* have been made. It seems adapted to those cases in which there is an anemic state of the reproductive organs, with lack of sexual desire or pleasure. It is a remedy for *sexual lassitude*, and has been suggested for *impotency* (Webster). It is regarded as an efficient remedy for the reduction of *uterine subinvolution* and *fibroids*. It should not be used where there is marked irritation or tendency to inflammation. Gossypium is also a stimulant diuretic. The dose of the decoction (see above); of the fluid extract, 1 to 60 minims; of specific gossypium, 1 to 60 drops.

Specific Indications and Uses.—Uterine inertia during parturition (large doses). Menstrual delay, with backache and dragging pelvic pain; fullness and weight in bladder, with difficult micturition; hysteria, with anemic condition of the reproductive tract; sexual lassitude, with anemia.

Other Parts of the Plant.—The seeds are reputed to possess superior antiperiodic properties. A pint of cotton seed placed in a quart of water and boiled down to 1 pint, and 1 gill of the warm tea given 1 or 2 hours before the expected chill, is said to cure *intermittent fever* with the first dose. The flowers and leaves are reputed diuretic, and useful in *urinary affections*; the leaves steeped in vinegar, are said to relieve *hemicrania* when locally applied, and a decoction is considered beneficial in the *bites of venomous reptiles* in Brazil. An infusion of the whole plant is reputed galactagogue.

GRANATUM (U. S. P.)—POMEGRANATE.

"The bark of the stem and root of *Punica Granatum*, Linné"—(*U. S. P.*).

Nat. Ord.—Lythrarieæ.

COMMON NAME: *Pomegranate root-bark.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 113.

Botanical Source.—Pomegranate is a small tree or shrub, with spinescent branchlets. The leaves are opposite, oblong, inclining to lanceolate, entire, smooth, with no marginal vein, 2 or 3 inches long, by 5 or 10 lines wide, obtuse, deciduous, shortly petioled, rarely verticillate or alternate, and often axillary and fascicled. The flowers are large, red, 2 or 3, nearly sessile, on somewhat terminal branchlets. Calyx turbinate, 5-cleft, thick, pale, and succulent; æstivation valvate. The corolla consists of 5 much crumpled, membranous petals. The stamens are numerous, inserted on the calyx, filaments distinct; anthers yellow. The ovary is roundish and inferior; the style simple and filiform, the stigma globular and capitate. The fruit is a large, globose pericarp, the size of a small muskmelon, leathery, crowned by the prominent hardened tube of the calyx, divided horizontally into 2 parts by a very irregular, confused dissepiment; the lower division 3-celled, the upper 5 to 9-celled; dissepiments membranaceous; placentæ in the lower division at the bottom; in the upper stretching from the side of the fruit to the middle. The seeds are numerous, angular and covered with a bright red, succulent, acrid coat. Embryo oblong; radicle short and acute; cotyledons foliaceous and spirally convolute (L.—W.).

Fig. 124.

Punica Granatum.

History.—The pomegranate grows on the Mediterranean shores, Persia, China, and other countries of Asia, and has been naturalized in the West Indies, and other civilized countries in warm latitudes. It has splendid, dark-scarlet flowers, often doubled, which appear in July and August. The flowers, called *balaustion* by the ancients, have a slightly styptic taste, without odor, and their infusion gives a deep bluish-black precipitate with ferric salts. The saliva is colored a violet-red upon chewing them. Both tannic and gallic acids enter into their composition. In some foreign Pharmacopœias, they, together with the seeds, are recognized as official. The rose-colored, juicy, acid pulp is edible, and is very grateful to febrile patients. The bark of root and stem is the only part employed in this country. The rind of the fruit was also official with us formerly. The fruit varies in size and flavor, that of the West Indies becoming the most perfect. The root is large, ligneous, knotty and hard. Its wood is not used in medicine. In this country the pomegranate shrub grows out of doors as far north as Washington, D. C. (Coville).

Description and Chemical Composition.—GRANATI FRUCTUS CORTEX. The *rind of the fruit* (*Granati fructus cortex*), when dry, is brown externally, yellow within, about a line in thickness, smooth or finely tuberculated, hard, dry, brittle, in irregular fragments, inodorous, and of a very astringent, somewhat bitter taste. Its infusion gives an abundant, dark-bluish precipitate with the salts of iron. Analysis showed 18.8 per cent of tannin, 17.1 of mucilage, 10.8 of extractive matter, 30 of lignin, a trace of resin, and 29.9 of moisture.

GRANATI RADICIS CORTEX.—The bark of the root (*Granati radicis cortex*) is described by the *U. S. P.* as follows: "In thin quills or fragments, from 5 to 10 Cm. (2 to 4 inches) long, and from 1 to 3 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ inch) thick; outer surface yellowish-gray, somewhat warty, or longitudinally and reticulately ridged; the stem-bark often partly covered with blackish lichens; the thicker pieces of the root-bark more or less scaly externally; inner surface smooth, finely striate, grayish-yellow; fracture short, granular, greenish-yellow; indistinctly radiate; inodorous; taste astringent, very slightly bitter"—(*U. S. P.*).

The bitterness of the bark is nearly lost by drying. When chewed, it tinges the saliva yellow. Its infusion yields a deep-blue precipitate with the salts of iron, a yellowish-white one with a solution of gelatin, a grayish-yellow with corrosive sublimate, and caustic potash or ammonia colors it purple. Paper which has been colored yellow by the moistened inner face of the bark, changes to blue by the action of sulphate of iron, and to a delicate rose color, which is evanescent, by nitric acid. These changes do not occur with the bark of barberry, or of box-root, which are sometimes fraudulently mixed with it; the box bark is nearly white, very bitter, but not astringent, and its infusion is not precipitated by salts of iron (Guibourt—Planchon, *Hist. des Drogues Simples*, 1876, Vol. III, p. 280). The barberry bark likewise very much resembles the pomegranate, but is very bitter and not astringent, and is not affected by the salts of iron, solution of isinglass, corrosive sublimate, or caustic potash. The ligneous part of pomegranate root is inert, and should, therefore, be always separated from the bark.

Pomegranate bark contains about 20 per cent of tannin, which was believed by Rembold (1867) to consist of two astringent principles, one being *gallotannic acid*, the other *punicotannic acid* ($C_{20}H_{16}O_{13}$), peculiar to this bark. Diluted sulphuric acid hydrolyzed it into sugar and *ellagic acid* ($C_{14}H_8O_9$) (Flückiger, *Pharmacognosie*, 1891). The presence of *gallic acid* and *mannit* has been observed by various authors (*Jahresb. der Pharm.*, 1867, p. 139). The bark leaves from 10.5 to 16.5 per cent of ash. It also contains a yellow coloring matter (see above). The anthelmintic properties of pomegranate bark are due to the presence of several (4) alkaloids, discovered by Tanret in 1878 and 1880 (*Amer. Jour. Pharm.*, 1880, p. 416), and to which he gave the collective name *pelletierine*, in honor of the celebrated French chemist Pelletier (1788–1842). C. J. Bender (1885) proposes the more euphonic name *punicine*. By mixing the powdered bark with milk of lime, exhausting with water, shaking with chloroform, and abstracting this solution with diluted acid, a solution of the 4 alkaloids is obtained. From this solution sodium bicarbonate liberates *methylpelletierine* and *pseudopelletierine*, which are removed by chloroform; the addition of caustic potash then sets free *pelletierine* and *isopelletierine*.

PELLETIERINE ($C_{16}H_{30}N_2O_2$) is a colorless liquid, of specific gravity 0.988, rapidly absorbs oxygen, and resinifies. It boils at 195° C. (383° F.), is soluble in 20 parts of cold water, and mixes in all proportions with ether, alcohol, and chloroform. Its salts are crystallizable, but give off the base upon heating either dry or in solution. Its sulphate is lævo-rotatory. *Isopelletierine* ($C_{16}H_{30}N_2O_2$) is a liquid optically inactive, forming salts with acids. Density, solubilities, and boiling point are the same as with its preceding isomer. Its sulphate is deliquescent and optically inactive. *Methylpelletierine* ($C_{18}H_{34}N_2O_2$) is a liquid whose boiling point is 215° C. (419° F.). Its hydrochlorate is dextrogyre. The alkaloid dissolves in 25 times its weight of water at 12° C. (53.6° F.), and is soluble in alcohol, ether, and chloroform. *Pseudopelletierine* ($C_{18}H_{30}N_2O_2$) is a crystalline body, fusing at 46° C. (114.8° F.), is optically inactive, soluble in water, alcohol, ether, and chloroform. The chemistry of this base (called also *granatonin*) was investigated more recently by Ciamician and Silber (see *Jahresb. der Pharm.*, 1893, p. 532, and 1894, p. 526).

Tanret recommended the *tannate of pelletierine* as the most efficient form of application. The bark of the stem contains principally *pelletierine*, while in the root-bark methylpelletierine predominates (Flückiger, 1891). As to the yield in total alkaloids, W. Stoeder (1894) obtained from Java root-bark from 1.29 to 1.86 per cent of hydrochlorates of alkaloids, the white-flowering variety yielding the most alkaloid. In 1890 (*Jahresb. der Pharm.*), the same author had obtained a yield as high as 3.75 per cent of hydrochlorates from the white-flowering variety. On the other hand, E. Aweng (*ibid.*, 1890), observed that the alkaloid may entirely disappear from the commercial bark upon storing.

Action, Medical Uses, and Dosage.—The flowers and rind of the fruit are astringent and have been used for arresting *chronic mucous discharges*, *passive hemorrhages*, *aphthous disorders of the mouth*, *night sweats*, *colliquative diarrhœa*, etc., but are now seldom employed. The rind has also been found serviceable in *intermittent fever* and *tapeworm*. The bark of the root possesses anthelmintic properties, and is chiefly serviceable in tapeworm. The bark of the wild pomegranate is considered by the French to be more active than the cultivated plant, and the fresh bark is more active than an old bark. It may be given in powder, but the decoction is more frequently used. Pomegranate is one of the oldest of drugs, having been used from time immemorial. The bark and its alkaloid *pelletierine*, are now by common consent, acknowledged as specifics for the removal of tapeworm. Dizziness, imperfect vision, sleepiness, or faintness, benumbing of the extremities, and occasionally convulsions have been produced by it. Foy, as well as Brenton, recommend to prepare the decoction by placing 2 ounces of the root in 1½ or 2 pints of water, and boiling down to 1 pint; this is to be strained, and from 2 to 4 fluid ounces given for a dose every half hour or hour, until the pint of the decoction has been taken. It commonly occasions several stools, an increased flow of urine, or nausea and vomiting, owing, it is supposed, to the agitation into which the worm is thrown from its presence. Sometimes joints of the worm begin to come away in less than an hour after the last dose. But often the doses must be repeated several successive mornings before they take effect, and it is right to repeat them occasionally for 4 or 5 days after the joints have ceased to come away. Laxatives should be administered from time to time. It is said to act with the greatest certainty when the joints of the worm come away naturally. The dose of the rind or flowers in powder, is from 20 to 40 grains, and in decoction from 1 to 3 fluid ounces. Eclectic physicians, as a rule, follow Prof. Locke's method of administering granatum. According to Dr. Locke, it is the best remedy for the removal of the worm, but as ordinarily recommended, the dose is too small. Its great drawback is its tendency to make the patient vomit, which may, in a measure, be prevented by administering a little lemon juice and keeping the patient quiet. When vomiting can be prevented, it seldom or never fails to bring the worm whole. Prof. Locke's method is as follows: Press 8 ounces (av.) of the coarse bark (not powdered), into a vessel, and pour upon it 3 pints of boiling water. Boil, strain, and then boil this down until the finished product will measure 1 pint. First prepare the patient by giving him at night a brisk cathartic, such as the antibilious physic, and in the morning allow a light breakfast. At about 10 o'clock in the forenoon administer 4 fluid ounces of the decoction. For the purpose of causing it to pass quickly into the intestines and thereby prevent its absorption as much as possible, a fluid drachm of fluid extract of jalap with a drop of oil of anise or cinnamon may be added to the dose. In 2 or 3 hours repeat this dose in the same manner. When its action begins give an enema to hasten its operation (see Locke's *Syllabus of Mat. Med.*). Should this treatment fail the first time, it may be repeated another day. As to treatment with the alkaloid the sulphate of pelletierine was first employed, but was superseded by the tannate which, on account of being tasteless and having less of a tendency to provoke nausea or vomiting, seems the preferable form to employ. The patient should have a light diet, preferably milk, the night previous to taking the medicine. Single doses of about 7 grains are now administered upon an empty stomach, the patient being kept quiet in a reclining posture. The dose is usually preceded by a drink of water, and followed at regular intervals by more water. A purgative, like fluid extract or compound tincture of jalap, is administered about 2 hours after taking the pelletierine tannate. Some prefer castor oil as an evacuant. To insure the passage of the worm entire it should be received into a vessel of warm water, which will prevent its separation into segments.

There seems to be a diversity of opinion regarding the effects of pelletierine upon the system. Undoubtedly it acts pronouncedly upon the nervous system, causing motor paralysis, while the contractility of the muscular fibers and sensation remain unaffected. Its action has been compared to that of curare (Dujardin-Beaumetz). Temporary general paralysis is said to have occurred in a woman after a dose of 5 grains. Marked congestion of the retina and diplopia are asserted to have followed the subcutaneous injection of 6 grains of the alkaloid. On account of its action upon the ocular nerves, it has been successfully used in *paralytic states of the sixth* and *third cranial nerves.* While many contend that it has a powerful control over certain of the nervous functions, others declare it innocuous. As great diversity exists in regard to dosage as to its effects. The dose of pelletierine has been given as ranging from ½ to 8 grains; the sulphate in about 5-grain doses; the tannate in doses of from 5 to 23 grains, about 7 grains being the average dose. Pelletierine preparations are usually sold in solution containing enough for one dose. Dose of pomegranate flowers or rind, 20 to 40 grains.

Specific Indications and Uses.—Tæniacide and tæniafuge for the destruction and expulsion of tapeworm (*Tænia Solium*).

GRATIOLA.—HEDGE-HYSSOP.

The plant and root of *Gratiola officinalis*, Linné.

Nat. Ord.—Scrophulariaceæ.

Common Name: *Hedge-hyssop.*

Botanical Source and History.—The genus Gratiola is composed of small herbs less than a foot high, and found growing in low, damp situations. They all possess bitter properties and cattle refuse to eat them. They have opposite, sessile leaves and small axillary flowers. The calyx is sub-equally 5-parted, and the corolla tubular and bilabiate. The stamens are 2, and there are often 2 or 3 sterile filaments. The fruit is a dry, many-seeded, 2-celled capsule opening by 4 valves.

Gratiola officinalis, Linné, is a native of Europe, and has a smooth, 4-angled stem, and lanceolate, 3 or 5-nerved leaves. The corolla is pale-yellow, and striped with light-purple. The calyx-lobes are often 7. This species has long been used as a medicine in the south of Europe, and was mentioned by Lewis in his *Materia Medica* (1761), under the names *Gratiola centaurioides*, *Gratia Dei*, *hedge-hyssop*, and *herb of grace.*

Gratiola virginica, Linné, is the most common indigenous species, and is found in large patches in damp soil. It is a small, much-branched plant, with an erect, glutinous stem. The leaves are lanceolate, dentate, and clasping. The flowers are very numerous, with small, white corollas variegated with yellow, and pubescent in the throat. The other indigenous species of Gratiola are mostly found in the southern states.

Chemical Composition.—Nothing is known about the chemical constituents of the indigenous species, but they are probably similar to those of *G. officinalis.* Vauquelin (1809) found in the latter a bitter resinous substance, an acid in combination with lime and soda, believed by him to be malic or acetic acid, and various earthy salts and principles common to plants. Marchand (*Journ. de Chim. Med.*, 1845, p. 518), proved the resin of Vauquelin to be a compound, identifying tannic acid and a white, bitter, crystallizable substance to which the name *gratiolin* was given. Afterward, Walz proved *gratiolin* to be a glucosid, and obtained in addition another glucosid, *gratiosolin*, and an acid named by him *gratiolic acid.* The chemical constituents of Gratiola officinalis are of little practical value, as the infusion, or tincture, or plant in substance, are alone used in medicine.

Action, Medical Uses, and Dosage.—Hedge-hyssop is rarely, if at all, used in this country. In Europe it has been employed as a hydragogue-cathartic in the treatment of *dropsical affections*, in doses of from 10 to 30 grains of the powdered root. Its use is frequently followed by emesis and diuresis. In large doses its irritant action is pronounced, inducing violent vomiting and purging, the stools often being bloody and attended with severe colic. Gastro-intestinal inflammation may follow, the rectum being most generally affected. In smaller doses, it has been advised in *chronic affections of the liver*, in *jaundice*, and also in certain *melancholic forms of insanity. Splenic engorgement*, *cerebral fullness* and *oppression*, and other conditions attended with an obstructed circulation are the states in which it is recommended by Prof. Scudder (*Spec. Med.*), who regards the indications to be "soreness and rawness of the mouth." It is an active agent, and should be administered with judgment. An infusion of 4 drachms to a pint of boiling water, may be given in ½ fluid-ounce doses. Thirty grains act as a drastic cathartic. Probably a tincture of the root might be useful; but every indication for this agent can be fulfilled by one of our indigenous plants, as podophyllum, iris, euphorbia, apocynum, etc.

GRINDELIA (U. S. P.)—GRINDELIA.

"The leaves and flowering tops of *Grindelia robusta*, Nuttall, and of *Grindelia squarrosa*, Dunal"—(*U. S. P.*).

Nat. Ord.—Compositæ.

Common Names: 1. *Hardy grindelia.* 2. *Scaly grindelia.*

Botanical Source and History.—*Grindelia robusta* is an erect perennial plant, native of California. It was brought to the notice of pharmacists and the medical profession generally, by Mr. Jas. G. Steele, of San Francisco, Cal., through a paper presented to the American Pharmaceutical Association, in 1875, although Dr. C. A. Canfield, long previously, had noticed it in the *Pacific Med. and Surg. Jour.* The plant has a smooth, round, striate stem, much divided into ascending branches, each of which ends in a large, yellow flower-head. The lower leaves are obovate-spatulate, and tapering at the base; the upper are alternate, ascending, and have broad, clasping bases. They are of a firm, coriaceous texture, and a light-green color; the margins are coarsely toothed. The flower-heads are large, nearly ¾ of an inch in diameter, and are solitary, terminating the branches. The involucre is very resinous and consists of many thick, imbricated scales, with recurved tips. The receptacle is flat, pitted like a honey-comb, and destitute of scales. The ray-flowers are large, yellow, spreading, and arranged in a single series. They are pistillate and fertile. The disk-flowers are very numerous and perfect. The achenia are smooth, oblong, and slightly 4-angled. The most distinguishing character of the genus Grindelia is the pappus, which consists of 3 or 4 very deciduous awns; they are rigid, more or less curved, white, very smooth, and, when magnified, have a waxy appearance. In the *G. robusta* they are about half the length of the disk-flowers. A very large variety (var. *latifolia*), of this species of Grindelia is frequent in California, and is often collected. It is much more robust in every particular, having heads over an inch in diameter. The upper stem-leaves are about an inch broad, and the flower-heads are surrounded at the base by a cluster of 3 or 4 leaves.

Grindelia squarrosa has the general appearance of Grindelia robusta, but is a smaller plant, and has lately been considered a variety of this species. It is more widely distributed than *G. robusta*, and is quite common on the plains, from the Rocky Mountains west to the Pacific. The mode of growth is different in the two species. In the *Grindelia squarrosa*, a perennial root-stalk sends up from its head a cluster of from 4 to 10 slender, erect, sub-parallel, and generally undivided branches, from 1 to 2 feet high. The stem-leaves are alternate, acute, sessile, and slightly clasping at the base, and serrate on the margin. They are about an inch long, one-quarter as wide, and are attached to the stem in an erect position. The scales of the flower-heads are narrow, and have long, slender, recurved points (whence the specific name). In other respects the flower-heads resemble those of the *Grindelia robusta*, but are smaller. The pappus of the *Grindelia squarrosa* is slender and about the length of the disk-flowers. *Grindelia squarrosa* was introduced as a remedial agent some years after Mr. Steele brought *G. robusta* into notice. Its sensible properties are exactly like those of *G. robusta*, and it is often found on the market and substituted largely for *G. robusta*.

Description—Owing to the fact that both species are often indiscriminately gathered, or that the one is frequently adulterated with the other, both are described by the *U. S. P.* under the name GRINDELIA, as follows:

"Leaves about 5 Cm. (2 inches), or less, long, varying from broadly spatulate or oblong to lanceolate, sessile or clasping, obtuse, more or less sharply serrate, often spinosely toothed, or even laciniate-pinnatifid, pale green, smooth, finely dotted, thickish, brittle, heads many-flowered, subglobular or somewhat conical; the involucre hemispherical, about 10 Mm. (⅖ inch) broad, composed of numerous imbricated, squarrosely-tipped or spreading scales; ray-florets yellow, ligulate, pistillate; disk-florets yellow, tubular, perfect; pappus consisting of 2 or 3 awns of the length of the disk-florets; odor balsamic; taste pungently aromatic and bitter"—(*U. S. P.*).

Chemical Composition.—C. J. Rademaker (*New Rem.*, 1876, p. 205), was probably the first to make an analysis of Grindelia robusta, yet with no positive results. G. Linwood Libby (*Pharm. Era*, 1888, p. 11), isolated from the same plant an oleoresin and a resin.

A complete parallel analysis of G. robusta and G. squarrosa was made by W. H. Clark, in 1888, with the result that the constituents were qualitatively the same in both plants except that Grindelia robusta contained tannin (1.5 per cent), while G. squarrosa seemed to be free from it. Volatile oil was found in both. A crystallizable saponin-like body also occurred in both species (G. robusta contained 2 per cent, and G. squarrosa 0.82 per cent), for which the author proposes the name *grindelin* (*Amer. Jour. Pharm.*, 1888, pp. 433–441). On the other hand, Mr. John L. Fischer applies the name *grindeline* to a bitter, crystallizable alkaloid which he found in Grindelia robusta, and the name *robustic acid* to a crystallizable acid found in the aqueous solution of the alcoholic extract of the same drug (*Pharm. Era*, 1888, p. 208). Mr. Clark had obtained contradictory results with regard to the presence of an alkaloid. Dr. Schneegans, in 1892, found the saponin-like body to consist of two glucosids, one being identical with, the other closely resembling Kobert's saponin, from senega and quillaja. The presence of small amounts of an alkaloid was also indicated (*Amer. Jour. Pharm.*, 1892, p. 370).

Action, Medical Uses, and Dosage.—The grindelias leave in the mouth a bitter, acrid sensation, which persists for some time and is accompanied or followed by an increased flow of saliva. On account of their irritant effects upon the kidneys, they act as diuretics. The brain and cord are first stimulated by them, followed by motor impairment of the lower extremities and a desire to sleep. The number of respirations are reduced by them.

Grindelia robusta has been found especially efficient in *asthma*, giving prompt relief, and effecting cures in cases previously rebellious to medication. Occasionally, however, as is, indeed, the case with all the therapeutical agents, it has failed, but the circumstances attending these failures have not yet been determined. Further investigations regarding its action in this disease, and the cause of its occasional failure are required. It has likewise been found efficient in *bronchial affections*, in *pertussis*, and in some *renal maladies*. Prof. Scudder was partial to this remedy as a local application in *chronic diseases of the skin* with feeble circulation, particularly old chronic and indolent *ulcers*. Specific grindelia robusta (ʒi to ʒii to water Oj), was employed with marked benefit. The fluid extract and specific grindelia robusta are the preparations generally employed, the former in doses of from 10 to 60 minims, and the latter in doses of 5 to 40 minims, repeated 3 or 4 times a day, as may be required. Children require doses of from 5 to 15 or 20 minims (fluid extract), and 1 to 10 minims (specific grindelia robusta).

Grindelia squarrosa has been highly eulogized as an efficient remedy in *intermittent fever*, and in other *malarial affections*, also to remove the *splenic enlargement* which so frequently follows those disorders. Why two plants so closely allied as the G. robusta and the G. squarrosa, and possessing nearly identical constituents, should give such discordant therapeutical results, is certainly enigmatical. The fact is, that many physicians have a great proneness to run after new remedies, especially when introduced under some pretentious name, and to place a marvelous credulity in the statements of interested parties, who are incapable of determining accurate conclusions as to the value of a remedy. Webster, however, asserts that the remedy has a special action upon the splenic circulation, and points out as the case for it one of *splenic congestion* associated with sluggish hepatic action and *dyspepsia*. Dull pain in the left hypochondrium, sallow skin, debility, and indigestion are the symptoms pointing to its selection (*Dynam. Therap.*). The same author recommends it in *chronic dyspepsia* due to prolonged malarial influence, *gastric pain* when the spleen is seemingly involved, and in the *splenic congestion of malarial cachexia*. As a local application, the fluid extract is stated to be of value in the painful *eczematous inflammation* and *vesicular eruption* resulting from contact with the *poison vine* or the *poison oak*. The dose of the fluid extract is from 15 minims to 1 fluid drachm, repeated every 3 or 4 hours; of specific grindelia squarrosa, 5 to 40 drops.

Specific Indications and Uses.—GRINDELIA ROBUSTA: Asthmatic breathing, with soreness and raw feeling in the chest; cough, harsh and dry; breathing labored, with a dusky coloration of the face in plethoric individuals. Locally, old atonic ulcers; full tissues; rhus poisoning.

GRINDELIA SQUARROSA: Splenic congestion, especially when dependent on malarial cachexia; fullness and dull pain in left hypochondrium, with indigestion, pallid, sallow countenance, and general debility; gastric pains associated with splenic congestion.

Related Species.—*Grindelia glutinosa*, Dunal, of California, and *Grindelia hirsutula*, Hooker and Arnott, have a similar odor and taste to Grindelia, and are probably gathered with it. The leaves of the former are smooth. It constitutes the Mexican *Calancapatle de Pueblo*. The second species is found along the Pacific to Puget's Sound.

Haplopappus Baylahuen (*Hysterionica Baylahuen*). *Nat. Ord.:* Compositæ.—This plant is a native of Chili and contains a resin, tannin, and volatile and fixed oils. The resin acts upon the bowels and the essential oil upon the respiratory organs after the manner of the terebinthinates, without, however, being an irritant to the gastro-intestinal tract. The *chronic looseness of the bowels* of tuberculous patients is controlled by it, and the remedy is reputed of value in *inflammation of the bladder*. Locally, the tincture has been used on *ulcers*, *wounds*, etc., both as a stimulant and protective. The tincture is prepared of the strength of 1 part to 5, and the dose is from 5 to 25 drops.

GUAIACI LIGNUM (U. S. P.)—GUAIACUM WOOD.

"The heart-wood of *Guaiacum officinale*, Linné, and of *Guaiacum sanctum*, Linné"—(*U. S. P.*).

Nat. Ord.—Zygophylleæ.

SYNONYMS: *Lignum vitæ, Lignum sanctum, Lignum benedictum, Palus sanctus.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 41.

Botanical Source.—*Guaiacum officinale.* This tree grows very slowly, varying in height from 15 to 50 feet. The trunk is usually crooked, with crowded, knobby, short-jointed, flexuose, spreading branches, about 4 feet in diameter; the bark is furrowed, spotted, and grayish. The leaves are opposite, bijugate or trijugate; the leaflets sessile, more or less obovate, rounded at the apex, nerved, and glabrous; the common petiole is terete and channeled above. The flowers are light-blue, on axillary peduncles, which are an inch long, 1-flowered, filiform, minutely downy, and several together. The calyx of sepals have the 2 exterior, somewhat broader than the others; all are obtuse and hoary with down. Petals 5, thrice the length of the sepals, oblong, bluntish, unguiculate, and internally downy. Stamens 10, without scales; filaments twice the length of the sepals, grooved on the back; anthers bifid at the base and curved. Ovary 2-celled, with numerous suspended ovules, and compressed; style short, acute and subulate; stigma simple; capsule obcordate, succulent, glabrous, yellow, 2 to 5-celled; on short stalks, somewhat fleshy, angular; the seeds are solitary, compressed, roundish, smooth, and pendulous (L.).

Guaiacum sanctum differs from the preceding in its leaflets, 6 or 8 of which compose the leaf, having an oblique-obovate, or rhomboid-ovate outline; in having a fruit with 5 cells; and in having smaller wood, which is less compact and lighter in color. It grows in Cuba, Bahama, and other West India Isles.

History, Description, and Chemical Composition.—The tree (*Guaiacum officinale*, Linné) inhabits the West Indian Islands, especially Jamaica, St. Thomas and St. Domingo. The wood and resin, or solidified juice, are the parts used in medicine, though the whole tree possesses medicinal virtues. The bark is said to be the most active part of it, but it is seldom met with in commerce. The wood of this tree was used as a medicine by the natives long previous to the discovery of the country, and they made it known to the Europeans; by these it was introduced into Europe in the sixteenth century, and employed to much advantage in syphilitic affections. Guaiacum wood, also known as *Lignum vitæ*, a name given to it from a belief that its medicinal virtues were of a superior kind, is largely imported into this country from the West Indies for making block-sheaves, wooden pestles, and many other objects, for which it is peculiarly fitted by its extraordinary hardness and toughness. It is imported in billets, about a foot in diameter, and generally without the bark. The bark is hard, flat, a few lines thick, of a greenish-black color, with yellowish and grayish spots, inodorous, but very acrid. The wood, used for medicinal purposes, consists of turnings from the workshop of the turner, and is a uniform mixture of the alburnum and duramen, but that used in medicine should consist only of the latter.

The alburnum or sap-wood is of a yellow color, that of the duramen or heart-wood, greenish-brown. Guaiacum wood is only odorous when burned or rasped, the odor being aromatic; its taste is acrid, aromatic, and amarous, succeeded by a pricking in the throat. It is very dense and tough, and has a specific gravity of 1.333. It is officially described as follows: "Heavier than water, hard, brown or greenish-brown, resinous, marked with irregular, concentric circles, surrounded by a yellowish alburnum, splitting irregularly; when heated, emitting a balsamic odor; taste slightly acrid. Guaiacum wood is generally used in the form of raspings or turnings, which should be greenish-brown, containing few particles of a whitish color, and should acquire a dark bluish-green color on the addition of nitric acid"—(*U. S. P.*). When a very fine powder of guaiacum wood is acted upon by the atmosphere, its color is converted into green. Nitric acid turns it bluish-green, and a solution of ferric chloride turns it blue. Solution of chlorinated lime effects no change in other woods, but causes the guaiacum to assume a green color in a few seconds. These tests may be employed to determine the authenticity of the wood. Alcohol takes up its active parts (see *Guaiaci Resina*). dissolving about 21 per cent. Flückiger (*Pharmacognosie*, 1891), by extracting with ether, obtained 22.12 per cent of resin from the duramen, and only 2.85 per cent from the alburnum. The same authority found a trace of essential oil by distilling the wood with water. Frémy and Urbain found *vasculose* (the incrustating substance in wood) to exist in guaiac wood to the extent of 36 per cent (see *Jour. Pharm. Chim.*, 1882, p. 325). Several other trees of this family are stated to furnish the guaiacum wood, as the *G. sanctum* (now official), which has a translucent, paler-yellow, and less heavy and hard wood, and also the *G. arboreum.*

Action, Medical Uses, and Dosage.—Taken internally, guaiacum, both the wood and resin, commonly excites a sense of warmth in the stomach, and a dryness of the mouth, with thirst. They act upon the economy like stimulants, increasing the heat of the body, and accelerating the circulation. If the body be kept warm while using the decoction, which is the form generally preferred, it will prove diaphoretic; if cool, diuretic. As a diaphoretic and alterative, it has been administered (but usually in compound decoction or syrup), in *chronic rheumatism*, *chronic cutaneous diseases*, *scrofula*, and *syphilitic disease.* As water can not take up much of the active principle in the wood, it is probable that its reputed efficiency was owing principally to the active agents associated with the syrup or decoction. The resin of guaiacum is the active principle (which see). The decoction of guaiacum shavings may be made by boiling 2 ounces of the shavings in 3 pints of water down to 2 pints, the dose of which is from 2 to 4 fluid ounces every 3 or 4 hours (see *Guaiaci Resina*).

Related Species.—*Guaiacum angustifolium*, Engelmann (*Porliera angustifolia*, Gray). Mexico and south Texas. The wood of this tree is employed like that of guaiac. It is a yellow-brown, heavy and hard wood, splitting irregularly.

BALSAM WOOD. *Palo balsamo.*—A South American tree of unknown botanical origin, the wood of which is thought to contain *guaiacin.* Upon distillation of the wood, about 6 parts of a thick, sticky, fragrant oil are obtained. This oil contains a crystalline solid, fusing at 91° C. (195.8° F.), and answering closely to the composition $C_{14}H_{24}O$ (Schimmel & Co., *Reports*, 1892).

GUAIACI RESINA (U. S. P.)—GUAIAC.

"The resin of the wood of *Guaiacum officinale*, Linné"—(*U. S. P.*).

Nat. Ord.—Zygophylleæ.

SYNONYMS: *Guaiacum*, *Guaiacum resin*, *Resina guajaci.*

Source and Preparation.—The resin of guaiacum, or *gum guaiacum* as it is erroneously called by some, is procured from the wood of the tree, by natural exudation; by jagging or wounding the tree in several places; by heat applied to the wood sawed into large billets; and by boiling the chips of the wood in water and salt, and skimming off the resin as it floats on the surface (*Ed.*—P.). The last two modes are the most frequent in use.

Description and Tests.—Guaiacum is ordinarily met with in amorphous, hard masses of varying sizes, in which are found pieces of wood, dirt, and other foreign matters. It has a sweetish, faintly bitter taste, succeeded by a lasting acrimony, especially in the fauces. It does not soften by the heat of the hand, becomes tough when chewed, and is fusible at a moderate heat. Its specific gravity is 1.20 to 1.23. It is readily reduced to powder, becoming somewhat tenacious, and quickly aggregating, by the action of the air. Guaiac resin is officially required to be in "irregular masses, or subglobular pieces, externally greenish-brown, internally of a glassy lustre, and, in recent guaiac, usually reddish-brown, transparent in thin splinters, fusible, feebly aromatic, the odor becoming stronger on heating; taste somewhat acrid; powder grayish, turning green on exposure to air. Soluble in potassium or sodium hydrate T.S. and in alcohol; the alcoholic solution is colored blue on the addition of tincture of ferric chloride"—(*U. S. P.*).

The resin is practically insoluble in water, soluble, although not completely, in ether and oil of turpentine, easily soluble in acetone, amyl alcohol, chloroform and in creosote· fixed and volatile oils scarcely dissolve it, although oil of cloves and cassia oil are capable of dissolving appreciable quantities. Benzin, benzol and carbon disulphide dissolve the resin very sparingly. Guaiac resin is remarkable for the blue color reaction it yields in alcoholic solution (1 in 100) with *ozonizers* (Schönbein's *ozonide*). Ozone, chlorine, bromine and iodine, nitrous acid, chromic acid, hypochlorites, ferric salts, lead and manganese dioxide, etc., and some organic substances, especially vegetable ferments and *enzymes* of the most obscure kind, *e. g.*, the enzymes existing on freshly cut raw potato, etc., (*oxidation ferments* of Schönbein), cause a rapid bluing of tincture of guaiac. According to Prof. Ed. Schaer (*Forschungsberichte über Lebensmittel*, Vol. III, 1896, p. 1), the blue color is due to a very unstable ozone compound of guaiaconic acid (see *Chemical Composition*). Its formation is prevented by light, heat, free acids, especially by alkalies, but acetic acid, even in the form of glacial acetic acid, singularly promotes its formation. In contrast with these ozonizers stand Schönbein's *antozonide* (*antozonizers*), substances otherwise capable of giving off oxygen, but incapable of reacting with tincture of guaiac. The type of these substances is hydrogen peroxide (H_2O_2). They become active, however, toward tincture of guaiac through the intervention of certain inorganic substances, and a number of fluids containing animal and vegetable ferments, *e. g.*, malt extract, saliva, fresh milk, or the red corpuscles of the blood. Schönbein, the discoverer of ozone, was the first to base upon this behavior the well-known guaiac test for blood, often believed to be fallacious, while Prof. Schaer pronounces it exceedingly characteristic and sensitive if properly carried out.

Prof. Schaer, in the paper mentioned, publishes a new mode of carrying out this test, to which he has given 30 years' time of successful trial. This test is based on the following observation: When an alcoholic tincture of guaiac is poured into an aqueous solution of blood acidified with acetic acid, the guaiac resins, in precipitating, carry along with them almost quantitatively the blood coloring matter present in the fluid. Filter through paper and dry the latter with its contents, taking especial care to exclude light and air as much as possible. The blood test is then produced by moistening small pieces of the filtering paper with water and adding hydrogen peroxide solution containing some acetic acid. If blood is present the paper and liquid assume a pure blue color. The test can be applied with equal success to dry blood stains, and after a period of 5 or even 10 years after drying the paper. A modification of this process, involving the use of a concentrated aqueous solution of chloral hydrate to dissolve dried blood stains, is carried out as follows: Moisten the blood stains with acetic acid, extract with a 70 per cent solution of chloral hydrate, add an equal volume of guaiac-chloral solution (1 per cent guaiac resin in 70–75 per cent chloral hydrate); if ammonium nitrate is absent, a yellow-brown mixture results (otherwise a blue coloration takes place at once). If now the mixture is superposed by Hünefeld's solution (15 Cc. of a 3 to 5 per cent solution of hydrogen peroxide, 25 Cc. of alcohol, 5 Cc. of chloroform, and 1.5 Cc. of glacial acetic acid), previously ascertained not to react with a mixture of chloral and guaiac, an intensely blue zone is developed at the surface of contact of both fluids if blood is present. Soluble ferrous salts mixed with the blood stain also give the reaction (*Archiv der Pharm.*, 1898, p. 574).

Reversely, this reaction with ozonizers can be used as a delicate test for the presence of the resin of guaiacum in other resins, *e. g.*, scammony, jalap, etc. Guaiac is subject to adulteration with pine resin and other substances. This may be detected by observing that the genuine article, when heated, does not exhale a turpentine odor, and that oil of turpentine dissolves resin but not guaiac. Sulphuric acid forms with guaiac a deep-red solution; nitric acid dissolves it without the aid of heat, and with strong effervescence yielding oxalic acid upon evaporation. The so-called *Peruvian guaiac resin*, analyzed by E. Kopp (*Archiv der Pharm.*, [3] Vol. IX, p. 193), is entirely different from guaiac resin, and therefore does not give the characteristic reaction for this resin.

Chemical Composition.—In 1862, Hadelich found the composition of guaiac resin to be as follows: "*Guaiaconic acid*, 70.3 per cent; *guaiac-resinic acid*, 10.5 per cent; *guaiac-beta-resin*, 9.8 per cent; *guaiacic acid*, *guaiac-yellow* and impurities, 4.9 per cent; gum, 3.7 per cent; ash constituents, 0.8 per cent" (Flückiger, *Pharmacognosie*, 1891). The first three substances may be differentiated from the guaiac resin as follows: To a concentrated alcoholic solution of the resin (1 part add a warm alcoholic solution of potassium hydrate (½ part), and allow the mixture to stand for 24 hours; a magma of crystals results, consisting of the potassium salt of *guaiac-resinic acid*. Strain through cloth, evaporate the mother liquor to a syrup, add absolute alcohol in order to remove some more of this potassium salt. Now charge the alcoholic solution with carbonic acid gas, which precipitates the potassium as carbonate, filter, add water, acidulate with hydrochloric acid and distill off the alcohol. The residual resin is then washed with warm water and treated with ether. *Guaiaconic acid* is thereby dissolved, while *guaiac-beta-resin* remains. The substances thus obtained are then purified by further treatment, for which see details in Husemann and Hilger, *Pflanzenstoffe*, p. 857

Guaiaconic acid ($C_{19}H_{20}O_5$), isolated by Hadelich, in 1862, is the chief constituent of guaiac resin (70 per cent), and is the substance to which is due the blue color reaction with oxidizing agents. Prof. E. Schaer (*Wittstein's Vierteljahrsschrift*, 1873, p. 68), however, remarks that guaiaconic acid, when exposed to direct sunlight loses its property of turning blue with oxidizers, even when the air is excluded. It is a tasteless and odorless, brownish, amorphous body, fusible near the boiling point of water, easily soluble in alcohol, ether, chloroform, acetic ether and acetic acid. It is optically lævo-rotatory, forms soluble amorphous salts with alkalies, decomposable by the carbonic acid of the air, and forms insoluble salts with heavy metals. It dissolves in concentrated sulphuric acid with a cherry-red color, water precipitating violet flakes from this solution. Dry distillation yields an oily distillate.

Guaiac-resinic acid ($C_{20}H_{26}O_4$) was discovered by Hlasiwetz, in 1859, and is a crystallizable substance, insoluble in water, soluble in alcohol, ether, chloroform, benzol, carbon disulphide, acetic ether and acetic acid, also in solution of caustic soda or potash, but not ammonia. It melts between 75° and 80° C. (167° and 176° F.). It dissolves in sulphuric acid with a cherry-red color. Water precipitates white flakes from this solution. When heated with hydrochloric acid this substance (as well as guaiaconic acid) yields methyl chloride and *pyrocatechin* ($C_6H_4[OH]_2$). Fused with caustic potash, it yields protocatechuic acid ($C_6H_3[OH]_2.COOH$) (Hlasiwetz and Barth). Upon dry distillation it yields *guaiacol* ($C_6H_4OCH_3[OH]$) (which see), and crystallizable *pyroguaiacin*. The yield of this substance is 0.5 per cent. It melts at 180° C. (356° F.), is soluble in alcohol and ether, insoluble in water, can be sublimed in the form of needles or scales, which turn green with ferric chloride, and blue with warm sulphuric acid. When heated with zinc dust, the hydrocarbon *guaien* ($C_{12}H_{12}$) is obtained, forming fluorescing plates.

Guaiacic acid ($C_6H_8O_3$, Deville) was first obtained, in 1837, by Righini from guaiac wood as a white crystallizable substance. In 1841, Thierry isolated it from both the wood and the resin. It forms white needles, resembling benzoic acid, but is more soluble in water than the latter; also soluble in alcohol and in ether. Only 0.005 per cent of this acid could be obtained by Hadelich from guaiac resin. Deville found this substance upon rapid sublimation to decompose into carbonic acid and *guajacen* (*guajol*) (C_5H_8O), a colorless oil, of the odor of bitter almonds. It was found by Lieben and Zeisel (confirmed by Herzog, *Berichte*, 1882, p. 1085) to be identical with *tiglin-aldehyde* ($CH_3CH:C[CH_3].CHO$), convertible by oxidation into *tiglic acid*, a constituent of Roman chamomile oil, as well as of croton oil.

Guaiac yellow was first observed by Pelletier, and obtained by Hadelich (1862) in yellowish quadratic plates of neutral reaction and bitter taste, not easily soluble in water, diluted acids and chloroform, soluble in alcohol, ether, carbon disulphide and alkalies, in the latter with yellow color. With concentrated sulphuric acid it forms a beautiful blue solution, turning green, then yellow.

The resin of guaiac, upon dry distillation, yields a brown-red tar containing *guaiacol* ($C_7H_8O_2$) (see *Guaiacolum*), *pyroguaiacin* ($C_{12}H_{10}OH.OC_6H_6[OH]$), *guaiol* (*guaiacen*, *tiglin-aldehyde*, C_5H_8O), and *kreosol* ($C_8H_{10}O_2$). Fusion with caustic potash yields *protocatcchuic acid*, and by distillation with zinc dust, K. Bötsch (*Amer. Jour. Pharm.*, 1881, p. 60) obtained 50 per cent kreosol, 30 per cent toluol, meta and paraxylol, pseudocumol, and the hydrocarbon *guajon* or *guaien* ($C_{12}H_{12}$), aforenamed, which is identical with the *guaiacen* prepared by Wiesner.

Action, Medical Uses, and Dosage.—(See *Guaiaci Ligni* also.) Guaiac is stimulant. Taken internally it produces the same effects as named in the wood, but in a more active degree. Large doses act as a cathartic. It is used in the same affections as guaiaci ligni or guaiacum wood. Several practitioners have found it beneficial in *amenorrhœa*, *dysmenorrhœa*, and other *uterine diseases*, all of atonic character, likewise in *acute dysentery*, in which its employment is said to be followed by speedy beneficial results. It is much used in *chronic rheumatism*, and in the abating stages of the acute form, and has proved a most valuable agent in these diseases. It is said to be an antidote to the effects of the tincture of *Rhus Toxicodendron*. If the preparations of guaiacum produce sickness, defective appetite, and irregularity of the bowels, their use must be discontinued. Guaiac gained its greatest reputation in the treatment of *constitutional syphilis*, having been liberally used for centuries in the treatment of that malady, but at the present day it is almost discarded as an antisyphilitic. It undoubtedly benefits some cases of rheumatism and is well endorsed as a remedy for *rheumatic sore throat* or *rheumatic pharyngitis*. A tincture of guaiac, or preferably the ammoniated tincture is to be used. The latter preparation, as well as troches of the powder, have been highly endorsed as a remedy to abort *tonsilitis*. For this purpose they must be given early or good effects fail to be produced. In *chronic rheumatism*, where the circulation of the blood is feeble and the vital functions greatly depressed, and the hands and feet are cold, from 30 to 60 drops of the tincture may be used with expectation of benefit. A good tincture is prepared by macerating 8 ounces of guaiac in 1 pint of alcohol. Guaiac is also of some value in *atonic dyspepsia*, provided no inflammation is present. Certain *chronic skin diseases*, requiring stimulation, are benefited by guaiac. From $\frac{1}{20}$ to $\frac{1}{10}$ grain of the resin in $\frac{1}{2}$ ounce of thick malt extract is recommended as a remedy for *habitual constipation*. Guaiac is a remedy in atonic conditions only. It is contraindicated in all active febrile, plethoric, or inflammatory conditions, or where there is vascular excitment, tending to hemorrhage, or impaired digestion, with tendency to irritation (Locke). Dose of the powdered resin, from 5 to 20 grains; of the tincture, from 1 to 4 fluid drachms, either of which may be repeated 3 or 4 times a day; ammoniated tincture of guaiac, 10 drops to 1 fluid drachm. A mixture of 10 grains each of guaiac and compound powder of ipecacuanha and opium has been found of advantage in *rheumatism* and *dysentery*.

Specific Indications and Uses.—Dryness and stiffness of the throat, with tumid, swollen tonsils, painful deglutition, and dribbling of saliva; incipient tonsilitis (if used early); rheumatic pharyngitis.

GUAIACOLUM.—GUAIACOL.

FORMULA: $C_7H_8O_2$ or $C_6H_4.OCH_3.OH$. MOLECULAR WEIGHT: 123.71.

SYNONYMS: *Methyl-pyrocatechin*, *Catechol monomethyl ether*.

Source and Preparation.—Guaiacol is obtained from beechwood creosote (see *Creosotum*), of which it forms from 60 to 90 per cent, the other constituents of importance being creosol ($C_7H_6.OCH_3.OH$), and the cresols ($C_7H_7.OH$). To obtain it, beechwood tar creosote is subjected to fractional distillation whereby crude guaiacol passes over in the portion distilling between 200° and 205° C. (392° and 401° F.). After washing out the acid compounds with weak solutions of ammonia, the purified guaiacol is again fractionally distilled, and the lower fraction treated with ether, from which solution potassium-guaiacol is separated by the addition of a strong solution of caustic potash in alcohol. The potassium guaiacol is then thoroughly washed with ether, and the guaiacol liberated by means of diluted sulphuric acid, after which it is once more rectified. Commercial guaiacol frequently contains cresols. It may be obtained pure by saponification of its benzoyl compound, previously purified by repeated crystallization. Guaiacol is also formed in the dry distillation of resin of guaiac (which see), and may be prepared synthetically by heating the potassium salt of methyl-sulphuric acid (CH_3SO_4K), with pyrocatechin ($C_6H_4[OH]_2$), and caustic potash, to 180° C. (356° F.).

Description.—Guaiacol, when pure, is a pleasantly aromatic, colorless liquid. Its specific gravity at 15° C. (59° F.), is, according to Helbing, 1.133, and its boiling point, according to the same authority, 206° to 207° C. (402.8° to 404.6° F.). It dissolves to some extent in water (1 in 85), and freely in ether, alcohol, and acetic acid. Solutions of caustic soda and caustic potash dissolve it, producing the unstable salts of sodium-guaiacol and potassium-guaiacol. Impure guaiacol forms a clear solution with twice its bulk of benzol at 20° C. (68° F.), but when pure, rapid and complete separation occurs. If to a solution of guaiacol in alcohol be added a small amount of ferric chloride, a blue color is formed which turns emerald-green upon the addition of more of the iron compound. This is a characteristic reaction (even when OH is replaced by OCH_3, as with guaiacol), for all *ortho-dioxy-phenols.*

Action, Medical Uses, and Dosage.—Guaiacol and its compounds (see below), have been used in wasting diseases, particularly *phthisis pulmonalis* and other *tubercular affections. Lupus* has likewise been treated with it. It is useful in *profuse bronchorrhœa.* The indications sought to be fulfilled are the diminution of diarrhœa, excessive sweating, cough, and expectoration. It was introduced as a substitute for creosote, and is reputed to act by combining with the toxic products of the tubercle bacillus, and thereby effecting their elimination from the system. The dose of guaiacol for adults is from 2 to 5 minims; for children, 1 to 3 minims, 4 times a day, in milk, cod-liver oil, or capsules. Wine may be used as its vehicle, and the drug may be given for a length of time. Formerly it was inhaled, and it has been unwisely used hypodermatically. It agrees with the stomach better than creosote and dispels *flatulence.*

Guaiacol Derivatives and Compounds.—GUAIACOL CARBONATE ($[C_6H_4.OCH_3.O]_2CO$). This salt is produced by precipitating a soda solution of guaiacol with carbonyl chloride and crystallizing the product from alcohol. It is a white, crystalline powder, neutral in reaction and almost without taste or odor. It is sparingly soluble in glycerin, fixed oils, and cold alcohol; easily soluble in hot alcohol, benzol, chloroform, and ether, and insoluble in water. This is the di-guaiacol ester of carbonic acid and contains about 91 per cent of guaiacol. It does not irritate the stomach, but, passing through that organ, is decomposed in the intestines. Ordinary dose, 2 to 8 grains, gradually increased to 60 grains a day.

GUAIACOL BENZOATE ($C_6H_4.OCH_3.C_6H_5CO_2$), *Benzosol, Benzoyl-guaiacol.*—This salt is produced by the interaction of potassium-guaiacol and benzoyl chloride. The product is crystallized from alcohol. It forms a colorless, crystalline powder, devoid of taste and odor, soluble in boiling alcohol, chloroform, and ether, and nearly insoluble in water. Does not give the guaiacol reaction with ferric chloride. Used in *phthisis* and other *tuberculous diseases.* Dose, 5 to 100 grains per day.

GUAIACOL CINNAMATE ($C_6H_5.CH:CH.CO_2C_6H_4OCH_3$), *Cinnamyl-guaiacol, Styracol.*—Colorless, needle crystals of styracol are formed by the interaction of cinnamyl chloride and guaiacol, the product being crystallized from alcohol. It is nearly insoluble in water. It fuses at 130° C. (266° F.). This agent has been used in *phthisis, catarrhal digestive affections, chronic diarrhœa, gleet,* and *catarrh of the bladder.*

GUAIACOL DIIODIDE, *Guaiacol biniodide.*—This new salt is produced by precipitating a solution of crystallized sodium-guaiacol in water by means of an iodide of potassium solution of iodine. It forms a red-brown compound, having an iodine-like odor. It is unstable and easily decomposed by heat. Alcohol and the fixed oils dissolve it. The uses and dose are the same as for guaiacol.

GUAIACOL-CARBONIC ACID ($C_6H_3OHOCH_3.CO_2H+2H_2O.$), *Methoxysalicylic acid.*—This substance is prepared by a patented process. It forms a bitter, white, crystalline powder, devoid of odor. The fusing point of the anhydrous acid is 148° to 150° C. (298.4° to 302° F.). Alcohol, ether, hot water, and sodium bicarbonate solution easily dissolve it, while it dissolves with difficulty in cold water. This substance and its alkali salts have been used as antirheumatics and antiseptics.

GUAIACOL SALICYLATE ($C_6H_4OHCO_2.C_6H_4OCH_3$), *Guaiacol-salol, Guaiacolic salol, Salicyl-guaiacol.*—This compound is obtained by acting on a mixture of sodium-guaiacol and sodium salicylate with phosphorus oxychloride. It is a white, tasteless, odorless, crystalline powder, soluble in alcohol, chloroform, and ether, but not in water. Fusing point, 62° C. (143.6° F.). This agent is used as an intestinal antiseptic and to aid the digestion of phthisical subjects. Dose, 5 to 15 grains.

GUAIACOL SUCCINATE and GUAIACOL PHOSPHATE are occasionally employed for the same purposes as guaiacol.

GUARANA (U. S. P.)—GUARANA.

"A dried paste chiefly consisting of the crushed or pounded seeds of *Paullinia Cupana,* Kunth (*Paullinia sorbilis,* Martius)"—(*U. S. P.*).

Nat. Ord.—Sapindaceæ.

COMMON NAMES: *Guarana, Uaranazeiro, Uabano.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants,* 67.

Botanical Source.—The genus Paullinia comprises about 80 species, natives of tropical America, with a single African exception. The *Paullinia Cupana* (*Paul-*

linia sorbilis) is a climbing, shrubby vine, growing in northern Brazil, in moist, sandy locations. The flexible stem is very long, and takes root readily wherever it touches the ground, so that a single plant often extends over considerable space. In the wild state the vine attaches itself to large trees, and the fruit is difficult to collect, and of small yield; the vine is cultivated without support. The leaves are alternate, stipulate, and consist each of 5 smooth leaflets; the leaflets have the same shape and dentation as those of Rhus Toxicodendron, and look very much like them. The flowers are small, numerous, and disposed in erect, axillary, close panicles; the sepals are 5, the petals are 4, and have each a large pubescent scale on the inside, near the base; the stamens are 8, attached to a thick column. The pistil has a 3-lobed ovary, and a sessile, 3-parted stigma. The fruit is pear-shaped, and generally has a single brownish seed attached to the base, and nearly filling the pericarp.

History and Preparation.—This plant is of interest to the medical profession from the fact that the drug known as *Guarana* is prepared from the seeds. Guarana was introduced into France in the year 1817, by a French officer, and was described in the same year by Gassicourt in the *Journal de Pharmacie*, the botanical source, however, being then unknown. It was called "*guarana*," after the tribe of South American Indians (Guaranis), who prepared it, and in 1826, Martius, after identifying the plant, gave it the name of *Pauilinia sorbilis*, in allusion to the fact that *guarana* is employed to produce a drink. The preparation of guarana from the cultivated plant is described by Prof. H. H. Rusby (*Amer. Jour. Pharm.*, 1888, p. 267), as follows: "When the ripe pods begin to open the seeds are shelled from the husk by hand, washed to remove a phlegmy substance, and subjected for 6 hours to a roasting process whereby a papery shell is loosened, which is removed by placing the seeds in sacks and beating them with clubs. A small amount of water is then added and the seeds kneaded by hand into a mass of the consistence of dough. The mass is then rolled into cylinders, spread out on the upper floors of large buildings erected for that purpose, and subjected to a slow fire, as nearly free from smoke as possible. The temperature is kept equable for several weeks, and the product as known in commerce is then ready for the market." Sometimes, it is said, the moistened magma of the coarsely powdered seed is incorporated with cocoa and tapioca before kneading and rolling, but in Prof. Rusby's experience such is not the case.

Description.—Guarana appears in our market, generally in cylindrical sticks, from 6 to 12 inches in length, and from 1¼ to 2 inches in diameter, rounding at the ends, and averaging from 8 to 20 ounces in weight. Throughout the roll are fissures caused by contraction in drying. It leaves a sweetish after-taste resembling that of dulcamara. The *U. S. P.* thus describes it: "Subglobular or elliptic cakes, or cylindrical sticks, hard, dark, reddish-brown; fracture uneven, somewhat glossy, pale reddish-brown, showing fragments of seeds invested with blackish-brown integuments; odor slight, peculiar, resembling that of chocolate; taste astringent and bitter. It is partly soluble in water, and in alcohol"—(*U. S. P.*).

Chemical Composition.—Guarana was first analyzed in 1826, by Th. Martius, who discovered in it a crystallizable substance and named it *guaranine;* but the fact of its identity with *caffeine* became known by the researches of Berthemot and Deschastelus (*Jour. Pharm. Chim.*, 1840, p. 518), who concluded that it existed in guarana in combination as *tannate of caffeine*, and that it was obtainable in greater quantity from guarana than from any source of caffeine hitherto known. Subsequent researches confirmed the presence of caffeine; Stenhouse (*Pharm. Jour. Trans.*, 1856, Vol. XVI, p. 212), found 5.07 per cent of this substance in guarana, and Mr. F. V. Greene (*Amer. Jour. Pharm.*, 1877, pp. 338 and 388), obtained about the same amount. Still others claim that the average is only about 3 per cent. The standard established by J. U. Lloyd as proper for fluid extract of guarana, is 4 per cent.

The tannic acid of guarana was believed by Fournier (*Jour. Pharm. Chim.*, 1861, p. 291), to be identical with caffeotannic acid, and Peckolt (1866), stated that it resembled *kinotannic acid;* F. V. Greene (1877), termed it *paullinitannic acid.* Recently the tannic acid of guarana was more closely studied by Ernst Kirmsse (*Dissert.*, Strassburg, 1897), who established its non-glucosidal nature, hence its non-identity with kino- or caffeo-tannic acids, and pointed out its close relationship to *catechu-tannic acid* (see *Catechu*). The same author confirmed the observation of Peckolt as to the presence of *saponin* in guarana. By exhausting guarana paste of its caffeine by repeated extraction with chloroform, and subsequently extracting with absolute ether, Dr. Kirmsse furthermore obtained 0.05 per cent of a micro-crystalline substance anticipated by Prof. Schaer in 1890 (*Archiv der Pharm.*, Vol. CCXXVIII, p. 279), which proved to be *catechin* (*catechuic acid*), and was distinguished by its discoverer as *Paullinia catechin* (see *Catechu*). This substance was mistaken by Peckolt, in 1866, for gallic acid, as Dr. Kirmsse proved by employing Wackenroder's test to distinguish between gallic acid and catechin. This test is based on the fact that the green coloration produced by gallic acid in a freshly prepared solution of ferrous sulphate containing some sodium acetate, does not disappear upon adding acetic acid, while the color produced by catechin disappears under the same conditions. For methods recorded and results obtained in assay of guarana, see Kirmsse's dissertation, H. W. Snow (*Amer. Jour. Pharm.*, 1886, p. 483), Chas. A. La Wall (*ibid.*, 1897, p. 350), and method by J. U. Lloyd.

Action, Medical Uses, and Dosage.—It is very probable that from the tannin contained in guarana, it has effected recovery from *diarrhœa*, *leucorrhœa*, etc., of a very mild form; but as we have more prompt and efficient articles for these affections, in which this agent was at first so loudly heralded, it is no longer employed therapeutically, except chiefly for the relief of certain forms of *headache.* Like coffee and tea, it appears to be a gentle excitant, and is serviceable in cases where the brain becomes irritated or depressed by mental over-exertion, and when there is a sensation of fatigue or exhaustion during very warm seasons; as it has practically the same chemical composition as caffeine and theine, we find it has likewise precisely the same physiological action. It is chiefly in *nervous headache*, in the cephalalgia sometimes accompanying menstruation, and that following a course of dissipation, in which the most benefit is derived from it. Its use appears to be contraindicated in most cases of neuralgia, neuralgic headache, and chronic headache, and in all cases in which it is not desirable to excite the heart, increase arterial tension, or increase the temperature. Its administration is often followed by dysuria. The dose of guarana, in powder, is from 10 grains to 1 drachm, but this is an unpleasant and objectionable form of administration. The indications for its use are a feeble pulse, pallid countenance, and expressionless eyes, with sick headache. It is asserted by Foltz to relieve the *temporary paralysis of the third nerve*, which occasionally succeeds headache. The smaller doses act better than the excessively large doses, the medium dose of specific guarana being 10 drops. Webster claims that it is serviceable in *occipital neuralgia* and *lumbago.* The fluid extract and specific guarana are probably the most eligible preparations for use; the former may be given in doses of from $\frac{1}{2}$ to 1 teaspoonful, in syrup or sweetened water, repeated 3 times a day; the latter in from 1 to 30-drop doses. M. Gubler states that *guaranine* possesses diuretic properties, having tested it with several patients; in doses of about $7\frac{1}{2}$ grains daily, it increased the urine from 27 to 67 and 107 fluid ounces in the course of 24 hours.

Specific Indications and Uses.—Headache, with pallor of the face, weak circulation, and the pain aggravated by exertion; sick headache (migraine), with cerebral anemia; headache of menstruation, with cerebral anemia; mental exhaustion or depression; headache from dissipation.

Related Species.—Timbo. Several leguminous plants of Brazil are known by this name. They are used to stupefy fish. An alkaloid, *timbonine*, has been obtained from *Paullinia pinnata* by Stanislas Martin (*Pharm. Jour. Trans.*, Vol. VII, 1877, p. 1020). From another timbo Pfaff obtained two crystalline substances, one *timboïn*, being a nerve poison, and chemically neutral; the other *anhydro-timboin*, a non-poisonous substance. Crude timboïn yielded to a light petroleum *timbol*, an oily compound, probably a poisonous constituent of the stem and branches of the plant (*Amer. Jour. Pharm.*, 1891, p. 544).

GUTTA-PERCHA.—GUTTA-PERCHA.

The concrete juice of *Isonandra Gutta*, Hooker (*Dichopsis Gutta*, Bentley), and other species of same order.

Nat. Ord.—Sapotaceæ.

Common Names: *Gutta-percha, Gutta-taban, Gutta-percha depurata, Gummi-plasticum.*

Illustration: Bentley and Trimen, *Med. Plants*, 167.

Botanical Source.—This is the concrete milky juice of a tall tree, a native of the Malayan Archipelago, especially of Singapore, where it is now becoming rapidly extinguished through ruthlessness in collecting gutta-percha. It has a straight and lofty trunk, about 3 feet in diameter at the base, with numerous ascending branches; the terminal buds are white from exuding gutta. The wood is hard; the leaves crowded at the extremity of the branches, alternate, petiolate. oblong, with a small point at the apex, base tapering, 4 or 5 inches long, 2 inches broad, upper surface bright-green, feather-nerved, under surface brownish-red, from dense pubescence; the midrib and petiole the same; the petiole 1 inch long, channeled, not articulated with the stem. Stipules none. The flowers are axillary, sessile, 4 together, disposed in a quadrangular manner, small and white. Bracts none. Calyx persistent, 6 sepals, brownish-red, in a double series, the outer largest; æstivation valvate. The corolla is monopetalous, 6-cleft, the lobes ¼ of an inch long, tubes ½ an inch and deciduous; æstivation twisted. Stamens 12, in a single series, equal, similar, and inserted in the mouth of the tube. The filaments are equal in length to the lobes of the corolla; the anthers sagittate, extrorse, and affixed by their base to the filaments; the pollen scanty. The ovary is superior, conical, sessile, seated on a disk, 6-celled, each cell containing a single ovule suspended from a central axis; the funiculus is conspicuous. Style longer than the stamens and persistent; stigmas undivided (E. White).

History and Description.—This substance was introduced in 1842 to the profession, by Dr. William Montgomerie, a surgeon in the British army in the Indies. The natives cut down the tree, remove its bark, and collect the milky juice in conic receptacles made from the spathe of the Areca palm. The juice soon concretes upon exposure to the air. The product is then put into a pot with water warmed to 70° C. (158° F.) and kneaded, which removes particles of wood and bark, this process being repeated several times until a uniform mass is obtained. It has been stated that the yield from one tree is 20 to 30 pounds, but according to data given by Prof. Tschirch (*Indische Heil und Nutzpflanzen*, 1892, p. 203) this must be an exaggeration. Dr. Burck, in Buitenzorg (Java), has shown that by making incisions in living trees 1400 grammes of gutta may be obtained annually, and that this yield may be maintained during a period of 3 or 4 years. As imported it contains various foreign matters from which it should be freed before using it. It is a white or dirty pinkish opaque solid, having a faint odor, no taste, and hardens at 15.5° C. (60° F.). Water, alcohol, alkaline solutions, hydrochloric and acetic acids, and fixed oils have no action on it. It is soluble in coal naphtha, oil of turpentine, benzol, chloroform, boiling ether, and bisulphide of carbon. Hot water softens it, and a heat of 71.1° C. (160° F.) renders it adhesive and pliable; when soft it may be easily cut or molded into various shapes—a temperature of 55° to 60° C. (120° to 128° F.) being the most favorable for this purpose. It resembles caoutchouc, and like this substance, has the property of combining with sulphur, and is thus capable of being vulcanized for use in the arts (see *Elastica*). Its specific gravity is 0.979. Gutta-percha, when in contact with air for some time, oxidizes and undergoes a peculiar change, becoming brittle and ultimately losing all coherence. In this process formic acid is liberated. The oxidized substance is soluble in cold alcohol. This change does not take place when gutta-percha is kept under water. It is a better insulator for electric wires and cables than caoutchouc, and is employed for insulating purposes in large quantities.

Chemical Composition.—When gutta-percha, according to Payen (1852), is purified by kneading in warm water, dried, and treated with hot absolute alcohol a hydrocarbon, *gutta* (75 to 82 per cent) remains. From the hot solution an oxygen compound, *alban* (14 to 16 per cent), falls out upon cooling, while another oxygen compound, *fluavil* (4 to 6 per cent), remains in solution. To these constituents Otto Oesterle, in Prof. Tschirch's laboratory (*Archiv der Pharm.*, 1892, p. 641), added *guttane*, an unstable, thread-like body resembling gutta. Crude gutta-percha of commerce also contains tannin, salts and saccharine substances. No volatile oil could be identified.

Gutta determines the elasticity of gutta-percha, and its plasticity at elevated temperatures. It is a white, amorphous hydrocarbon of the formula $(C_{10}H_{16})_n$ (Oesterle); $C_{20}H_{32}$ (Oudemans, Baumhauer); $(C_4H_7)_n$ (Payen), etc., insoluble in alcohol and cold ether, little soluble in benzol and oil of turpentine, easily soluble in carbon disulphide and chloroform. It melts at 53° C. (127.4° F.) (Oesterle) and absorbs oxygen rapidly, whereby formic acid is liberated (Payen). Exposed to air and light pure gutta becomes yellow, friable, and partly soluble in alcohol, caustic potash and benzol.

Alban is a light powder, not dissolved by water, diluted acids or alkalies, dissolves in boiling, but not in cold, absolute alcohol; readily soluble in ether, chloroform, carbon disulphide, benzol, and oil of turpentine. It has the composition $C_{40}H_{64}O_2$ (Oesterle), yielding a hydrocarbon, *alben*, by heating with alcoholic potassa. It melts at 195° C. (383° F.). The presence of alban does not seem to have any harmful effect upon the technical properties of gutta-percha.

Fluavil is a lemon-yellow, amorphous body, having the composition $(C_{10}H_{16}O)_n$ (Oesterle), melting between 82° and 85° C. (179.6° and 185° F.), but becoming soft at a much lower temperature. When it occurs in gutta in larger quantities it renders this article brittle. Fluavil is more soluble in the solvents mentioned than the other constituents. Whether alban and fluavil are decomposition products of gutta, was not determined.

Action, Medical Uses, and Dosage.—Gutta-percha serves several useful ends in medicine, surgery, and pharmacy, and is likewise used for ornamental and various other purposes. Splints, etc., have been made of it, and employed in cases of *fractures*, *diseased joints*, and other cases where it is desired to keep the parts in a permanent position, and it is also formed into bougies, injection pipes, catheters, pessaries, specula, forceps, handles, etc. Its pliability after having been immersed into hot water renders it especially adapted for the preparation of splints, and such splints are preferable to carved wooden splints. The solution in bisulphide of carbon has been employed by M. Vogel in *wounds* effected by cutting instruments—the fluid evaporates with great rapidity, and leaves a thin layer which protects the wound from atmospheric action, at the same time keeping its edges in close contact. The following compound is recommended for the *hemorrhage* supervening the extraction of teeth: Take of gutta-percha, 1 ounce; best tar, 1½ ounces; creosote, 1 drachm; shellac, 1 ounce. Boil these in a crucible, stirring or beating them well, until they are blended into a stiff, homogeneous mass. The compound is readily softened between the fingers, and is easily introduced into the bleeding socket. It must be pressed in, and the hemorrhage will be speedily checked. For dental purposes solution of gutta-percha is purified by agitating it with calcium sulphate. Mixed with silica, powdered glass, zinc oxide, and similar mineral substances, to give hardness and the proper consistence, it is largely used by dentists to fill the cavities of *carious teeth*. Mr. Aiton recommends the following preparation, applied to the skin in the same manner as collodion, as a protection against poisonous or deleterious vapors or fluids: Add 30 grains of gutta-percha to ½ an ounce of benzene, and expose to a moderate heat; when the gutta-percha is dissolved, add to it a solution of 5 grains of caoutchouc dissolved in ½ ounce of benzene (benzol). A clear *solution of gutta-percha* may be made by adding to the solution a mixture of ⅔ of a part of finely powdered carbonate of lead in 2 parts of chloroform; agitating the whole 2 or 3 times, and then allowing the mixture to stand 10 or 12 days. The carbonate of lead, in becoming deposited, carries with it coloring and insoluble matters; the clear solution should then be decanted and placed in ½ fluid ounce vials, with closely-fitting glass stoppers (see *Liquor Gutta-perchæ*). This will be found very valuable as a local application to *irritated* and *abraded surfaces*, *chaps*, *small wounds*, etc., as it forms a kind of cuticle over the parts.

Dr. Maunoury recommends mixing 2 parts of chloride of zinc with 1 part of powdered gutta-percha, in a tube or porcelain dish, and gently heating the mixture over a lamp. The gutta-percha softens, the particles cohere in a spongy mass, which retains the chloride of zinc, and may be made into any convenient shape, which it retains on cooling. This he recommends as a manageable caustic, as it retains its consistence and flexibility, and can be easily inserted into the urethra, nostrils, fistulous or other passages, and, by its porosity, permits the exudation of the caustic, and thus opens a free passage for the result of the action of the caustic on the tissues. Other caustics or agents may be applied in the same way. Chrysarobin is well applied with solution of gutta-percha.

It has been extolled by dermatologists as an efficient application in certain *skin affections*, to prevent access of air and the formation of crusts, to lessen the quantity of secretions, and to limit the action of the medicaments employed. It has thus been employed in *smallpox* (to prevent pitting), in *erysipelas*, *psoriasis*, *herpes tonsurans*, *prurigo*, and certain *eczemas*.

Prof. J. M. Maisch proposed the following solution as preferable to collodion, in having no gloss or contractile power, and in its close resemblance to the skin: Take 1 part of the best commercial gutta-percha, cut it into small pieces, and, by agitation, dissolve it in 12 parts of chloroform; on standing for a day, all the coloring matter rises like a scum to the surface, leaving the solution clear; this may then be easily drawn off to the last drop. A wide glass tube, narrower at the bottom, and so arranged that both ends may be closed by corks, is the only instrument necessary; after the separation is complete, the upper cork must be removed, and the lower one loosened so as to allow the liquid to run out slowly. Gutta-percha is acted upon by the strong mineral acids, but not by sea water, alkalies, vegetable acids, or weak mineral acids, hence gutta-percha vessels are highly valuable.

Related Products and Preparation.—Several *guttas*, some of which are closely allied to caoutchouc, are used to adulterate gutta-percha, among which may be mentioned the following: *Gutta-soo-soo*—two kinds—one from Perek, the other, a caoutchouc, from Borneo, *Gutta-singgarip*, *Gutta-rambong*, and *Gutta-sundek* (*Gutta-putih*).

BALATA (GUM CHICLE).—This is a milky exudate, known in tropical America as *Chicle*, or *Tuno-gum*, derived from the Bully tree (*Mimusops globoso*, Gaertner), which grows along the Amazon and Orinoco rivers of South America. It is very much like gutta-percha, and is employed sometimes in plasters. Within recent years the demand for this substance has increased enormously in the United States, where the bulk is employed in making *chewing gum*.

GUTTA-PERCHA CEMENTS.—An improved cement for uniting the parts of boots and shoes, and in the manufacture of articles of dress in which cement is required, is made of 64 parts, by weight, of gutta-percha, 16 parts of caoutchouc, 8 parts of pitch, 4 parts of shellac, and 8 parts of oil. The ingredients are melted together, the caoutchouc having been previously dissolved. A cement for uniting sheet gutta-percha to silk or other fabrics, is composed of gutta-percha, 40 pounds; caoutchouc, 3 pounds; shellac, 3 pounds; Canada balsam, 14 pounds; liquid styrax, 35 pounds; gum mastic, 4 pounds; and oxide of lead, 1 pound. Another for uniting it to leather, as soles of shoes, etc., consists of gutta-percha, 50 pounds; Venice turpentine, 40 pounds; shellac, 4 pounds; caoutchouc, 1 pound; and liquid styrax, 5 pounds. A cement for repairing or patching shoes and boots has been in vogue among shoemakers. It is made by dissolving 1 ounce of raw gutta-percha in 1 pound of bisulphide of carbon, and then adding a piece of resin. The leather must be well buffed to make the cement adhere.

GYMNOCLADUS.—AMERICAN COFFEE-NUT.

The seeds and pulp of the pods of *Gymnocladus canadensis*, Lamarck.

Nat. Ord.—Leguminosæ.

COMMON NAMES: *American coffee-bean tree*, *Coffee tree*, *Kentucky mahogany*.

Botanical Source.—This is a slender and unarmed tree, attaining the height of 50 or 60 feet, with a trunk from 12 to 15 inches in diameter. For about 25 feet from the ground the trunk is straight and simple, and covered with a rough, scaly bark. The leaves are compound, unequally bipinnate, 2 or 3 feet long, and 15 to 20 inches wide; the leaflets 7 to 13 in number, ovate, acuminate, and dull-green, the single leaflets often occupying the place of some of the pinnæ. The flowers are large, regular, diœcious, whitish, in axillary racemes, succeeded by pods. Petals 5, oblong, equal, inserted on the summit of the calyx tube. Calyx tubular, 5-cleft, and equal. Stamens 10, short, distinct, inserted with the petals. Style 1. The legume is 8 to 10 inches long, 2 to 2½ inches wide, oblong, flattened, curving, pulpy within, and several-seeded. The seeds are from 2 to 4, quite hard, and somewhat egg-shaped, of a dark-olive color externally, slightly compressed, and about ¾ inch in length by ½ inch wide (W.—G.).

History and Chemical Composition.—This tree is indigenous to the United States, and is found growing in rich woods and along rivers and lakes in western New York, Ohio, Indiana, Kentucky, etc. It is known by several names, as *Coffee tree*, *Kentucky coffee tree*. The seeds were roasted and used by the earlier settlers instead of coffee. The trunk is naked for some distance above the ground, above which is a rather small but regular head, formed by a few, quite long branches. The wood is quite hard and strong, is reddish or light yellowish, rather fine grained, and susceptible of taking a very fine polish and presenting a most beautiful grained appearance; on this account it is highly prized in architecture and cabinet work. In our eastern cities it has been represented as a wood from Japan and brought most fabulous prices. The pulp and the seeds of the pods are the parts to be used; the former has some reputation as a fly poison. It is greenish and viscid. The active principle of these is taken up by alcohol, which gives a yellowish-brown tincture, or, if the pulp alone be used, a beautiful green, and, upon standing, crystals are deposited. The tincture has an unpleasant, bitterish taste, followed by a persistent pungent acrimony in the fauces. Rafinesque states that the leaves are purgative and contain a principle, *cysticine*, of a nauseous, bitter taste. The seeds are said to produce emesis. S. S. Mell (1887) obtained from the seeds a yellowish, saponifiable, fixed oil (specific gravity 0.919) to the extent of 10 per cent. Wax, resin and fat were extracted by ether, some tannin and a glucosid, burning to the taste and possessing a distinctive odor, were abstracted by alcohol. The seeds also contained mucilage, starch, and albuminoids (*Amer. Jour. Pharm.*, 1887, p. 230). J. H. Martin largely confirms these results, but found *saponin* in all parts of the plant, and concludes that to this principle the physiological activity of the plant is probably due. Tannic and gallic acids are absent in the seeds. The pulp surrounding it contains sugar, tartaric and citric acids, and probably saponin (*Amer. Jour. Pharm.*, 1892, p. 558). The carbohydrates of the fruit were investigated by W. E. Stone and W. H. Fest (*Amer. Chem. Jour.*, 1893, p. 660).

Action, Medical Uses, and Dosage.—The tincture of the pulp and pods, and in some instances of the bark also, has been used with benefit in *intermittent fever*. More recently it has been tried, and with advantage, in cases of abnormal states of the nervous centers, as indicated, among other symptoms, by impaired sense of touch and vision, numbness, dull headache, apathy, and formication. In one case of *locomotor ataxia* it proved decidedly beneficial, and is valuable in some of the more serious symptoms resulting from excessive *masturbation*. Recent reports (Dr. N. G. Vassar) confirm its value as a remedy for *spermatorrhœa*. Prof. Roberts Bartholow, M. D., investigated physiologically the purified tincture of the leaves as prepared for him by J. U. Lloyd and found it to be very marked in its qualities. It has likewise been recommended in *laryngeal cough* with chronic irritation of the mucous lining membrane of the air passages, in *erysipelas*, in all *fevers* presenting a typhoid condition, in *puerperal peritonitis*, and in the *exanthematous affections*. It is certainly deserving the attention of our practitioners. The tincture is best made by taking 2 ounces of the coarsely bruised seed and 1 ounce of the pulp, and adding to them 8 fluid ounces each of water and alcohol; let it macerate 12 or 14 days with frequent agitation, and then filter. One fluid drachm of this is to be added to 3 fluid ounces of water, of which the dose is a teaspoonful, to be repeated every 3 or 4 hours.

Related Species.—*Cercis canadensis*, Linné. *Nat. Ord.*—Leguminosæ. The *Red bud* or *Judas tree*, is a small tree growing in rich woods in the middle states. The flowers expand in early spring before the leaves come out. They are borne in lateral clusters and are of a pale-reddish color. They have an agreeably acid taste, and are often eaten by children. The leaves are simple, acute, cordate, and are supported on slender stalks. The fruit is a dry, brown, flat pod, which hangs on the branches during the winter. The name Judas tree is inapplicable, and the tree is so-called because its relative, the *Cercis siliquastrum*, abundant in Palestine, is said to have been the tree upon which Judas hanged himself. It only required a little further credulity to transfer the notion to the American species. The bark of the root is the preferred part, and is exceedingly astringent, even surpassing oak and hemlock. "When chewed it puckers the mucous membranes of the mouth almost as sensibly as the green fruit of the persimmon tree, or as the seed of the fruit of black haw (*Viburnum prunifolium*)" (Lloyd, in *Drugs and Medicines of North America*). Prof. J. U. Lloyd could detect neither alkaloid nor crystalline glucosid, the chief constituent being the tannin (*ibid.*, Vol. II, 124). The leaves and bark of this tree, especially the bark of the root, possess powerfully astringent properties, and may be administered in cases in which this class of agents is indicated, as in *diarrhœa* and *dysentery*, particularly in the chronic forms, and in *chronic catarrhal conditions*; also recommended as a local application in *chronic gonorrhœa*, *gleet*, *leucorrhœa*, and *chronic conjunctivitis*, and other affections attended with *mucous profluvia*.

GYNOCARDIA.—CHAULMOOGRA.

The seeds and oil of *Gynocardia odorata*, Robert Brown (*Chaulmoogra odorata*, Roxburgh; *Hydnocarpus odorata*, Lindley).

Nat. Ord.—Bixineæ.

COMMON NAMES: *Chaulmugra seeds, Chaulmogra.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 28.

Botanical Source, History, and Description.—This is a very large and handsome East Indian tree. The leaves are glossy, entire, and alternate; the flowers yellow and sweet-scented. The fruit is round, ash-colored, and when mature, averages in weight from 10 to 20 pounds. The numerous seeds are imbedded in its pulp, and contain an oil, which, according to Roxburgh, is mixed with fresh butter, and used by the natives as a remedy for cutaneous diseases. They are known as *Chaulmoogra* (or Chaulmugra), and are said, when powdered, to have been used with advantage in scrofula, skin diseases, and rheumatism, the dose being about 6 grains. The seeds are grayish, irregularly ovoid, compressed, somewhat angular and smooth, a little over an inch long, and have an oily taste and a peculiar, nauseous odor.

Chemical Composition.—*Chaulmugra oil* was obtained by pressure from the seeds about twenty years ago, and has attracted some little attention outside of India, where it has long been used. It is said that, in consequence of its high price, it is extensively adulterated by the natives of India, and so adroitly as to cause even the physicians in India to discontinue its use (*New Remedies*, 1879). This oil is granular, melts at 42° C. (107.6° F.); but after melting may be reduced much below this point without solidifying, and has, at 42° C. (107.6° F.), the specific gravity of 0.930. It has an acid reaction, an acrid taste, and a slight scammony-like odor. It is insoluble in water, partly soluble in alcohol, and, excepting impurities, seems to perfectly dissolve in ether, chloroform, carbon disulphide, and benzin. Mr. J. Moss (*Pharm. Jour. Trans.*, 1879, Vol. X, p. 251), found it to yield, upon the application of appropriate reagents, *palmitic acid;* a new acid, to which he gave the name, *gynocardic acid; hypogaic acid* (named from the seed of *Arachis hypogæa*), and *cocinic acid*. Of these four acids *palmitic* constitutes the largest proportion (63 per cent), altogether making 81 per cent, the weight of the oil. These acids exist in the form of glycerides, as fats, the first two acids also in a free condition. *Gynocardic acid* ($C_{14}H_{24}O_2$), however, is the important constituent (11.7 per cent), and gives the burning taste to the oil. Chaulmoogra oil strikes a green color with sulphuric acid.

Action, Medical Uses, and Dosage.—Chaulmugra oil is used both internally and externally in *leprosy*, *secondary syphilis*, *rheumatism*, *scrofula*, and in *phthisis*. The dose for an infant is 1 or 2 drops daily; for an adult, from 2 to 4 minims, repeated 3 times a day. Drachm doses are said to have been given without any unpleasant results. As a remedy for *leprosy*, it has been thought by some to give good results in the *macular* and *anæsthetic* forms (early stage), while other and equally good authorities pronounce it inoperative. The seeds, when powdered, are reputed more active than the oil. The oil has relieved the *dyspepsia* and *bronchitis* occurring in lepers. Externally, it has been successfully applied in the above-named diseases, likewise in *herpes*, *tinea*, *stiffness of joints*, *ulcers*, and various *cutaneous eruptions*. In the latter class it generally proves too irritating except in *eczemas* and *psoriasis*. It is said to destroy *pediculi* and the *itch insect*. It is usually triturated with from 4 to 6 parts of simple ointment, and thoroughly rubbed in with the palm of the hand, or with the fingers' ends. Moss recommends the following formula for its economical use: Take of chaulmugra oil, 2 parts; paraffin wax, at 41° C. (106° F.), 1 part, and ozokerine, 5 parts, and triturate thoroughly together. (Ozokerine is produced from ozokerite, or earth wax, and forms a tasteless and odorless basis for preparing ointments.) He also advises, as a more pleasant mode of administration, the use of perles or capsules, each containing the required dose. Children may take it in a little warm milk. It may also be given in emulsion with oil of almonds or glycerin. The powdered seeds are given in pills, from 3 to 6 grains being a dose. Salt meat, sweetmeats, spices, acids, and tobacco are strictly forbidden while taking this oil. Webster (*Dynam.*

Therap.), praises chaulmoogra oil in the *anemia of syphilis*, and states that by its action as a deobstruant, it averts indurations and banishes skin and mucous patches. He believes it to promise more than any other remedy if used early, to abort the constitutional effects of *syphilis*. Prof. Scudder mentions its internal and local use to allay itching and burning, being specially beneficial where the circulation is feeble and common sensation impaired.

Related Species.—*Hydnocarpus venenata*, Gærtner. Ceylon.

Hydnocarpus Wightiana, Blume. Western India. The seeds of both this and the preceding species yield an oil which may be used for the same purpose as *Chaulmugra oil*. It resembles the latter in odor and color, and strikes with sulphuric acid a blue coloration, not so pronounced, however, as that produced by Chaulmugra oil. This coloration is due to the presence of *gynocardic acid*, which Moss also found in this species (Dymock, *Mat. Med. of Western India*).

HÆMATOXYLON (U. S. P.)—HÆMATOXYLON.

"The heart-wood of *Hæmatoxylon campechianum*, Linné"—(*U. S. P.*).

Nat. Ord.—Leguminosæ.

Common Name: *Logwood.*

Illustrations: Woodville, *Med. Bot.*, 17; Bentley and Trimen, *Med. Plants*, 86.

Botanical Source.—This is a tree of from 20 to 25 feet in height, and occasionally reaching 40 or 50 feet. The trunk or stem is generally crooked and deformed, seldom exceeding 18 inches in diameter, and covered with a rough, ash-colored bark. The branches are somewhat flexuous, terete, and covered with whitish spots; in mountains and moist situations unarmed, but in localities where the tree is stunted in growth, furnished with sharp spines below the leaves. The leaves are alternate, from 2 to 4 from the same irregular, rough, tubercular prominence, pinnate, sometimes dividing, in a bipinnate manner, at the lowest pair of leaflets; the leaflets are 4-paired, shortly stalked, obovate, or obcordate. The flowers are yellow, slightly fragrant, on pedicels ½ inch in length, borne in axillary and subterminal racemes. The calyx is deeply 5-parted, brownish-purple, with thin membranous, deciduous, unequal lobes, and a short, green, campanulate tube. The petals are nearly equal, obovate, wedge-shaped at base, scarcely longer than the sepals, and of a lemon-yellowish color. Stamens 10, alternately short, inserted on the inside of the margin of the persistent tube of the calyx; filaments hairy at base; anthers ovate, without glands. Ovary lanceolate, compressed, 3-seeded, bearing a capillary style, which projects beyond the stamens and petals; stigma capitate and expanded. The pod or legume is flat, compressed, lanceolate, acuminate at both ends, 1-celled, 2-seeded, not opening at the sutures, but bursting in the middle longitudinally (L.).

Fig. 125.

Hæmatoxylon campechianum.

History and Description.—This tree grows in Jamaica, on the eastern shore of the bay of Campeachy, and in many of the West India Islands. The wood consists of a yellowish alburnum, and a dingy cherry-red inner wood, which last is the part used in medicine and the arts; it forms a useful commercial commodity, and is extensively used as a dye-stuff. It becomes darker-colored by exposure. Water or alcohol extracts its coloring matter, forming deep-purple solutions. Its aqueous solution yields a fine blue precipitate with lime-water, alum, and acetate of lead; a deep violet-blue with the higher salts of iron, and curdy flakes with solution of gelatin; sulphuric, nitric, hydrochloric, and acetic acids, and sulphate of copper also produce precipitates. Water is the menstruum usually employed to extract its virtues. A pound of the wood yields about 2 ounces of the extract. The medicinal article is thus described in the Pharmacopœia:

"Heavy, hard, externally purplish-black, internally brownish-red, and marked with irregular, concentric circles, splitting irregularly; odor faint, agreeable; taste sweetish, astringent. When chewed, it colors the saliva dark pink. Logwood is generally met with in the form of small chips or coarse powder of a dark brownish-red color, often with a greenish luster"—(*U. S. P.*).

Mr. Louis Siebold (*Brit. Pharm. Conf.*, 1887, [see *Amer. Jour. Pharm.*]), considers the logwood of San Domingo and Jamaica inferior to that of Campeachy or Honduras, and points out the great chemical difference between the commercial wood sold in logs, and that which comes to us ground or in chips, for the latter has mostly undergone a process of fermentation during which it is considerably modified, and loses its sweet taste. Howdver, for the purpose of testing water for traces of metals by means of logwood extract (see below), the fermented wood is preferable.

Chemical Composition.—Besides the usual plant constituents, logwood contains *tannin* (3.5 per cent, according to Chas. F. Kramer, *Amer. Jour. Pharm.*, 1882, p. 388); *phlobaphenes* (which are coloring matters produced by decomposition of tannin substance), and *hæmatoxylin* or *hæmatin*. The latter body was discovered by Chevreul in 1811, and obtained pure in 1842 by Erdmann. Commercial logwood extract often contains from 9 to 12 per cent of this principle which frequently crystallizes therefrom spontaneously in long needles. It is obtained by extraction with aqueous ether and crystallization from hot water containing reducing agents, *e. g.*, sulphurous acid or acid sulphites.

Hæmatoxylin ($C_{16}H_{14}O_6$, Erdmann), crystallizes with 3 molecules of water in the quadratic, with 1 molecule, in the rhombic system. It is not easily soluble in cold, but readily dissolves in hot water, alcohol, and in salts of alkaline reaction, *e. g.*, borax; from the latter solutions it can not be obtained crystallizable unless the solution is slightly acidified. Hæmatoxylin is very sensitive to light and air, turning reddish when exposed to light. When exposed to moist air or other oxidizers, it rapidly deliquesces, turns brown, and finally yields a colorless mass containing oxalic acid. By milder oxidation it is converted into *hæmateïn*. Solution of hæmatoxylin yields a black violet precipitate with ferric salts (ink), and is also precipitated by solutions of other metallic salts. The precipitates with lead and copper salts turn blue upon exposure to the air. When subjected to destructive distillation hæmatoxylin yields *pyrogallol* and *resorcin;* accordingly, a purple-colored *phtalein* (see *Aniline Dyes*), has been prepared by the interaction of 2 molecules of hæmatoxylin and 1 molecule of phtalic anhydride (E. A. Letts, *Berichte*, 1879). Hæmatoxylin undergoes a remarkable change with ammonia water in the presence of air. It is dissolved with rose-red, then purple-red color. The solution, by absorbing oxygen from the air becomes blackish-red, and upon evaporation, yields violet prismatic crystals of *hæmatein-ammonia* ($C_{16}H_{12}O_6.2NH_3$). These are soluble in water and alcohol. When heated to 130° C. (266° F.), ammonia is given off and *hæmatein* ($C_{16}H_{12}O_6$), is formed. Acetic acid likewise precipitates it from the aqueous solution of its ammonia compound. Another method of obtaining it is to add a few drops of nitric acid to an ethereal solution of hæmatoxylin. It forms a dark-violet, crystalline powder, soluble with difficulty in alcohol and glacial acetic acid, insoluble in chloroform and benzol. It dissolves at 20° C. (68° F.), in water at the rate of 6 in 10,000, and is about twice as soluble in ether. In alkalies it dissolves with blue color, which changes to brown. Hæmatoxylin has been proposed as a delicate test for ammonia; the presence of $\frac{1}{1000000}$ part of ammonia in water is indicated by an orange-red color assumed by blotting paper saturated with an alcoholic solution of hæmatoxylin (see Husemann and Hilger, *Pflanzenstoffe*). Arthur Weddell likewise recommends hæmatoxylin as a delicate test for calcium bicarbonate in water, and for the presence of lead (1 in 200,000), in the same medium, by the characteristic color reaction which takes place in the presence of air (*Amer. Jour. Pharm.*, 1884, p. 214). L. Siebold (*Amer. Jour. Pharm.*, 1887, p. 526), was able to detect even much smaller quantities of metals in potable water by this method. For the application of hæmatoxylin as an indicator in alkaloidal assay, see *Proc. Amer. Pharm. Assoc.*, 1896, p. 109.

Action, Medical Uses, and Dosage.—Logwood is a tonic and unirritating astringent, less constipating than many other astringents, and is useful in *hemorrhage from the uterus, lungs*, and *bowels*, in *old diarrhœas* and *dysenteries*, in *summer* *complaint of children*, and in *night-sweats*. A favorable preparation with many of the older practitioners in *cholera infantum*, after a proper employment of the syrup of rhubarb and potassa, is the following: Dissolve 2 drachms of extract of logwood in 4 fluid ounces of boiling water, to this solution add 2 fluid drachms of ammoniated tincture of opium, 3 fluid drachms of tincture of catechu, 1 fluid drachm of compound spirits of lavender, and 4 fluid ounces of simple syrup, or syrup of ginger. The dose is a teaspoonful every 3 or 4 hours. An infusion of logwood taken internally, and also used locally, in form of spray or injection, has effectually cured several cases of obstinate and offensive *ozœna*. In constitutions broken down by disease, dissipation, or the excessive use of mercury, the decoction of logwood, used freely in connection with the other treatment, will be found highly beneficial. Dose of the decoction, from 2 to 4 fluid ounces; of the extract, 5 to 30 grains. The use of logwood imparts a blood-red color to the stools and the urine. It should never be combined with chalk or lime-water, as they are incompatibles.

Red Ink.—A good red ink may be made as follows: Take of pernambuco wood, a Brazilian wood said to be derived from *Cæsalpinia echinata*, 4 ounces; diluted acetic acid, distilled water, of each, 16 ounces; boil together until 24 ounces remain. Then add 1 ounce of alum, evaporate the liquid to 16 ounces, dissolve 1 ounce of gum Arabic in it, strain, and to the cold liquid add 1 drachm of chloride of tin. This ink is preferable to the cochineal ink, being free from its bluish tint and more permanent.

Related Species.—ALGAROBILLA, the pod-like fruit of *Balsamocarpum brevifolium* of Chili. Contains a large proportion of *ellagic acid* and more than 60 per cent of tannin.

HAMAMELIS (U. S. P.)—HAMAMELIS.

"The leaves of *Hamamelis virginiana*, Linné, collected in autumn"—(*U. S. P.*). also the bark and twigs of same.

Nat. Ord.—Hamamelaceæ.

COMMON NAMES: *Witch-hazel, Winterbloom, Snapping hazelnut, Spotted alder*, etc.

Botanical Source.—This is an indigenous shrub, and consists of several crooked, branching trunks from the same root, from 4 to 6 inches in diameter, 10 or 12 feet in height, and covered with a smooth gray bark. The leaves are borne on short petioles, alternate, oval or obovate, acuminate, obliquely subcordate at base, margin crenate-dentate, scabrous, with minute elevated spots beneath, and from 3 to 5 inches long, two-thirds as wide. The flowers are yellow, on short pedicels 3 or 4 together in an involucrate, axillary, subsessile glomerule. The calyx is small, divided into 4 thick, oval, downy segments, with an involucel of 2 or 3 bracts at base. The petals, 4 in number, are yellow, ¾ of an inch long, linear, curled or twisted. Sterile stamens 4, scale-like, opposite the petals, alternating with the 4 fertile ones. Ovary ovate; styles 2, short; stigmas obtuse. The capsule or pod is nut-like, 2-celled, 2-beaked, opening loculicidally from the top; the outer coat separating from the inner, which incloses the oblong, black seeds, but soon bursts elastically into 2 pieces (W.—G.—R.).

Fig. 126.

Hamamelis virginiana.

History and Description.—This shrub grows in nearly all parts of the United States, especially in damp woods, flowering from September to November, when the leaves are falling, and maturing its seeds the next summer. The bark and leaves are the parts used in medicine; they possess a degree of fragrance, and, when chewed, are at first somewhat bitter, very sensibly astringent, and then leave a pungent sweetish taste, which remains for a considerable time. Water extracts their virtues. No analysis has been made of the leaves, though they are known to contain a bitter body and tannin. The bark and root probably contain a very small amount of volatile oil (see Drs. J. Marshall and H. C. Wood, in *Therap. Gaz.*, 1886, p. 295). Dr. Charles A. Lee (*Jour. Mat. Med.*, 1859, p. 200) found in the bark 5½ per cent of tannin, while H. K. Bowman (*Amer. Jour. Pharm.*, 1869, p. 194) records 8.10 per cent, and Walter B. Cheney (*ibid.*, 1886, p. 418) 6.75 per cent. No glucosid nor alkaloid was obtainable by the latter author or by others. F. Grüttner (*Archiv der Pharm.*, 1898, pp. 278–320) obtained from the bark 3 per cent of a crystallizable and optically active tannin (*hamamelitannin*, $C_{14}H_{14}O_9+5H_2O$), gallic acid, dextrose, fatty and waxy matter, including *phytosterin* ($C_{26}H_{44}O+H_2O$), etc. A preparation made by distilling water, or water containing some alcohol, from the green twigs and leaves of hamamelis is very popular under the term *Distilled Extract of Hamamelis*. The *U. S. P.* describes hamamelis leaves as follows: "Short-petiolate, about 10 Cm. (4 inches) long, obovate or oval, slightly heart-shaped, and oblique at the base, sinuate-toothed, thickish, nearly smooth; inodorous; taste astringent and bitter"—*U. S. P.*). The shoots are used as divining-rods to discover water and metals under ground, by certain adepts (?) in the occult arts.

Action, Medical Uses, and Dosage.—Witch-hazel is tonic and astringent. Some have pronounced it sedative also. The decoction of the bark is very useful in *hemoptysis*, *hematemesis*, and other *hemorrhages*, as well as in *diarrhœa*, *dysentery*, and *excessive mucous discharges*, with full, pale, and relaxed tissues. It has been employed with advantage in *incipient phthisis;* in which it is supposed to unite anodyne influences with its others. It is useful in the form of poultice in *swellings* and *tumors* of a painful character, as well as in external *inflammations*. The American Indians used it for this purpose. The decoction may be advantageously used as a wash or injection for *sore mouth*, *painful tumors*, *external inflammations*, *bowel complaints*, *prolapsus ani* and *uteri*, *leucorrhœa*, *gleet*, and *ophthalmia*.

Since the introduction of the distilled extract of witch-hazel and the specific hamamelis, the use of decoctions of the bark has been largely abandoned. The fluid extract has but little to recommend it. The particular field for hamamelis is in disorders involving the venous structures. Its most pronounced virtue is its stimulating and tonic action upon the venous coats, exhibited so markedly in its power over *varicoses*, *hemorrhoids*, *hemorrhages*, and other conditions due to relaxation of venous structures. The parts are usually pale and relaxed, though occasionally a deep redness, due to venous engorgement, is observed. Here, and especially as great pain is usually an accompaniment, belladonna may be associated with it. It is adapted to the whole venous system, overcoming debility, differing therein from such agents as act only upon localized vascular areas.

Prof. J. M. Scudder and others have found witch-hazel a valuable remedy in *passive hemorrhages* and *congestion*, especially in *epistaxis*, *hemorrhoids*, *phlegmasia dolens* (after acute phases have passed away), *phlebitis*, and *varicose veins*. He also found it valuable in *diarrhœa*, in *chronic pharyngitis*, and in *chronic uterine congestion*, where the cervix is enlarged without abnormal hardness, the os uteri being soft, open, and patulous, and perhaps *leucorrhœa* and some *prolapsus* present. It is specially adapted to diarrhœa with a tendency to or associated with passive hemorrhage. It also forms an excellent application to *chronic vascular conditions of mucous tissues*, and to old, flabby, fetid *ulcers*. Prof. A. J. Howe stated that in "several cases of *uterine hemorrhage*, all occurring within 2 years, he administered witch-hazel with success. In some instances, the cause of the flow, and the conditions upon which it depended, were unknown or rested on conjecture, yet the exhibition of the medicine was always followed by satisfactory results." Half-teaspoonful doses of specific hamamelis were mixed with water and repeated every few minutes while the flow lasted, and afterward every few hours to prevent a return of the hemorrhage. In *menorrhagia* and those wasting states so common after *abortion*, in the early months of pregnancy, he used no remedy that exerted such beneficial effects as witch-hazel. In *uterine hemorrhage* following delivery at full term, the remedy is probably not equal to ergot, but in the kind of cases referred to it is a safer agent. In *chronic diarrhœa* and *cholera infantum* it is a valuable medicine. Hamamelis, both internally and topically, arrests *oozing of blood* from mucous surfaces. This action is well shown in *non-inflammatory hematuria*. It is not the remedy for active hemorrhage, but for *passive bleeding*, as from the lungs, stomach, bowels, renal or genital organs its action is satisfactory.

Besides its control over actual hematuria, hamamelis is often serviceable in renal affections due chiefly to vascular relaxation. Thus in *diabetes insipidus* it has been of some value, but it is of greater service in *mucous profluvia of the urino-genital tract*. It is of benefit in *vesical catarrh*, with tenesmus, and in *irritation of the bladder*, due to enlarged and relaxed scrotal veins. It should be used both internally and locally to the scrotum. While it relieves *varicocele*, too much must not be expected of it in the way of a cure. In *female disorders* it is indicated by venous fullness and relaxation. Dull, aching, ovarian pain is relieved by hamamelis, and in *leucorrhœa*, with fullness of the pelvic veins and relaxation of the uterine and vaginal walls, its internal and external exhibition is of marked benefit. It relieves *ovarian* and *testicular congestion*. Hamamelis is of pronounced value in *hemorrhages into the eye ball*, and locally relieves *ecchymosis of the lids and conjunctiva*.

Hamamelis is justly popular as a remedy for *sprains*, *contusions*, *wounds*, *swellings*, etc. A solution of a few grains of asepsin in distilled hamamelis forms an elegant and efficient dressing for *burns*, *scalds*, *cuts*, *abrasions*, *crushed fingers*, etc. Ten grains of menthol to 4 fluid ounces of distilled hamamelis are also efficient in *burns* and *scalds* (Ellingwood). Glycerin and hamamelis, or Lloyd's hydrastis and hamamelis, equal parts, has rendered us excellent service in *irritated* and *inflammatory conditions of the external auditory meatus*, especially when due to irritation from the presence of *inspissated cerumen*. Locally, hamamelis forms an excellent soothing application for *chafing*, due to excessive discharges; it is likewise useful in *diffusive cutaneous inflammations*. Few agents are more grateful in various subacute forms of *sore throat*, also in sore throat with deep redness and great pain, and it is particularly soothing in *scarlatinal angina*. It is a very valuable aid, locally, in the treatment of *tonsilitis*, *phlegmonous ulceration of the throat*, *diphtheria*, and *acute catarrh*. *Chronic conjunctivitis*, with vascularity of the palpebral and ocular conjunctiva, has yielded to a decoction of equal parts of hamamelis (bark), hydrastis, and lobelia, boiling the first two ingredients, and adding the lobelia to the hot liquid. Cover, allow to cool, and strain. Hamamelis should not be neglected as a part of the treatment of *inflamed breasts*, and applied hot it gives great relief to the soreness of abdominal muscles and pelvic parts following *childbirth*. *Muscular soreness* and *aching* sensations, as of having been bruised, whether from colds, exposures, strains, bruises, or severe muscular action, are greatly relieved by the application of distilled hamamelis, either hot or cold, by means of compresses, while specific hamamelis may be given internally. It forms a good face wash for *burning of the skin*, for *tan* and *freckles*, for *dilated facial capillaries*, and a good application after shaving. Distilled hamamelis and Lloyd's colorless hydrastis form a safe and efficient injection for most cases of *gonorrhœa*. Witch-hazel enters into many of the ointments designed for application to *piles*. An ointment made with lard and a decoction of white oak bark, apple-tree bark, and witch-hazel has been successfully employed for this purpose. Dose of decoction of witch-hazel, from 2 to 4 fluid ounces, 3 or 4 times a day; of distilled hamamelis, 5 to 60 drops; of specific hamamelis, 1 to 30 drops.

Specific Indications and Uses.—Venous debility, with relaxation and fullness; pale mucous tissues (occasionally deep-red from venous engorgement, or deep-blue from venous stasis); mucous profluvia, with venous relaxation; passive hemorrhages; varicoses; capillary stasis; hemorrhoids, with full feeling; relaxed and painful sore throat; dull, aching pain in rectum, pelvis, or female organs; perineal relaxation, with fullness; muscular relaxation; muscular soreness and aching and bruised sensation, whether from cold, exposure, bruises, strains, or from physical exertion.

HEDEOMA (U. S. P.)—HEDEOMA.

"The leaves and tops of *Hedeoma pulegioides* (Linné), Persoon"—(*U. S. P.*): (*Melissa pulegioides*, Linné; *Cunila pulegioides*, Willdenow; *Ziziphora pulegioides*, Desfontaines).

Nat. Ord.—Labiatæ.

COMMON NAMES: *Pennyroyal*, *American pennyroyal*, *Tick-weed*, *Squawmint*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 200; Barton, *Med. Bot.*, 41.

Botanical Source.—This is an indigenous annual plant. It has a fibrous, yellowish root, an erect, branching, pubescent, rather angular stem, from 6 to 12 inches high. The leaves are ½ inch or more long, opposite, oblong, have 1 or 2 teeth on each side, are smooth above, rough below, narrowed at the base, and borne on short petioles; the floral leaves are similar. The flowers are quite small, light-blue, in 6-flowered, axillary whorls. Calyx ovoid or tubular; gibbous on the lower side near the base, with 13 striæ; upper lip 3-toothed; lower 2-cleft; throat hairy. The corolla tube is as long as the calyx, downy, and 2-lipped; upper lip erect, flat and notched at the apex; the lower spreading and 3-cleft, the lobes being nearly equal. Stamens 2, ascending and filiform; the cells of the anthers diverging. Seeds 4, and oblong (W.—G. L.).

Fig. 127.

Hedeoma pulegioides.

History, Description, and Chemical Composition.—This herb was placed by Linnæus in the genus *Melissa*, and afterward *Cunila*, from which it was removed by Persoon, and placed in the genus *Hedeoma*. It must not be confounded with *Mentha Pulegium*, Linné, or *European pennyroyal*, which has similar action and uses. It is a well-known plant, growing in barren woods and dry fields, and particularly in limestone countries, flowering from June to September and October, rendering the air fragrant for some distance around it. It is common to nearly all parts of the United States. It has a peculiar, aromatic odor, which, however, is very offensive to some persons, and a hot, pungent, aromatic taste. It imparts its virtues to boiling water by infusion; boiling destroys its activity by evaporating the volatile oil, on which its properties depend. The oil (see *Oleum Hedeomæ*), its chief constituent, may be obtained by distillation with water, and is often employed, or its tincture, instead of the herb itself; it is of a light-yellow color, and specific gravity ranging from 0.930 to 0.940. *Hedeoma thymoides*, Gray, a Texan plant, has similar properties. The official drug is thus described: "Leaves opposite, short-petioled, about 12 Mm. (½ inch) long, oblong-ovate, obscurely serrate, glandular beneath; branches roundish, quadrangular, hairy; flowers in small, axillary cymules, with a tubular-ovoid, bilabiate and five-toothed calyx, and a pale blue, spotted, bilabiate corolla, containing 2 sterile and 2 fertile, exserted stamens; odor strong, mint-like, taste warm and pungent"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Pennyroyal is a stimulant, diaphoretic, emmenagogue, and carminative. The warm infusion used freely, will promote perspiration, restore *suppressed lochia*, and excite the menstrual discharge when recently checked, especially by colds; it is often used by females for this last purpose, a large draught being taken at bedtime, the feet having been previously bathed in warm water. It is an excellent remedy for *common colds*. A gill of brewer's yeast added to the draught is reputed a safe and certain abortive. The warm infusion may likewise be employed with advantage in the *flatulent colic* of children. The oil, or its tincture, is also administered as a carminative and anti-emetic, and has been of benefit in *hysteria*, *whooping-cough*, *spasms*, etc. Hedeoma is accredited with galactagogue powers, but it acts best probably when diminished lactation is due to acute colds. Dr. M. H. Hennell (*Trans. Ohio E. M. Assoc.*, 1895, p. 31), justly extols the remedy in *flatulent colic*, not only to serve as an anti-spasmodic, but to act as a calmative of the nervous phenomena. He uses it extensively in threatened *convulsions* of children, in *hysteria* from menstrual derangements, in *puerperal septicæmia*, and to hasten or aid the eruptive process in the *exanthemata*. Dr. Hennell praises it especially as a remedy for *chronic amenorrhœa*, and gives the indications below named. It is likewise used as a rubefacient in *rheumatism*, and united with linseed oil, as an application to *burns* and *scalds*. Dose of the oil, from 2 to 10 drops; of a saturated tincture, 1 to 2 fluid drachms. The infusion may be freely administered. Dr. Toothacker (*Phila. Jour. of Hom.*, Vol. II, p. 655) reports a case of poisoning in a woman from one fluid drachm of oil of pennyroyal. The symptoms were: Severe headache, difficult swallowing, intense nausea, with severe retchings without emesis, intolerable bearing down, labor-like pains, abdominal tenderness, constipation, dyspnœa, limbs semiparalytic, and nervous weakness and prostration (Millspaugh's *Amer. Med. Plants*).

Specific Indications and Uses.—Amenorrhœa of long standing, with pallor and anemia, and dark circles about the eyes. Patient complains of languor and lassitude, takes cold easily, has pain in the back and limbs, and exhibits full, prominent veins (Hennell).

HEDERA.—Ivy.

The leaves, berries, and gum-resin of *Hedera Helix*, Linné.

Nat. Ord.—Araliaceæ.

Common Names: *Ivy, Common ivy.*

Botanical Source.—This is an evergreen creeper, with long and flexible stems and branches, which attach themselves to the earth, or trees, or walls, by numerous root-like fibers. The leaves are coriaceous, smooth, shining, dark-green, with veins petiolate, the lower ones 5-angled or 5-lobed, the upper or old ones ovate and acute. The flowers are greenish-white, disposed in numerous, simple, and downy umbels, forming a corymb. The berries are black, with a mealy pulp (W.—L.).

Fig. 128.

Hedera Helix.

History, Description, and Chemical Composition.—This plant is common all over Europe, and is cultivated in many parts of the United States; it flowers in September. The gum-resin (*Gummiresina Hederæ*, or *Ivy gum*), exudes from the incised bark, and comes to us in yellowish or red-brown, irregular pieces. The edges are translucent and of a garnet hue. It is acrid, faintly bitter, and when heated emits a pleasant, aromatic odor. The leaves and berries are the parts used. The former possess a peculiar, rather fragrant odor, and a nauseously bitter and astringent taste. The taste of the latter is somewhat acid, piquant, and terebinthine. A. Jandous (*Amer. Jour. Pharm.*, 1883, p. 371), reports the ivy berries to contain in their fleshy part 70 per cent of water, a dark-red coloring matter soluble in alcohol and water, resinous matter first tasting sweet, then sharp and bitter, and grape sugar, gum, albumin, and salts. The seeds contain a fatty oil of irritating taste and producing a green color with ferric chloride. The poisonous properties of the fruit are neither due to the resinous matter in the pulp, nor to the oil in the seeds.

A bitter substance believed to be an alkaloid and named *hederin*, was obtained from the seeds by Vendamme and Chevalier (see *Amer. Jour. Pharm.*, 1842, p. 172). Posselt, in 1849, isolated from the seeds two proximate principles, viz., crystallizable *hederic acid* ($C_{16}H_{26}O_4$, according to Davies, 1878), which Kingzett believed to be a glucosid, and amorphous *hederatannic acid.* (For details regarding these substances see Husemann and Hilger, *Pflanzenstoffe*, p, 968.) The bitter *hederin* is probably identical with *hederatannic acid.* The leaves of ivy have a peculiar fragrant odor and an astringent, bitter taste. Mr. F. A. Hartsen, in 1875, by extraction with 85 per cent alcohol, obtained therefrom in impure form, a glucosid resembling saponin, but differing from the latter by not being soluble in water. L. Vernet (*Jour. Pharm. Chim.*, 1881, p. 347), isolated this glucosid ($C_{32}H_{54}O_{11}$), which was later named *helixin* (Joulin, *Jour. Pharm. Chim.*, 1891, p. 215), by boiling out the bruised leaves with water repeatedly, then extracting them with alcohol, evaporating the latter, washing with cold benzin, and crystallizing from solution in boiling acetone. It forms silky needles melting at 233° C. (451.4° F.), insoluble in water, chloroform, and benzin, soluble in warm acetone, benzol, and ether; also in warm alkalies and hot alcohol. It reduces Fehling's solution only after being heated with diluted sulphuric acid, sugar, and a neutral, crystallizable substance ($C_{26}H_{44}O_6$), melting at 278° to 280° C. (532.4° to 536° F.), being formed. The latter is not fermentable with yeast; *helixigenin* is the name recorded for the helixin derivative in C. E. Sohn's *Dict. Active Principles of Plants*, 1894.

Action, Medical Uses, and Dosage.—The leaves are stimulating, and have been employed as an application to *issues;* and have likewise been efficient in *diseases of the skin*, *indolent ulcers*, *eczemas*, *itch*, etc., in the form of decoction, and applied locally; this will also destroy *vermin* in the hair, which, it is stated, is stained black by the application. They are reputed beneficial as a cataplasm in *glandular enlargements. Marasmus of children*, *rachitis*, and *pulmonary affections* have been benefited by the dried leaves in powder, in doses of 20 grains or more. The berries act as an emetic and cathartic, and were formerly esteemed in *febrile affections*, having been supposed to possess sudorific virtues. Associated with vinegar, they were considerably used during the *London plague*. The gum-resin has been used for *toothache*, *ulcerations*, *local pains*, and to control *excessive discharges*.

HELENIUM.—SNEEZEWORT.

The plant *Helenium autumnale*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Sneezewort*, *Sneezeweed*, *Swamp sunflower*, *Wild sunflower*.

ILLUSTRATION: Meehan's *Native Flowers and Ferns*, II, 113.

Botanical Source.—This plant, likewise called Swamp, or False sunflower, is an indigenous, perennial herb, having a fibrous root, and several erect, branching, angular stems, 2 or 3 feet high, and strongly winged by the decurrent leaves. The leaves are alternate, smooth, or slightly pubescent, elliptic-lanceolate, more or less deeply serrate, and often sprinkled with bitter and aromatic resinous globules. The flowers are large, numerous, bright yellow, terminal in loose, showy corymbs, with flat, drooping, wedge-shaped rays, each ending in 3 obtuse teeth, longer than the large, globose disk. The involucre is small, reflexed, with the scales linear or subulate. The receptacle is globose or oblong, naked in the disk, and chaffy in the ray only. Achenia top-shaped and ribbed. Pappus of 5 thin and 1 nerved chaffy scales, the nerve extending into a bristle or point (G.—W.).

History and Chemical Composition.—Sneezewort is a plant common to the United States, growing in low, damp fields and meadows, and on alluvial river banks, flowering from August to October. It is nearly inodorous, with a rather acrimonious, amarous taste. It has been analyzed by F. J. Koch (*Amer. Jour. Pharm.*, 1874, p. 221). It contains a trace of tannin and volatile oil, malic acid, and, besides the ordinary plant principles, an amorphous glucosid to which the bitter taste of the herb is due. When boiled with diluted acid it splits into a bitter, non-crystalline body of acid reaction, and glucose. This glucosid is soluble in boiling water, alcohol, and ether.

Action, Medical Uses, and Dosage.—Tonic, diaphoretic, and errhine. Reputed valuable in *chills and fever* and other *febrile diseases*. The whole plant possesses errhine properties, but the flowers, particularly the florets of the disk, are the most active, and may be used, in powder, as a snuff, in *headache*, *incipient coryza*, *catarrh*, *deafness*, and other affections where errhines are desired.

Related Species.—*Helenium tenuifolium*, Nuttall. United States, from Georgia west to Texas and north to Kansas (for illustration, see Meehan's *Native Flowers and Ferns*, II, 37). This species is poisonous. According to Galloway (*Amer. Jour. Pharm.*, 1872), spasms, with delirium and unconsciousness, were produced in four negroes by this plant, while in animals it resulted in twitching of the muscles, violent convulsions, and death.

Helenium parviflorum, Nuttall.—Georgia. Properties similar to those of *Helenium autumnale*.

HELIANTHEMUM.—FROSTWORT.

The plant *Helianthemum canadense*, Michaux (*Cistus canadensis*, Linné).

Nat. Ord.—Cistaceæ.

COMMON NAMES: *Frostweed*, *Frostwort*, *Frostplant*, *Rock-rose*.

Botanical Source.—This plant is a perennial herb, with a simple, ascending downy stem, about 1 foot high, at length shrubby at base. The leaves are alternate, from 8 to 12 lines long, about one-fourth as wide, oblong, acute, lanceolate, erect, entire, subsessile, tomentose beneath, and without stipules. The flowers are large and bright yellow, few, in terminal corymbs; apetalous ones smaller, lateral, solitary or racemose, clustered in the axils of the leaves, and nearly sessile. The corolla, of the petaliferous flowers, are 1 inch wide, with 5 petals, crumpled in the bud, and fugacious. Calyx of the large flowers hairy-pubescent, and 5; of the small flowers, hoary. Stamens of the large flowers numerous and declinate; of the small flowers, few. Style short or none. Stigmas 3-lobed, scarcely distinct; capsule smooth, shining, triangular, 3-valved, 1-celled, opening at top, about 3 lines long; of the apetalous flowers not larger than a pin's head; the seeds are angular, few, and brown. The yellow flowers open in sunshine, and cast their petals by the next day (G.—W.).

History.—This plant grows throughout the United States in dry, sandy soils, and flowers from May to July. The large flowers make their appearance first and later in the season the smaller flowers are produced on the same or other plants. The whole plant is medicinal. The leaves and stems of the plant are covered with a white down, and Prof. Eaton, in his work on botany, says: "In November and December of 1816, I saw hundreds of these plants sending out broad, thin, curved ice crystals, about an inch in breadth, from near the roots. These were melted away by day, and renewed every morning for more than 25 days in succession." These spicules of ice are sent out from fissures in the bark of the plant near its base. The plant has a bitterish, astringent, slightly aromatic taste, and yields its properties to hot water.

Fig. 129

Helianthemum canadense.

Chemical Composition.—Analyzed in 1888 by W. Crutcher (*Amer. Jour. Pharm.*, 1888, p. 390), frostweed was found to contain tannin (10.8 per cent), wax, fatty and volatile oils. A white crystalline principle, thought to be a glucosid, was obtained in fine needles by treating an alcoholic extract with water and shaking out with benzol. These crystals were not further examined.

Action, Medical Uses, and Dosage.—This plant has long been used in practice as a valuable remedy for *scrofula*, in which disease it has been reported to have effected some astonishing cures. It is used in the form of decoction, syrup, or fluid extract; if taken in too large doses it will sometimes vomit. It is tonic and astringent, as well as antiscrofulous. In *secondary syphilis*, either alone, or in combination with corydalis and stillingia, it was formerly regarded as a most valuable remedy. In the form of infusion, it has also been found very serviceable in *chronic diarrhœa* and *dysentery*, especially when occurring among persons disposed to scrofula, also as a remedy in several forms of *cutaneous disease;* also as a gargle in *scarlatina* and *aphthous ulcerations*, and as a wash in *scrofulous ophthalmia*, *prurigo*, and other cutaneous diseases. Externally, a poultice of the leaves is applied to *scrofulous tumors and ulcers*. The fluid extract is the best form for internal use; dose, 1 or 2 fluid drachms, 3 or 4 times a day. (For a list of physiological phenomena produced by this plant, in small and large doses, consult Millspaugh's *Amer. Med. Plants*, Vol. I, p. 28.)

Related Species and Drugs.—*Helianthemum corymbosum*, or *Frostweed*, with an erect, branching, canescent stem; lance-oblong, alternate leaves, canescently tomentose beneath; flowers in crowded, fastigiate cymes; primary ones elongated, filiform pedicels, and with petals twice longer than the calyx; sepals villous-canescent, outer ones linear, obtuse; inner ones ovate, acute; is found growing in pine-barrens and sterile sands, in the southern and middle states. It possesses properties analogous to the preceding, and may be indiscriminately employed with it. F. J. Kruell, in 1874 (*Amer. Jour. Pharm.*), found it to contain resin, chlorophyll, gum, extractive, glucose, salts, and a large amount of tannin.

Helianthemum vulgare, Gaertner (*Cistus Helianthemum*, Linné). Europe. It has properties similar to the rock-rose.

LABDANUM, *Resina ladanum*.—This resinous exudate is derived from several species of *Cistus*, of the *Nat. Ord.*—Cistaceæ, especially the *Cistus creticus*, Linné; *Cistus ladaniferus*, Linné; and *Cistus cyprius*, Lamarck. These are handsome evergreen shrubs, natives of the Levant and Grecian Archipelago. The resin is collected from the branches by means of a leather instrument somewhat like a rake—called *labdanisterion*—the implement being drawn over the branches and leaves, and the product scraped off the leather, to which it adheres. It is then kneaded or mixed together with sand or other solid material. Two grades of labdanum are met in commerce. The first form, *cake labdanum*, occurs as dark-brown or blackish masses, becoming soft and sticky by the warmth of the hands. When freshly broken it has a grayish aspect, soon changing to a darker hue. The second form, *common labdanum*, comes in cylindrical sticks, or spiral pieces, which are hard, brittle, light, porous, and of a gray-black color. Unlike the purer grade, it does not soften by the heat of the hand. Both varieties are bitter, and have a balsamic, pleasant odor. The second grade is usually much adulterated or wholly artificial. Pure labdanum is fusible, and burns with a vivid flame, is nearly completely dissolved by alcohol, but insoluble in water. The poorer grades are said to be gathered from the hair of goats and wool of sheep, which are allowed to browse on the plants. *Cake labdanum*, according to Guibourt (*Hist. d. Drogues*, 1875, Vol. III, p. 675), contains of resin and a small amount of volatile oil, 86 per cent; wax, 7 per cent; extractive, 1 per cent; hair, sand, and other insoluble matter, 6 per cent. *Roll labdanum* yielded to Pelletier, sand, 72 per cent; and resin, but 20 per cent. Labdanum was formerly regarded diuretic and expectorant, and was employed in *bronchitis*, *leucorrhœa*, *catarrh*, *dysentery*, etc. It is now used only in plasters, and is nearly obsolete as a medicine. Owing to its agreeable aroma when burned, it was employed by the ancients for fumigating purposes.

HELIANTHUS.—SUNFLOWER.

The seeds and stems of *Helianthus annuus*, Linné.

Nat. Ord.—Compositæ.

COMMON NAME: *Sunflower.*

Botanical Source.—This is an annual plant, with an erect, rough stem, usually about 7 feet high, but which, under favorable circumstances, attains the height of 15 and even 20 feet. The leaves are large, cordate, and 3-nerved; the upper ones alternate, the lower ones opposite. Peduncles thickening upward. The flowers are large and nodding; the rays yellow; the disk dark-purple. The seeds are numerous and dark-purple when ripe. A splendid variety occurs with the flowers all radiate (W.).

History and Description.—This well-known plant is a native of South America, and is extensively cultivated in the gardens of this country on account of its beautiful, brilliant, yellow flowers, which appear in July and August. The ripe seeds are the parts used; they are of a purplish color externally, about 4 or 5 lines long, between 2 and 3 wide, 2-angled, margins parallel, apex somewhat pointed, the base truncate, compressed, with longitudinal convex surfaces, so as nearly to present 4 angles; internally the testa is whitish, and the kernel is whitish, oily, rather sweetish, and edible. They contain a fixed oil which may be obtained by expression. The leaves are large, and when carefully dried, may be made into cigars, very much resembling in flavor that of mild Spanish ones. The virtue of the seeds chiefly depends upon the fixed oil they contain.

The finely prepared fiber of the stalks is said to be used in China to adulterate silks. Sunflower plants are now planted to some extent in malarial quarters under the belief that they have a beneficial influence in warding off miasmata. Its action in this direction, if effective at all, is probably due to its power of absorbing large amounts of water from damp grounds.

Chemical Composition.—All parts of the plant are rich in mineral matters, 10.8 per cent of ash being yielded by the dry plant (Brandenburg). John found the fresh pith to contain 1.5 per cent of potassium nitrate, corresponding to 9 per cent of the dried pith. *Asparagin* occurs in the young plant (Dessaignes), and *inulin*, according to Braconnot, in the root (*Archiv der Pharm.*, 1859, p. 1). The kernels of the seeds yield 40 per cent of a limpid, fixed oil, *Sunflower oil*. It is colorless or pale-yellow, odorless and almost without taste. Its specific gravity is 0.926; and at —15° C. (+5° F.), it congeals. It is an excellent burning fluid, and the plants are largely cultivated in China and some other countries for the purpose of obtaining the oil, of which an acre of ground will yield between 200 and 300 pounds. Sunflower oil dries slowly. *Helianthic acid* ($C_7H_9O_4$), was obtained from the seeds by Ludwig and Kromayer (*Archiv der Pharm.*, 1859, p. 1). It dissolves in water and alcohol; the aqueous solution is colored intensely yellow by alkalies. With ferric salts it strikes a deep-green color, but is not precipitated by gelatin. Boiling with diluted acids liberates a sugar, reducing alkaline cupric tartrate solution. Its reactions show it to be a peculiar tannic acid, differing at least from caffeotannic acid. A sunflower of Algerian growth yielded, according to Chardon, a distinctive oleoresin (*Pharm. Jour. Trans.*, 1873, p. 322).

Action, Medical Uses, and Dosage.—Sunflower seeds and leaves are diuretic and expectorant, and have been used in *pulmonary affections* with considerable benefit. The following preparation has been of much efficacy in *bronchial* and *laryngeal affections*, and even in the *cough of phthisis;* it acts as a mild expectorant and diuretic: Take of sunflower seeds, bruised, 2 pounds; water, 5 gallons; boil the two together until but 3 gallons of liquid remain, then strain, add 12 pounds of sugar, and 1½ gallons of good Holland gin. The dose of this is from 2 fluid drachms to 2 fluid ounces, 3 or 4 times a day, or whenever tickling or irritation of the throat, or cough is excessive, or when expectoration is difficult. Various agents may be added to this preparation, according to indications, as tincture of stillingia, tincture of balsam of tolu, etc. An infusion of the pith of sunflower stem is diuretic, and may be used where this class of agents is indicated, also in many *febrile* and *inflammatory forms of disease;* it likewise makes a good local application in some forms of *acute ophthalmia*. The pith contains nitre, and has been recommended for the making of moxa; the quantity of nitre, however, varies, depending entirely upon the locality and character of soil in which the plant grows. The oil obtained from the seeds by expression, has been employed with benefit in *cough*, in *dysentery*, in *inflammation of the mucous coat of the bladder*, and in *disease of the kidneys*. To be given in doses of from 10 to 15 drops, 2 or 3 times a day. A teaspoonful of the oil taken at one dose, has produced active diuresis for four consecutive days, accompanied toward the termination with pain and debility in the lumbar region. The leaves are astringent.

Related Species.—*Actinomeris helianthoides*, Nuttall. *Gravel* or *Diabetes weed.*—This plant is diuretic and has been successfully employed in *chronic cystitis, dropsy*, and *gravel.*

Helianthus tuberosus, Linné. *Jerusalem artichoke.*—The tubers of this species resemble artichokes, and have been used as a substitute for potatoes. The carbohydrates of the tubers have been investigated repeatedly by O. Popp (1870 and 1878); Dieck and Tollens (*Jahresb. der Pharm.*, 1878, p. 81), and more recently by Ch. Tanret (*Jour. Pharm. Chim.*, 1893, p. 107). The latter author finds the juice of the tuber before its maturity to contain 16 per cent of the following carbohydrates: *Saccharose, inulin, pseudo-inulin, inulenin*, and two newly isolated substances, *helianthenin* and *synanthrin.* The formulæ of all these substances have the nucleus $C_{12}H_{10}O_{10}$ (also see *Amer. Jour. Pharm.*, 1893, p. 498). A small quantity of lævulose and dextrose is formed when the tuber ripens.

HELLEBORUS.—BLACK HELLEBORE.

The rhizome and rootlets of *Helleborus niger*, Linné.

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Black hellebore, Christmas rose.*

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 2; Woodville, *Med. Bot.*, 169.

Fig. 130.

Helleborus niger.

Botanical Source.—Black hellebore has a black, perennial, tuberculated, horizontal, scaly root or rhizome, whitish internally, and sending off numerous, long, fleshy, brownish-yellow fibers, which become darker upon drying. Its leaves are large, radical, on cylindrical stalks from 4 to 8 inches long, pedate, of a deep-green color above, and paler and strongly reticulated beneath; leaflets 5 or more, 1 terminal, cuneate-obovate, entire and unequal at the base, and coarsely serrated near the point. The scape is shorter than the petiole, 1 or 2-flowered, with ovate lacerated bracts immediately beneath the calyx, and 5 or 10 inches high. The flowers are large and rose-like. The calyx consists of 5 large, ovate or roundish, spreading sepals, at first white, then rose-red, eventually becoming green. The petals are yellowish-green, tubular, shorter than the stamens, and narrowed to the base; stamens numerous; anthers yellow; capsules leathery; seeds many, arranged in 2 rows, elliptical, umbilicated, black, and glossy (L.).

History and Description.—Black hellebore inhabits the subalpine woodland regions in the middle and southern parts of Europe, flowering between December and February; it is also called *Christmas rose.* It is not the Melampodium of the ancients, so celebrated in mental diseases, which is now shown to be a distinct species, the *Helleborus orientalis*, and which probably possesses similar medicinal virtues, as well as do the roots of some other species of the same genus. Another species should be mentioned here on account of its rhizome having a commercial name liable to become confused with *Veratrum viride* (green hellebore). It is the *Helleborus viridis*, Linné. The commercial name of the drug (rhizome and rootlets), is *Radix hellebori viridis*, or *green hellebore root.* This species is regarded by some as more useful than the black hellebore, and has consequently obtained official recognition in Europe. The medicinal parts of hellebore are the radicles or root fibers, which are generally met with the rhizome attached. It is a many-headed root with a caudex or body seldom over ½ inch in thickness, and several inches long, horizontal, sometimes contorted, uneven, knotty, with transverse ridges, slightly striated longitudinally, its upper surface having the remains of the leaf and flower-stalks, and thickly beset upon the sides and under surface with fibers, which, when uninjured, are from 3 inches to a foot in length, 2 or 3 lines in diameter, dark brownish-black externally, whitish within, spongy, not woody, brittle, with a feeble odor, and a faint, bitter taste (C.). When fresh they are said to be very acrid and nauseous, occasioning, when chewed for a short time a pungent, numb sensation, resembling that which accompanies the eating or drinking of anything hot. Desiccation, as well as age, gradually lessens this acridity. Its properties are taken up by water or alcohol; long-continued heat diminishes its activity.

The rhizomes of *Adonis vernalis*, Linné, and *Actæa spicata*, Linné, of Europe, have been employed as adulterants of black hellebore.

Chemical Composition —The root and the root-leaves of the various species of Helleborus contain two glucosids, *helleborein*, which is a cardiac poison, also having drastic powers, and *helleborin*, a narcotic poison; also fatty oil, acrid resins, etc., but no tannin. *Helleborus viridis* is stated to yield a more active helleborein than *H niger;* the same plant yields the largest amount of helleborin (0.04 per cent). *Helleborein* was discovered in 1864 by Husemann and Marmé (*Ann. Chem. Pharm.*, Vol. CXXXV, p. 55). These authors also studied more closely the *helleborin* discovered in 1853 by Bastick (*Pharm. Jour. Trans.*). Both substances were carefully investigated quite recently by K. Thaeter (*Archiv der Pharm.*, 1898, pp. 414–424 . The isolation of the two substances from the root was effected by means of their opposite behavior toward water and ether, *helleborein* being freely soluble in water, but insoluble in ether, while *helleborin* is insoluble in water and soluble in ether.

HELLEBOREIN crystallizes from absolute alcohol in fine needles, which are not hygroscopic when pure; it is of a sweetish taste, and in powder form has sternutatory properties. Its aqueous solution is precipitated by mercurous nitrate, tannic acid, etc. On boiling with diluted acids, it is decomposed into sugar and dark blue flakes of *helleboretin*, which are insoluble in water and ether, but soluble in alcohol with violet color (Husemann and Marmé). K. Thaeter has quantitatively established the mechanism of this reaction, in which 2 molecules of dextrose and 3 molecules of acetic acid are formed, the equation being as follows: $C_{37}H_{56}O_{18}$ (*helleborein*) $+5H_2O = C_{19}H_{30}O_5$ (*helleboretin*) $+2C_6H_{12}O_6 + 3C_2H_4O_2$. *Helleboretin* is permanent toward hot diluted acids, and is a member of the fatty series of organic compounds. Concentrated nitric acid produces with helleboretin a characteristic deep-violet color which, on dilution with water, is permanent for some time. Thus the formation of blue flakes upon boiling with acids, and the subsequent color reaction with nitric acid may serve as a characteristic test for *helleborein*.

HELLEBORIN.—K. Thaeter confirmed all the properties found by Husemann and Marme for this substance, except its formula, for which he finds $(C_6H_{10}O)_n$, while his predecessors arrived at the formula $C_{36}H_{42}O_6$. This substance forms white, odorless, and tasteless needles, but in alcoholic solution they impart an acrid taste. It is insoluble in cold water, quite soluble in alcohol and chloroform. Prolonged boiling with diluted acids decomposes it into sugar and *helleboresin* $(C_{30}H_{38}O_4)$. *Helleborin* gives a characteristic violet-red color with concentrated sulphuric acid; when poured into water white flakes are precipitated.

Action, Medical Uses, and Dosage.—Black hellebore is a drastic cathartic, and is reputed to possess emmenagogue powers, but the latter is probably due to its purgative effects. In smaller doses it is a cardiac stimulant, and diuretic and anthelmintic properties are also ascribed to it. In large doses, it is a powerful poison, causing gastro-intestinal inflammation, dizziness, painful spasms, severe emesis, catharsis, heart failure, dilatation of the pupils, thirst with abdominal heat, cold sweats, convulsions, and even death. Death occurs from spasms and exhaustion. The recent root produces rubefaction, and sometimes blisters, when held in contact with the skin. Hellebore was formerly used in *palsy*, *insanity*, *apoplexy*, *dropsy*, *epilepsy*, etc., but is seldom used at present; occasionally it is found useful in *chlorosis*, *amenorrhœa*, etc. In nervous disorders it might still be used, if properly employed, in cases of *melancholia* and *mania* when due to gastro-hepatic disturbances, or in acute forms of *mental aberrations* due to menstrual wrongs. *Hysteria* and *hypochondria* may be benefited by it, especially when dependent upon abdominal wrongs. As an agent for *dropsy*, it is regarded as less useful than apocynum. It has been used to reduce dropsy through its purgative action, but since it has been found that small doses of the drug tend to stimulate the heart and increase diuresis, there is reason to believe that we have not yet fully appreciated the power of the drug. Dropsies due to atonic states of the bowels, serous effusion after inflammations, with deficient absorption, and *hydrothorax* and *anasarca* following the specific *eruptive diseases*, are specially mentioned as coming within its curative power. The dose for this purpose should be from a fraction of a drop to 5 drops of specific hellebore. Bryonia, apocynum, and digitalis act well with it.

The drug in small doses increases the force of the heart's contraction, slows the pulse, and increases arterial tension. Renal activity is increased under its action, and non-compensatory symptoms in *heart affections* have rapidly disappeared under the use of this drug. Prof. Scudder (*Spec. Med.*) suggests it as an emmenagogue when the patient is annoyed by heat flashes, burning of the surface of the thighs and nates, and sensitiveness of the pelvic and perineal tissues. It has been used in *bowel disorders* with jelly-like passages. The agent requires and deserves restudy. For the specific uses the minute dose is preferable. ℞ Specific helleborus niger gtt. v, aqua fl℥iv. Mix. Sig. Dose, a teaspoonful every 1, 2, or 3 hours. For its old uses as a drastic purgative, etc., the dose of the powder is from 5 to 10 grains; of the tincture, from 1 to 2 fluid drachms; of the extract, 2 to 5 grains.

Helleborein, besides possessing similar properties, has been found to be a depressant of the nervous functions, and to possess decided anæsthetic properties. From the fact that it has no apparent effect upon the pupil, nor affects the intraocular tension, it has been preferred by some over cocaine as a local anæsthetic in *eye diseases*, and is reputed more permanent in its effects than the latter. From 3 to 4 drops of a solution, representing in all from $\frac{1}{55}$ to $\frac{1}{40}$ grain, is thus employed. Owing to its powerful action upon the heart, it is not used subcutaneously to produce local anæsthesia.

Specific Indications and Uses.—(The minute doses only.) Dropsy; heavy feeling in head, with cold forehead and clammy sweat; amenorrhœa, with flashes of heat, burning of surface of thighs and buttocks, and pelvic and perineal sensitiveness; discharges of gelatinous mucus from the bowels.

Related Species.—*Helleborus fœtidus. Bear's foot.* This European perennial, of fetid odor, is the most active of the hellebores. The acrid, bitterish, and pungent leaves and stem-stalks, when chewed, excoriate the membranes of the mouth. It acts as a powerful emetic and purgative, and in large doses is a dangerous agent. It has been used in powder and decoction to expel *tapeworm*, and in *asthma*, *hypochondriasis*, and *hysteria*. Dose of the drug, from 5 to 20 grains; of the decoction (1 ʒ of drug to 8 fl℥ of water), a fluid ounce. It contains the same constituents as hellebore. Therapeutically, it is scarcely known in this country.

HEMIDESMUS.—INDIAN SARSAPARILLA.

The root of *Hemidesmus indicus*, Robert Brown (*Periploca emetica*, Retzius).

Nat. Ord.—Asclepiadaceæ.

COMMON NAMES: *Indian sarsaparilla*, *Kunnari.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 174.

Botanical Source.—This is a climbing plant with a long and slender root, with few ramifications, covered with rust-colored bark, and with twining, diffuse or climbing, woody, slender stems, from the thickness of a crow's quill to that of goose's, and nearly smooth. The leaves are opposite, on short petioles, entire, smooth, shining, and of firm texture; they vary much in shape and size, those of the young shoots that issue from old roots, being linear, acute, and striated down the middle with white; while the others are generally broad-lanceolate, sometimes ovate or oval. The stipules are 4-fold, small, on each side of each petiole, and caducous. The flowers are small, externally green, internally a deep-purple, in axillary, sessile racemes, which are imbricated with flowers, and then with scales like bracts. Calyx 5-cleft, with acute divisions; corolla flat, rotate, with oblong, pointed divisions, and rugose inside. Follicles long, slender, and spreading (L.—Ro.).

History, Description, and Chemical Composition.—This plant is the *Periploca indica* of Willdenow, and the *Asclepias pseudosarsa* of Roxburgh. It is common all over the peninsula of India. It has long been used as a medicine in

India, but was not known to the medical profession of this country and Europe, until its introduction by Dr. Ashburner, in 1831 (*Lond. and Edinb. Phys. Jour.*, Vol. LXV, p. 189). Its root is long, tortuous, cylindrical, rugose, furrowed longitudinally, and has its cortex divided by tranverse fissures into moniliform rings. It is brownish externally, has a feeble, bitter taste, and a peculiar aromatic odor, somewhat like that of sassafras, but which has been compared to that of new hay. The cortical portion has a corky consistence, and surrounds a ligneous meditullium. Mr. Garden (*Lond. Med. Gaz.*, 1837, p. 800) obtained from it a volatile, crystallizable acid, on which the taste, smell, and probably the medicinal properties depend. From an erroneous notion of the origin of the root, he called the acid the *smilasperic acid*, but it may with more propriety be termed *hemidesmic acid* or *hemidesmin* (P.) (also see *Amer. Jour. Pharm.*, Vol. XX, p. 289).

Action, Medical Uses, and Dosage.—Indian sarsaparilla has been successfully employed in *venereal diseases*, especially in cases where the South American sarsaparilla has proved inefficient. Dr. Ashburner says that it increases the appetite, acts as a diuretic, and improves the general health; "plumpness, clearness, and strength, succeeding to emaciation, muddiness, and debility." Likewise said to be useful in *affections of the kidneys*, *scrofula*, *cutaneous diseases*, and *thrush*. Notwithstanding these statements it is by no means so efficient and certain as many of our indigenous remedies. It is used in the form of infusion, as boiling dissipates its active volatile principle. Two ounces of the root may be infused in a pint of boiling water for an hour, the whole of which may be taken in the course of 24 hours. A syrup of hemidesmus is used for flavoring medicinal mixtures.

Related Species.—*Gymnema sylvestre*, Robert Brown (*Asclepias geminata*, Roxburgh). This asclepiadaceous climber is indigenous to India and Africa. The vine is woody and bears little yellow flowers. The root is nearly an inch, or about two-thirds of an inch, in thickness, and is covered with a red-brown, spongy bark. To the taste it is acrid and saline. The leaves of this plant are said to possess the peculiar property of temporarily obliterating the sense of taste for sweetness or bitterness, so that sugar does not taste sweet, and that quinine tastes like chalk (*Amer. Jour. Pharm.*, 1888, p. 339; also *ibid.*, 1848, p. 153). This property is thought to be due to an acid having some likeness to chrysophanic acid. It was isolated by D. Hooper, in 1887, and named by him *gymnemic acid*. The taste of sour, saline, and astringent substances is not altered by this principle. Dr. Hooper also found coloring matter, resins, albumen, various carbohydrates, tartaric acid, and a bitter neutral body. The powdered root is a remedy in India for *snake-bites*.

HEPATICA.—LIVERLEAF.

The leaves of *Anemone acutiloba*, Lawson, and *Anemone Hepatica*, Linné.

Nat. Ord.—Ranunculaceæ.

Common Names: *Liverleaf*, *Liverwort*, *Noble liverwort*, *American liverleaf*, *Kidney liverleaf* (*A. Hep.*), *Heart liverleaf* (*A. acut.*), *Hepatica*, etc.

Illustration: Lloyd's *Drugs and Med. of N. A.*, Plate V, Figs. 10 to 17.

Botanical Source.—I. Anemone Hepatica (*Hepatica americana* of De Candolle and *Hepatica triloba* of Willdenow). This is a perennial plant, the root of which consists of numerous strong fibers. The leaves are all radical, on long, hairy petioles, with 3 ovate, obtuse, or rounded, entire lobes, smooth, evergreen, coriaceous, cordate at base, the new ones appearing later than the flowers. The flowers appear almost as soon as the snow leaves the ground in the spring; are single, generally blue, sometimes white and flesh-colored, nodding at first, then erect, on hairy scapes, 3 or 4 inches long; by cultivation they become double. The involucre is simple and composed of 3 entire, ovate, obtuse bracts, resembling a calyx, and situated a little below the flower. The calyx consists of 2 or 3 rows of petaloid sepals; the stamens are awl-shaped; the anthers elliptic; and the achenia ovate, acute, and awnless (W.—G.).

Fig. 131.

Anemone Hepatica

II. Anemone acutiloba (*Hepatica acutiloba*) differs in having the leaves with 3 ovate and pointed lobes, or sometimes 5-lobed; leaves of the involucre acute or acutish (G.).

History and Description.—The *Anemone Hepatica* has been viewed as the only species of this genus, the differences observed as to color, form, etc., being looked upon as fortuitous. De Candolle, however, divided it into two species. These plants are common to the United States, growing in woods and upon elevated situations; the *A. Hepatica* (*H. americana*), which is the least common, being found, as Eaton states, on the side of hills exposed to the north, and the other on that facing the south. They both bear white, blue, or purplish flowers, which appear late in March or early in April, and are among the most beautiful and most sought-for of our vernal flowers. The entire plant is employed. It occurs in market in broken masses of leaves, sometimes intermixed with broken roots, and of a green color. It is odorless, and has a subastringent and viscid taste, and yields its virtues to water. The name *liverwort* sometimes erroneously applied to it, belongs to the cryptogam *Marchantia polymorpha*, and others of the same family. Undoubtedly it was the demand for the latter plant that led to the wonderful "hepatica boom" about the year 1880. In 1883, the consumption of liverleaf in this country alone was about 450,000 pounds. (For an exhaustive article on hepatica, the reader is referred to *Drugs and Medicines of North America*, by J. U. and C. G. Lloyd, Vol. I, pp. 37–54.) According to Prof. J. U. Lloyd, the blunt-lobed variety is seldom found in commerce, and does not form one-fiftieth part of that collected in America, the supply being almost wholly from the acute-lobed hepatica.

Fig. 132.

Anemone acutiloba.

Chemical Composition.—Rafinesque (1828) stated that the plant contained "tannin, mucilage, extractive," etc. C. B. Smith (1863) demonstrated the existence of tannin in the plant. Prof. J. U. Lloyd and Mr. Harter analyzed it, summing up the result as follows: "It contains none of the classes of active constituents found in medicinal plants, but consists of the usual constituents of plants, such as a tannin, gum, sugar, chlorophyll, and small amounts of a bland oleoresin (Harter, *Pharm. Record*, 1884). Of the substances named, none were in amount sufficient to render them conspicuous. It may be accepted that hepatica does not contain a single prominently marked constituent, and that few herbs present less decided peculiarities" (J. U. Lloyd, in *Drugs and Med. of N. A.*).

Action, Medical Uses, and Dosage.—A mild mucilaginous astringent. It has been used in infusion, taken freely in *fevers, hepatic complaints, bleeding from the lungs, coughs*, etc., but in severe cases it is unavailable. The infusion may be taken *ad libitum.*

HERACLEUM.—MASTERWORT.

The root of *Heracleum lanatum*, Linné.

Nat. Ord.—Umbelliferæ.

COMMON NAMES: *Masterwort, Cow-parsnip.*

Botanical Source.—This plant, sometimes called *Cow-parsnip*, has a large, spindle-shaped, perennial root, of a strong, disagreeable smell, from which arises a hollow, thick, furrowed, branching and pubescent stem, from 3 to 5 feet high, and often an inch or more in width at the base. The leaves are very large, on downy, channeled petioles, and ternately compound; the leaflets roundish-cordate, and unequally lobed; the lobes acuminate, almost glabrous above, and woolly underneath. The flowers are white, in huge umbels, often a foot broad, with deciduous involucres. Involucels long-pointed, lanceolate, and many-leaved. The calyx limb is composed of 5 small, acute teeth. The petals are obcordate, with the point inflexed, the outer larger and radiant, appearing deeply 2-cleft.

The fruit is compressed, oval, with a broad, flat margin, and 3 obtuse dorsal ribs to each carpel; intervals with single vittæ, and seeds flat (G.—W.—R.).

History, Description, and Chemical Composition.—Found growing in moist meadows and cultivated grounds from Labrador to Pennsylvania, and west to Oregon, flowering in June. The root is the part used; is somewhat analogous to parsley in appearance, has a strong, peculiar, unpleasant odor, and an ill-flavored acrimonious taste. The recent root and leaves, when placed in contact with the skin, irritate and inflame it; and that which inhabits very damp localities is considered poisonous (B.). The leaves and seeds have also been used medicinally. The root probably contains acrid principles, volatile oil, and resin. The plant is stated by Nuttall (*Amer. Jour. Pharm.*, 1836, Vol. VII, p. 281) to be hardly distinct from *Heracleum sphondylium*, Linné, of Europe and Asia. This plant is also known as *Cow-parsnip*, and has similar medicinal properties. The fruits of all species of Heracleum thus far analyzed, abound in volatile oil, free ethyl and methyl alcohol and solid hydrocarbons of the paraffine series. From *Heracleum giganteum*, Gutzeit obtained 2 per cent of volatile oil, which was differentiated into 10 per cent of a mixture of *ethyl-butyrate* and *acetate*, and 55 per cent of *hexyl-butyrate* and *octyl-acetate*. Besides, a crystallizable substance, *heraclin* ($C_{32}H_{22}O_{10}$), was obtained from the immature fruits. It is a colorless, odorless substance, melting at 185° C. (365° F.), insoluble in water, not easily soluble in ether, soluble in chloroform, boiling carbon disulphide (1:400) and in cold (1:700) and boiling (1:60) absolute alcohol (*Amer. Jour. Pharm.*, 1880, p. 136). The fruits of *Heracleum sphondylium* yielded to Zincke (*Diss.*, 1869), 0.3 per cent and to Möslinger (*Jahresb. der Pharm.*, 1876, p. 165), 0.8 to 0.9 per cent of a volatile oil. (For a review of its constituents, which are similar to those of *H. giganteum*, see Husemann and Hilger, *Pflanzenstoffe*.)

Action, Medical Uses, and Dosage.—Stimulant, antispasmodic, and carminative. Used in decoction in *flatulency* and *dyspepsia*, and 2 or 3 drachms of the powdered root, taken daily in *epilepsy*, and continued some time, with a strong infusion of the leaves and tops at night, has been found successful. Recent trials with a saturated tincture of the root seem to indicate that it has some power over epilepsy though the conditions in which it is specifically applicable have not yet been determined. Recommended also in *asthma*, *colic*, *amenorrhœa*, *dysmenorrhœa*, *palsy*, *apoplexy*, *intermittents*, etc., in doses of 1 drachm. The dose of a strong tincture (℥viii of root to Oj of alcohol), ranges from 5 to 60 minims.

Related Species.—*Imperatoria Ostruthium*. The rootstock of *Peucedanum Ostruthium*, Koch *Imperatoria Ostruthium*, Linné), *Nat. Ord.*—Umbelliferæ. *Masterwort*. This drug consists of a somewhat flattened, subconical rootstock, of about a finger's thickness, and ranging from 2 to 4 inches in length. Its surface is wrinkled, scarred, and warty; its upper portion has a finely annulated appearance. Its color externally is a deep brown-gray; internally dirty white. It has a large central pith, while its bark is thin, and all parts abound in resin cells of a brownish-yellow hue. Its taste is pungent, aromatic, and bitter, giving a prolonged sense of warmth to the mouth. Its odor is markedly balsamic, somewhat resembling angelica. Masterwort is scarcely at all used in America, and is noticed here chiefly on account of its having been used as an adulterant of aconite (Holmes). In former years it was much esteemed as a medicine, being known, on account of its extensive uses, as *divinum remedium*. It grows in the mountains of central and south Europe. It contains from 0.2 to 0.7 per cent of volatile oil. Osann and Wackenroder, in 1831, obtained from it *imperatorin*, a principle believed by R. Wagner 854) to be identical with *peucedanin*, obtained from *Peucedanum officinale*, Linné, an allied species, by Schlatter, in 1833. However, more recent authors (A. Jassoy, 1890) believe it to be identical with *ostruthin* (see below). *Peucedanin* forms colorless, rhombic prisms, or plates, or fine needles, which are odorless and tasteless when pure; they are insoluble in water, but soluble in ether, chloroform, and alcohol, the latter solution having a faintly bitter taste. The pure substance melts at 108° C. (226.4° F.) (P. Haensel, 1891). When concentrated hydrochloric acid solution is added to an alcoholic solution of *peucedanin*, the latter loses a methyl group and is quantitatively converted into *oreoselon* (Hlasiwetz and Weidel). The formulæ of the two compounds have been differently stated, but the researches of A. Jassoy (1890) and P. Haensel (1891), in Prof. Schmidt's laboratory, and those of M. Popper (1898), have demonstrated the formula of *peucedanin* to be $C_{14}H_{11}(OCH_3).O_3$, or $C_{15}H_{14}O_4$, while *oreoselon* was found by Hlasiwetz and Weidel (*Ann. Chem. Pharm.*, 1822, Vol. 174, p. 67) to have the (analogous) composition $C_{14}H_{11}(OH).O_3$, or $C_{14}H_{12}O_4$ (see *Archiv der Pharm.*, 1898, pp. 662–692). The latter substance is a crystallizable, tasteless body, hardly soluble in cold alcohol or ether, almost insoluble in cold water, better soluble in boiling water, soluble in chloroform, alkalies, and even concentrated mineral acids without undergoing chemical alteration. The melting point of the pure substance is stated to be 175° C. (347° F.) or 177° C. (351.5° F.). Another constituent of imperatoria is a colorless, odorless tasteless body, *ostruthin* ($C_{16}H_{20}O_3$, A. Jassoy, in *Archiv der Pharm.*, 1890, p. 544), which forms characteristic, rhombic crystals, insoluble in water, but soluble in alcohol and ether. It was obtained from the root, in 1874, by Gorup-Besanez (0.6 per cent). Alkalies dissolve it with beautiful blue fluorescence; weak acids precipitate from this solution *ostruthin* unchanged. Upon fusing it with caustic alkalies, Gorup-Besanez obtained a small yield of *resorcin*, and butyric and acetic acids. The same author found in this root *oxypeucedanin*, a bitter, crystallizable principle, insoluble in ether, soluble in chloroform, and previously observed by Erdmann in older roots of *Peucedanum officinale*. Heut (1874) found its melting point to be 140° C. (284° F.), a result confirmed by Jassoy and Haensel (1898). The root here considered is stimulant, and was formerly used locally in *indolent ulcers, buccal paralysis*, and *toothache*, the root being chewed in the latter instances; internally in *low fevers* and *inflammation, flatulence, colic, dyspepsia, delirium tremens, hysteria*, etc., and in other debilities, both general or local. It has not been used in Eclectic medicine.

HEUCHERA.—ALUM-ROOT.

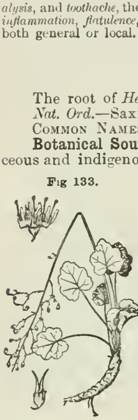
The root of *Heuchera americana*, Linné.

Nat. Ord.—Saxifrageæ.

COMMON NAMES: *Alum-root, American sanicle.*

Botanical Source.—This plant, sometimes called American sanicle, is herbaceous and indigenous, with a perennial, knotty, yellowish root. The leaves are all radical, on very long, downy petioles from 2 to 8 inches in length, roundish-cordate, hispidly pilose, about 7-lobed, and from 2 to 3½ inches in diameter; the lobes are short, roundish, and crenate-dentate, with dilated mucronate teeth. Many scapes or flower stems arise from the same root, from 2 to 4 feet high, erect, naked, viscid-pubescent in their upper part, terminating in loose, pyramidal, forked panicles, which are nearly one-third the length of the scape. The calyx is permanent, 5-cleft, campanulate, small, obovate, striated with very obtuse segments, and more conspicuous than the petals. The petals are purplish-white, or rose-colored, minute, spatulate, and inserted into the margin of the calyx, between its segments. The filaments are twice as long as the petals, yellowish, inserted opposite the segments of the calyx, persistent, and surmounted by small, red, globose anthers. Capsule ovate. Seeds minute, oblong, black, and very hispid (L.—W.—R.).

Fig 133.



Heuchera americana.

History, Description, and Chemical Composition.—This plant is a native of North America, and is found in shady, rocky woodlands from Connecticut to Illinois and southward, flowering from May to August. The root is the part used; it is perennial, yellowish, horizontal, somewhat flattened, rough and unequal, with an intensely astringent taste. It yields its medicinal virtues to water. It should be collected in September. Bowman (1869) found tannin present to the extent of 20 per cent, but Jos. C. Peacock (*Amer. Jour. Pharm.*, 1891, p. 172) found only 5.55 per cent tannin and 12.2 per cent phlobaphene. Roots collected in October were richest in tannin (19.66 per cent, calculated upon dry substance), and richest in starch granules (13.62 per cent) in March. Compare also Prof. E. S. Bastin, on the structure of *Heuchera americana* (*Amer. Jour. Pharm.*, 1894, p. 467). There are several species of Heuchera, the *Heuchera caulescens, H. pubescens*, and others which possess similar properties, and are often collected and sold with the roots of *H. americana*. *H. hispida*, Pursh; *H. parviflora*, Nuttall; and *H. cylindrica*, Douglas, are said by F. W. Anderson to be much employed by the hunters of the northwest as astringents to check the diarrhœa produced by the alkali-water of the plains. The root of *Mitella pentandra*, Hooker, belonging to the same natural order, is recommended by F. W. Anderson as being far superior to alum-root for this purpose (*Bot. Gaz.*, 1887, p. 65).

Action, Medical Uses, and Dosage.—Alum-root, as its name would indicate, is a powerful astringent of such intensity as seldom to be administered internally, yet it would undoubtedly prove useful in small doses, in all cases where astringents are indicated. An aqueous extract will be found very beneficial in *diarrhœa* and *dysentery* in the second stages, in *hemorrhages*, and other similar diseases. Externally the powdered root may be applied to *hemorrhages, epistaxis*, *wounds, foul and indolent ulcers*, etc. The decoction is useful in *aphthous sore mouth* and *soreness of the throat and fauces;* it may be used as a wash or gargle. Taken internally, in doses of a wineglass half full 3 or 4 times a day, it has been efficient in *diabetes*, and in *bleeding piles*, employing it, in this last complaint, by injection also. Equal parts of alum-root and black cohosh-root in decoction, form an excellent local application in *leucorrhœa* and *excoriation of the cervix uteri*. Some practitioners employ this root indiscriminately with that of the *Geranium maculatum;* it is, however, more powerfully astringent.

HIBISCUS ESCULENTUS.—OKRA.

The unripe fruit of the *Hibiscus esculentus*, Linné (*Abelmoschus esculentus* of Wight and Arnott).

Nat. Ord.—Malvaceæ.

COMMON NAMES: *Okra, Gombo, Bendee.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 36.

Botanical Source.—This plant is an herbaceous annual, with a stem somewhat woody at the base, attaining a height of from 3 to 6 feet, and being 3 or 4 inches thick, bearing alternate, serrate leaves of 3 varieties, angular, palmate, and subdigitate. The flowers are solitary, large, and showy; of a pale yellow, tinged at the base a dark crimson. The herbaceous portions of the plant are clothed with sharp bristles, and often bear purplish spots.

Description.—The gombo fruit is a pentagonal, narrow, cylindrical capsule, from 2 to 12 inches long, tapering at the base, and about 1 inch in diameter. It is often curved, and is covered with hairs, especially along the ridges. The pods contain several roundish or kidney-shaped smooth seeds in each of the several cells.

History.—Okra was well-known to the Spanish Moors and Persians, and as early as 1216 was described by a native Sevillian botanist, Abul-Abbas-el-Nebate, who states that the young and tender fruit was eaten with meat by the people of Egypt, who also employed it medicinally for its emollient properties (*Pharmacographia*). The Indian Pharmacopœia has an official decoction of the immature capsules to be employed as a demulcent diuretic in catarrhal affections of the urinary tract, as gonorrhœa, and in dysuria, and ardor urinæ. Okra is indigenous to tropical Africa, where the natives call it *bameea*, and to the West Indies, and is cultivated throughout the tropical and subtropical regions. It is raised on a large scale near Constantinople, where the fruit is employed on account of its demulcent properties. The fiber of the bark is used in the arts to make paper and ropes. Its fruit is valued chiefly, and especially in the southern states, for a mucilaginous substance, *gombine* (Landrin, *Jahresb. der Pharm.*, 1874, p. 172), which it imparts to soups, being often used in combination with tomatoes. It is also used for pickles. According to Porcher, the parched seeds are used by the negroes of South Carolina as a substitute for coffee.

Action and Medical Uses.—Okra is demulcent, mucilaginous, and the leaves are said to make an excellent emollient cataplasm. The seeds of the *H. Abelmoschus* (see below) were formerly considered a stomachic stimulant, antispasmodic, and nervine, but are now employed chiefly by the perfumer.

Related Species.—*Hibiscus Abelmoschus*, Linné. (*Abelmoschus moschatus*, Mœnch). An evergreen tree, introduced into tropical America, but indigenous to Egypt and southern Asia. The seeds, known as *grana moschata*, have a musk-like odor, and are warm and spicy to the taste. The odor resides in the testa of the seeds, and is more noticeable if the seeds be heated or rubbed. According to Ainslie, the seeds are used by the Arabs to impart a pleasant flavor to their coffee. They are also used to adulterate musk and employed in the making of perfumes. In Bombay they are used to protect woolens from the ravages of the moth, and rubbed to a paste with milk, employed to cure the *itch* (Dymock, *Mat. Med. of Western India*).

HIERACIUM.—HAWKWEED.

The root and leaves of *Hieracium venosum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Hawkweed, Veiny-leaved hawkweed, Rattlesnake weed, Striped bloodwort.*

Botanical Source.—This plant has a perennial root, with a stem or scape from 1 to 2 feet in height, dark-brown, slender, sometimes naked, sometimes with 1 or more glabrous, cauline leaves, forking above several times into a spreading, loose corymb, with an awl-shaped bract at each division. The radical leaves are obovate or oblong, somewhat acute, nearly entire, subsessile, thin and pale, purplish, and glaucous underneath, a little hairy above, often hairy along the midrib, marked with purple veins, and the first that unfold are close to the ground. The heads are very small, in a loose panicle on slender diverging peduncles, 12 to 20-flowered; the involucre glabrous, hispid at the base; the flowers bright-yellow; the achenia short, linear, and not tapering at the summit (G.—W.).

History and Description.—Hawkweed grows in many parts of the United States, but more commonly in the East and North, upon dry hills and in pine woods. It bears yellow flowers from May to July. The leaves and roots are employed; they are inodorous, with a bitter and astringent taste; they seem not to have been analyzed. Water extracts their virtues.

Action, Medical Uses, and Dosage.—This plant is tonic, astringent, and expectorant; it has been used in decoction in *scrofula*, *menorrhagia*, *hemoptysis*, and other *hemorrhages*. The powdered leaves and root, combined with bloodroot, have been used as a snuff in *polypus of the nose*. Said to be efficient against the *bites of poisonous snakes*, over which it undoubtedly has some power. The juice of the fresh leaves is recommended as a cure for *warts*. Dose, of the infusion or syrup, from 2 to 4 fluid ounces.

Related Species.—The following species of Hieracium have also been used to some extent in medicine, and, unless otherwise stated, have the same uses as the preceding plant.

Hieracium scabrum, Linné. *Rough hawkweed.*—Has been employed for the relief of *toothache*

Hieracium Gronovii, Linné. *Hairy hawkweed.*—Used like the preceding. Said to be fully as useful in *snake-bites* as *H. venosum*.

Hieracium murorum, Linné.—Astringent and faintly bitter. Vulnerary.

Hieracium pilosella, Linné.—Astringent and bitter.

HIPPOCASTANUM.—HORSE-CHESTNUT.

The bark and fruit of *Æsculus Hippocastanum*, Linné.

Nat. Ord.—Sapindaceæ.

COMMON NAME: *Horse-chestnut.*

Botanical Source.—The Æsculus Hippocastanum is a beautiful middle-sized, round-headed tree, 50 or 60 feet in height, with many branches, a rugose, tawny bark, and a white, not very firm wood. The leaves are opposite, digitate, long-stalked, and consist of 7 obovate-lanceolate, acuminate, bright-green, coarsely and irregularly serrated leaflets which diminish in size from the center. The flowers, which are pink-colored and white, are borne in terminal thyrses, or pyramidal racemes. The corolla is spreading and composed of 5 oblong, unguiculate, fringed, wavy petals, with a small reddish spot above each claw. The calyx is 5-toothed, bright-green, and campanulate. The stamens are 7 in number, and support reddish-brown, oblong anthers. The fruit is a prickly, thick, and tough capsule, 3-valved, 1 to 3-celled, with usually 2 large, deep chestnut-brown seeds, and a large broad space forming a hilum.

Fig. 134.

Æsculus Hippocastanum.

Description.—THE BARK. Horse-chestnut bark is of a gray color externally, showing leaf scars and wart-like excrescences sparingly distributed. The internal surface is whitish and smooth. The bark is thin, and throughout its internal structure presents a brown or brownish color. The inner bark has a rough, bitter taste, and is nearly odorless; and is tough and fibrous on fracture. It yields its properties to water and diluted alcohol. The aqueous infusion is bitter, fawn-colored, and non-astringent. Gelatin separates its tannic acid; iron gives a green precipitate; infusion of galls and tartar-emetic produce no effect upon it.

THE NUT, when dry, is subglobular, compressed, from 1 to 1½ inches in diameter, with a shining, chestnut-brown testa, marked by a reddish or yellowish-gray hilum, nearly an inch in diameter. In the middle of the hilum is a smaller spot, in the center of which is a slightly roughened elevation. Passing from the hilum around to the opposite surface may be observed an elevated ridge terminating in a bulbous extremity, and resting in a horseshoe-shaped depression. The surface of the nut is slightly corrugated. The internal portion is starchy, yellowish-white in color, and has an unpleasant, bitter taste. The nut has a slight, peculiar odor.

History.—Horse-chestnut is indigenous to certain parts of southern Asia (Persia, northern India), from whence it was conveyed into Europe. It is now common to many parts of the United States, where it grows rapidly, blossoming from April to July, and maturing its fruits in the autumnal months. It is extensively cultivated for shade and ornamentation in gardens and along sidewalks.

Chemical Composition.—All parts of the plant, especially the bark of the root, trunk, and branches, and the testa of the seeds, contain a peculiar *tannic acid*, which forms an uncrystallizable, nearly colorless mass, whose solutions turn red-brown when exposed to the air. Heating with diluted mineral acids to the temperature of boiling water produces a red *phlobaphene*, a substance which also occurs ready-formed in the bark and the leaves of the tree (Rochleder). *Æsculin* ($C_{15}H_{16}O_9$), discovered by Canzoneri and first obtained pure by Minor (1831), is a faintly bitter glucosid occurring principally in the bark, also in the testa of the seeds, but not in the leaves (F. O. Ray, *Amer. Jour. Pharm.*, 1886, p. 409). From 2 to 3 per cent have been obtained from the bark. It is a white, microcrystalline powder, soluble in 672 parts of cold and 12.5 parts of boiling water, and in 24 parts of boiling alcohol, but insoluble in absolute ether. *Æsculin* is distinguished by the blue fluorescence it displays in aqueous, but more markedly in alkaline solution. This glucosid is easily decomposed into its constituents, if it be heated above its melting point, 160° C. (320° F.), and also by the action of the ferment *emulsin* (see *Amygdalus*), or when boiling it with diluted acids, when it is decomposed into dextrose and *æsculetin* ($C_9H_6O_4$). The latter substance, which is also to be found in the bark, is a *dioxy-coumarin* ($C_6H_2[OH]_2CH:CH.CO.O$), and an isomer to *daphnetin*, a derivative of certain species of *Daphne*. *Æsculin* has been repeatedly demonstrated to be different from *gelsemic acid*, with which it was at one time supposed to be identical (see *Gelsemium*).

A crystallizable, bitter glucosid, *argyræscin* ($C_{27}H_{42}O_{12}$), found by Rochleder in the cotyledons of the seeds, occurs most largely shortly before maturity. A yellow coloring matter (*quercæscitrin* of Rochleder), occurs in the leaves of horse-chestnut, as well as in the cotyledons of the seeds, and especially in the flowers. More recently N. Rudolph (see *Amer. Jour. Pharm.*, 1894, p. 35), established its chemical relationship to other quercitrin-like bodies, and gave it the formula $C_{21}H_{22}O_{12}$, while *quercitrin* (of quercitrin bark), was found to contain 1 molecule less of water. Boiling with diluted acids decomposes the horse-chestnut quercitrin into *isodulcite* ($C_6H_{14}O_6$), and *quercetin* ($C_{15}H_{10}O_7$).

A variety of other substances, such as *æscic* and *capsulæscic acids*, *telæscin*, *fraxin*, etc., mostly intermediary products in the development of the different parts of the plant, have been isolated by Rochleder, for which see details in Husemann and Hilger, *Pflanzenstoffe*, p. 870. *Saponin* (*aphrodæscin* of Rochleder, 1858), is also a constituent of the seeds, and the latter have long been known to be useful in powder form for washing purposes and as a sternutatory (see *Pharm. Centralh.*, 1892, p. 687, and 1896, p. 163). A fatty oil (*Oleum Hippocastani*), has been obtained from the seeds in the amount of 0.1 per cent. It is of a rich yellow color, has a specific gravity of 0.927, and solidifies at a temperature of +1.25° C. (34.3° F.). The seeds also contain starch, and on this account attempts have been made to utilize horse-chestnut seeds as a food material, but these efforts have not met with success, owing to the difficulty of economically removing saponin from the seeds (see P. Soltsien, *Chem. Zeitung*, 1891, p. 1374).

In the seeds of *Æsculus Pavia*, Linné, the Red buckeye of the southern states, E. C. Batchelor (*Amer. Jour. Pharm.*, 1873, p. 145), found a poisonous glucosid, insoluble in ether and chloroform, soluble in hot alcohol, and freely soluble in cold water; this solution froths upon being shaken. The principle is not identical with the *argyræscin* and the *aphrodæscin* of Rochleder.

Action, Medical Uses, and Dosage.—Undoubtedly horse-chestnut acts upon the human system very much after the manner of buckeye (*Æsculus glabra*). By some, however, its power over the circulation is thought to be more pronounced, particularly its control over the portal vessels. The virtues formerly ascribed to the bark and nut are as follows: Horse-chestnut bark is tonic, astringent, febrifuge, narcotic, and antiseptic. In *intermittent fever* the bark has effected cures when given in doses of a teaspoonful 4 or 6 times a day. Ten grains of the powder of the rinds of the nuts have been asserted to be equivalent in narcotic power to three grains of opium. This claim, however, requires substantiation. *Gangrenous and ill-conditioned ulcers* have been benefited by a strong infusion of the bark. The whitish, central part of the nuts, when in powder, has been recommended as a sternutatory in some cases of *ophthalmia* and *headache*. The oil of horse-chestnuts is considered in Europe a valuable local application in *neuralgic* and *rheumatic affections;* it is made by exhausting the powdered horse-chestnut in ether, filtering and evaporating. Æsculin, in doses of from 5 to 30 grains, repeated 2 or 3 times a day, has proved beneficial in *periodical febrile affections*, and in *neuralgia of the internal viscera*. Of all the uses formerly made of hippocastanum, only the latter is recognized to-day, its power of controlling *neuralgia of the viscera*, and then only in cases of *abdominal plethora*. Specific medication has taught us that it is a remedy, not for active conditions, but for congestion and engorgement. It is indicated in general by capillary engorgement—a condition of stasis—with vascular fullness and sense of soreness, throbbing, and malaise all over the body. An uneasy, full, aching pain in the hepatic region is also an indication. Rectal disorders, such as *rectal irritation* and *hemorrhoids*, with marked congestion and a sense of constriction, as if closing spasmodically upon some foreign body, with itching, heat, pain, aching, or simple uneasiness, are fields in which hippocastanum exerts a specific influence. The pile-tumors are purple, large, do not bleed as a rule, but there is a sense of fullness, or spasm of the parts, and a free diarrhœa may be present. Not only does it relieve such rectal complaints, but cures disorders hinging upon them, such as *rectal neuralgia*, *proctitis*, etc., and the reflexes induced by them, proceeding from the rectal involvement. Among these reflex manifestations may be mentioned *dyspnœa*, *asthmatic seizures*, *dizziness*, *headache*, *backache*, and disturbed gastric functions amounting to veritable forms of *dyspepsia*. These conditions pass away when hippocastanum overcomes the rectal difficulties. Dose of specific horse-chestnut (prepared from the nut only), from ½ to 5 minims in water every 1 to 3 hours.

Specific Indications and Uses.—Visceral neuralgia, due to congestion; soreness of the whole body, with vascular fullness, throbbing, and general malaise; throbbing, fullness, and aching in the hepatic region; rectal uneasiness with burning or aching pain; sense of constriction, with itching; large, purple pile-tumors; uneasy sensations and reflex disturbances depending upon hemorrhoids or rectal vascular engorgement.

HIRUDO.—LEECH.

The *Sanguisuga medicinalis*, Savigny, and *Sanguisuga officinalis*, Savigny.

Class: Vermes. *Order:* Annulata. *Sub-order:* Apoda. *Family:* Hirudineæ.

Description.—The leech belongs to the class of *Vermes* in the Zoological arrangement, and order *Annulata*. This class is characterized by a more or less elongated body; soft skin, segmented and annulated; articulated members and wings absent, and blood red. The general zoological characters of the order are: "Jaws with 2 rows of pointed, numerous teeth, which are mutually inclined at an acute angle" (Brandt).

"Body elongated. Back convex. Belly flat. Extremities somewhat narrowed, furnished with disks or suckers; anterior extremity somewhat narrower than the posterior one. Rings from 90 to 100. Eyes represented by 10 blackish points.

Mouth triradiate. Jaws cartilaginous, armed with numerous cutting teeth. Anus small, placed on the dorsum of the last ring" (P.).

Two species of leeches are recognized in commerce, the *Sanguisuga officinalis* (*Hirudo officinalis*) and the *Sanguisuga medicinalis* (*Hirudo medicinalis*, Linne; *Hirudo provincialis*, Carena), though some excellent zoologists consider them to be only varieties of the same species. "Both have a soft extensile body composed of about 98 rings. They vary in length from 1½ to 6 inches when in repose, but can contract themselves to a third of their length, and stretch themselves out to nearly the double of it. They present along the back and flanks 6 continuous or interrupted stripes of a rusty or greenish-yellow color, by which they are easily distinguished from all other species that resemble them. They can attach themselves by both ends to adjacent objects by means of a particular apparatus. The *S. medicinalis* is distinguished by a dark-brown or greenish-brown back, with rusty stripes generally spotted with black, and a grayish or yellowish belly, also more or less speckled with black spots. The *S. officinalis* has a paler greenish-black back, less bright and unspotted stripes, often interrupted and intercommunicating, and a paler, more yellowish, or greenish unspotted belly. The former, commonly called the *English*, *German*, *Swedish*, or *Speckled leech*, is a native of Britain, Germany, Poland, Sweden, northern France, and European Russia. The latter, usually known as the *Hungary*, or *Green leech*, is a native of that country, and likewise of the south of France. Both species have 3 converging mandibles, furnished at their edge with minute sharp teeth, from 69 to 71 in number in each jaw in the Hungary leech, and from 79 to 90 in the other. By means of these teeth, when the skin is sucked in the mouth, it is pierced with a sawing motion, so as to present 3 incisions meeting in a common center. These incisions often penetrate through the whole thickness of the integuments into the cellular tissue. The animal becomes filled with blood in the course of 15 minutes, if it be vigorous, and draws about a drachm and a half" (Christison). The *American leech* (*Hirudo decora*, Say), is frequently used in this country, though it does not draw as much blood, by one-third, as the foreign leech. It has a back of a dark-green color, and having 3 rows of quadrangular dots running lengthwise, the central row being pale brownish-yellow, and the others quite black. The abdomen is also pale brownish-yellow, and interspersed with dark spots. It is ordinarily about 3 inches long, and occasionally longer. (For an account of the repulsive mode of collecting leeches in Greece, see *Amer. Druggist*, 1891, p. 81.)

Preservation.—There is considerable difficulty in preserving leeches, especially on a large scale, as they often die suddenly and in great numbers. Various means have been adopted to keep them healthy. The most common cause of their sickness and death is the formation of a slimy matter on their skin, and which they are in the habit of removing by drawing themselves through moss and small stones. Dr. Johnson names certain diseases as a cause of their death, and Brostat describes three epidemic disorders. Leeches are more liable to disease and mortality, when kept together in large quantities, than when preserved in small numbers. They should be kept in glass or earthenware jars, in clean rain or soft water, which should be changed every day or two, and at the bottom of which is placed some loose moss, pebbles, etc., for them to move among. "It is stated that the presence of metallic iron in water prevents it from becoming putrid. This influence is said to be very marked in water in which leeches are preserved, and renders the changing of the water unnecessary for very long periods. The slimy excretions of the animal appears to combine with the oxide of iron, which is constantly being formed." The jar in which the animals are kept should be covered with a thin cloth, and placed in a locality where the temperature is equable. A dead leech should be at once removed, and fresh water be immediately supplied to the remaining ones. M. Allchin has prepared a leech conservatory, in which the leeches were kept in a healthy state, and the water clear and sweet, without changing the water for 10 or 12 months. It consists of a glass tank with a movable glass cover, and arrangement for admitting air through a perforated metallic plate. Some coarse gravel is placed at the bottom of the tank, which is about half filled with water, and into it are put 1 plant of Valisneria, 10 water snails (*Planorbis corneus*), and about 100 leeches. A permanent balance of animal and vegetable life is thus obtained, and no necessity occurs for changing the water. It has been tried to propagate leeches in confinement, but in all these cases, after a few years, there remained only those which were placed in the water, and those just hatched. This depopulation of the artificial ponds in which they were kept has been attributed, by Dr. Berard, to the "enemies of the leech," or those animals which devour them, among which he names the pig, the otter, the mole, the hedgehog, the rat, water-shrew mice, teal, ducks, heron, fowls, serpents, toads, fresh-water shrimp, and other crustaceæ. The goose, aquatic toad, water-lizard, and frog he does not consider enemies of the leech. If these statements are found to be correct, they will aid materially in determining the best plan by which to preserve and propagate leeches artificially.

Artificial or *mechanical leeches* are now to be had. They are in reality small cupping instruments.

Action, Medical and Surgical Uses.—Leeches are occasionally used as a substitute for general blood-letting (which is scarcely ever now practiced) among children and delicate adults, or when it is required to abstract blood from some part whose locality or sensitiveness contraindicates the lancet or cupping. The abstraction of blood by means of leeching has, however, a decidedly different effect from that obtained by bleeding. A local impression may be made without seriously disturbing the whole system, as is the case in venesection. They are also very beneficial when applied with care to *hemorrhoidal tumors*, *prolapsed rectum*, *inflamed vulva*, etc., watching that they do not creep out of reach within any of the internal cavities of the body, as serious results might ensue. Salt is a speedy poison to the leech, and whenever one gets within the stomach, or other cavity beyond reach, the introduction of a strong solution of salt will destroy it. They are more commonly used in *local inflammations*, *bruises*, etc., in which they often render excellent service. In applying them, any hair growing on the part must be removed by shaving, and the part must be thoroughly cleansed by soap and water, followed by clear water. Should the leech not fasten quickly, various means have been advised to overcome this difficulty, as moistening the part with warm milk and water, sugar and water, or with a drop of blood, or by immersing the leech for a moment in porter. It has also been recommended to hold the leech in a dry cloth, direct its head to the selected part, and slowly withdraw it along the skin, thus forcing it to take hold in order to find a firm attachment. But it must be recollected that there are certain states of the body, in which the leech will not attach itself, or speedily perish if it does. In poisoning by nux vomica, strychnine, oxalic acid, etc., and where sulphur has been used, the leech dies if it abstracts blood. In order to hold leeches to any part of the body, they are placed in a narrow tube called a leech-glass, which confines them to one spot.

When it is desired to remove leeches from the skin, this may be accomplished readily by dropping a little salt upon them, which sickens them. The usual mode is to draw the leech gently through the thumb and index finger, in a direction from its tail to its head, thus forcing out the blood, and then place the animal in clean water, to remain there for several days before employing it again, frequently renewing the water. Soubeiran and Bouchardat recommend as the best plan, first, to sicken the leech by placing it in a solution of 8 parts of salt to 50 of water, then, holding it by the tail, to dip it into hot water, but which can be borne by the hand, and then to strip it by gently passing it between the fingers; the leech is then to be placed in fresh water, which should be changed every day. A little white sugar dissolved in the water will, it is said, speedily restore them to their original activity. When the hemorrhage from leech-bites is troublesome, or too long continued, it may be checked by applying tannic acid or other astringents, collodion, eau de Pagliari, or by a very superficial stitch with a fine sewing needle.

HOMATROPINÆ HYDROBROMAS.—HOMATROPINE HYDROBROMATE.

FORMULA: $C_{16}H_{21}NO_3.HBr$. MOLECULAR WEIGHT: 355.17.

Source and Preparation.—*Homatropine* (*Oxytoluyl-tropeïne*) is the most important of the tropeïnes (which see)—a series produced by heating *tropine* ($C_8H_{15}NO$) in the presence of diluted hydrochloric acid and certain organic acids.

Thus homatropine is prepared by the action of tropine upon mandelic (phenylglycolic) acid ($C_8H_8O_3$) (see article on homatropine by Prof. F. B. Power, in *Amer. Jour. Pharm.*, 1882, p. 145). Homatropine is an alkaloid, forming transparent, prismatic crystals (Merck, 1880), soluble in ether, alcohol, and chloroform, but less soluble in carbon disulphide, from a solution of which it readily crystallizes. A peculiarity of this alkaloid is that, though hygroscopic and extremely deliquescent, it dissolves with difficulty in water. The alkaloid forms salts with hydrochloric, hydrobromic, and sulphuric acids; also with picric acid. The most valuable salt of homatropine, therapeutically, is homatropine hydrobromate.

HOMATROPINE HYDROBROMATE ($C_{16}H_{21}NO_3.HBr.$) can be easily obtained in crystallized form by the action of hydrobromic acid upon crude homatropine and subsequent recrystallization from water.

Description and Tests.—Homatropine hydrobromate occurs in small, white, lustrous, non-hygroscopic crystals, soluble in 6 parts of water and 130 parts of alcohol. The *Br. Pharm.* (1898) for homatropine hydrobromate directs that the solutions should be neutral to litmus. The same authority demands that: "Heated on platinum foil it fuses and burns without leaving an appreciable residue. If 0.2 Cc. of chloroform be shaken with 1 Cc. of a 10 per cent aqueous solution, to which a solution of chlorine has been cautiously added, the chloroform will assume a brownish color. A 2 per cent aqueous solution yields no precipitate, nor does the cautious addition of solution of ammonia, previously diluted with twice its volume of water, but diluted solution of potassium hydroxide produces in it a white precipitate, soluble in excess of the reagent. Solution of iodine causes a brown, and test solution of mercuric chloride a white precipitate. If about 0.01 Gm. be dissolved in a little water, and the solution rendered alkaline with solution of ammonia, and shaken with chloroform, the separated chloroform will leave on evaporation a residue which will turn yellow and finally brick-red, when warmed with about 1.5 Cc. of a 2 per cent solution of mercuric chloride in a mixture of 5 volumes of alcohol (90 per cent), and 3 volumes of water. When treated with fuming nitric acid and potassium hydroxide, as described under 'Atropina,' no reddish-violet coloration is developed (distinction from atropine), the residue becoming reddish-yellow. It affords the reactions characteristic of hydrobromides" (*Br. Pharm.*, 1898). The sulphate, hydrochlorate, and salicylate of homatropine, each in white crystals, soluble in water and alcohol, are occasionally employed therapeutically.

Action, Medical Uses, and Dosage.—This salt acts very much like atropine, causing a quick, full dilatation of the pupil, but the paralyzing influence upon the muscles of accommodation is much less, and the effects of the agent more transient. Homatropine dilatation seldom lasts over 24 hours, and usually begins to diminish after a few hours, whereas atropine dilatation may persist for several days. Homatropine, after the instillation of large doses, imparts a bitter taste, but, unlike atropine, no dryness of the pharynx is induced. Homatropine hydrobromate is a safer agent than atropine, and does not produce such marked systemic disturbances as the latter. A 1 per cent solution is usually preferred for ophthalmic work. The solution is fairly permanent. Under the use of this drug pupillary dilatation takes place in from 15 to 25 minutes, reaches the maximum in about 1 hour, and usually disappears in about 6 hours; accommodation paresis occurs in ¾ to 1½ hours, and passes off before the dilatation is overcome. Instillation of this agent produces some smarting, and occasionally conjunctival irritation results, but these effects are less likely to occur than with atropine. Poisoning by homatropine and its salts should be treated by means of emetics and the stomach-pump, followed by tannin and animal charcoal, and emesis again resorted to. Then a cathartic dose of castor oil is advisable. Heat, stimulation, and artificial respiration should not be neglected. Hartridge advises a combination of cocaine and homatropine for producing quick maximum dilatation.

Foltz (Webster's *Dynam. Therap.*, p. 580) states that for use in middle-aged persons, the drug is all that can be desired, but for refractive troubles, particularly of children, with ciliary spasm, he regards it of little value. It is contraindicated in glaucoma. The agent is seldom used internally. However, homatropine is now by far the most commonly employed mydriatic for use in *refraction work*. For *ophthalmoscopic examinations* it has largely replaced atropine, as it has in estimating refraction in patients over 25 years of age. Homatropine is antagonistic to muscarine and pilocarpine. Homatropine hydrobromate has been successfully used in the *night-sweats of phthisis*. Doses of $\frac{1}{20}$ grain have been advised for this purpose, but the practice can not be strongly recommended. The dose of homatropine hydrobromate is from $\frac{1}{120}$ to $\frac{1}{60}$ grain; the maximum amount for a day being $\frac{1}{20}$ grain; as a collyrium, 3 to 4 grains to 1 fluid ounce of water.

Related Preparation.—MYDRINE. This is a white powder—a combination of the alkaloids homatropine and ephedrine—introduced into ocular therapeutics by Dr. Cattaneo, in 1895. It dissolves freely in water, and is employed chiefly in 10 per cent solution. It is promptly mydriatic, scarcely irritant, causing at first slight burning, and has no effect upon accommodation. Claimed to be quicker and more transient than other mydriatics, and consequently of marked value for diagnostic purposes.

HORDEUM.—BARLEY.

The decorticated seeds of *Hordeum distichon*, Linné.

COMMON NAMES: *Barley, Pearl barley.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 293.

Botanical Source.—There are several kinds of barley, the more general ones being the following: *Hordeum vulgare*, Linné, has an erect, smooth, fistular culm or stem, from 2 to 4 feet in height, with alternate, carinate, lanceolate, linear, and roughish leaves; the sheaths are auriculate at the throat. The flowers are all hermaphrodite and awned; the spikes thick, and about 3 inches long; the spikelets 3, all fertile, 1-flowered, with an awn-like rudiment at the base of the upper paleæ. Glumes 2, subulate, nearly equal, and awned. Paleæ 2 and herbaceous; the lower one lance-ovate, concave, and long awned; the upper obtusely acuminate, and bicarinate. The stamens are 3 in number; ovary hairy at the apex. Stigmas 2, sessile, somewhat terminal, and feathery. Scales 2, ciliated. Caryopsis adhering to the paleæ. Fruit or seeds in 4 rows (L.—W.).

Hordeum distichon, Linné, differs from the preceding by having a compressed spike or ear, with the lateral spikelets abortive and awnless; the spikelets on the edge only being fertile, and the fruit is disposed in 2 rows.

Hordeum hexastichon, Linné, has the fruit in 6 rows.

History and Description.—Barley is thought to be a native of central Asia, but the subject is involved in much uncertainty. The seeds are the parts employed. They are oblong-ovoid, with a furrow on one side running lengthwise, yellow outside, white internally, of a feeble odor, and a moderately saccharine taste. When the seeds are stripped of their husks, and made round by a particular process, it constitutes *pearl barley* (*Hordeum Perlatum*), which is the best form for use; when this is ground into a coarse flour it forms barley meal. Pearl barley occurs in subspherical or nearly ovoid grains, of a white, starchy aspect. Sometimes remaining portions of the husk give to it a yellowish cast. This is especially the case along the longitudinal groove. Its taste resembles that of the farinaceæ in general. When the seeds are but partially decorticated it is known as *hulled*, *Scotch*, or *pot barley*. When the entire grain is moistened and exposed in mass to a summer temperature until it begins to germinate, and is then devitalized at a definite stage of the germinating process, by a stronger heat, it is converted into MALT, which is extensively employed in making ale, beer, and porter During the process of making malt, the temperature rises appreciably, much carbon dioxide is given off, and the nitrogenized matter in the seeds undergoes a change, being in part converted into a peculiar ferment, called *diastase*. It has the power, peculiar to infusions of malt, of converting large quantities of starch into dextrin and a fermentable sugar, *maltose*. To obtain the greatest possible yield of *diastase* from a given amount of barley, at the same time reducing the loss of carbohydrates to a minimum, is the object of successful malting (see special works on brewing, etc., for details of this process).

Chemical Composition.—König (*Nahrungs und Genussmittel*, 3d ed., 1893, Vol. II, p. 467) gives the following percentage composition of barley seed, the results being the average of 766 recorded analyses of barley from many countries, including the United States: Water, 14.05; nitrogenous matter, 9.66; fatty matter, 1.93; sugar (*maltose*), 1.51; dextrin, 6.39; starch, 59.09; fibre, 4.95; ash, 2.42. The nitrogenous matter consists of *gluten casein*, *gluten-fibrin*, *mucedin*, and albumin. The gliadin contained in wheat being absent, it is therefore impossible to obtain gluten from barley (see *Avena*). Albumin varies in barley from 0.5 to 1.77 per cent. As regards carbohydrates, sugar is stated to predominate over dextrin in American barley. Stellwaag (1886) found the fatty matter in barley to consist of 13.62 per cent free fatty acids (containing *hordeic acid*, or *lauro-stearic acid* of Beckmann, 1855), 71.78 per cent neutral fats, 4.24 per cent *lecithin*, and 6.08 per cent *phytosterin*.

J. C. Lermer, in 1863 (Wittstein's *Vierteljahrsschrift*, Vol. XII, p. 4), made a comparative analysis of barley seeds and the malt obtained therefrom, and observed a loss in starch of 14.57 per cent, and an increase of sugar by 2.03 per cent, also the fatty oil became reduced in quantity, while dextrin, cellulose, and proteids remained constant. Mr. Frank X. Moerk has more recently (*Amer. Jour. Pharm.*, 1884, p. 366 and 465) made some diligent analyses of Canada barley as well as the malt prepared from it, to which articles the reader is referred. A peculiar, optically lævogyre carbohydrate, *sinistrin* (*synanthrose*), was found in hordeum by Kühnemann (1875). The ash of barley seeds contains chiefly phosphate of potassium, magnesium and calcium, and large amounts of silica (in the husks).

A peculiar principle has been found in barley seeds subsequent to the germinating process, by MM. Payen and Persoz, which they have named *diastase*. The same substance has likewise been found in the seeds of oats and wheat, and in the potato, but only after these have undergone germination. Diastase may be obtained by macerating ground malt in cold water, subjecting to pressure, and filtering and heating the liquid to the temperature of 70° C. (158° F.). Another nitrogenous body existing in the liquid is thus coagulated and removed. The liquid, being filtered again, is to be mixed with a sufficient quantity of alcohol to throw down the *diastase*. To obtain the diastase pure, it should be again dissolved in water, and thrown down by alcohol, and this ought to be repeated several times. Diastase thus obtained is solid, white, amorphous, insoluble in alcohol, but soluble in water and diluted alcohol. Its aqueous solution possesses neither acid or alkaline qualities, and has little taste. Diastase, after purification, is best obtained in the dry state by exposing it in thin layers to a current of air at about 43.3° C. (110° F.). Its aqueous solution is not precipitated, like that of starch, by lime, baryta, or acetate of lead; on keeping it becomes acid. Its most remarkable property is that of converting starch in the presence of water, at a temperature of about 50° C. (122° F.), into a peculiar sugar (*maltose*, $C_{12}H_{22}O_{11}$) and dextrin. It has no action upon either gum or sugar, and yet 1 part of it added to 2000 parts of starch, suspended in water, causes the starch globules speedily to burst, the teguments separating from the contained granulose, which readily undergoes this extraordinary conversion without any perceptible difference in the weight of the substance employed. Diastase has also been called *maltine*. A second ferment, *peptase*, forms during malting, whose action is to change the proteids into peptones and parapeptones, the beer depending upon the latter bodies for its (asserted) nutritive qualities (Wagner, *Handbuch der Chem. Technologie*, 1889, p. 901).

The different kinds of beer, ale, and porter are made from malt, with the addition of hops and other articles. Malt has a sweetish, mucilaginous, rather agreeable taste. An infusion of it at 71.1° C. (160° F.) completes the conversion of the starch into sugar and gum; yeast being then added at a temperature between 15.5° and 26.6° C. (60° and 80° F.), vinous fermentation takes place, carbonic acid gas is disengaged and alcohol formed. The sugar is the source of the alcohol existing in malt liquors, while the gummy dextrin is the cause of their viscidity, and the permanence of their effervescence and frothy top.

Action, Medical Uses, and Dosage.—Pearl barley in decoction is nutritive and demulcent, and, on account of its mild and unirritating qualities, is much used as an article of diet for the sick and convalescent, acting at the same time, if the barley itself be swallowed, as a gentle aperient. The decoction is employed for suspending powdered drugs insoluble in water, and also as a drink in *febrile diseases*, *catarrh*, *dysentery*, *inflammation of the bladder*, *gonorrhœa*, and *chronic mucous inflammations*. Combined with hops, or in the form of beer, ale, or porter, it forms a valuable tonic in many *chronic exhausting diseases*, and in convalescence. From

2 to 4 ounces of malt boiled in a quart of water, afford a more demulcent and nutritious liquor than barley, and is consequently better adapted to cases requiring a sustaining course of treatment. In making the decoction of barley, 2 ounces must first be washed with cold water, and all extraneous matters removed, then place the barley in ½ pint of water, boil for a short time, strain off the water, and throw it away, as this is only employed to remove mustiness, or any disagreeable flavor which the barley may have acquired. To the barley thus prepared, add 4 pints of boiling water, boil down to 2 pints, and strain. The decoction may have other articles added in the course of its preparation, varied to suit the taste of the patient, as sugar, sliced figs, raisins, liquorice-root, etc. It may be drank freely.

HUMULUS (U. S. P.)—HOPS.

"The strobiles of *Humulus Lupulus*, Linné"—(*U. S. P.*).

Nat. Ord.—Urticaceæ.

COMMON NAME: *Hop.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 230.

Botanical Source.—This plant has a perennial root, with many annual, angular stems, rough backward, with minute, reflexed hairs, twining around surrounding objects in a volute direction with the sun, and climbing to a great height. The leaves are opposite, on long, winding, rough petioles; the smaller ones cordate, the larger from 3 to 5-lobed; all are deep-green, serrated, veiny, and very rough. The flowering branches are axillary, angular, and rough. Stipules, 2 or 4, between the petioles, smooth, ovate, and reflexed. The flowers are numerous, axillary, and of a greenish color. Male flowers very numerous, panicled, yellowish-white; sepals 5, oblong, obtuse, spreading, concave; stamens short; anthers oblong, opening by 2 terminal pores. Female flowers pale-green, grow on a separate plant, in the form of an ament, having each pair of flowers supported by a bract, which is ovate, acute, and tubular at the base; sepals solitary, obtuse, smaller than the bracts, enfolding the ovary; ovary roundish and compressed; stigmas 2, long, subulate, and downy. The bracts enlarge into a persistent catkin or strobile, each bract inclosing a nut enveloped in its permanent bractlet, and some yellow, resinous grains (L.—B.).

Fig. 135.

Humulus Lupulus.

History and Description.—This plant is common in hedges and thickets in many parts of Europe, and grows spontaneously in various sections of the United States; said also to inhabit China and the Canary Islands. It is largely cultivated for its cones or strobiles, which are used medicinally, and in the manufacture of beer, ale, porter, etc. A few rows of the barren vines planted among the fertile ones, are said to be profitable by increasing the weight of the produce. The strobiles or cones are the parts employed; these are collected when thoroughly matured, properly desiccated, and then placed in large bags or pockets, and sold as *Hops.* They consist of ovate, membranous, semi-transparent, light-green scales, tinged more or less of a yellow color, which are glandular at their base, near which they develop 2 minute, globular, hard nuts or achenia of a bay-brown color, and which are covered with aromatic, superficial, globose, golden-yellow glands or grains. To these the name *lupulin* was given by Ives (*Amer. Jour. Science*, 1820, p. 302). The active properties of hops are owing to the lupulin, although the scales possess them also, but in an inferior degree. *Lupulin* (see *Lupulinum*), is procured by beating or rubbing the strobiles, and then sifting out the grains, which form about ⅙ part of the hops. The official description of hops is as follows:

"Ovate, about 3 Cm. (1¼ inch) long, consisting of a thin, hairy, undulated axis, and many obliquely-ovate, membranous scales, in the upper part reticulately veined, and toward the base parallel-veined, glandular, and surrounding a subglobular achene; color of the scales greenish, free from reddish or brownish spots; odor aromatic; taste bitter, aromatic and slightly astringent"—(*U. S. P.*).

Chemical Composition.—Boiling water takes up the virtues of hops; however, they are impaired by long-continued heat. The decoction turns litmus paper red, becomes deep-green with the salts of iron, and turbid with the solution of isinglass. A better solvent than water is diluted alcohol. By distillation with water, hops yield a limpid *volatile oil* (0.8 per cent, v. Wagner), lighter than water; Payen and Chevallier (1822) obtained from lupulin 2 per cent. The oil in part contains *humulene* (a sesquiterpene, $C_{15}H_{24}$), and unsaturated hydrocarbons not belonging to the terpene series. The formation of *butyric* and *valerianic acids*, observed in the distillation of old hops or lupulin with water, is not due to oxidation of the volatile oil (A. C. Chapman, *Pharm. Centralh.*, 1899, p. 73).

A *bitter* principle was obtained as an amorphous, water-soluble mass, by M. Isseib (*Archiv der Pharm.*, 1880, p. 345), by exhausting lupulin of its bitterness by cold water, abstracting the bitter, with some resin, by animal charcoal, abstracting with alcohol, and separating the bitter from the resin by means of ether, which dissolves the bitter part only. The bitter principle, upon boiling with diluted sulphuric acid, is resolved into brown, amorphous *lupuliretin* (also supposed to be an oxidation product of the volatile oil), and crystallizable *lupulic acid*. A *crystallizable*, bitter principle, called *hop-bitter acid*, was first obtained pure by Lermer in 1863 (*Dingl. Pol. Jour.*, Vol. CLXIX, p. 54), by an elaborate process. This substance is insoluble in water, soluble in alcohol, ether, chloroform, and other liquids, notably the volatile oil of hops. The same compound was more recently obtained by H. Bungener (*Amer. Jour. Pharm.*, 1884, p. 427, from *Pharm. Jour. Trans.*, 1883–4, p. 1008). Six kilograms of fresh lupulin from unsulphured hops were extracted with low-boiling petroleum ether, and yielded 400 Gm. (6.6 per cent), of crude *hop-bitter acid*. The pure substance melts at 92° to 93° C. (197.6° to 199.4° F.), and when exposed to the air, soon turns yellow, resinifies, and develops an odor of fatty acids and aldehydes. Oxidizers produce *valerianic acid* in considerable quantity.

The *resins* of hops were differentiated by Dr. Hayduck (see *Amer. Jour. Pharm.*, 1888, p. 25. into three resins, two of which are soluble in petroleum-ether and form ether-soluble copper salts. The *hop-bitter acid* aforementioned is spontaneously convertible into one of these two resins, namely, that which is not precipitated by lead acetate. These two resins, as well as the *hop-biter acid*, were established to be the principles antagonistic to lactic ferments, while the oil of hops does not possess such untiseptic properties. A peculiar tannin, called *humuli-tannic acid*, was found to be present in hops to the extent of 2 to 5 per cent (v. Wagner, 1853, and Etti, 1876). A crystallizable alkaloid was believed by Lermer to exist in hops, although Gresshoff (1887) established its absence in lupulin (see Flückiger, *Pharmacognosie*, 1891). In this connection, the nature of the poisonous, crystallizable substance abstracted by F. Davis from the green strobiles of hops with ether (*Pharm. Jour. Trans.*, 1886, Vol. XVIII, p. 20), probably deserves further investigation. Other constituents are: Wax (about 10 per cent in *lupulin*), chlorophyll, dextrose (3 per cent, by Griessmayer, 1874), *asparagine* (1 per cent, Bungener and Fries, *Amer. Jour. Pharm.*, 1886, p. 91), *trimethylamine* and *choline* ($C_2H_4[OH]N[CH_3]_3OH$), *lupuline* of Griessmayer, 1874); of the latter base, Griess and Harrow obtained from hops 0.02 per cent; diluted aqueous solutions of this substance dissolve comparatively large amounts of *hop resin*, producing an intensely bitter solution. (Also see *Lupulinum* for special points.)

Action, Medical Uses, and Dosage.—Hops are tonic, hypnotic, febrifuge, antilithic, and anthelmintic. Their tonic and anthelmintic properties are small, and probably depend upon their bitterness; they possess no antiperiodic virtues. Sometimes they cause diuresis, and are said to correct *lithic acid deposits*. They are principally used for their sedative or hypnotic action—producing sleep, removing restlessness, and abating pain, but which they often fail to accomplish. A pillow stuffed with hops has long been a popular remedy for procuring sleep. Hops, as well as lupulin, are useful in *delirium tremens* to allay the morbid excitement and vigilance, while at the same time it exerts its stomachic effects. It is extremely efficient in *dyspepsia* where restlessness and a brooding disposition are prominent features. *Fermentative dyspepsia*, with consequent eructations, often yields to hops or lupulin. Externally, in the form of a fomentation alone, or combined with boneset or other bitter herbs, hops have proved beneficial in *pneumonia, pleurisy, gastritis, enteritis;* also as an application to *painful swellings* or *tumors.* An ointment made by boiling 2 parts of stramonium leaves and 1 of hops, in lard, has proved an effectual application in *eczema, ulcers*, and *painful tumors.*

Lupulin exerts a more certain influence than hops, and should be preferred for internal use, as the dose is much less bulky. The properties here ascribed to hops are possessed by lupulin, and the conditions benefited by lupulin are also those in which hops act beneficially. The subject will be further discussed under *Lupulin* (see *Lupulinum*).

The decoction of hops is seldom employed. Ale, porter, and beer are frequently administered in cases of *debility* in the absence of inflammatory symptoms, as tonic, stimulant, and nutritive agents. (For specific indications see *Lupulinum.*)

HYDRANGEA.—HYDRANGEA.

The root of *Hydrangea arborescens*, Linné *(Hydrangea vulgaris*, Michaux and Pursh).

Nat. Ord.—Saxifragaceæ.

Common Names: *Seven barks, Wild hydrangea.*

Botanical Source.—This plant is the *Hydrangea vulgaris* of Michaux and Pursh. It is an indigenous shrub, smooth, or nearly so, attaining the height of 5 or 6 feet, with opposite, petiolate leaves, which are ovate, obtuse at the base, rarely cordate, acuminate, serrate-dentate, nearly smooth, and green on both sides. The flowers are often all fertile, numerous, small, white, becoming roseate, and borne in fastigiate cymes. The calyx tube is hemispherical, 8 or 10-ribbed, and coherent with the ovary; the limb 4 or 5-toothed, and persistent; the petals ovate and sessile; the stamens 8 or 10, and slender; the capsule crowned with the 2 divergent styles, 2-celled below, and opening by a foramen between the styles; and the seeds are numerous (W.—G.).

History and Description.—This elegant shrub grows abundantly in the southern, and middle-western states, in mountains and hills, and on rocks and near streams. The bark is rough, pealing off—each layer being of a different color, and which has probably given origin to the name "seven barks." It is quite common in the Susquehanna and Schuylkill valleys, and its flowers are often met with in bouquets in the markets of Philadelphia. The root is the part that has been employed. It is formed of numerous radicles, sometimes not larger than a goose-quill, and again half an inch or more in diameter, and of considerable length. These proceed from a caudex, which sends upward numerous divergent branches. When fresh, the root and stalks are very succulent, containing much water, and can easily be cut, and the root likewise contains a great deal of mucilage, with albumen and starch. When dry they are very tough and resistent, and exceedingly difficult to bruise or cut, hence they should be bruised while fresh, or which is better, cut into short transverse sections, which facilitates the drying. The bark of the dried root has a rather pungent, aromatic, not disagreeable taste, somewhat similar to that of cascarilla bark. The stalks contain a pith which is easily removed, and they are used in some parts of the country for pipe-stems.

Chemical Composition.—Mr. Joseph Laidley, of Richmond, Va. (*Amer. Jour. Pharm.*, 1852, p. 20), found the root to contain gum, albumen, starch, resin, and inorganic salts. It was subsequently analyzed by Jos. Baur (*ibid.*, 1881, p. 157), who found, in addition, probable indications of an alkaloid and a crystallizable body. A glucosid, *hydrangin*, fluorescing with opal-blue color in alkaline solution, was obtained later by C. S. Boudurant (*Amer. Jour. Pharm.*, 1887, p. 123). It forms star-like masses of crystals, soluble in ether and alcohol, and when treated with diluted acids, splits into grape sugar and a resinous body. Acids destroy the fluorescence. Sugar, saponin, several resins, fixed and volatile oils (2.28 per cent), and starch (7.28 per cent) were also found. Sulphur is a constituent of the volatile oil. Contrary to Baur's statement, no tannin was found. Mr. H. J. M. Schroeter (*Amer. Jour. Pharm.*, 1889, p. 117) obtained a yield of 0.08 per cent of *hydrangin*, for which he established the formula $C_{34}H_{25}O_{11}$, and found the melting point to be 228° C. (442.4° F.).

The root of *Hydrangea paniculata*, var. *grandiflora*, a shrub frequently cultivated in the northern and middle states, was analyzed quite recently (A. G. Luebert, *Amer. Jour. Pharm.*, 1898, p. 550). A glucosidal, crystallizable principle was obtained, melting at 178° C. (352.4° F.), and probably not identical with the *hydrangin* of Bondurant. The name *para-hydrangin* is suggested for this substance.

Action, Medical Uses, and Dosage.—This plant was introduced to the profession by Dr. S. W. Butler, of Burlington, N. J., as a remedy for the removal of *calculous* or *gravelly deposits in the bladder*, and for relieving the excruciating pain attendant on the passing of a calculus through the ureter; and from reports made, it certainly deserves a full and thorough investigation. The power of curing or dissolving stone in the bladder is not claimed for it; it is only while the deposits are small, when in that form of the disease known as *gravel*, that it is an efficient remedy; then by removing the nucleus, which, if allowed to remain in the organ, would increase in size and form stone, the disease is averted, and when employed at this stage, it is said to have proved beneficial in every instance, and as many as 120 calculi have been known to come from one person under the use of this remedy. The effect of the plant, Dr. Butler states, is to remove, by its own specific action on the bladder, such deposits as may be contained in that viscus, provided they are small enough to pass through the urethra. Thus it has chiefly an eliminatory action rather than any power to dissolve gravel. By its soothing action it relieves vesical and urethral irritation. Probably its greatest value lies in its power of preventing the formation of alkaline and phosphatic deposits. The former mode of using it was to prepare a concentrated syrup of it with sugar or honey, and give a teaspoonful 3 times a day. Now specific hydrangea, in doses of 5 to 30 drops, 3 times a day, preferably in hot water, or a simple decoction of the root to be taken freely are preferred. If taken in overdoses it will produce some unpleasant symptoms, as dizziness of the head, oppression of the chest, etc. It is a good remedy in *acute nephritis*. The leaves of hydrangea are said by Dr. Eoff to be tonic, sialagogue, cathartic, and diuretic. The specific hydrangea and fluid extract of hydrangea are principally used in the earthy deposits, as phosphates of calcium, ammonium, and magnesium, in alkaline urine, and in *chronic gleet*, and *mucous irritation of the bladder* in aged persons. Its alterative powers, chiefly due to its washing away of strumous and other unhealthy products, are not to be underrated. It is not without some value in *broncho-pulmonic affections*, relieving irritation; also in some forms of *gastric irritation*.

Specific Indications and Uses.—Vesical and urethral irritation, with gravelly deposits; difficult urination; bloody urine; deep-seated renal pain; hepatic pain; irritation of bronchial tract. It improves the nutrition of the urinary mucous tissues.

Preparation of Hydrangea.—LITHIATED HYDRANGEA. This specialty of the Lambert Pharmacal Co., of St. Louis, Mo., is a compound of fresh hydrangea and benzo-salicylate of lithium, prepared by special process. It is employed in renal and cystic affections, viz.: *Lithuria, gout, rheumatism, calculus, diabetes, cystitis*, and *vesical irritation*. The dose is from 1 to 2 fluid drachms, 4 times a day, preferably between meals.

HYDRARGYRI CHLORIDUM CORROSIVUM (U. S. P.)

CORROSIVE MERCURIC CHLORIDE.

FORMULA: $HgCl_2$. MOLECULAR WEIGHT: 270.54.

SYNONYMS: *Corrosive chloride of mercury, Corrosive sublimate, Hydrargyri perchloridum, Perchloride of mercury, Bichloride of mercury, Chloride of mercury, Corrosive muriate of mercury, Oxymuriate of mercury, Hydrargyrum muriaticum corrosivum, Hydrargyrum corrosivum sublimatum, Hydrargyri bichloridum, Mercurius sublimatus corrosivus, Sublimatum corrosivum, Sublimatus corrosivus, Chloruretum (Chloretum) hydrargyricum, Mercuric chloride.*

"Corrosive mercuric chloride should be kept in well stoppered bottles"—(*U. S. P.*).

Preparation.—"Take of persulphate of mercury, 20 ounces (av.); chloride of sodium, dried, 16 ounces (av.); black oxide of manganese, 1 ounce (av.). Reduce the persulphate of mercury and the chloride of sodium, each, to fine powder, and, having mixed them and the oxide of manganese thoroughly by trituration in a mortar, put the mixture into an apparatus adapted for sublimation, and apply sufficient heat to cause vapors of perchloride of mercury to rise into the less heated part of the apparatus which has been arranged for their condensation"—(*Br. Pharm.*).

Double decomposition takes place thus: $HgSO_4+2NaCl=HgCl_2+Na_2SO_4$. Any mercurous compound that may contaminate the mercuric sulphate, and any mercurous chloride generated during this process, are converted into mercuric chloride by the chlorine generated from the action of the manganese dioxide employed upon the sodium chloride. This process differs from the *U. S. P.* (1870) in the employment of an already prepared mercuric sulphate, and in the introduction of the manganese salt.

Description.—Mercuric chloride, when obtained by sublimation, forms in beautiful white, semitransparent masses, composed of very small prismatic needles. It has the specific gravity 5.14 to 5.42. In the light it becomes reduced, first to mercurous chloride (calomel), and finally to the metallic state. Its incompatibles are alkalies and their carbonates, tartar emetic, sulphide of potassium, soaps, albumen, iron, copper, lead, metallic mercury, vegetable substances containing tannic acid, etc. It is officially described as "heavy, colorless, rhombic crystals, or crystalline masses, odorless, and having an acrid and persistent, metallic taste; permanent in the air. Soluble, at 15° C. (59° F.), in 16 parts of water, and in 3 parts of alcohol, in 2 parts of boiling water, 1.2 parts of boiling alcohol, 4 parts of ether, and about 14 parts of glycerin. It fuses at 265° C. (509° F.) to a colorless liquid, and at about 300° C. (572° F.) it volatilizes in dense, white vapors, leaving no residue. The aqueous solution reddens blue litmus paper, but becomes neutral to litmus on the addition of sodium chloride. With ammonia water it yields a white precipitate; with an excess of hydrogen sulphide a black one; with potassium iodide T.S. a red one, soluble in an excess of the reagent; and with silver nitrate T.S. a white precipitate, insoluble in nitric acid"—(*U. S. P.*). The white precipitate produced in solutions of corrosive sublimate by ammonia water, has the composition $HgCl.NH_2$; the analogous precipitate produced in solutions of mercurous salts with ammonia water, is black. Mercuric chloride is easily reduced to insoluble mercurous chloride (calomel) by such reducing agents as sulphurous acid or stannous chloride. An excess of the latter reagent will further reduce the calomel formed to metallic mercury. The reactions involved are as follows: $2HgCl_2+SnCl_2=Hg_2Cl_2+SnCl_4$ and $Hg_2Cl_2+SnCl_2=Hg_2+SnCl_4$. Mercuric chloride forms crystallizable double salts with the chlorides of potassium, sodium, and ammonium, and also combines with hydrochloric acid. The *Alembroth Salt* of the alchemists was a mixture obtained by evaporating to dryness a solution of equal weights of mercuric chloride and ammonium chloride.

Tests.—"If a saturated, aqueous solution of the salt be heated nearly to boiling, then completely saturated with hydrogen sulphide, and allowed to stand for several hours in a well-corked flask, it should yield a colorless filtrate, which, on evaporation, should leave no residue (absence of many foreign salts). If the precipitated mercuric sulphide obtained in the last test be washed with water, then shaken for a few minutes with ammonia water, and filtered, the filtrate should be colorless, and, on the addition of a slight excess of hydrochloric acid, should afford neither a yellow color, nor a yellow precipitate (absence of arsenic)"—(*U. S. P.*). The presence of calomel (mercurous chloride) in corrosive sublimate is recognized by an insoluble residue being left upon dissolving in water, this residue turning black with ammonia water.

Action and Toxicology.—In this article the action of the mercurials in general will first be given, followed by such special statements as apply to individual members of the group. In the metallic state mercury is inert as a medicine, except when in a state of minute division; but its oxides and other compounds possess exceedingly active properties. Metallic mercury, undivided, may be taken in considerable amount, acting by its weight merely as a purgative. If, however, it be retained in the intestinal tract so as to form soluble salts, or if in prolonged contact with the skin, it will produce the constitutional effects. Thus the blue ointment and mercurial plaster have caused alarming symptoms. The vapor of metallic mercury is exceedingly poisonous. Murrell records an account of the wrecking, near Cadiz, of a vessel, and the recovery of several tons of quicksilver by the crew of an English man-of-war, whereby 200 of the crew were sickened, with 2 fatalities, besides the destruction of animals, fowls, and roaches, all in consequence of the rotting of the sacks containing the metal. From the vapors from a fire in the quicksilver mines at Idria, over 900 individuals residing in the vicinity were attacked with trembles.

Almost all the mercurial preparations act in the same way, possessing sialagogue, deobstruent, alterative, etc., properties, the character and degree of which are frequently diminished or augmented by the peculiar agents in combination with them. These effects, however, are rarely increased physiological effects, but pathological in character. Bartholow, in considering the action of the mercurials upon the glandular system, very properly observes that "these actions of mercury should not be regarded as a physiological stimulation of the intestinal glands, in the sense that the foods are stimulant to these organs. The action is pathological, and the products of the action are pathological" (*Mat. Med.*, p. 248). The mercurials, when long continued, and, in many instances but few doses, with some very susceptible constitutions, induce a succession of very serious symptoms, as emaciation, general debility, œdema, tremor of the limbs, diseased liver, pain in the bones, caries, palsy, ulcerations of the pharynx and other parts, gangrenous ulceration of the mouth and face, and a sort of scorbutic marasmus. It likewise occasionally produces a febrile condition of the system, with profound prostration (*mercurial erethism*), profuse perspiration, several forms of cutaneous disease, as eczema, herpes, inflammation or congestion of the eye, fauces, or peritoneum, nodes, enlargement of the inguinal, axillary, mesenteric, parotid, pancreatic, etc., glands, together with various painful and nervous attacks. It was introduced to the medical profession by the notorious Paracelsus.

The *modus operandi* of the mercurials is not well understood. In the stomach it probably forms an albuminate, which, though insoluble in water, is readily dissolved by chloride of sodium and by an excess of albumen. Minute doses are said to increase the red blood discs; large doses destroy the blood discs, reduce fibrin, and poison the heart. Mercurials have a special affinity for the glandular structures. This is well marked in its action upon the salivary glands. The former practice of "touching the gums," or producing profuse salivation (mercurial ptyalism), has been, largely through the stand taken by the Eclectic school, abandoned. This disagreeable condition, which formerly produced untold misery, exhibited itself in its worst form by an enormous increase of thick, ropy, albuminous saliva, subsequently becoming thin and watery, and amounting to several pints in a day. Then followed extensive ulceration, or gangrenous stomatitis of the cheeks and adjacent structures, with tender and swollen glands, sloughing of the cheek and gum, allowing the teeth to fall out and the jaw to become carious. Practical medicine has no greater stain upon her escutcheon than the memory of the horrors of acute mercurialism, as formerly practiced. So profound was the condition of *mercurial cachexia*, *hydrargism*, or *mercurial erethism* from continued doses of these drugs, that profound marasmus, anemia, and excessive purging soon led the victim to an untimely grave. This condition was frequently accompanied by the mercurial tremor, neuralgia, paralysis, or epileptiform convulsions. Scrofulous individuals and those laboring under renal affections are said to be more susceptible to the untoward action of the mercurials, while children are less readily salivated.

Artisans who are employed as gilders, and who work in looking-glass, thermometer, and barometer factories, and miners of quicksilver, are afflicted with a somewhat different form of mercurialism, marked features of which are prostration and anemia, mercurial fever, pustular or vesicular eruptions, jerky, stammering speech, convulsions, and particularly a peculiar form of muscular weakness denominated "the trembles." These tremors (or "shaking palsy") manifest themselves first in the upper limbs, then in the legs, and finally in the trunk. They are readily brought on, gradually increase in extent and severity, and are quite persistent and uncontrollable. The prehensile movements lack precision and the lower extremities, in walking, tremble as if strung on wires. For a graphic account of this condition, see Murrell's *Manual of Materia Medica and Therapeutics*, 1896, p. 204.)

Before the vigorous fight of the Eclectics against the mercurials as cholagogues, it was the prevailing opinion that these salts, particularly calomel, increased the natural secretions of the liver, thereby causing an augmented flow of bile. Reliable experimentation by several old school observers has proved the claims of our practitioners to be largely true. While it is still admitted by some that corrosive sublimate is slightly stimulant to the liver, the majority deny even to this salt cholagogue powers. That calomel has no such action is now universally acknowledged. If an increased flow of bile into the intestinal canal does take place under the action of the mercurial, it is caused, as with croton oil, by the reflex contraction of the gall-bladder and duct, due to the duodenal irritation produced. This is the view held by Bartholow, among others. The long-continued use of mercury has caused an altered biliary secretion, and has even checked hepatic activity.

Briefly, the distinctive effects, aside from the general mercurial impression, of mercury and its chief salts, are as follows: Metallic mercury, undivided is a mechanical purgative; in a divided state, as in gray powder, blue mass, and blue ointment, it becomes an active agent capable of all the untoward effects of this class of agents. Blue pill readily causes salivation, calomel less frequently. The general action of calomel closely resembles that of mercury in the divided state. Calomel probably passes for the most part into the intestines, where the alkaline secretions convert it into oxide of mercury. Mercuric chloride, mercuric iodide, mercuric cyanide, and mercuric nitrate are exceedingly energetic and toxic agents. Some of the mercurials, particularly the corrosive chloride and the biniodide are energetic germicides. The anthrax spores are destroyed by the first in a solution of 1 to 1000.

Taken internally, corrosive sublimate is an active, corrosive poison, acting very quickly, and producing in over-doses a coppery, metallic taste, and violent burning pain in the mouth, throat, œsophagus, and stomach; great difficulty of swallowing, sense of suffocation, nausea, violent vomiting, increased by everything taken into the stomach; the pain soon becomes diffused over the whole abdomen, which becomes very sensitive to pressure; violent purging, often of blood; great anxiety; flushed (occasionally pale), and even swollen countenance; restlessness; pulse quick, small, and contracted; cold sweats; burning thirst; short and laborious breathing; urine frequently suppressed; and finally stupor, coma, convulsive movements, partial paralysis, or paraplegia, and death. Fainting often precedes death. Sometimes before death ensues, if time enough has elapsed, there may be profuse salivation, ulceration of the mouth, fetor of the breath, and other secondary mercurial symptoms. The mouth and œsophagus appear whitish, as if having been painted with silver nitrate solution (Taylor). On inspection after death, the membranes of the mouth, throat, and œsophagus are softened and whitish or bluish-gray, and show marked inflammation, while the stomach and bowels will be found excessively inflamed, sometimes with patches of ulceration or gangrene. (Arsenic lesions are confined chiefly to the stomach and bowels.) Corrosive sublimate poisoning differs from arsenical poisoning in the metallic taste produced, in the violent symptoms almost immediately occurring, and in the evacuations being more often mixed with blood. If death is produced quickly, the symptoms closely resemble those of cholera; if several days elapse before death, the symptoms are more like dysentery, with violent tenesmus and shreddy, blood-mixed mucous discharges (Taylor, *Med. Juris.*).

In poisoning by corrosive sublimate, death may not take place for several days. Such cases may show a total inactivity of the renal organs. Death usually occurs in from 1 to 5 days, though it may occur earlier or later, having been known to take place in less than ½ hour. The smallest dose known to have killed (a child), is 3 grains; it is thought that from 3 to 5 grains or less will kill an adult (Taylor). Death may occur from the external application of the drug to tumors, ulcers, etc.; and serious symptoms have followed from the use of the solutions even when the skin is unbroken.

In the bodies of persons, who, during life had employed mercury or some of its preparations, either internally or externally, metallic mercury has been found, as in the bones, brain, pleura, liver, cellular tissue, lungs, kidneys, etc. It has also been detected in the secretions of patients who were under its influence, as in the perspiration, urine, saliva, bile, gastro-intestinal secretions, and in the fluids of ulcers. The salivation and gangrenous inflammation of the mouth occasioned by mercurials are best overcome by astringent infusions, as tincture of myrrh, both taken internally and used as a gargle, and the administration of chlorate of potassium. Its constitutional effects are best remedied by vegetable alteratives with iodide of potassium, tonics, attention to the excretions, malic acid, exercise, etc.; though it is rarely the case that a perfect recovery of health ensues where the system has suffered considerably from the effects of the mercury.

In the treatment of cases of poisoning by corrosive sublimate, the antidotes must be given promptly, without the least delay. Thus the white and yolks of eggs, well beaten with water; milk, or a mixture of wheat flour, oat-meal, or barley-meal, and water; these form a compound whose chemical action on the tissues are slight when compared with that of the poison. One egg is said to be required for every 4 grains of corrosive sublimate swallowed. The above, as well as mucilaginous draughts should be given freely until relief is afforded; and as soon as possible the stomach should be evacuated by the stomach-pump, and likewise be well washed out. Chemical antidotes, or those which decompose the poison, or form harmless compounds with it, should also be used, as a mixture of 2 parts of very fine iron filings, and 1 of fine zinc filings, which is said to reduce the corrosive sublimate to the metallic state; or, the hydrated sulphide of iron, which completely destroys the poisonous quality of the mercurial salt, if given within 10 or 15 minutes after it has been swallowed. After the poisonous symptoms have been overcome, any inflammation which may remain, must be treated on general principles.

Medical Uses and Dosage.—Mercury and its preparations have been little employed by Eclectic physicians, and have even been absolutely proscribed by many members of the Eclectic school. While it is true that the use of the drug has been discouraged by the teachers and writers of our school, it is also true that their ground of opposition is well taken, for these are drugs so pernicious in their effects, as ordinarily employed, that their abuse should be strongly guarded. They should only be used when the specific indications for their employment can be unmistakably pointed out. Therefore it is desirable that we reiterate what has been declared again and again by the *leaders and teachers* of the Eclectic school, that it is not the *use*, but the *abuse* of mercury to which objection is made. The earlier Eclectics, many of whom would not use mercury in any form, sought to find substitutes for the mercurials (as with podophyllin, etc., for hepatic disorders), for, as stated by Prof. King in the original preface to the *American Dispensatory* (p. 8), "there is no single remedy known to man which has produced a greater amount of mischief by its *indiscriminate* use than mercury; nor is there any other drug which has done one-hundredth part as much to create a prejudice against scientific medicine, to destroy the confidence of the community in its practitioners, and to repel them from the physicians to the nostrum dealer." That the Eclectic fathers were justified in their objections to the viciously injudicious employment of mercurials prevalent in regular medicine in the early days of our school, is now evident from the position taken by many of the most conspicuous old school authors of to-day, and by the very conservative use of the drug at present by old school physicians, as well as by their kindlier feelings toward their professional brethren, whose opinions relating to some problems in therapy do not agree with their own. In referring to the medical uses of the preparations of mercury, unless attention is called to Eclectic authority, the reader is to understand that the uses given in this work are in accordance with the authorities of the regular school, and are designed to give scientific information concerning a class of preparations we can do without or replace by better and more kindly remedies.

Corrosive sublimate is little used by Eclectic practitioners, either as an internal or external remedy. Nor is its use as extensive among allopathic practitioners as it was some years back. In fact, in reviewing the old school works upon practice and materia medica of the past and present, one is struck with the comparative conservatism in the use of these preparations as compared with former times. Corrosive sublimate has been employed as an alterative in *cutaneous*, *scrofulous*, and *rheumatic diseases*, *nervous disorders*, *diseases of the bones*, in *obstinate* [illegible], *acne*, and other eruptions on the face, etc. It was, however, more generally administered, and is still largely used in the treatment of *syphilitic maladies*. At the present day, besides its use in syphilis, it is advocated internally in *gastric ulcer*, to promote cicatrization and internally and locally in *diphtheria*. Murrell advises its use (1 grain to 10 fluid ounces of water; dose, 1 teaspoonful every hour), in *infantile diarrhœa* with green, slimy, offensive stools. Externally, it is the chief antiseptic agent for use as a germicide, being used more largely for that purpose than any other drug by these practitioners. It destroys *pediculi*, and in the form of solution or ointment is largely employed in *parasitic skin affections*, in *acne*, *pityriasis*, *chloasma*, *freckles*, *gonorrhœa*, *pruritis vulvæ*, in the treatment of *wounds*, and in general *surgical*, *gynæcological*, and *obstetrical manipulations*. (For a more detailed account of its employment by the old school profession, consult any "regular" materia medica.) The solutions employed for general antiseptic purposes should never be stronger than 1 in 2000. Solutions of 1 to 10,000 in vaginal injections during operations have produced violent toxic effects. Death has resulted from solutions of 1 to 1500 employed in surgical operations. Many fatalities have occurred from its employment even in dilutions of 1 to 6000, when used in the peritoneal cavity and in other operations on the viscera. Used in this way it frequently produces albuminuria. For these reasons, corrosive sublimate solutions are rarely used by Eclectic surgeons.

Internally, corrosive sublimate has been employed to some extent by Eclectic physicians. Prof. Scudder, who opposed its use chiefly because of the lack of discrimination on the part of physicians, believed that if rightly studied, mercury might fill a valuable place in medicine, but only in chronic cases (*Spec. Med.*, p. 179). He stated that if he were administering it, he would be guided by the small, contracted, elongated, and pointed tongue, of natural or more than usual degree of redness, with prominent papillæ. The urine should be of normal specific gravity, depositing no sediment, the lips of good color, the circulation good, and the skin elastic. He declared the mercurials were contraindicated by a pale mouth and tongue with absence of papillæ, pale and full fauces, tonsils, and palate, shiny red spots over the tongue, pallid, expressionless face, full lips, and increased secretion of saliva.

Prof. H. T. Webster advocates the use of corrosive sublimate 3x (adults) to 6x trituration (children), in 2-grain doses every 2 or 3 hours, for its effects upon the mucous membrane of the colon, the vitality of which has been impaired by long-continued inflammation in *chronic cholera infantum* and *dysentery*. *Ulcers of the colon* and *rectum* form, the evacuations are semipurulent, and convalescence lingering. Here he claims that it lessens the pain and tenesmus, checks the evacuations, and restores normal energy to the parts.

Externally, solutions of corrosive sublimate have been advised as a collyrium (1 to 1000 to 1 to 10,000), in various affections of the eye, as *ophthalmia neonatorum*, *acute catarrhal conjunctivitis*, *phlychtenular conjunctivitis*, *keratitis*, *xerosis*, *trachoma*, *lachrymal blenorrhœa*, and *hypopyon keratitis* (Foltz). *Corneal opacities* have resulted from its local use. Foltz employs $\frac{1}{100}$ to $\frac{1}{60}$ grain doses in *syphilitic eye disorders*. In *ear disorders* he advises internally $\frac{1}{200}$ to $\frac{1}{100}$ grain doses in *syphilitic suppurative otitis media*, and in *internal ear affections*. Washes (1 to 1000 to 1 to 4000) have been recommended in *suppurative otitis media*, *furuncles*, *diffuse otitis media*, and in operations for *mastoid disease*. A wash composed of solutions of borax and corrosive sublimate is asserted signally useful in the treatment of *cracks*, *fissures*, and other *sores* affecting the face, corners of the mouth, behind the ears, etc., in children. The ordinary doses of mercuric chloride range from $\frac{1}{16}$ to $\frac{1}{2}$ grain. The dose preferred by Webster is 2 grains of the 3x trituration for adults, and of the 6x trituration for children.

Yellow Wash (*Lotio Flava*), used as an application to *venereal*, *scrofulous*, and *phagedenic ulcers*, is prepared by adding 2 or 3 grains of corrosive sublimate to a fluid ounce of lime-water. When employed, it should be well shaken and used in the turbid state.

Specific Indications and Uses.—Tongue small, contracted, elongated, and pointed, and of normal color, or of increased redness, and prominent papillæ; urine must be normal in specific gravity and deposit no sediment; circulation good; lips of good color, and skin elastic (Scudder). Impaired mucous membrane of colon and rectum in chronic dysentery and cholera infantum, with ulceration, pain, tenesmus, and semipurulent discharges (Webster).

Mercury and Mercurial Compounds.—HYDRARGYRUM (*U. S. P.*), *Mercury, Quicksilver, Argentum vivum, Hydrargyrum vivum, Mercurius vivus.* Symbol: Hg. Atomic Weight: 199.8. Mercury often occurs in a native state, but it is met with more abundantly in the form of cinnabar, or sulphide of mercury. It is also met with, although rarely, in the form of an amalgam, in combination with gold and silver, also in the form of mercurous chloride, and in certain copper ores. The bulk of mercury comes from Almaden, Spain, and New Almaden California. Idria, in Austria, likewise furnishes it, as well as mines in China, Japan, Peru, etc. The process for obtaining pure mercury from its sulphide is very simple. The cinnabar ore is mixed with half its weight of lime, and then distilled in iron retorts. Mercury distills over, and the sulphide of calcium remains in the retort. At Idria, in Austria, and Almaden, in Spain, the ore is roasted, by which the sulphur is converted into sulphurous acid, and the mercury is volatilized and condensed in suitable apparatus. This is the process most generally employed. The mercury thus obtained is shipped in cylindrical iron flasks, holding about 75 pounds. The *U. S. P.* directs that "mercury should be kept in strong, well-stoppered bottles," and describes it as "a shining, silver-white metal, without odor or taste. It is liquid at the ordinary temperature, and easily divisible into spherical globules; but, when cooled to —39.38° C. (—38.88° F.), it forms a ductile, malleable mass. Specific gravity 13.5584 at 15° C. (59° F.). Insoluble in the ordinary solvents, also in concentrated hydrochloric acid, and, at common temperatures, in sulphuric acid; but it dissolves in the latter, when boiled with it, and is readily and completely soluble in nitric acid. At ordinary temperatures it volatilizes very slowly, more rapidly as the temperature increases, and at 357.25° C. (675.05° F.) it boils, and is completely volatilized, yielding a colorless and very poisonous vapor. When globules of mercury are dropped upon white paper, they should roll about freely, retaining their globular form, and leaving no streaks or traces. It should be perfectly dry and present a bright surface. On boiling 5 Gm. of mercury with 5 Cc. of water and 4.5 Gm. of sodium hyposulphite, in a test-tube, for about 1 minute, the mercury should not lose its luster, and should not acquire more than a slightly yellowish shade (absence of more than slight traces of foreign metals)"—(*U. S. P.*). Mercury, when frozen, has the specific gravity 14.931, and crystallizes in octahedra. Mercury is not altered by being kept under water, but its surface becomes gradually tarnished when exposed to the action of the air, becoming covered with a black oxide, especially when impure. In order to purify it for certain scientific purposes, *e. g.*, the making of barometers and thermometers, it must be redistilled. By this process such impurities as lead and tin remain in the residue. It may also be purified by digesting 100 parts of mercury for 3 days in 5 parts each of water and nitric acid, and subsequently washing it well with distilled water and drying it with bibulous paper; or the mercury is allowed to fall in a fine stream through a high column of diluted nitric acid (L. Meyer). Mercury combines with bromine, chlorine, iodine, oxygen, lead, phosphorus, sulphur, bismuth, arsenic, etc. Gold, silver, tin, cadmium, etc., combine with it when cold, forming alloys called *amalgams.* When heated in open air to near its boiling point, mercury unites with oxygen, producing the red oxide in scales. Mercury does not decompose water; but if boiled in this liquid it absorbs $\frac{1}{500}$ of its weight. Triturated with fat, or agitated for a great length of time with water, it is divided to such a degree as to lose its metallic luster, and then forms a blackish powder, which is the metal in a state of great division (*extinguished* or *killed*).

Two oxides of mercury are known, the higher (HgO) and lower (Hg_2O), and the two corresponding series of salts are known respectively as *mercuric* and *mercurous* compounds. All soluble compounds of mercury are poisonous, acid in reaction, and disagreeably metallic to the taste. White is the usual color of the normal salts, while the basic compounds are yellow. *Mercurous* salts form a white, insoluble precipitate with soluble chlorides (calomel), which turns black upon the addition of ammonia. They precipitate black with caustic potash or caustic soda, mercurous oxide (Hg_2O) being formed. *Mercuric* salts precipitate yellow with caustic potash or caustic soda. They yield a scarlet precipitate, mercuric iodide (HgI_2), if carefully added to solution of potassium iodide, but this precipitate dissolves in excess of the latter reagent.

Mercury, in combination with other substances, may be detected by dissolving the substance in nitric acid; in the solution place a piece of bright copper, and after some time remove it, and rub it with a clean paper, when, if mercury be present, a silvery stain will be found on the copper, which is removed by heat, and may be collected in a minute globule of quicksilver if the volatilization be conducted in a small glass tube. If a strong solution of iodide of potassium be added to a minute portion of any of the salts of mercury, placed on a clean, bright plate of copper, the mercury is immediately deposited in the metallic state, appearing as a silvery stain on the copper; no other metal is deposited by the same means. The solution of mercury previous to the application of this test, must be concentrated by evaporation (A. Morgan, *Pharm. Jour. and Trans.*, XI, 372). Any solid mercury compound may be recognized by mixing it with dry sodium carbonate, placing the mixture into a small, dry glass tube closed at the bottom and heating over a flame. The mercury will then be set free, and will collect at the colder part of the tube in the form of minute globules. In addition to its chemical and pharmaceutical uses, mercury is employed extensively for a variety of purposes, viz., the extraction of gold and silver from their ores by the process known as *amalgamation;* in electrolytic processes; in the manufacture of physical apparatus, such as barometers, thermometers, and mercury air pumps; in the form of amalgams in the making of mirrors, etc

Hydrargyrum Cum Creta (*U. S. P.*), *Mercury with chalk, Æthiops cretaceus.*—"Mercury, thirty-eight grammes (38 Gm.) [1 oz. av., 149 grs.]; clarified honey, ten grammes (10 Gm.) [154 grs.]; prepared chalk, fifty-seven grammes (57 Gm.) [2 ozs. av., 5 grs.]; water, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Weigh the mercury and clarified honey successively into a strong bottle of the capacity of one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏], and add two cubic centimeters (2 Cc.) [33 ♏] of water. Cork the bottle, and shake it for about half an hour at a time, until the aggregate time of shaking reaches 10 hours, or until the globules of mercury are no longer visible under a lens magnifying 4 diameters. The shaking may be more conveniently performed by mechanical means. Rub the prepared chalk with water, in a mortar, to a thick, creamy paste, and, having added the contents of the bottle, washing the last portions in with a little water, triturate the whole to a uniform mixture. Finally dry the mixture, first between ample layers of bibulous paper, and afterward in a capsule, at the ordinary temperature, until it weighs one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]. Then reduce it to a uniform powder, without trituration, and keep it in well-stoppered bottles, protected from light"—(*U. S. P.*). Mr. Francis Hemm (*Amer. Jour. Pharm.*, 1894, p. 391) states that the process is not suitable to the wants of the retail pharmacist.

Several methods have been devised for the preparation of this powder, but the official process above described is probably as efficient as any. It is based upon Squibb's succussion process. The *Br. Pharm.* employs 1 part of mercury and 2 parts of chalk, but excludes the honey. In this preparation the mercury becomes minutely divided, with, perhaps, a conversion of a very little of it into mercurous oxide. It forms a powder of a gray color, which effervesces when diluted acids are added to it. When acetic acid is added, an insoluble precipitate remains, which is dissolved by diluted nitric acid, and consists principally of mercury. The substance under consideration is officially described as "a light gray, rather damp powder, free from grittiness, without odor, and having a slightly sweetish taste. If a portion of the powder be digested with warm acetic acid, the chalk is dissolved with effervescence, leaving a residue of finely divided mercury. The filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide). If another portion of the powder be digested with warm, diluted hydrochloric acid, the filtrate should not be affected by hydrogen sulphide T. S., or by stannous chloride T. S. (absence of mercuric oxide)"—(*U. S. P.*). This salt is used as a laxative, cholagogue, and alterative (many prominent old school physicians deny it these properties), though it produces all the deleterious constitutional effects of mercury, by continued use. It has been used in *biliary derangements, strumous diseases, syphilis in infants, diarrhœa*, etc. The dose for an adult is from 5 to 10 or 20 grains, 1 or 2 times daily; to children from 1 to 3 grains. It may be given alone, in powder, or in combination with rhubarb, bicarbonate of sodium, or other compatible agents. Jonathan Hutchinson regards this as the best preparation of mercury for use in *syphilis*.

Hydrargyrum Cum Magnesia, *Mercury with magnesia*, is used in the same doses and for the same purposes as the preceding compound. It is prepared by triturating together the same as in the above, 1 part of mercury with 2 parts of carbonate of magnesium.

Massa Hydrargyri (*U. S. P.*), *Mass of mercury, Blue mass, Blue pill.*—(See *Massa Hydrargyri.*) Blue pill is used as an alterative, sialagogue, and purgative, and is said to be less irritating than the other mercurials. It has been used in *constipation, biliary derangement, syphilitic diseases*, and wherever it is desirable to bring the system under the influence of mercury. As an alterative, 2 or 3 grains are given daily, or on alternate days, bedtime being usually preferred for their administration. As a purgative and reputed cholagogue, the dose is from 1 to 3 pills, to be taken on going to bed; when thus given, it is customary to administer a dose of castor oil, infusion of senna, or other cathartic on the next morning, as recommended by Abernethy. To cause salivation, from 3 to 5 grains, taken in the morning, and twice this quantity at bedtime, in conjunction with opium to prevent purging, is usually prescribed. Blue pill is frequently associated with other purgatives, as rhubarb, aloes, jalap, colocynth, etc., also with quinine, antimony, or other agents, according to the indications to be fulfilled.

Hydrargyri Cyanidum (*U. S. P.*), *Mercuric cyanide, Hydrargyri cyanuretum*, (*U. S. P.*, 1850), *Cyanuret of mercury, Mercurius cyanatus* (or *borussicus*), *Cyanuretum hydrargyricum, Hydrargyrum borussicum, Cyanide of mercury, Prussiate of mercury, Bicyanide of mercury.* $Hg(CN)_2$ = 251.76.—"Mercuric cyanide should be kept in well-stoppered, dark amber-colored bottles"—(*U. S. P.*). It may be easily prepared by dissolving red precipitate (*Hydrargyrum oxidum rubrum*) in diluted hydrocyanic acid, filtering and evaporating to crystallization, thus: $HgO + 2HCN = H_2O + Hg(CN)_2$. (For its preparation from ferrocyanide of potassium and mercuric sulphate, see directions in *U. S. P.*, 1850.) "Colorless or white, prismatic crystals, odorless, and having a bitter, metallic taste (the salt is exceedingly poisonous); becoming dark-colored on exposure to light. Soluble at 15° C. (59° F.) in 12.8 parts of water, and in 15 parts of alcohol; in 3 parts of boiling water, and in 6 parts of boiling alcohol; very sparingly soluble in ether. When slowly heated in a glass tube, the salt decrepitates, and decomposes into metallic mercury and inflammable cyanogen gas, which burns with a purple flame. On further heating, the blackish residue, consisting of para-cyanogen with globules of metallic mercury, is wholly dissipated. If 1 part of the salt be gently heated with 1 part of iodine in a dry test-tube, it will afford at first a yellow sublimate which afterward becomes red, and above this a sublimate of colorless needle-shaped crystals will be formed. On adding hydrochloric acid to the aqueous solution of the salt, the odor of hydrocyanic acid is evolved. A 5 per cent aqueous solution of the salt should be neutral to litmus paper, and should not yield, on the gradual addition of a few drops of potassium iodide T. S., either a red or a reddish precipitate, soluble in an excess of the precipitant, nor should it yield a white precipitate with silver nitrate T. S. (absence of mercuric chloride"—(*U. S. P.*). Mercuric cyanide is a corrosive poison, combining also the poisonous effects of prussic acid, but has been used in *venereal diseases, humid squamous tetters, porrigo,* and other *cutaneous diseases*, as well as in some *chronic inflammations.* It has also been advocated in *diphtheria.* Its dose is from 1/16 to 1/8 grain, in pill form, with opium and crumb of bread. Chibret claims to have averted meningeal infection from *panophthalmitis* by washing the contents of the eye with a solution of mercuric cyanide (1 to 15,000). An ointment for external application in skin diseases, etc., may be made by rubbing together cyanide of mercury, 16 grains, with lard, 1 ounce, and oil of lemon, 15 drops. Not employed in Eclectic therapeutics.

Hydrargyrum Ammoniatum (*U. S. P.*), *Ammoniated mercury* ($NH_2HgCl = 251.18$), *White precipitate, Mercuric ammonium chloride, Mercur-ammonium chloride, Mercurius præcipitatus albus, Hydrargyrum præcipitatum album, Hydrargyri ammonio-chloridum, Hydrargyrum amido-chloridum, Hydrargyri amidato-bichloridum, Hydrargyrum ammoniato muriaticum, White oxide of mercury, Infusible white precipitate.*—"Corrosive mercuric chloride, in powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; ammonia water, distilled water, each, a sufficient quantity. Dissolve the corrosive mercuric chloride in two thousand cubic centimeters (2000 Cc.) [67 fl℥, 300 ♏] of warm distilled water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of ammonia water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of distilled water and twenty cubic centimeters (20 Cc.) [325 ♏] of ammonia water. Finally, dry the precipitate between sheets of bibulous paper in a dark place, at a temperature not exceeding 30° C. (86° F.). Keep the product in well-stoppered bottles, protected from light"—(*U. S. P.*). The washing directed in the *U. S. P.* process with ammonia water is for the purpose of removing the ammonium chloride. If water only be used, the washing must be quickly performed, and cold instead of hot water employed. This will prevent the change into a basic salt—*oxy-dimercur-ammonium chloride* ($NH_2HgOHgCl$), a lemon-yellow compound. If iodine and ammoniated mercury be triturated together, nitrogen iodide (iodamine), will gradually form and after a time the mixture "puffs up." But should iodine and alcohol both be present a dangerous explosion results.

Ammoniated mercury is officially described as occurring in "white, pulverulent pieces, or a white, amorphous powder, without odor, and having an earthy, afterward styptic and metallic taste. Permanent in the air. Almost insoluble in water or in alcohol. By prolonged washing with water, it is gradually decomposed, assuming a yellow color, and becoming converted into a basic salt. Readily soluble in warm hydrochloric, nitric, or acetic acid, and in a cold solution of ammonium carbonate. Also completely soluble in a cold solution of sodium hyposulphite, with the evolution of ammonia. When this solution is heated for a short time, red mercuric sulphide is separated, which, on protracted boiling, turns black. At a temperature below a red heat the salt is decomposed without fusion, and at a red heat it is wholly volatilized. When heated with potassium or sodium hydrate T.S., the salt turns yellow, and evolves vapor of ammonia. The solution of the salt in diluted nitric acid, gives with potassium iodide T.S. a red precipitate, with silver nitrate T.S. a white one. The salt should be soluble in hydrochloric acid without effervescence (absence of carbonate), and without leaving a residue (absence of mercurous salt). Its solution in acetic acid should not be rendered turbid by diluted sulphuric acid (absence of lead)"—(*U. S. P.*). The salt, when heated to a temperature below a red heat, forms ammonia, nitrogen, calomel, and water. Caustic ammonia does not alter it. White precipitate is used externally only, in *herpes, impetigo, porrigo,* and other *affections of the skin,* and in *ophthalmia tarsi.* One part of the salt to 12 parts of lard, or simple cerate, forms an ointment for application in the above-named maladies. Rarely employed in Eclectic practice, but is a constituent in the popular old Eclectic Ophthalmic Balsam.

Mercuric-diammonium chloride ($[NH_3]_2HgCl_2$), *Fusible white precipitate.*—This compound was at one time confused with ammoniated mercury (NH_2HgCl). It is produced by boiling the latter with ammonium chloride solution, or by precipitating mercuric nitrate with ammonium chloride and potassium carbonate. It differs from ammoniated mercury in *fusing* at a temperature less than redness.

Mercurius Solubilis Hahnemanni, *Soluble mercury of Hahnemann, Ammonio-nitrate of mercury, Hydrargyrum oxydulatum nigrum, Hydrargyrum oxydulatum nitricum ammoniatum.*—This compound is of a variable composition; according to Mitscherlich, it is trimercuroso-ammonium nitrate ($Hg_3HN.NO_3)_2.2H_2O$. This Hahnemannian preparation is a velvety black powder, with a slightly metallic taste. It is sublimable without decomposition and contains no globules of metallic mercury. Hahnemann discarded this preparation in favor of Mercurius vivus (*Am. Hom. Pharm.*, which see for methods of preparation).

Hydrargyri Subsulphas Flavus (*U. S. P.*), *Yellow mercuric subsulphate* ($Hg(HgO)_2SO_4$ = 727.14), *Basic mercuric sulphate, Turpeth mineral, Yellow subsulphate of mercury, Subsulphate of mercury, Tribasic sulphate of the oxide of mercury, Hydrargyri oxidum sulphuricum, Hydrargyri subsulphas, Mercurius emeticus flavus, Turpethum minerale, Hydrargyrum sulphuricum flavum, Sulphas hydrargyricus flavus, Hydrargyri sulphas flavus* (*U. S. P.*, 1870), *Oxy-mercuric sulphate.* This preparation may be obtained by triturating mercuric sulphate with hot water; the yellow powder resulting therefrom is to be well washed with distilled water, and then dried. The *U. S. P.* process first prepares the mercuric sulphate, and afterward the subsulphate, as follows: "Mercury, one hundred grammes (100 Gm.) [2 ozs. av., 231 grs.]; sulphuric acid, thirty cubic centimeters (30 Cc.) [487 ♏]; nitric acid, twenty-five cubic centimeters (25 Cc.) [406 ♏]; distilled water, a sufficient quantity. Upon the mercury, contained in a capacious flask, pour the sulphuric acid, previously mixed with fifteen cubic centimeters (15 Cc.) [243 ♏] of distilled water, then add, very gradually, the nitric acid, previously mixed with twenty-five cubic centimeters (25 Cc.) [406 ♏] of distilled water, and digest at a gentle heat until reddish fumes are no longer given off. Transfer the mixture to a porcelain capsule, and heat it on a sand-bath under a hood or in the open air, with frequent stirring, until a dry, white mass remains. Reduce this to a fine powder, and add it in small portions at a time, with constant stirring, to two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏] of boiling distilled water. When all has been added, continue the boiling for 10 minutes; then allow the mixture to settle, decant the supernatant liquid, transfer the precipitate to a strainer, wash it with warm distilled water, until the washings no longer have an acid reaction, and dry it in a moderately warm place. Keep the product in well-stoppered bottles, protected from the light"—(*U. S. P.*). Boiling the mercury with sulphuric acid and hastening the process by nitric acid, results in the formation of mercuric sulphate. When this is added to boiling water, the basic or oxysulphate precipitates, while a corresponding quantity of sulphuric acid goes into solution. The temperature and quantity of the water influences the yield. About 75 per cent is realized. "A heavy, lemon-yellow powder, odorless and almost tasteless; permanent in the air. Soluble in about 2000 parts of water at 15° C. (59° F.), and in 600 parts of boiling water; insoluble in alcohol; readily soluble in nitric or hydrochloric acid. When heated, the salt turns red, becoming yellow again on cooling. At a red heat it is volatilized, evolving vapors of mercury and of sulphur dioxide, and leaving no residue. A solution of the salt in nitric or hydrochloric acid, diluted with water, gives with potassium iodide T.S. a red precipitate, and with barium chloride T.S. a white one. The salt should be completely soluble, in 10 parts of hydrochloric acid (absence of mercurous salt or of lead)"—(*U. S. P.*). Its aqueous solution is colorless. Its specific gravity is 6.444. Boiled with caustic soda or potash, a red precipitate is thrown down, while the solution contains sulphate of potassium. It was once employed as an emetic, in doses of from 3 to 5 grains, in *swelled testicle*, its nauseating and emetic action being supposed to promote absorption; it has also been recommended in *membranous croup*. In doses of from ¼ grain to ½ grain per day, it has been given as an alterative. One grain mixed with 5 or 6 grains of some mild powder, has been used as an errhine in *ophthalmic affections, chronic catarrh, cerebral difficulties*, etc.; it excites sneezing. One part of turpeth mineral triturated with 100 or 125 parts of lard, forms an ointment which has been used in frictions, in cases of *herpes, slightly inflammatory tetters*, etc. Like other mercurials, this is apt to cause salivation; and in improper doses acts as a violent poison. It is seldom used at the present day, and is even condemned as dangerous and superfluous by some of the old school authors.

HYDRARGYRI PERSULPHAS ($HgSO_4$). *Mercuric sulphate, Persulphate of mercury, Sulphate of mercury, Normal mercuric sulphate, Sulfas mercuricus, Hydrargyrum sulphuricum, Mercuricus vitriolatus.*—This salt is prepared by placing in a porcelain capsule, quicksilver, 10 ounces (av.), in 6 fluid ounces (Imp.), of commercial oil of vitriol; apply heat and constantly stir with a porcelain spatula until effervescence ceases, and nothing remains but a white and dry crystalline salt (Dub.). This accords with the *Br. Pharm.* process. The salt is a white, opaque solid, which becomes orange-colored at a dull red heat, but white on cooling; at a full red heat it is decomposed. Water decomposes it, producing turpeth mineral (which see), and a soluble persalt. It is not used as a medicine, but is employed in the manufacture of calomel, corrosive sublimate, and subsulphate (oxysulphate) of mercury.

HYDRARGYRI DIPERNITRAS, *Basic mercuric nitrate, Bibasic nitrate of mercury.*—Prepared by boiling mercury in strong nitric acid until the liquid, when diluted with water, ceases to yield a white precipitate (calomel) on the addition of a solution of common salt. Then concentrate until it has the sp. gr. 3.47. This liquor has an acrid, metallic taste, and colors the skin, when exposed to light, purplish red. By careful evaporation over concentrated sulphuric acid, crystals of the normal nitrate $(Hg[NO_3]_2)_2.H_2O$, are formed. When evaporated to crystallization, the bibasic nitrate $Hg_2O(NO_3)_2+2H_2O$, separates; if the crystals be washed with cold water, as long as it gives an acid reaction, a heavy yellow powder is obtained, which is a more basic nitrate of mercury ($Hg_8O_4[NO_3]_4$); this, when boiled in water, yields a brick-red powder, which is still more basic ($Hg_8O_5[NO_3]_2$). The bibasic nitrate of mercury is acrid and caustic, more so than the nitrate ($Hg[NO_3]_2$), and exerts an influence upon the system similar to that of corrosive sublimate, into which salt it becomes converted by the action of the alkaline chlorides in the alimentary canal. It is now seldom used.

HYDRARGYRI PHOSPHAS, *Mercurous phosphate, Phosphate of mercury, Protophosphate of mercury.*—This salt is made by triturating 8 parts of dry mercurous nitrate, in a porcelain mortar, with 16 parts of distilled water, in which is mixed 1 part of nitric acid, sp. gr. 1.20; to this is added about 60 parts of pure water, and the whole gently warmed until dissolved, filtered if necessary, the clear solution diluted with 8 times its weight of pure water, and then treated with a solution of crystallized sodium phosphate, so long as a precipitate is formed. Wash this carefully with water until it no longer gives an acid reaction, dry with a gentle heat, and keep in a closed bottle excluded from the light. It is a white, fine, crystalline, odorless, and tasteless powder. Heated it fuses, evolving oxygen and metallic mercury, and leaving a colorless, glacial mass, which is the phosphoric acid with a trifling quantity of mercury. It is insoluble in water, but is completely dissolved in nitric acid by the aid of heat. It has been highly spoken of as an efficient remedy in *secondary syphilis*, in doses of ½ grain or 1 grain in pill form. Phosphate of mercury 4½ grains, opium 3 grains, tartar emetic ½ grain, formed into 9 pills, with a sufficient quantity of conserve of roses, has been used with asserted advantage. One pill to be taken every night and morning.

HYDRARGYRI SULPHIDUM RUBRUM (HgS. Molecular weight: 231.78), *Red mercuric sulphide, Hydrargyri sulphuretum rubrum* (*U. S. P.*, 1870), *Sulphuret of mercury*; also known as [illegible] *lized*, or *Red sulphuret of mercury, Cinnabar, Vermilion, Paris red, Bisulphuret of mercury, Sulfuretum hydrargyricum, Hydrargyrum sulfuratum rubrum, Cinnabaris, Minium.*—This compound is found in large quantity in nature, and is the chief source from which mercury is prepared. The *U. S. P.* (1870), directed for its preparation: Gradually add to 8 troy ounces of melted sulphur, 40 troy ounces of mercury; stir continually, and heat until the mass commences to swell, then remove from the fire and cover the vessel closely to prevent its taking fire, and when cold, powder the mass and sublime it. Vermilion may also be prepared in the wet way by agitating mercury with a solution of sulphur in caustic potash. (For the details of Wittstein's process, see this Dispensatory, last edition.) When prepared by the first process, cinnabar forms in dark reddish-brown masses, composed of crystalline needles, which furnish a powder of a beautiful scarlet-red color. Prepared by the latter method, a fiery-red, soft, heavy powder is obtained, distinguishable from that prepared by sublimation, especially by its bright color. Cinnabar is odorless, tasteless, insoluble in water, alcohol, cold nitric acid (sp. gr. 1.2), cold hydrochloric acid, diluted sulphuric acid, and acetic acid. Hot nitric acid decomposes it, precipitating a portion of the sulphur, and converting the other portion into sulphuric acid, sulphate and nitrate of mercury; fuming nitric acid totally converts it into mercuric sulphate. Nitro-hydrochloric acid dissolves it with decomposition, sulphur being liberated and mercuric chloride and sulphuric acid being formed. Exposed to the light, it gradually acquires on the surface a gray tint, arising from the separation of the mercury and sulphur, both of which in their free state remain in admixture with the compound. Heated in a test-tube it acquires nearly a black color, and sublimes without fusing, to a shining iron-gray mass, becoming red on trituration; any adulterations in the cinnabar, as red lead, colcothar, chalk, or brick-dust, remain behind. If this residue yields on charcoal before the blow-pipe a bead of lead, red lead is present; but if it undergoes no change, either brick-dust or colcothar is present. If dragon's blood be present, it will color alcohol in which the cinnabar has been shaken. If the addition of a mineral acid causes effervescence, chalk is present. If cinnabar be boiled with acetic acid, iodide of potassium will give a yellow precipitate of iodide of lead in the filtrate, if red lead be present; and hydrogen sulphide a black precipitate. If it completely volatilizes upon heat *American vermilion* (basic lead chromate), is absent.

Cinnabar was formerly exhibited internally in *diseases of the skin, gout, chronic rheumatism*, and *worms*, in doses of from 10 to 20 grains, in pills, or incorporated in an electuary. It is at the present day rarely, if ever, used internally. In *syphilitic ulcerations* of the air passages, and in several *chronic cutaneous diseases*, it has been used as a fumigating agent, about ½ drachm being placed upon an iron plate heated to redness, and the vapors which are evolved being inhaled or directed upon the diseased parts. Owing to the irritating nature of the sulphurous vapor, the suboxide of mercury is preferred to cinnabar for fumigation.

HYDRARGYRI SULPHIDUM NIGRUM, *Black sulphide of mercury, Æthiops mineral, Hydrargyri sulphuretum nigrum, Black sulphuret of mercury, Amorphous sulphuret of mercury, Ethiops mineral, Hydrargyri sulphuretum cum sulphure*, etc.—It is procured by rubbing together, in a porcelain mortar, equal parts of mercury and washed flowers of sulphur (with the occasional addition of a few drops of water to prevent any dust from ascending), until they form a grayish-black powder, and neither mercury nor sulphur is visible with a magnifying glass; the labor is greatly diminished by employing diluted sulphide of ammonium instead of water. It is also formed by precipitating a solution of a mercuric salt with an excess of hydrogen sulphide gas. Black sulphide of mercury is a heavy, somewhat grayish-black, inodorous, tasteless, insoluble, amorphous powder, insoluble in water, hydrochloric acid, and diluted nitric acid, the latter taking up at the most only small traces of uncombined mercury. Heated in a test-tube, it first loses sulphur, which deposits on the cool portion of the tube, and partly combines with the oxygen of the air present, to sulphurous acid; then sulphide of mercury sublimes, and deposits itself as an iron-gray mass, becoming red when rubbed. If there is a residue, either the mercury or sulphur was impure, or charcoal may have been added. In composition it is undoubtedly black amorphous mercuric sulphide mixed with sulphur in excess.

Ethiops mineral was formerly employed as a diaphoretic, alterative, and vermifuge; in doses of from 5 grains to ½ drachm, 2 or 3 times a day, it has been used in *scrofulous* and *skin diseases*. It acts very mildly, and as stated by Dr. Duncan, may be continued for a considerable length of time in doses of several drachms without producing scarcely any sensible effect. It is seldom used, except in the form of ointment as an application to *itch, tetter*, and some other *cutaneous affections*.

HYDRARGYRI PROTONITRAS ($Hg_2[NO_3]_2$), *Protonitrate of mercury, Mercurous nitrate, Nitrate of mercury, Neutral nitrate of mercury.*—This salt is obtained by digesting excess of mercury in cold nitric acid until short prismatic crystals are formed. Nitrate of mercury may be distinguished from other nitrates by the white precipitate of calomel formed when it is dissolved in water and mixed with a soluble chloride, *e. g.*, sodium chloride. Nitrate of mercury is rarely used as a medicine, on account of its tendency to decompose. A solution of mercurous nitrate is one of the first steps in the preparation of citrine ointment. The composition of the salt after having been acted upon by the hot grease, is problematical, a portion of it probably being converted into mercuric nitrate, which change is accelerated by the free nitric acid. An ounce of the salt dissolved in ½ pint of distilled water, acidulated with 70 grains of nitric acid, and the solution made of sp. gr. 1.100, has been used as a mild caustic in *venereal ulcerations* and *growths*. Two parts of the salt to 50 of the lard, form an ointment which has been used in *lepra, psoriasis*, etc. In Eclectic practice brown citrine ointment has been used by Prof. Scudder and others in *chronic eczema, sycosis, barber's itch*, and some cases of *pruritis* (*Spec. Med.*)

HYDRARGYRI ET QUININÆ CHLORIDUM, *Chloride of mercury and quinine.*—Take 1 part of the bichloride of mercury, and 3 parts of hydrochlorate of quinine. Dissolve each separately in the least possible quantity of water, mix the solutions, filter, and dry the precipitate by a gentle heat. This has been used in *obstinate cutaneous diseases*, and in cases where it is desirable to produce the influence of quinine and mercury. The dose is from ½ grain to 1 grain, every 4 or 6 hours, in pill form with opium and crumb of bread.

HYDRARGYRI BORAS, *Borate of mercury.*—Rub together 11 parts of calomel and 13 parts of biborate of sodium, for about 15 minutes, then add small quantities of water from time to time, continuing the trituration throughout; then filter, wash the precipitate till the washings are tasteless, and dry. At one time recommended as a substitute for calomel, in doses of 2 grains daily, increasing gradually.

HYDRARGYRI BROMIDUM, *Mercurous bromide* (Hg_2Br_2), *Bromide of mercury.*—To a weak solution of mercurous nitrate add a solution of bromide of potassium so long as a precipitate falls· filter, wash, and dry by a gentle heat. It forms a white powder resembling calomel. This is given for the same purpose as the iodide of mercury, in doses of 1 grain per day, gradually increased. A *bibromide of mercury* (mercuric bromide [$HgBr_2$]), is made by mixing together equal parts of mercury and bromine; sublime the white powder formed by the mixture. It is white, soluble in water, alcohol, or ether; its solution gives a red or yellow precipitate with alkalies, and nitric or sulphuric acid decomposes it with evolution of vapors of bromine. It is a powerful poison, and has been recommended in *syphilis*, *lepra*, etc., in doses of $\frac{1}{20}$ grain, gradually increased to ¼ grain. It may be given in pill.

HYDRARGYRI ACETAS, *Acetate of mercury.*—It forms in rectangular tables and plates, having their angles frequently truncated. They are white, but become black on exposure to light are inodorous, of an acrid, metallic taste, and almost insoluble in water or alcohol. Heat decomposes it. It has been occasionally used in *syphilitic affections*, in doses of from 1 to 5 grains. One or 2 grains dissolved in water, has been used as a wash in obstinate cutaneous affections. This salt is seldom used.

HYDRARGYRI BENZOAS ($Hg[C_6H_5COO]_2+H_2O$), *Mercuric benzoate.*—A crystalline, white powder, tasteless and odorless, and formed by mutual decomposition between a mercuric compound and an alkali benzoate. It dissolves easily in alcohol, solution of common salt, but sparingly in water. It may be used by injection (1 in 1000 or 1 in 2000), into the urethra for *gonorrhœa*, or it may be hypodermatically administered. For the first purpose it is added to an equal amount of sodium chloride, and for subcutaneous uses, combined with cocaine and sodium chloride (Stukowenkow).

HYDRARGYRI CARBOLAS, *Mercuric carbolate* ($Hg[C_6H_5O]_2$), *Mercuric phenylate* (*phenate*), *Hydrargyrum phenylicum*, *Mercuric diphenate* (Merck's).—Caustic potash 56 parts, carbolic acid (liquefied), 188 parts. Dissolve by aid of heat in just enough alcohol to effect solution, and add, with continual stirring, corrosive sublimate (135 parts), dissolved in alcohol. Evaporate. The yellowish precipitate becomes nearly colorless as dryness approaches. Wash with water slightly acidulated with acetic acid, and crystallize from boiling alcohol. This compound forms stable, needle crystals, colorless, soluble in hot alcohol, alcoholic ether, ether, and glacial acetic acid; not soluble in alcohol and water. Reputed antisyphilitic. Dose, ⅛ to ¼ grain, twice a day. An inferior, less stable preparation, known also as mercuric phenate, is *basic mercuric phenate* ($HgOHOC_6H_5$) (Gamberini's).

HYDRARGYRUM BICHLORATUM CARBAMIDATUM SOLUTUM, *Solution of mercuric chloride and urea.*—This preparation quickly undergoes change, and is generally directed to be prepared extemporaneously. Dissolve mercuric chloride (1 Gm.) in hot water (100 Cc.); when cold, add urea (5 Gm.). Filter. Dose, 1 Cc., equal to ⅙ grain, once a day, hypodermatically, for *syphilis*.

HYDRARGYRUM FORMAMIDATUM SOLUTUM, *Solution of mercuric formamide.*—This is prepared by dissolving the oxide, freshly precipitated, from 10 Gm. of mercuric chloride, in enough formamide to dissolve it, and bringing the measure to 1000 Cc. with distilled water. Dose, 1 Cc. (16 minims), equal to ⅙ grain, hypodermatically, in *syphilis*.

HYDRARGYRUM PEPTONATUM SOLUTUM, *Solution of mercuric peptonate.*—Prepared by mixing aqueous solutions of mercuric chloride and dry peptone, filtering, and adding sodium chloride to the solution, and bringing the whole to the desired strength with water. The dose, hypodermatically, is 1 Cc., equal to ⅙ grain of mercuric chloride. *Gluten peptone sublimate*, in 1 per cent solution (25 per cent mercuric chloride), has been recommended as a substitute.

HYDRARGYRUM TANNICUM OXYDULATUM, *Mercurous tannate*, *Hydrargyri tannas.*—This was introduced by Lustgarten as possessing advantages over other mercurials in *syphilis*. It is prepared by precipitating freshly prepared mercurous nitrate with a strong solution of tannic acid. Three to 5-grain doses are administered daily until 150 grains have been taken. It is without taste or odor, insoluble in the common solvents, and yields its tannin to alcohol or water. It contains about 50 per cent of mercury.

HYDRARGYRI SALICYLAS, *Neutral*, or *Secondary mercuric salicylate.*—From mercuric chloride (27 parts), precipitate oxide of mercury, wash it well, and rub with water to a soft magma. Add salicylic acid (15 parts), heat on a water-bath, and shake frequently until the yellowness changes to snow-white. Wash the resulting salicylate with warm water to remove all free acid, drain, and dry. It forms an odorless, tasteless, non-crystalline salt, soluble in solution of sodium chloride, and in soda solution (a double salt forming), but not soluble in water or alcohol. It is administered in pill, the dose being ⅛ to ½ grain, three times a day, the dose being gradually increased to 1 to 1½ grains. Preferred by Aurajo and others, over other mercurials as an antiseptic and antisyphilitic.

HYDRARGYRI ET ZINCI CYANIDUM, *Mercuric and zinc cyanide* ($Zn_4Hg[CN]_{10}$).—An insoluble white powder, lauded by Lister as a non-poisonous antiseptic.

HYDRARGYRI OXYCYANIDUM, *Oxycyanide of mercury* ($Hg_2O[CN]_2$).—A solution in water (1 to 1500) of this compound is recommended as an antiseptic in ocular therapeutics.

Hydrargyri Pyroboras, *Mercury pyroborate* (HgB_4O_7).—An insoluble, non-crystalline, brown powder, recommended as a topical agent in *syphilitic* and other *ulcerations*.

Among other mercurials, the following are newer introductions for use in *syphilis: Thymolsulphate of mercury* ($[(C_{10}H_{13}O)Hg.Hg]_2SO_4$); *Thymolacetate of mercury* ($[C_{10}H_{13}O].Hg.Hg.C_2H_3O_2$); *Thymolnitrate of mercury* ($[C_{10}H_{13}O]Hg.HgNO_3$); *Naphtholate of mercury* (mercury 30.8 per cent), a yellow powder; and *Tribromphenol acetate of mercury*. *Hydrargyri sulphocyanas* or *Sulphocyanate of mercury* (sulphocyanide formerly), is employed in making the trinket, "*Pharaoh's Serpent.*"

HYDRARGYRI CHLORIDUM MITE (U. S. P.)—MILD MERCUROUS CHLORIDE.

"Obtained in the form of powder by the rapid condensation of the vapor of mercurous chloride. Mild mercurous chloride should be kept in dark amber-colored bottles"—(*U. S. P.*).

Formula: Hg_2Cl_2. Molecular Weight: 470.34.

Synonyms: *Calomel, Mild chloride of mercury, Hydrargyri subchloridum, Hydrargyri chloridum, Hydrargyrum chloratum dulce, Hydrargyrum muriaticum dulce, Chloruretum hydrargyrosum, Chloretum hydrargyrosum, Mercurius dulcis, Calomelas, Mercurous chloride, Subchloride (Submuriate) of mercury, Protochloride of mercury.*

Preparation.—Calomel is never prepared by the pharmacist. "Take of persulphate of mercury 10 ounces (av.), mercury 7 ounces (av.), chloride of sodium, dried, 5 ounces (av.), boiling distilled water a sufficiency. Moisten the persulphate of mercury with some of the water, and rub it and the mercury together until globules are no longer visible; add the chloride of sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling distilled water until the washings cease to be darkened by a drop of sulphhydrate of ammonium. Finally, dry at a temperature not exceeding 100° C. (212° F.)"—(*Br. Pharm.*, 1885).

In this process double decomposition takes place, as follows: $2NaCl+Hg_2SO_4=Na_2SO_4+Hg_2Cl_2$. Mercurous chloride sublimes, and if passed into a small receiver crystalline crusts or masses are obtained; if in a large receiver, as directed, a fine crystalline powder results. A still softer or finer powder may be obtained if a jet of steam be allowed to pass into the receiver, or, according to Soubeiran, if a blast of cold air be admitted. The best calomel is that produced by aid of the steam vapor, as this agent at the same time dissolves out any mercuric chloride which may be present, due to possible admixture of the mercurous sulphate employed with mercuric sulphate.

Description and Tests.—"A white, impalpable powder, becoming yellowish-white on being triturated with strong pressure, and showing only small, isolated crystals under a magnifying power of 100 diameters. It is odorless and tasteless, and permanent in the air. Insoluble in water, alcohol, or ether, and also in cold dilute acids. When strongly heated, it is wholly volatilized, without melting. In contact with calcium hydrate T.S., or with solutions of alkali hydrates, or with ammonia water the salt is blackened. When heated with dried sodium carbonate in a dry glass tube, it yields metallic mercury"—(*U. S. P.*). Calomel is incompatible with the alkalies, lime-water, and sulphide of potassium, which blacken it, forming the suboxide or black oxide of mercury (Hg_2O); also with antimony, copper, iron, lead, etc. It has been stated that if calomel be given at the same time with either common salt, nitrohydrochloric acid, or the alkaline chlorides, it may give rise to serious, if not fatal results. This is due to the calomel being soluble in aqueous solutions of alkali chlorides, especially in solution of chloride of ammonium at 40° to 50° C. (104° to 122° F.). When warmed for several hours to this temperature, 100 parts of sodium chloride, dissolved in 833 parts of water, form 0.33 parts of corrosive sublimate from 25 parts of calomel, (equal to 1.2 per cent) (Mialke, in A. M. Comey, *Dict. of Chem. Solubilities*, 1896). Likewise, calomel should never be given in connection with articles containing hydrocyanic acid, either in a free or latent condition, as it may be converted into the bicyanide of mercury, and mercuric chloride. The alkaline earths and carbonates (calcium carbonate excepted), and citric acid, convert it partially into corrosive sublimate. The same is effected when it is rubbed with sugar contaminated with lime, but not when lime-free. Calomel of a gray color contains free mercury. If cold water which has been agitated with it for some time gives, with sulphide of ammonium, a black precipitate, it contains corrosive sublimate. Ether, in this case, readily dissolves out the corrosive sublimate. In testing calomel for corrosive sublimate, it must not be treated with boiling water, since calomel is slowly decomposed with boiling water, corrosive sublimate being formed. After 1 hour's boiling of calomel with 20 Cc. of water, 2 Mgr. of corrosive sublimate were in solution (A. M. Comey, see above reference). "If 1 Gm. of the salt be shaken with 10 Cc. of water or alcohol, the respective filtrates should not be affected by hydrogen sulphide T.S., or silver nitrate T.S. (absence of mercuric chloride), nor should they leave any residue on evaporation (absence of other soluble impurities). On heating a portion of the salt, in a test-tube, with potassium or sodium hydrate T.S., it should not evolve the odor of ammonia; and if another portion be shaken with acetic acid, the filtrate should not be affected by hydrogen sulphide T.S., nor by silver nitrate T.S. (distinction from and absence of ammoniated mercury)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See remarks under *Hydrargyri Chloridum Corrosivum.*) Internally, calomel acts as a *purgative*, in doses of from 2 to 5 grains; on account of its uncertainty of action, it is usually given in combination with other purgatives, as jalap, senna, scammony, colocynth, etc. It has been much used as a purgative in *torpid states of the bowels*, in *torpor of the liver*, *deranged conditions of the biliary organs*, *jaundice*, some *febrile disorders*, *worms*, *dropsy*, and various *disordered conditions of the alimentary canal unaccompanied by inflammation*. Large doses of calomel, as 20 to 40 grains, every half hour or hour, are said to act as a *sedative*, and have been administered in *yellow fever*, *dysentery*, *Asiatic cholera*, *diseases of the liver*, etc. As an *alterative*, it has been exhibited in *chronic cutaneous diseases*, *glandular affections*, *hepatitis*, etc., in doses of from ½ to 1 grain every 1 or 2 days, as circumstances may require, with occasional doses of castor oil, or some mild saline laxative to keep the bowels free. As a *sialagogue*, it has been used in various forms of disease, as all *febrile*, *inflammatory*, *syphilitic*, and *chronic visceral diseases*, etc., in doses of 1, 2, or 3 grains, every 3 or 4 hours, usually combined with Dover's powder, or some other opiate, when there is no condition of the nervous system contraindicating the use of narcotics. Very few, however, use it at the present day for its sialagogue effects; and it may be said the number who use it for the preceding affections is becoming less and less as the years pass by. Calomel increases the action of the secreting organs; when its use is continued for a long time, according to the susceptibility of the patient's system, it produces the constitutional effects of mercury. Sometimes it produces nausea, griping, and great faintness. Large doses are always dangerous, as the agent is very uncertain in its action at all times; I have known as small a dose as 3 grains to cause phagedenic ulceration of the face and jaw (King). This kind of ulceration is by no means uncommon among patients under mercurial treatment. Combined with other remedies, calomel is said to increase their effects—hence, those who use it have combined it with antimonials to promote *diaphoresis;* and with squills to favor diuresis in *dropsical affections.* Many judicious physicians of the regular school now condemn the employment of calomel in acute hepatitis, hepatic cirrhosis, hepatic abscess, acute yellow atrophy of the liver, jaundice from gall-stones, yellow fever, remittent fever, many acute inflammatory disorders, such as pneumonia, pleurisy, endocarditis, pericarditis, peritonitis, meningitis, etc. Notwithstanding that it has been shown to actually lessen the biliary discharge, it is still considerably used in so-called "*bilious attacks.*" Externally, it has been used as a snuff combined with other substances, in *nasal polypus*, and *diseases of the Schneiderian membrane;* and blown into the eye in *chronic rheumatic* and *scrofulous ophthalmia*, and *spots on the cornea*. One part of calomel to 8 parts of lard, is said to form an excellent ointment in *porrigo favosa*, *herpes*, *impetigo*, *lepra*, *psoriasis*, and other *chronic skin diseases*. *Condylomata* are treated among other ways, by dusting them with calomel; likewise *herpes* and *irritation around the genitalia;* also used to diminish *exuberant granulations*, and it forms an ingredient of some cancer powders. One drachm of calomel added to a pint of lime-water forms the BLACK WASH (*Lotio Nigra*), which is a favorite application with some old school physicians, to all *syphilitic ulcers*. Sometimes the wash is made 2 or 4 times the strength of the above. For further remarks, see any standard "regular" materia medica.

In the Eclectic school of medicine calomel in minute doses has been recommended by Webster (*Dynam. Therap.*), in *lethargic states* characterized chiefly by a long-continued tired feeling, associated with marked diurnal drowsiness and nocturnal wakefulness. The patient, though apparently in good health, awakens tired in the morning, is averse to exertion of any kind, and retires at night still tired, and the drowsiness is of such a pronounced character as to require much effort to remain awake. Such a condition, he states, often follows malarial infection, though he does not consider that it depends upon such a cause. The trouble must be idiopathic and not dependent upon "sympathetic local trouble." The dose is 2 or 3 grains of the 3 x trituration, 3 times a day.

Calomel forms an excellent topical application in *corneal ulcer* of a sluggish character. It should be freely dusted upon the lesions. *Phlyctenular conjunctivitis* may be similarly treated. Foltz warns us that it should not be used when corneal ulcers are forming, or when they are enlarging. He uses calomel to provoke irritative action in *superficial corneal opacities*, thereby inducing reparative action. Calomel forms a good application in *syphilitic chancre* and *chancroid*, particularly the latter. Prof. J. M. Scudder employed it in such lesions when the sores were pale and coated with a pultaceous secretion. Dose of calomel for specific effects, 2 or 3 grains of the 3 x trituration, 3 times a day. Not employed by Eclectics as a purgative. The use of calomel internally or locally is contraindicated while taking iodide of potassium, lest it be converted into iodide and iodate of mercury.

Specific Indications and Uses.—(See under *Hydrargyri Chloridum Corrosivum* for general indications for the mercurials.) Tired, apathetic, or lethargic condition, with marked drowsiness in daytime, and sleeplessness at night. Locally, to sluggish corneal ulcers and pale chancroids covered with a pultaceous secretion.

HYDRARGYRI IODIDUM RUBRUM (U. S. P.)—RED MERCURIC IODIDE.

FORMULA: HgI_2. MOLECULAR WEIGHT: 452.86.

SYNONYMS: *Biniodide of mercury, Red iodide of mercury, Hydrargyri periodidum, Periodide of mercury, Deutiodide of mercury, Hydrargyri iodidi rubrum, Mercuric iodide, Ioduretum hydrargyricum, Deutoioduretum hydrargyri, Biniodidum hydrargyri, Mercurius iodatus ruber.*

Preparation.—"Corrosive mercuric chloride, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; potassium iodide, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; distilled water, a sufficient quantity. Dissolve the corrosive mercuric chloride and the potassium iodide, each, in eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏] of distilled water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, under constant and very active stirring, into two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏] of distilled water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold distilled water, until the washings give not more than a slight opalescence with silver nitrate test solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stoppered bottles, protected from light"—(*U. S. P.*).

Description and Tests.—Mercuric iodide (HgI_2) is remarkable for its being *dimorphous, i. e.*, occurring in two different physical modifications. The salt, as obtained by the official process (precipitation), is scarlet red; this is the stable modification, which may be obtained also in quadratic crystals by crystallization from hot alcohol and other solvents. Heat converts this salt into the unstable, yellow modification which assumes the form of rhombic prisms when the salt is subjected to sublimation. These crystals turn red again upon cooling, but should they retain their yellow color upon cooling, friction with a hard body will suddenly restore it. The official salt is described as "a scarlet-red, amorphous powder, odorless and tasteless; permanent in the air. Almost insoluble in water, but soluble in 130 parts of alcohol at 15° C. (59° F.), and in 15 parts of boiling alcohol; also soluble in a solution of potassium iodide, or of mercuric chloride, and in a solution of sodium hyposulphite. When heated to about 150° C. (302° F.), the salt becomes yellow, but again assumes a red color on cooling; at 238° C. (400.4° F.), it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass, and at higher temperatures, volatilizes without decomposition, leaving no residue. On heating the salt with potassium or sodium hydrate T.S., and adding a little sugar of milk, metallic mercury is precipitated. When it is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved. If the salt be dissolved in hot alcohol, the solution, after cooling, should be colorless; and when this solution is diluted with an equal volume of water, it should not redden blue litmus paper (absence of mercuric chloride). If about 0.5 Gm. of the salt be shaken with 10 Cc. of water, the filtered liquid should not become more than very slightly colored by hydrogen sulphide T.S., nor give more than a slight opalescence with silver nitrate T.S. (limit of soluble chlorides or iodides)"—(*U. S. P.*). Fixed oils, chloroform, carbon disulphide, mercuric solutions, potassium chloride, and some ammonium compounds dissolve it. Red iodide of mercury enters into the formation of Mayer's and Nessler's *Test Solutions* (see *List of Reagents*).

Action, Medical Uses, and Dosage.—Mercuric iodide is an active poison, nearly as powerful as corrosive sublimate. In doses of $\frac{1}{16}$ of a grain, carefully augmented to $\frac{1}{4}$ of a grain, it has been largely employed in *syphilitic* and *scrofulous affections*. This is the preparation usually selected by Eclectic physicians when a mercurial is to be employed in *constitutional syphilis*, and in *cutaneous*, *ocular*, and *aural affections*, depending on a syphilitic taint. Its use was particularly advocated by Prof. Howe. The minute doses are usually preferred. The indications are those given under mercuric chloride (which see). In diseases of the eye, of syphilitic origin, as in *syphilitic iritis*, it has given results when iodide of potassium has failed. Similar results are obtainable in *keratitis, choroiditis, choroido-retinitis*, etc. Locally, it has been employed chiefly as Panas' solution, as in *incipient trachoma*, and in *phlyctenular* and *catarrhal conjunctivitis*. This solution (mercuric iodide 1 part, absolute alcohol 400 parts, and distilled water 20,000 parts) is frequently employed as an irrigating fluid for use previous to operations upon the eye, as in *iridectomy*, *removal of cataract*, etc. *Diseases of the internal and middle ear*, when of specific origin, frequently yield to the judicious use of this drug.

Externally, a solution of it, 6 grains to a fluid ounce of distilled water, has been used as a lotion to *scrofulous* and *syphilitic ulcers*, etc. An ointment composed of 2 grains of mercuric iodide, 40 grains of cerate, and 20 grains of almond oil, has also been used in *obstinate ophthalmia tarsi*, with thickening of the meibomian glands, *opacity of the cornea, obstinate venereal ulcers, chronic cutaneous diseases*, etc. A drachm each, of mercuric iodide, lard, and olive oil, has been successfully employed as a caustic application to *lupus*. It is to be used in very small quantities at a time, being careful to place it only on a limited amount of diseased surface, repeating its application about once in every week, and extending its action from one part of the disease to another, as the cure progresses (Cazenave, *Ann. de Therap.*, 1852, p. 175). Mercuric iodide may be administered in pill, trituration, or in solution in alcohol, or ether, to be administered in water. The dose ranges from $\frac{1}{1000}$ grain to $\frac{1}{4}$ grain, the doses of $\frac{1}{200}$ to $\frac{1}{60}$ grain usually being preferred by our physicians.

Specific Indications and Uses.—(See *Hydrargyri Chloridum Corrosivum*, for indications for, and general action of, the mercurials.)

Related Preparation.—SOLUTION OF IODO-HYDRARGYRATE OF POTASSIUM.—A preparation was recommended by Dr. Channing, called *Solution of iodo-hydrargyrate of potassium*, which is said to be efficient in *chronic tuberculous affections, dyspepsia, chronic hepatitis* and *splenitis, ague-cake, anasarca, ascites, scrofulous* and *syphilitic diseases, leucorrhœa*, and *menstrual derangements*, some *cutaneous affections*, etc. It is prepared by dissolving 7 grains of iodide of potassium in 2 fluid ounces of distilled water, and then adding 9 grains of mercuric iodide. There will be about 16 grains of the iodo-hydrargyrate of potassium in this solution, with a slight excess of iodide of potassium. The dose is 2, 3, or 5 drops, repeated 3 times a day; it may be given largely diluted with water, or in some vegetable alterative syrup.

Related Salt.—HYDRARGYRI IODIDUM FLAVUM (*U. S. P.*), *Yellow mercurous iodide*. Hg_2I_2 =652.66). *Hydrargyri iodidum viride* (*Pharm.*, 1880), *Protiodide of mercury, Yellow* [illegible] *iodide of mercury, Hydrargyri subiodidum, Subiodide of mercury, Protoiodide of mercury*. [illegible] *mercury, Hydrargyri iodidum* (*U. S. P.*, 1850), *Hydrargyrum iodatum flavum, Joduretum hydrargyrosum, Hydrargyri proto-ioduretum.* "Mercury, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; nitric acid, potassium iodide, distilled water, alcohol, each, a sufficient quantity. Mix twenty cubic centimeters (20 Cc.) [325 ♏], each, of nitric acid and distilled water, and, when the liquid is cold, pour it upon the mercury contained in a small glass flask. Set the mixture aside in a cool and dark place, and agitate it occasionally, until the reaction ceases, and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother liquid, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark place. When the salt is dry, weigh off forty grammes (40 Gm. [1 oz. av., 180 grs.] of it, and dissolve it in one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of distilled water, to which ten cubic centimeters (10 Cc.) [162 ♏] of nitric acid had previously been added. Having prepared a solution of twenty-four grammes (24 Gm.) [370 grs.] of potassium iodide in 1000 cubic centimeters (1000 Cc.) [33 fl℥. 391 ♏] of distilled water, slowly pour the solution of potassium iodide into that of the mercurous nitrate, with constant stirring, allow the precipitate to subside, decant the supernatant liquid, and transfer the precipitate, together with the remainder of the liquid, to a filter. When the precipitate has drained, wash it with distilled water until the washings no longer have an acid reaction upon litmus paper, and afterward wash it with alcohol, as long as the clear, colorless washings give any color with hydrogen sulphide test-solution. Lastly, dry the product in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep it in dark amber-colored vials, with the least possible exposure to light. Instead of weighing off forty grammes (40 Gm.) [1 oz. av., 180 grs.] of the mercurous nitrate as above directed, the whole of the crystallized salt may be taken and the amount of potassium iodide, etc., adjusted on the proportions given above"—(*U. S. P.*).

The process involved is represented by the equation: $2KI+Hg_2(NO_3)_2 \quad 2KNO_3+2\,HgI$). The potassium iodide must be added *to* (not the reverse) the solution of mercurous nitrate, to prevent the formation of mercuric iodide. The alcohol is employed to wash away traces of the mercuric iodide, should any be present. Its absence will be shown by the hydrogen sulphide test employed.

The official salt is "a bright yellow, amorphous powder, odorless and tasteless. By exposure to light it becomes darker, in proportion as it undergoes decomposition into metallic mercury and mercuric iodide. Almost insoluble in water, and wholly insoluble in alcohol or ether. When slowly and moderately heated, it assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is completely volatilized. When it is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved. In contact with a solution of potassium iodide, the salt is decomposed into mercuric iodide, which dissolves, leaving a residue of metallic mercury. If 0.5 Gm. of the salt be shaken with 10 Cc. of alcohol, a portion of the filtrate should be scarcely affected by hydrogen sulphide T.S., nor should it produce more than a very faint, transient opalescence when dropped into water; and if 5 Cc. of the filtrate be evaporated from a white porcelain surface, not more than a very faint, red stain should remain (absence of more than traces of mercuric iodide)"—(*U. S. P.*).

(Compare *Hydrargyri Chloridum Corrosivum.*) Yellow iodide of mercury is a powerful irritant poison, but has been administered in small doses in *syphilis* and *scrofula*, especially when they occur in the same individual. The dose is ¾ to 1 grain per day, cautiously carrying it to 3 or 4 grains. Children of 6 months old require $\frac{1}{16}$ of a grain, gradually increased to ½ grain. It may be given in pill form, conjoined with some narcotic, as conium, opium, etc.; or, 1 part of the iodide may be dissolved in 48 parts of ether, of which solution, 12 drops contain about ¼ of a grain. It is now preferred by some physicians in the treatment of *constitutional syphilis*. It is seldom employed by Eclectic physicians. Prof. Webster, however, declares that the 3x trituration (dose 2 or 3 grains), has a specific action upon the larynx, making it a prompt remedy in *hoarseness* and *croup* (*Dynam. Therap.*, p. 407). An ointment used as a dressing for *strumo-syphilitic ulcers*, and as an application to *sycosis, lupus, rosacea*, and other *tubercular skin diseases*, is made by triturating together 6 ounces of the iodide with a mixture of white wax 2 ounces, lard 6 ounces.

HYDRARGYRI OXIDUM FLAVUM (U. S. P.)—YELLOW MERCURIC OXIDE.

FORMULA: HgO. MOLECULAR WEIGHT: 215.76.

SYNONYMS: *Mercuric oxide, Precipitated oxide of mercury, Hydrargyrum oxydatum præcipitatum* (*vel flavum*), *Yellow oxide of mercury.*

Preparation.—"Corrosive mercuric chloride, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; soda, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; distilled water, a sufficient quantity. Dissolve the corrosive mercuric chloride in one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of warm distilled water, and filter the solution. Dissolve the soda (which should contain 90 per cent of sodium hydrate), in one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of cold distilled water, and into this solution pour gradually, and with constant stirring, the solution of corrosive mercuric chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the affusion and decantation of distilled water, using one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water each time. Collect the precipitate on a strainer, and continue the washing with warm distilled water, until a small portion of the washings, when poured on a little mercuric chloride test-solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.). Keep the product in well-stoppered bottles, protected from the light"—(*U. S. P.*). This is Dr. Hoffman's process, and is represented by the following equation: $HgCl_2 + (NaOH)_2 = (NaCl)_2 + HgO + H_2O$. An excess of alkali is essential, that brown mercuric oxychloride be not formed and precipitated with the oxide; for this reason the corrosive chloride must be poured into the alkaline solution. The soda solution must be free from carbonate, else a brownish mercuric carbonate will be formed. If the temperature be too high the tendency is to form a reddish-colored salt, therefore it is best to operate at as low a temperature as practicable, to produce the bright-yellow oxide.

Description and Tests.—"A light orange-yellow, amorphous, heavy, impalpable powder, odorless, and having a somewhat metallic taste; permanent in the air, but turning darker on exposure to light. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When moderately heated, the salt assumes a red color. At red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no residue. If 0.5 Gm. of the oxide be digested on a water-bath for 15 minutes, with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will be converted into white mercuric oxalate (distinction from red mercuric oxide). On dissolving 1 Gm. of the oxide in 100 Cc. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate T.S. (limit of chloride)"—(*U. S. P.*).

Action and Medical Uses.—This agent has not been employed in Eclectic practice as an internal medicine. It is, however, an important topical remedy in ocular therapeutics. For *ciliary blepharitis* the ointment is probably the best local application, especially in chronic cases. The dried scales should be softened and removed by means of an alkaline wash, as of potassium bicarbonate, and the lids dried. Then the ointment should be thoroughly applied to the margins of the lids. If too strong, marked irritation and conjunctival hyperemia may be produced. Foltz states that in *phlyctenular keratitis* in children it is indicated in nearly all cases (Webster's *Dynam. Therap.*). The ointment is also advised in *corneal maculæ, indolent corneal ulcers, conjunctival granulations, xerosis, episcleritis*, and *pannus*. Foltz declares it of negative value in *suppurative otitis media*, but has obtained good results from its use to heal the tympanic lesion after the cessation of the discharge. ℞ Yellow oxide of mercury, grs. xxx, petrolatum ℥j. Mix. An ointment containing 2 per cent each of the yellow oxide and morphine sulphate in connection with dry heat is reputed efficient in the early stage of *furuncular inflammation of the external auditory canal* (see also *Unguentum Hydrargyri Oxidi Flavi*).

Other Oxides of Mercury.—HYDRARGYRI OXIDUM RUBRUM (*U. S. P.*), *Red mercuric oxide, Peroxide of mercury, Red precipitate, Oxydum hydrargyricum, Hydrargyri nitrico-oxidum, Mercurius corrosivus ruber, Mercurius præcipitatus ruber, Red oxide of mercury, Deutoxide of mercury.* Formula HgO. Molecular weight: 215.76. Red mercuric oxide should be kept in well-stoppered bottles, protected from light. This preparation is obtained by dissolving mercury, 3 pounds, in nitric acid, 18 fluid ounces, and distilled water, 2 pints, with the aid of a gentle heat. Boil down the liquor and rub what remains to a powder. Put this into another very shallow vessel, and apply a gradual heat until red vapors cease to rise (*Lond.*). In this instance nitrate of mercury is first formed, and then decomposed by the aid of heat. A trace of nitrate is liable to remain if the heat is not sufficiently high; on the other hand, an excess of heat would cause decomposition of the oxide into mercury and oxygen, and consequent loss of oxide.

Officially described, it is in "heavy, orange-red, crystalline scales, or a crystalline powder, becoming more yellow the finer it is divided, odorless, and having a somewhat metallic taste, permanent in the air. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When heated to about 400° C. (752° F.), it becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no residue. If 0.5 Gm. of the oxide be digested, on a water-bath, with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will not change color within 2 hours (distinction from yellow mercuric oxide). If a little of the oxide be strongly heated in a test-tube, the vapors should not redden moistened blue litmus paper (absence of nitrate). On dissolving 1 Gm. of the oxide in 100 Cc. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate T.S. (limit of chloride)"—(*U. S. P.*).

Red precipitate is a powerful irritant, and when taken internally, even in small doses, readily excites vomiting and purging; large doses cause gastro-enteritis. It is rarely employed internally on account of these dangerous effects, though it has been recommended in *syphilitic diseases.* The dose of it is from $\frac{1}{16}$ to $\frac{1}{2}$ grain, combined with $\frac{1}{2}$ grain of opium, in pill form, to be repeated once or twice a day. It is principally used externally, as an escharotic and stimulant, to reduce *fungous fleshy excrescences*, to *chancres*, to excite certain *syphilitic ulcerations*, and *indolent ulcers* generally, and principally to reduce *chronic ophthalmia*, maintained by the ulceration of the free margin of the eyelids. One part of the finely levigated powder of red precipitate, mixed with 8 parts of simple ointment, forms a stimulating application to *ulcers*, *chronic ophthalmia*, some *diseases of the skin*, etc. Mackenzie recommends 1 part of the powdered red precipitate to be triturated with 8 parts of white sugar, a portion of which may be blown into the eye, through a quill, in *opacity of the cornea.* In *syphilitic ulceration of the throat*, *uvula*, *tonsils*, etc., the following has been recommended as a fumigation: Mix together red precipitate, 2 drachms; frankincense, myrrh, each, 40 grains; camphor, 16 grains. Throw a portion of this on a hot shovel, and inhale the vapor. It must be remembered that it is capable of being absorbed, and of producing very serious accidents. Rarely employed in Eclectic practice.

HYDRARGYRI OXIDUM NIGRUM, *Hydrargyri suboxydum* (Hg_2O) *Suboxide of mercury*, *Mercurous oxide;* also called *Protoxide*, *Gray* or *Black oxide of mercury*, etc.—This oxide is prepared by treating 1 part of finely divided calomel in a porcelain mortar, with 1 part of solution of caustic potash, sp. gr. 1.233, which has previously been diluted with 3 parts of water; after rubbing together for about $\frac{1}{2}$ hour, throw it on a filter, protecting the residue as much as possible from the light, and wash with cold water as long as the filtrate exhibits an alkaline reaction; then dry at the ordinary temperature, and keep in a vessel excluded from the light. An excess of potassa is necessary to insure the entire decomposition of the mercurous chloride; and heat, during the process, must be carefully avoided, as it will cause the protoxide to separate into mercuric oxide and mercury. Nevertheless, with every precaution, a small portion will decompose, and during the washing and drying the black color becomes tinged with green.

Pure mercurous oxide (suboxide of mercury), should be quite black, but from the presence of a little mercuric oxide, it has generally a green tinge; it is very heavy, inodorous, without taste, insoluble in water, alcohol, or alkalies, but readily soluble in diluted nitric acid, and acetic acid. It is readily decomposed by light, becomes olive-colored, and is resolved into mercuric oxide and metallic mercury. Heated in a tube it acquires at first a red color, from decomposition into oxide and metal, it then becomes darker, separating into oxygen and metal, and volatilizes without leaving a residue. Its purity may be determined by this last experiment. Its solution in diluted hydrochloric acid should give no precipitate with either potassa, or oxalate of ammonium; if any red oxide had been dissolved, the potassa would throw it down as a reddish or yellowish hydrate; if calcium be present, the oxalate will give a white precipitate. It is one of the least irritating of the mercurial preparations, when pure, and, like them, produces constitutional effects, especially when its use is continued for a time. In doses of from $\frac{1}{4}$ grain to 1 grain per day, it acts as an alterative; 2 or 3 grains, repeated every 3 or 4 hours, will produce salivation. On account of its varying composition, and tendency to operate severely, owing to the presence of mercuric oxide, it is seldom exhibited internally. One part of the mercurous oxide, well rubbed up with 3 or 4 parts of lard, has been used as a substitute for mercurial ointment.

HYDRASTININÆ HYDROCHLORAS (U. S. P.)—HYDRASTININE HYDROCHLORATE.

FORMULA: $C_{11}H_{11}NO_2HCl$. MOLECULAR WEIGHT: 224.97.

"The hydrochlorate of an artificial alkaloid derived from hydrastine, the latter being a colorless alkaloid obtained from hydrastis. Hydrastinine hydrochlorate should be kept in well-stoppered vials"—(*U. S. P.*).

Source.—The colorless alkaloid of hydrastis, hydrastine, when oxidized by such agents as sulphuric acid and manganese dioxide combined, or with potassium permanganate, platinic chloride, or chromic acid, yields an artificial alkaloid known as hydrastinine, and an acid, *opianic acid* (M. Freund and W. Will, 1885; also see Schmidt and Wilhelm, 1888). Hydrastinine is introduced into the *Pharmacopœia* for the first time in the form of the hydrochlorate. Its pharmacopœial recognition, however, has not been followed by any considerable use and physicians neglect it in favor of natural preparations of hydrastis.

Description.—This new salt is officially described as follows: "Light-yellow, amorphous granules, or a pale-yellow, crystalline powder, odorless, and having a bitter, saline taste; deliquescent on exposure to damp air. Soluble at 15° C. 59° F.), in 0.3 part of water, and in 3 parts of alcohol; difficultly soluble in ether or chloroform. When heated to 173° C. (343.4° F.), the salt undergoes partial fusion, but does not liquefy. Upon ignition, it is consumed, leaving no residue. The salt has an acid reaction upon litmus paper. A dilute aqueous solution of the salt (up to about 1 in 100,000), has a decided blue fluorescence. The salt dissolves in sulphuric acid with effervescence, coloring the acid yellowish-red. An aqueous solution of the salt is not precipitated by ammonia water. An aqueous solution of the salt yields, with silver nitrate T.S., a white precipitate insoluble in nitric acid. On adding to 2 Cc. of an aqueous solution of the salt (1 in 100), an excess of bromine water, a yellow precipitate is produced, which is dissolved by ammonia water to a nearly colorless liquid (difference from hydrastine, with which the ammonia produced a brick-red precipitate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Recent investigations of this body seem to indicate that paralysis (without tetanus) of the motor tract of the spinal marrow, is an effect of its physiological doses. Acting mainly upon the arterial walls, and less so upon the cardiac muscle, it increases arterial tension and slows the pulse, the latter effect being largely due to the irritation it produces of the pneumogastric nerve. Its chief use, and that for which it has been introduced, is in *hemorrhage from the uterus—menorrhagia, metrorrhagia*, etc., having been successfully treated with it. It has likewise been extolled in *endometritis* of a mild type, and *dysmenorrhœa* of a congestive form. The weight of testimony seems to favor the view that it acts upon the small arterial terminals in the uterine mucous surfaces, and that it possesses no oxytocic properties. On the other hand, there is good evidence that it produces strong tetanic contractions of the uterine muscles, producing abortion. Several abortions have thus been attributed to its use. It is asserted that it is preferable to ergot in controlling uterine hemorrhage. The astringent action of hydrastine was noticed by Prof. J. A. Jeançon in 1886 (see *Ec. Med. Jour.*, 1886, p. 586). Hydrastinine hydrochlorate is employed hypodermatically in doses of ½ to 1½ grain.

Specific Indications and Uses.—To control uterine hemorrhage, especially when due to congestion.

HYDRASTIS (U. S. P.)—HYDRASTIS.

"The rhizome and roots of *Hydrastis canadensis*, Linné"—(*U. S. P*).

Nat. Ord.—Ranunculaceæ.

Common Names: (See below.)

Illustrations: Lloyd's *Drugs and Med. of N. A.*, Pl. 8; Bentley and Trimen, *Med. Plants*, 1; Köhler's *Med. Pflanzen*, Pl. 180.

Fig. 136.

Dried rhizome of Hydrastis canadensis.

Botanical Source.—This indigenous plant has a perennial root or rhizome, which is tortuous, knotty, creeping, internally of a bright-yellow color, with numerous long fibers. The stem is erect, simple, herbaceous, rounded, pubescent upward, from 6 to 12 inches in height, becoming purplish, and bearing 2 unequal terminal leaves. The leaves are 2 only, alternate, palmate, with from 3 to 5 lobes, hairy, dark-green, cordate at base, veiny, the lower leaf petiolate, the other sessile, from 4 to 9 inches wide when full-grown, and the segments serrated. The flowers solitary, terminal, small, white or rose-colored, and borne on a peduncle about 2 inches in length. The calyx consists of 3 petaloid, deciduous, broadly-ovate, pale greenish-white, concave, slightly downy sepals, which fall away when the flower opens. The stamens are many, and longer than the pistils. Filaments flat, linear-lanceolate, and having the cells of an anther on their edge at the apex. Pistils several; ovary oval, glabrous and attenuated upward into a short style. Stigma obtuse and scarcely lobed. The fruit resembles a raspberry, is red, and consists of many little 2-seeded drupes collected into a globose head, each crowned with the persistent style; the seeds are nearly black, obovate, and polished, having a minute embryo at the base of a fleshy and oily albumen (L.—W.—G.).

History.—This plant is found growing in shady woods, in rich soil, and damp meadows, in different parts of the United States and Canada, but is more abundant west of the Alleghanies. From about 1847, and especially since the first appearance of the *Eclectic Dispensatory of the United States* (now *American Dispensatory*), in 1852, hydrastis has figured conspicuously among the leading Eclectic drugs, and few have been in greater esteem. This plant is well known to botanists as *Yellow puccoon* and *Orange root.* The present pharmacopœial name, *Golden seal*, was introduced by the Thomsonians, who employed the root to a limited extent. It has reference both to the color of the root and to its seal-like scars produced by the death of the stalk of the plant of the preceding year. It has several other common names, some of them applicable and some being shared by other plants, one in particular, *Yellow root*, being the commercial drug name for *Xanthorrhiza apiifolia.* Some of these common names are derived from some physical characteristics of the plant; others from its therapeutic uses; while still others have reference to its resemblance to other substances. The following are some of its popular appellatives: *Golden seal, Yellow puccoon, Yellow root, Orange root, Eye balm, Eye root, Ground raspberry, Indian paint, Yellow paint, Indian dye, Yellow eye, Jaundice root, Wild curcuma, Ohio curcuma, Curcuma, Golden root, Wild turmeric*, and *Indian turmeric.* In commerce, both golden seal and yellow root are the terms employed. The other names should be dropped, and only the name of golden seal, as recognized by the Pharmacopœia, should be retained. The scientific name *Hydrastis*, given it by Linnæus, on authority of Ellis, is a misnomer, derived from old English authorities, who supposed that the plant grew in boggy places, an error which also appears in Wood's *Class Book of Botany* (C. G. Lloyd), whereas the plant is never found in wet or boggy situations, on prairies, or in sterile soil, but rather in rich open woodlands, preferring a hillside richly strewn with leaf mold. An attempt, which unfortunately failed, was made by Miller, in 1759, to change the name to *Warneria*, in honor of Richard Warner, of Woodford, Essex, England.

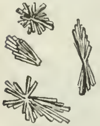
In our article on podophyllum, we call attention to the fact that that plant can not easily be exterminated by the advance of agriculture. With hydrastis, however, the opposite is true; the plant disappears as soon as the ground is disturbed by the settler. Once plentiful along the Ohio river banks, it is now found only in isolated spots, having suffered extermination as fast as the woodland yielded to the pioneer's axe. At present the geographical center of the plant is around Cincinnati. But four states now grow sufficient hydrastis to make it profitable for gathering for commercial use. These are Ohio, Indiana, Kentucky, and West Virginia. There is one redeeming feature, however, in the fact that in the mountainous parts of the states in which it grows, it is not very likely to disappear soon. These districts are inhabited by a class of individuals commonly known as "white trash," and also by negroes. They are perfectly contented to exist with the least possible exertion on their part, consequently they do not take kindly to cultivation of the soil. These virgin forests of the mountain contain an abundance of medicinal roots, among them hydrastis. While the plow exterminates it forever, simply digging the roots, as is done by these contented, happy root diggers, will never absolutely exhaust the resources of those regions. Hence, we may hope to have a moderate supply of this drug as long as these people are left to enjoy their seclusion; but it must grow scarcer each year, and, if the demand continues in medicine, increasingly more expensive.

Hydrastis is of very rapid growth, so much so that those who are searching for botanical specimens must be on the alert, as the plant, when favored by a continuance of warm weather during May, will, in a week or 10 days, send up a stem and open its blossom. This bloom is white and small, the stamens, on account of their whiteness, being the most conspicuous portion of the flower. The stem of the plant ranges from 6 inches to 1 foot in height, forking near the top, and each part of the division thus made, bears a roundish cordate leaf, each having from 5 to 7 lobes. These leaves, after the flowering periods, often become 6 or 8 inches broad, being but partly developed at the time of flowering. The lower leaf is the larger at this time, while the smaller is sessile at the base of the flower stem, enclosing the bud, and is but partially unfolded when the flower expands. A whole patch of hydrastis, for it grows in patches in rich, hilly woods, will not remain in bloom over a week. The fruit, consisting of several drupes aggregated together, known botanically as an *etærio*, matures in July. It resembles somewhat a red raspberry, though larger. Each of the drupes, which are from 8 to 10 in number, contains 1 round, shining, black seed, imbedded in a white, sweetish pulp.

Description.—The rhizome of hydrastis—the part employed in medicine—does not attain a very great size, for after from 4 to 6 years' growth, a gradual decay sets in at the end of the root remote from the stem. It consists of a crooked, knotty, wrinkled rootstock, 1 or 2 inches long, giving off a number of yellow fibers. The younger rhizomes are well marked on the upper surface with cup-like depressions, showing where the stems of the previous years were articulated. The cotyloid cavities become less marked as the rhizome advances in age, and it is from these seal-like depressions that the name, golden seal, is derived. Fresh hydrastis is vivid yellow, both within and without, but upon drying, becomes dull-brown. The best rhizome has a large amount of yellow juice, which, in drying may leave the interior yellow or orange-yellow, or, by aggregations of it, the central portion may assume a reddish hue. Dry hydrastis usually, however, is of a lemon-yellow color on fracture, if the root be not old. If old, it may be of a greenish-yellow hue, or even brown, the latter color being due to the disintegration of the yellow principles. Therefore, specimens of hydrastis, showing a greenish-brown or brown color, should be rejected as being of inferior quality. The juice was used by the Indians to color their clothing, and to stain their faces. Hydrastis has a peculiar odor and a bitter taste, added to which is a persistent acridity, which causes the abundant salivary flow following the chewing of the rhizome. Hydrastis loses about two-thirds of its weight by drying. Its virtues are imparted to water, glycerin, or alcohol. The official drug is thus described: "Rhizome about 4 Cm. (1½ inches) long and 6 Mm. (¼ inch) thick; oblique, with short branches, somewhat annulate and longitudinally wrinkled; externally brownish-gray; fracture short, waxy, bright reddish-yellow, with a thickish bark, about 10 narrow wood-wedges, broad medullary rays, and large pith. Roots thin, brittle, with a thick, yellow bark and subquadrangular, woody center. Odor slight, taste bitter"—(*U. S. P.*).

Chemical History and Composition.—The root of hydrastis contains the usual plant constituents, starch, albuminous matter, resin, sugar, fatty matter, inorganic salts, and three alkaloids, *berberine*, of yellow color, and *hydrastine* and *canadine*, both of which are white.

Fig. 137.



Crystals of Berberine, slightly magnified.

BERBERINE has received different names, according to the botanical sources in which it was discovered, and to this alkaloid the name *hydrastine* was first affixed. In 1824, Hüttenschmid found a yellow coloring matter in what he believed to be *Geoffroya inermis*, the Jamaica cabbage-tree, and gave it the name *jamaicine*. This substance, Wittstein (*Organic Principles of Plants*), accepts as berberine. In 1826, Chevallier and Pelletan found a rich yellow alkaloid in the bark of *Xanthoxylum Clava Herculis* (Hercules' club), which they named *xanthopicrite*. This was subsequently also proved identical with berberine. In 1828, C. S. Rafinesque, whose works were authority with the Eclectic fathers, stated in his *Medical Flora of the United States* (1828), that the constituents of Hydrastis canadensis were: "Amarin, extractive, several salts, and a peculiar principle, *hydrastine*, of a yellow color," taking pains to italicize the word *hydrastine*. Again, in 1830, Buchner and Herberger obtained from *Berberis vulgaris*, a purified yellow extract, which they named *berberine*. In 1839, Dr. George Kemp prepared a salt of berberine and picric acid, and was the first to class berberine among the alkaloids. This name at last superseded the terms *jamaicine*, *xanthopicrite*, and Rafinesque's *hydrastine*, although the latter name clung to it for a long time afterward. Even to this day, the name *hydrastine* is frequently preferred in America owing to the priority of the appellation given by Rafinesque, and, as an act of right, due to priority, it has been insisted upon by the earlier Eclectics. *Hydrastine* (*berberine*), was not the exact substance employed by the members of our school as a medicine, but rather a salt of the above was used—a hydrochlorate of hydrastine (muriate of hydrastine), which was called *hydrastine*, or *neutral hydrastine*. It was not shown to be a salt until after Durand (1851) gave a process for making a product similar to that which had long been prepared by Eclectic pharmacists and employed medicinally by Eclectic physicians. As late as 1862, Mr F. Mahla, of Chicago, proved this Eclectic hydrastine to be an alkaloidal salt, and showed that the base was *berberine*. Eclectic physicians, however, refused then to change the name of the medicinal salt, and to this day it frequently bear the old name, hydrastine.

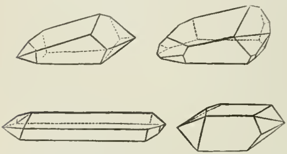
The demand for "concentrated medicines," or so-called "Eclectic concentrations," was the means of introducing *muriate of hydrastine* (*hydrochlorate of berberine*) into medicine. Arguing that if podophyllum yielded an active medicinal product by precipitation of its alcoholic preparations with water, the early Eclectics also thought that an active product could be thus obtained from hydrastis. Upon trial, a yellow, bitter, resinous body was obtained and put on the market as a "concentrated powder," under the name, *resinoid hydrastin*. It soon became evident that this resinous precipitate, or "resinoid," did not possess the medicinal qualities of the crude drug, hence a desire to further investigate led to the method of adding hydrochloric acid to the supernatant liquid after precipitation of the resinoid (which solution was shown to possess the major part of the active properties of the root), with the result of obtaining a very bitter, brilliant yellow precipitate. To distinguish it from the resinoid *hydrastin*, this yellow salt was called *hydrastin* (*hydrastine*) *neutral*, and was put on the market by three manufacturers under the following names: *Muriate of hydrastin*, *hydrastin neutral*, and *hydrastine*. The name *hydrastin neutral* being finally dropped, it entered the lists as *hydrastine*, *muriate of hydrastine*, and *hydrastin*, the resinoid of the latter name having gone out of market.

To recapitulate we find: (1) That the yellow alkaloid now known as *berberine* was the *hydrastine* of Rafinesque; (2) that the medicinal *hydrastine* of the Eclectic fathers was *hydrochlorate of berberine*, and was known to them as *hydrastine* or *neutral hydrastine*, or *muriate of hydrastin;* and still later as *hydrastin;* (3) that the name *hydrastin* originally referred to the resinous precipitate prepared by treating the alcoholic tincture with water and drying and powdering the precipitate. To make matters still worse a mixture of various substances supposed to represent all the peculiar constituents and virtues of hydrastis was named "*combined hydrastin*." This is the only drug now known simply as *hydrastin*, or combined principles *hydrastine*. Several berberine salts have been used in medicine. For further particulars concerning the early history of berberine, see J. U. and C. G. Lloyd (*D. and M. of N. A.*, Vol. I, p. 96.)

Berberine may be obtained by the following process, recommended by Mr. Wm. Procter, Jr.: "Take the root of Hydrastis canadensis, or of Berberis vulgaris, preferably the former, in coarse powder, exhaust it by repeated decoction or digestion in boiling water, and evaporate the filtered liquid to a soft extract. Treat this with stronger alcohol by digestion in a water-bath still, at several times until it is exhausted (or until a quart of alcohol has been employed for the extract from each pound of the root). Add to the tincture one-fourth of its bulk of water, distill off five-sixths of the alcohol, and add to the hot, watery residue an excess of diluted sulphuric acid, and allow it to cool. The sulphate of berberine crystallizes out, and if necessary, may be drained from the mother liquid, redissolved, in the smallest quantity of boiling water, and again crystallized. The sulphate of berberine thus obtained is dissolved in boiling water, and decomposed by the addition, in excess, of oxide of lead (freshly obtained by precipitation from the acetate or nitrate of lead by liquor potassa, and well washed), the solution being kept hot during the decomposition. When a drop of the hot, clear liquid will not be precipitated by baryta water or acetate of lead, the decomposition is finished. The solution should then be filtered off hot, evaporated, and set aside for crystallization" (*Amer. Jour. Pharm.*, 1864, p. 10).

The authors of *D. and M. of N. A.* prefer the preparation of berberine by the decomposition of berberine sulphate with a very slight excess of baryta water. *Berberine* ($C_{20}H_{17}NO_4$, J. Dyson Perrins, 1862) crystallizes in tufts of dark, brownred needles, soluble in water and alcohol, and practically insoluble in sulphuric ether, chloroform, carbon disulphide, and benzol. It forms crystallizable salts with acids, such as the hydrochlorate, the nitrate, the acid and the neutral sulphate (mono- and di-berberine sulphate), etc. It also forms a crystallizable compound with acetone, called *acetone berberine* ($C_{20}H_{17}NO_4.C_3H_6O$) (For the history and description of the salts. see *D. and M. of N. A.* The graphic formula of berberine was brought to light by W. H. Perkins. Jr., in 1890.

Fig. 138.



Crystals of Hydrastine, natural size.

HYDRASTINE, the principal white alkaloid of hydrastis, must not be confused with Rafinesque's *hydrastine* or with the Eclectic medicine *hydrastine muriate*. It was discovered in 1850, by Mr. Alfred B. Durand (*Amer. Jour. Pharm.*, Vol. XXIII, p. 13), who described it as being insoluble in water, sparingly so in cold ether and alcohol, more soluble in boiling ether, entirely soluble in chloroform and boiling alcohol, but speaks of the crystals as being of a brilliant yellow color, which was undoubtedly due to contamination with traces of berberine. Mr. J. Dyson Perrins (*Pharm. Jour Trans.*, May, 1862) was the first to obtain it white. Mr. F. Mahla, of Chicago, prepared it in 1863 (*Amer. Jour. Pharm.*, Vol. XXXV, p. 433), by adding aqua ammoniæ in slight excess to the mother liquor from which berberine was previously separated as hydrochlorate by the addition of hydrochloric acid. The crude hydrastine was then purified by recrystallization from alcohol. Also, see paper by Prof. F. B. Power, on the preparation of hydrastine in *Proc. Amer. Pharm. Assoc.*, 1884, p. 448. *Hydrastine* ($C_{21}H_{21}NO_6$, Freund and Will, *Ber. d. Deutsch. Chem. Ges.*, 1887, p. 88) is tasteless in the alkaline saliva; it forms salts with acids which, however, are not crystallizable. Its soluble salts are acrid, the hydrochlorate, and occasionally the citrate, being the preferred medicinal salts. Hydrastine salts in solution are decomposed by alkalies, which liberate the alkaloid as a precipitate. A fluorescent body has been found adhering to crystals of *hydrastine*, its effects are produced in the presence of alkalies (see *D. and M. of N. A.*, Vol. I, p. 143). The melting point of hydrastine, according to Prof. Power, is 132° C. (269.6° F.). By reduction with nascent hydrogen, this author obtained crystallizable *tetra-hydro-hydrastine*. *Hydrastine*, when oxidized in acid media, is converted into *opianic acid* ($C_6H_{10}O_6$) and *hydrastinine* ($C_{11}H_{11}NO_2$), Freund and Will, 1888; also see E. Schmidt and Wilhelm (*Archiv der Pharm.*, 1888, p. 353). In alkaline solution *methylamine* and *hemipinic* and *nicotinic acids* result. An interesting account of the chemical relationship between *hydrastine* and *narcotine* on the one hand, and *berberine* and *papaverine* on the other, is given by Dr. Alfred R. L. Dohme in the *Western Druggist*, 1895, p. 58. The statement made by Dr. Freund is also recorded, that hydrastine and berberine exist in the root of golden seal, most probably in the free state.

CANADINE ($C_{20}H_{21}NO_4$). In 1873, Mr. A. K. Hale (*Amer. Jour. Pharm.*, 1873, p. 247), announced the presence of a third alkaloid in hydrastis root, resembling berberine, but being darker in color, and behaving differently toward solvents. Mr. John C. Burt (*Amer. Jour. Pharm.*, 1875, p. 481), confirmed these observations. and gave additional reactions. Again, Mr. Herman Lerchen (*Amer. Jour. Pharm.*, 1879, p. 470), prepared the new base, naming it *xanthopuccine*, on account of the yellow color of the alkaloid as he obtained it. Lastly, F. Wilhelm, in Prof. Schmidt's laboratory, incidentally obtained minute quantities of a new alkaloid (*Archiv der Pharm.*, 1888, p. 345), which Prof. Schmidt named *canadine*, and which he believes to be identical with the third alkaloid of hydrastis obtained by his predecessors. More recently, Prof. Schmidt found *canadine* to be *tetra-hydro-berberine*, having the formula $C_{20}H_{21}NO_4$ (*Archiv der Pharm.*, 1894, pp. 136–154; also see resume by Mr. F. X. Moerk, in *Amer. Jour. Pharm.*, 1894, p. 304). *Canadine* forms an almost insoluble nitrate by means of which the alkaloid was obtained from hydrastis. The free base forms white, acicular crystals melting at 132.5° C. (270.5° F.). It is insoluble in water, soluble in alcohol, ether, chloroform, benzol, and hot petroleum-ether; the hydrochlorate and hydrobromate, especially in excess of acid, are not easily soluble, while the sulphate forms an exception, being soluble in water. When exposed to light, *canadine* gradually turns yellow, being converted into berberine, especially in sulphuric acid solution.

From the researches of Prof. Schmidt, it becomes probable that hydrastis root contains in addition several alkaloids related to those already known, but occurring only in minute quantity. (For a special dissertation on hydrastis, the reader is referred to Vol. I, of *D. and M. of N. A.*, by J. U. and C. G. Lloyd, from which publication is derived much of the botanical and chemical material embodied in this article on hydrastis.)

Medical History, Action, Uses, and Dosage.—For many years the salts of berberine and powdered hydrastis were the chief forms in which this drug was administered. At the present time these salts and the crude drug are but little used, and in this paper we shall confine ourselves principally to the liquid preparations of hydrastis—chief among which are the specific hydrastis and Lloyd's hydrastis. As there have been many preparations of this drug thrown on the market (since Lloyd's was introduced), under the name "colorless hydrastis," and accompanied by the statement that they are preparations of the white alkaloid *hydrastine*, it is but fair, in speaking of Lloyd's hydrastis, that we should state that it is not merely a solution of *hydrastine*, which is probably the least valuable constituent of hydrastis, but a preparation containing the *combined colorless constituents* of the drug. It is a well-known fact, though often overlooked by those who wish to make it appear that the alkaloidal constituents of a plant are alone the valuable and active therapeutic factors, that the combination or association of principles formed naturally in the plant, or held together naturally even when derived from the plant, more completely represents the crude drug than do the isolated and forcibly separated alkaloids, and that medicinal virtues are possessed by the former that can not be even approximated by the latter. Thus it is, that Lloyd's hydrastis is much superior as a remedy, than if it were merely a fluid preparation of the white alkaloid. From some experiments made by Prof. J. A. Jeançon (*Ec. Med. Jour.*, 1886, p. 586), with a concentrated solution of the associated colorless principles divested of the alkaloid, hydrastine, it was shown that marked therapeutic effects could be obtained from them alone. It acted principally as an astringent, gradually decreasing and finally arresting hypersecretion. As an intrauterine astringent he preferred it above all others. In determining its physiological effects, he administered it to animals in health, but could not observe any appreciable effect upon temperature, pulse, or respiratory apparatus. These physiological doses, however, produced constipation and anorexia. Thus, we observe, as is very frequently the case, a marked contrast between the almost negative physiological effects and the very positive therapeutic results. In this connection we can state that Prof. Lloyd has been led, from his great experience in observing the results of the uses of hydrastis, to seriously consider the advisability of excluding, to the great extent, the white alkaloid from Lloyd's Hydrastis. Reports, unquestionably reliable, indicate that it is often irritating and objectionable.

The whole drug, including the alkaloid hydrastine, appears to stimulate the respiratory and circulatory apparatus, imparting increased tone and power. Arterial tension is augmented, and blood pressure in the capillaries increased, rendering it valuable, like belladonna and ergot, in overcoming blood stasis. Its action upon the nervous system has been compared to that of strychnine (Ellingwood), though less energetic, but more permanent. Thus the tone imparted to the heart muscle is permanent, rather than intermittent or spasmodic (*ibid.*). The sensibility of the nerve endings is blunted by hydrastis in excessive doses, and in the lower animals large doses of the alkaloid have produced death. No such toxic action, however, has been observed upon man. Muscular nutrition is increased under the judicious administration of hydrastis, making it a valuable agent in *muscular debility*, and in altered states of the muscles, particularly of the unstriped variety.

It is a little singular that hydrastis was not mentioned by our earliest writers on indigenous materia medica, for it was in extensive use among certain of the aboriginal tribes of North America, being used both as a medicine and as a coloring material. Prof. Benjamin Smith Barton in his first edition of "*Collections for* *an Essay Toward a Materia Medica of the United States*" (1798), refers to the Cherokee use of it as a cure for cancer. Later, he calls attention to its properties as a bitter tonic, and as a local wash for ophthalmia From that time on it was endorsed by Rafinesque, Hand, Smith, and the various writers of the botanic and of the medical reform schools. The extensive range of uses given by the foregoing writers was not included in the first edition of the *American Dispensatory* (1852), Prof. King evidently believing the virtues of the drug to have been greatly overdrawn. He gave, however, a careful review of its properties and uses, and thus, for the first time, it became firmly established as an Eclectic medicine. At the present time it is a great favorite with Homœopathic practitioners and with a large proportion of Allopathic physicians. It was introduced into Homœopathic medicine by the late Prof. E. M. Hale, M. D., who was familiar with the Eclectic uses of the plant.

Hydrastis is bitter to the taste, and induces increased activity of the salivary glands. It sharpens the appetite and aids digestion when indicated. Schatz has shown that it increases contraction of the muscular fibers of arteries without affecting other muscular tissues of the tubular organs. He has also shown that it decreases congestion of the genito-urinary tract. Rutherford, who investigated it, concluded that it was a hepatic stimulant, and in less degree stimulant to the intestinal tract. Its power as a hepatic stimulant is, however, probably overrated, while as a stimulant of the gastric and intestinal mucous surfaces its action is marked. Hydrastis exerts its chief action upon the mucous and glandular structures, and to some extent, through its white alkaloid, upon the nervous system.

Hydrastis is a valuable drug in disordered states of the digestive apparatus, especially when functional in character. It is not adapted to all classes of cases, but is rather to be considered as indicated in disorders of a sub-acute character and in atonic states with increased flow of mucus. In *sub-acute and chronic inflammation with free secretion* it will be found to render good service. As a general bitter tonic it resembles, though does not equal calumba and gentian, but is more applicable to debilitated conditions of mucous tissues. Beginning at the mouth, its beneficial action may be traced throughout the alimentary canal. For *aphthous stomatitis* it is equaled only by coptis and phytolacca. It is not the remedy in this disorder when the mucous secretions are checked, but is best adapted to subacute forms, bordering on a chronic state. As a remedy for various *gastric disorders* it will take a leading place, especially if it be borne in mind that it is never beneficial, but on the contrary, does harm, in acute inflammatory conditions. When, however, the trouble is subacute and semi-chronic, and especially with mucorrhœa, or even secretion of pus, the drug will give good results. It is indicated in *gastric irritability*, relieving the irritation, and afterward restoring the tone of the parts. For years the powdered root was made into aqueous infusion, which, when cold, was employed with marked benefit, but now we have pleasanter preparations which give equally as good results without entailing the unpleasantness of swallowing a large quantity of bitter and crude medicine. Lloyd's hydrastis has proved an excellent form of administration in cases of "*ice water dyspepsia*," a diseased condition said to be peculiarly American, on account of the almost universal practice in this country of drinking ice water and iced tea. The hydrastis should be given in 10-drop doses, before each meal and at bedtime. *Chronic gastritis*, with increased secretion (*chronic gastric catarrh*), is often promptly met with this drug. It is very valuable in *gastric ulcer*. Several physicians have observed that it is a very useful remedy to exhibit in cases of gastric catarrh following the inordinate use of alcoholic stimulants. Prof. Bartholow, who among the "regulars," has made extensive use of hydrastis, goes so far as to state that in sufficient doses (tincture or fluid extract), it is probably the best substitute for alcoholic beverages when it is desired to abandon the use of spirituous stimulants. This statement is ridiculed by the therapeutic editor of the *National Dispensatory*. However, it is certain that it is valuable in any form of gastric disorder, no matter what its origin may be, if there be irritation, or subacute inflammatory symptoms *with increased secretion*—a condition of *atony*. In *chronic alcoholism* it may be associated with capsicum or strychnine, or both, together with a liberal quantity of beef tea and other easily digested food, regularly administered. Small doses of hydrastis will be found indicated in that form of *dyspepsia* exhibiting a belching of putrescent gases, and followed by a weakness, or sensation of "goneness" in the pit of the stomach. If great irritability of the stomach is present, minute doses of the fluid preparations or of hydrastine hydrochlorate are to be preferred. When there is less irritation and great inactivity, powdered hydrastis may be used. When the larger doses are employed it should be immediately after meals.

This drug is equally as beneficial in *catarrhal states of the intestines* and *gall ducts*. In *duodenal catarrh*, with jaundice, and in those forms of *catarrh of the biliary passages* due to accretions of inspissated bile mixed with crystallized cholesterin the remedy will be found serviceable if continued for a considerable length of time. Hydrastis should be remembered in *obstinate constipation*. It is especially useful in those disordered states due to *hepatic obstruction* or to *hepatic congestion*, accompanied or not with intestinal or biliary catarrh. The constipation best met with hydrastis is that hinging on atonic conditions of the intestinal glands, which may be gently stimulated to normal activity by small doses of either the specific preparation or Lloyd's hydrastis. Prof. King considered it a valuable tonic for enfeebled states of the alimentary tract in infants and children, and recommended it for the same purpose in convalescence from "severe attacks of *diarrhœa*, *dysentery*, and other debilitating maladies." Local application, with the internal use of hydrastis, has been resorted to in *hemorrhoids*, *fissured anus*, *ulcers* and *eczema of the anus*, and *prolapsed and ulcerated rectum*, with apparent benefit.

For the use of hydrastis in respiratory affections we insert the following from a previous article: "Golden seal is a valuable local agent in affections of the nose and throat. It acts as a subastringent tonic to the parts to which it is applied. Simple *catarrhal*, *follicular*, or *granular pharyngitis* is often cured by it. *Syphilitic ulcerations of the naso-pharyngeal passages* are relieved and often cured by it. The colorless hydrastis (Lloyd's) has a beneficial effect in the various forms of *sore throat*, *rhinitis*, and also *ulcerated* or *aphthous varieties of tonsillar*, *pharyngeal*, and *retro-pharyngeal catarrh*. *Subacute* and *naso-pharyngeal catarrh* where the mucous membranes are dry and parched, the secretions being altered in quantity and character, is cured by it. In *catarrhal hypertrophy* with profuse discharge and thickening of the Schneiderian membrane, this preparation is without an equal. It should be somewhat diluted, and is never the remedy for active, inflammatory lesions" (Felter). For that disagreeble state accompanying nasal and pharyngeal catarrh, in which the mucus forms in gelatinous masses and drops into the throat, hydrastis is probably without an equal. It should be applied locally and also administered internally. Locally, it is especially serviceable in subacute forms of *tonsilitis*, and occasionally in *diphtheria*. The drug is more especially indicated in catarrhal affections of any of the mucous membranes if there be also muscular debility.

In aural and ophthalmological practice this drug is a favorite local application. In the earlier history of its use as a medicine, infusion of the root, as employed by the Indians met by Captain Lewis, in 1804 (during the famous Lewis and Clark Expedition), and solutions of berberine salts, as used by the "Eclectic Fathers," were employed in various *ophthalmias*. These forms gave excellent results, the one objection to their employment being their staining qualities. At the present day these colored preparations are seldom used, but in their stead Lloyd's hydrastis gives fully as great satisfaction therapeutically, as well as being pleasant in taste and much more cleanly as a local application. It may be employed in the proportion of about 1 part in 10 or 20 of pure water in *conjunctival diseases*. It is only useful in superficial disorders of the eye, having no value in intraocular affections. It is valuable in all *conjunctival inflammations*, particularly so in the catarrhal forms. Foltz regards it as an excellent remedy in *follicular conjunctivitis*. *Superficial corneal ulcerations* are benefited by it, and in *ciliary blepharitis* it may be employed with confidence. It is well, however, in the latter disorder to wash the edges of the lids thoroughly with a weak solution of potassium bicarbonate, rinse well with pure water, and lastly apply the hydrastis lotion. It has been recommended and used with a degree of success in *trachomic lids*; but it is not nearly so effective in this complaint as the ointment of non-alcoholic thuja. The principal use of this drug in *ear diseases* has been for the cure of *purulent inflammation of the middle ear*, provided granulations do not exist. It may be employed here in both acute and chronic inflammations, and is especially indicated where the discharge is abundant. It may be dropped in the ear, or the ear may be cleansed with water to which a quantity of the medicine has been added. About 10 drops of solution (1 to 6 or 8) is about the proper amount to be employed when instilled into the aural aperture. Excellent results have been obtained by using it in this manner, mixed with specific hamamelis, to which water is added if too much smarting be produced. This combination has served us well in *eczema of the aural canal* and in *irritation* due to *inspissated cerumen*, the latter being readily softened by it.

Prof. Webster (*Dynam. Therap.*) calls attention to the use of specific hydrastis in cases of *myalgic tenderness and soreness.* He regards it as indicated where the unpleasant symptoms are masked during rest but aggravated by pressure and by motion. These myalgic symptoms may be due to various causes, often resulting as reflexes from *uterine, rectal*, and *prostatic disorders.* He also includes in the category of myalgic complaints, *headaches* resulting from reflexes in which the scalp-muscles are involved; *pectoral tenderness* due to lacerated cervix uteri; and the *muscular pains* caused by *anemia*, resulting from *uterine, hemorrhoidal*, and other *hemorrhages.* The dose recommended is from the fraction of a drop to 1 drop.

Taking advantage of the results of Prof. Schatz's investigation of the action of this drug on the circulation, several physicians have employed it in hemorrhagic conditions and in pathological states upon which hemorrhages are likely to depend. Schatz found it useful in *hemorrhage from uterine fibroids (myomata); congestive dysmenorrhœa; hemorrhage in virgins*, persisting even after the use of the curette; *hemorrhages from subinvolution, endometritis, metritis, parametritis, cicatrices, stenotic conditions*, and *climacteric hemorrhage.* Operations and other means had failed in the cases above mentioned, but hydrastis cured. The dose administered was 20 drops of the tincture 3 times daily. Too small a dose is without this controlling power over the walls of the vessels, according to Schatz, while large doses have an effect further than is desired. It is too slow a remedy for active *post-partum hemorrhage*, but may be employed for the control of *passive hemorrhage.* It is useful in *metrorrhagia.* Like ergot, it may be employed for the relief of chronic *cerebral hyperæmia*, and other forms of *cerebral engorgement.* Other observers have seen its beneficial action in the cure of *fungoid endometritis, lacerated cervix*, and *pelvic cellulitis.* Locally and internally, excellent results are obtained from hydrastis in *leucorrhœa*, both vaginal and uterine. For *gonorrhœa*, Lloyd's hydrastis probably enjoys a more extensive use as a local application than any other drug, and this use of it is not confined to Eclectic practitioners alone. For *gleet* it is equally as beneficial. For this purpose it may frequently be combined with aqueous thuja. Salts of zinc and lead, in very small amounts, may be added to the solution of hydrastis. If carefully employed, stricture as a result need never be feared. Other preparations of hydrastis will give good results, but their staining qualities condemn them. To Prof. John King must be accorded the first mention of this use of the drug. He also used it successfully in "*incipient stricture, spermatorrhœa*, and *inflammation and ulceration of the internal coat of the bladder.*" As a remedy for *cystitis*, it may be given internally, and used largely diluted to wash out the bladder. Prof. Jeançon, in discussing the concentrated solution of the associated principles of hydrastis (devoid of hydrastine), says: "Formerly, I used to apply locally a tampon or wad of absorbent cotton, well saturated with a solution of the double sulphate of alumina and copper, in cases of *cervical erosions* and *light papillary vegetations.* Now I apply the cotton saturated with the concentrated solution of these hydrastis substances, and find that the effect is all that can be desired. The eroded surface becomes smooth, the vegetations disappear, and a fine glistening layer of mucous structure soon makes its appearance."

Hydrastis has been used to some extent in *cutaneous diseases.* Prof Jeançon cured a stubborn case of *eczema of the scrotum* with it. Other cases of *eczema*, depending upon gastro-intestinal disturbances, have been cured by its internal exhibition alone. *Acne, seborrhœa sicca* or *oleosa, scrofula, acne rosacea, lupus, sycosis, boils, carbuncles*, and *ulcers*, when dependent upon gastric difficulties, have been greatly benefited and some cases cured by the internal use of the drug alone. The local use at the same time hastens the cure. Eczematous manifestations around the outlets of the body also yield to the kindly action of golden seal locally applied It has been said to cure *cancer*, though this use of the drug is overrated. Still.

many believe it to have a beneficial effect in prolonging life and in mitigating the severity of the disease. On this point Prof. Scudder remarks, "In some cases of cancer with sloughing of tissues, and in malignant ulceration, no application will do more to retard the progress of the disease than an infusion of the crude article or a solution of the alkaloid (*berberine*). It has been claimed that the internal administration of the remedy alone will prove curative. I am satisfied that in some cases this use of hydrastis will do much to relieve pain and lengthen life, even if it does not prove curative." Hale and others consider the long-continued use of hydrastis internally excellent in retarding *scirrhus of the breast*, when the tumor is hard and painful, but has not yet advanced to ulceration.

Hydrastis should be remembered in *convalescence from diseases* having excessive mucoid discharges, or where hemorrhage has played an important part. For *malarial disorders* it probably has but little to recommend it. It has been used as an anti-malarial drug, but as it has usually been employed with some of the cinchona alkaloids, the beneficial, or at least the antiperiodic effects were probably due to the latter. Hydrastis should not be overlooked, nevertheless, in convalescence from *general debility*, *protracted fevers*, *inflammatory affections*, and *nervous prostration*. Hence it is useful to combine with it capsicum, strychnine, nux vomica, iron salts, and quinine, when there are clear indications for their selection. *Prostrating night-sweats* are very often controlled by it. In hepatic and stomachic disorders it may be greatly aided by iris, phytolacca, bryonia, arnica, leptandra, chionanthus, and podophyllin, provided any of these are indicated. Powdered hydrastis and the extract are now seldom employed. The usual dose of specific hydrastis ranges from the fraction of a drop to 30 drops; of Lloyd's hydrastis, from 5 drops to 1 drachm; of infusion of hydrastis (℥i to aqua Oj) from ½ to 2 fluid ounces; locally, Lloyd's hydrastis, from full strength (ulcerated cervix uteri), to a dilution of 1 in 20 in water. Dose of the powder, from 10 to 30 grains; of the tincture, from 1 to 2 fluid drachms; of the hydro-alcoholic extract, from 2 to 5 grains; of the fluid extract, 10 to 60 minims; hydrastine (Eclectic), 1 to 6 grains; of hydrastinine hydrochlorate, ¼ to 1½ grains; berberine (see below), 2 to 20 grains; berberine hydrochlorate, 1 to 5 grains; berberine sulphate, 1 to 5 grains.

Specific Indications and Uses.—Hydrastis is specifically indicated in catarrhal states of the mucous membranes, when unaccompanied with acute inflammation. An apparent exception to this is in acute purulent otitis media, in which it is said to act better than in chronic conditions; gastric irritability; irritation of parts with feeble circulation; muscular tenderness and soreness, worse under pressure or on motion; passive hemorrhages from uterus and other pelvic tissues; skin diseases depending on a gastric abnormality, indicating hydrastis.

Related Drug.—*Cœlocline polycarpa*, A. De Candolle (*Unona polycarpa*, De Candolle), *Yellow-dye tree of Soudan*, *Berberine tree*. An African tree inhabiting Sierra Leone, Soudan, and other points in western Africa, which, when wounded, exudes a juice which leaves an indelible yellow stain upon linen, and tinges the saliva yellow. It is used as a yellow dye by the natives, and imparts both color and bitterness to water. Stenhouse has shown the coloring principle to be *berberine*. Medicinally, it has been used in decoction and powder by the inhabitants of Sierra Leone, as a topical dressing for *obstinate ulcerations*.

Preparation of Hydrastis.—LIQUID HYDRASTIS. This is a glycerin preparation introduced by the William S. Merrell Chemical Company, of Cincinnati, and is properly a specialty of this firm. Fluid hydrastis is employed both externally and internally.

Related Preparations.—BERBERINE AND ITS SALTS. *Berberina*, *Berberine*. For a description of *berberine* see above.) Berberine is an excellent tonic, and also appears to possess slightly laxative properties. It will be found to exert an efficient action upon all abnormal mucous tissues, and may be employed in cases where barberry or hydrastis is indicated. It may be used in powder, in doses of from 2 to 20 grains; or in water, to which citric, tartaric, or acetic acid has been added to aid its solution. *Acetate of berberine* will be found a very soluble salt, and of much efficacy.

BERBERINÆ HYDROCHLORAS, *Berberine hydrochlorate* (see above).—Hydrochlorate of berberine is a tonic, with an especial action on diseased mucous tissues; it possesses, in an eminent degree, the tonic virtues of the root, and was formerly much used, and is still employed, by some physicians as a substitute for it. It is more beneficial as a tonic during convalescence from *exhausting diseases*, such as *bilious* and *typhoid fevers*, *acute hepatitis*, *gastritis*, *enteritis*, *diarrhœa*, *dysentery*, etc. In *dyspepsia* and *chronic inflammation of the stomach* it is very valuable, and will be found of especial advantage in the treatment of persons who are intemperate, gradually removing the abnormal condition of the stomach, and in many instances destroying the appetite for liquor; it may be combined in these cases with sulphate of quinine, extract of quassia, or other bitter tonic. In *jaundice*, a combination of equal parts of hydrochlorate of berberine, extract of bayberry bark, and oleoresin of prickly ash bark, will often prove efficient. Combined with sulphate of quinine and extract of leptandra, it was once considered useful in *infantile remittent fever*. Equal parts of hydrochlorate of berberine, resin of caulophyllum, and extract of leptandra, form an excellent medicine for *aphthæ* and other *ulcerations of the mouth and throat*, in infants, as well as adults; it should be administered internally. A pill composed of 1 grain of hydrochlorate of berberine, $\frac{1}{20}$ of a grain of alcoholic extract of nux vomica, and sufficient oleoresin of ptelea to form a pill-mass, is found an efficient remedy for some forms of *dyspepsia*, and loss of appetite; 1 pill to be given for a dose, and repeated 3 times a day. Dose of hydrochlorate of berberine: For an adult, from 1 to 5 grains; for children, from $\frac{1}{2}$ a grain to 3 grains; and which may be repeated from 3 to 6 times a day, if required.

BERBERINÆ SULPHAS, *Berberine sulphate*.—Four grains of sulphate of berberine, dissolved in 1 fluid ounce of hot water, forms, when cold, an excellent collyrium in *purulent* and *phlyctenular conjunctivitis*, and an efficient injection in *otorrhœa*, *ozæna*, *leucorrhœa*, *catarrh of the bladder*, *chronic gonorrhœa*, *prostatorrhœa*, and *relaxed or enfeebled conditions of mucous membranes*. Staining of garments, etc., is an objection to the local use of berberine salts.

HYDROCOTYLE.—WATER PENNYWORT.

The entire plant of *Hydrocotyle Asiatica*, Linné.

Nat. Ord.—Umbelliferæ.

COMMON NAMES: *Water pennywort*, *Thick-leaved pennywort*, *Indian pennywort*, *Bevilacqua*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 117.

Botanical Source and History.—The genus Hydrocotyle is an extensive family, comprising nearly 100 species that are found throughout the temperate world, consisting mostly of small, inconspicuous marsh herbs. The generic characters are: Flowers small, in simple umbels; petals 5, white, the points not inflexed; calyx margin wanting; fruit of 2 carpels, which are flattened laterally, 5-ribbed, and not furnished with oil-tubes.

Hydrocotyle Asiatica is a low, creeping plant, widely diffused over the warmer parts of the world, and abundantly met with in India, Cape of Good Hope, and Australia. The leaves are kidney-shaped, crenate, and the petioles attached at the base of the leaf.

In England the genus is represented by a single species, *H. vulgaris*, which is found growing in most parts of Europe. The leaves of this species are nearly orbicular, and about the size of an English penny; hence the common name "*pennywort*." The name "*sheep-rot*" is sometimes applied from the supposition that it causes the "rot" when eaten by sheep. The leaf-stalks are attached to the leaf-blade near the center of the under surface, a position comparatively rare among plants.

There are five American species of Hydrocotyle, all small herbs, growing in swamps. *H. umbellata* and *H. interrupta* have the leaves peltate; while in *H. Americana*, *H. ranunculoides*, and *H. repanda* the leaves are attached to the leaf-stalks at the base of the blades. *Hydrocotyle Americana* is the most common native species, and is found farther north than the others. It is a delicate, slender plant growing in damp, shady places; the leaves are thin and smooth, and are borne on short leaf-stalks; the minute white flowers are in close sessile umbels, in the axes of the leaves. The *Hydrocotyle vulgaris* and the 5 American species have properties probably similar to those of the *H. Asiatica*.

Medical History and Chemical Composition.—In 1852, Dr. Boileau, of India, having been for many years afflicted with leprosy, heard that the American plant, called *Chinchunchulli*, was of value. This plant was said to resemble the violet, and, while waiting for the arrival of a supply, the doctor experimented with *Hydrocotyle Asiatica*, and recovered. He subsequently used the remedy with other lepers. His experience was published, the plant being called *Bevilacqua*.

In 1853 or 1854, M. Jules Lepine continued the subject in the *Madras Gazette* (*Pharm. Jour. and Trans.*, 1853 and 1854), and confirmed the assertions of Dr. Boileau regarding its efficiency in leprosy. Before this, however, the plant is said to have occupied a place in the Indian Materia Medica. The composition of the plant is not known, beyond the experiments of Lepine, who decided that an oily substance, named by him *vellarin*, was the active medicinal principle. (See Christy, *New Commercial Plants*, 1885, p. 58.)

Action, Medical Uses, and Dosage. This plant should be ranked among the acronarcotic poisons, along with the Œnantha crocata, and the Cicutas. Boileau, Lepine, and others have found it useful as a remedy against *elephantiasis* of the Greeks (leprosy). Devergie, Cazenave, Waring, Hunter, etc., have derived benefit from it in *chronic eczema* and other *cutaneous maladies*, in *scrofula*, *secondary syphilis*, *ulcers*, and *chronic rheumatism*. It is an active agent, large amounts inducing headache, dizziness, and stupor, as well as bloody passages from the bowels. Itching of the skin is said to be occasioned by it also. As the root is very hygroscopic, and is not well preserved in powder, its best form for administration is in infusion, or syrup, 1 ounce of the root to 1 pint of fluid, and which may be given in doses of from ½ to 1 fluid ounce, repeated 3 or 4 times a day. An alcoholic extract may likewise be used in doses of from ¼ to ¾ of a grain. Notwithstanding the favorable reports concerning the efficiency of this plant, it has fallen into disuse, and is seldom employed at the present day.

The *Hydrocotyle gummifera*, growing in Brazil and in the Antilles, has been used in *hepatic* and *renal affections*.

HYOSCINÆ HYDROBROMAS (U. S. P.)—HYOSCINE HYDROBROMATE.

"The hydrobromate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials"—(*U. S. P.*).

FORMULA: $C_{17}H_{21}NO_4HBr+3H_2O$. MOLECULAR WEIGHT: 436.98.

Preparation.—The mother liquors from the preparation of hyoscyamine were found by Ladenburg, in 1880, to yield the syrupy alkaloid *hyoscine*. It is freed from hyoscyamine by producing the gold chloride double salts, and that of hyoscine is more soluble than its corresponding hyoscyamine salt, thereby allowing its separation. The melting point of the hyoscine salt is 198° C. (388.4° F.). The union of the alkaloid with hydrobromic acid yields *hyoscine hydrobromate*.

Description.—"Colorless, transparent, rhombic crystals, odorless, and having an acrid, slightly bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 1.9 parts of water, and in 13 parts of alcohol; very slightly soluble in ether or chloroform. When heated to 100° C. (212° F.), the salt loses its water of crystallization, and fuses to a thick, syrupy mass, which becomes quite fluid at 160° C. (320° F.). When ignited, it is consumed, leaving no residue. The salt is neutral to litmus paper. Addition of ammonia water to the aqueous solution of the salt (1 in 60) produces no change, but sodium or potassium hydrate T.S., causes a white turbidity. Addition of silver nitrate T.S. to the aqueous solution produces a yellowish-white precipitate, which is insoluble in nitric acid, but, when filtered off and washed, is soluble in ammonia water diluted with its own volume of water. If 5 drops of fuming nitric acid be added to 0.01 Gm. of the salt, in a small porcelain capsule, and the mixture be evaporated to dryness on a water-bath, a scarcely tinted residue will be left, which, when treated, after cooling, with a few drops of an alcoholic solution of potassium hydrate, will assume a violet color"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Hyoscyamus*.)

HYOSCYAMINÆ HYDROBROMAS (U. S. P.)—HYOSCYAMINE HYDROBROMATE.

"The hydrobromate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials"—(*U. S. P.*).

FORMULA: $C_{17}H_{23}NO_3HBr$. MOLECULAR WEIGHT: 369.14.

SYNONYM: *Hyoscyaminum hydrobromicum*.

Description.—"A yellowish-white, amorphous, resin-like mass, or prismatic crystals, having, particularly when damp, a tobacco-like odor, and an acrid, nauseous, and bitter taste; deliquescent on exposure to air. Soluble, at 15° C. (59° F.), in about 0.3 part of water, 2 parts of alcohol, 3000 parts of ether, or 250 parts of chloroform. At 78° C. (172.4° F.), the salt melts, forming a nearly colorless liquid. When ignited, it is consumed, leaving no residue. The salt is neutral to litmus paper. An aqueous solution of the salt is not precipitated by platinic chloride T.S. (difference from most other alkaloids). With gold chloride T.S. it yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (difference from atropine). The aqueous solution of the salt yields, with silver nitrate T.S., a yellowish-white precipitate, which is insoluble in nitric acid; but, when filtered off and washed, is soluble in ammonia water diluted with its own volume of water"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Hyoscyamus.*)

HYOSCYAMINÆ SULPHAS (U. S. P.)—HYOSCYAMINE SULPHATE.

"The neutral sulphate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials"—(*U. S. P.*).

FORMULA: $(C_{17}H_{23}NO_3)_2H_2SO_4$. MOLECULAR WEIGHT: 674.58.

Preparation.—Carefully neutralize an alcoholic solution of hyoscyamine with diluted sulphuric acid and evaporate in the cold. It may also be obtained by slowly concentrating the diluted sulphuric acid solution of hyoscyamine over concentrated sulphuric acid. It is claimed by some that this salt forms in small crystals, but Ladenburg maintains that only hyoscine salts and not those of hyoscyamine are crystallizable. As found in market both lines of salts are somewhat colored, but when pure are white or colorless.

Description.—"White, indistinct crystals, or a white powder, without odor, and having a bitter, acrid taste; deliquescent in damp air. Soluble, at 15° C. (59° F.), in 0.5 part of water, and in 2.5 parts of alcohol; very slightly soluble in ether or chloroform. At 140° to 160° C. (284° to 320° F.) the salt melts, and, upon ignition, is consumed, leaving no residue. The salt is neutral to litmus paper. An aqueous solution of the salt is not precipitated by platinic chloride T.S. (difference from most other alkaloids). With gold chloride T.S. it yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (difference from atropine). The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Hyoscyamus.*)

HYOSCYAMUS (U. S. P.)—HYOSCYAMUS.

"The leaves and flowering tops of *Hyoscyamus niger*, Linné," "collected from plants of the second year's growth"—(*U. S. P.*). Also the seeds of *Hyoscyamus niger*, Linné.

Nat. Ord.—Solanaceæ.

COMMON NAME: *Henbane.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 194.

Botanical Source.—Henbane is a biennial plant, with a long, spindle-shaped, thick and corrugated root, of an internal, whitish color, and externally brown. The stem is from 6 inches to 2 feet high, erect, tapering scarcely branched, and covered closely with long, weak hairs, tipped with a minute black gland. The leaves are large, oblong, acute, alternate, coarsely and unequally sinuated, occasionally somewhat decurrent, stem-clasping at the base, pale dull-green, and slightly pubescent, with long, glandular hairs upon the midrib. The flowers are numerous, axillary, subsolitary, nearly sessile, and embosomed in the uppermost leaves, than which they are much shorter. The corolla is of a dull, dirty yellow, strongly netted with purple veins, deep-purple at the orifice, funnel-shaped, with a somewhat erect, 5-lobed limb; lobes rounded, spreading, the 2 anterior a little smaller than the others, and separated at base by a deep slit in the tube. Calyx villous, funnel-shaped, 5-lobed, regular, wider than the corolla, to whose tube it is equal in length and persistent; each lobe is ovate and acute, with an open æstivation. Stamens 5, declinate, straight, shorter than the corolla, the 3 lower longer than the others, filaments pubescent, inserted about the middle of the tube of the corolla, and inclined; anthers cordate and purple. The ovary is nearly round, shining, pale-green, 2-celled, with numerous ovules, adhering to the dissepiment; style filiform, declinate, and purple at the apex; stigma blunt, round, and capitate. The fruit is an ovate, 2-celled capsule, opening transversely by a convex lid. The seeds are many, small, obovate, and brownish (L.—B.). The whole plant has a disagreeable, fetid odor, and a repulsive appearance.

Fig. 139.

Hyoscyamus niger.

History.—Henbane is an European herb, naturalized in this country, growing in waste grounds and commons, and flowering from June to September. Botanists are divided as to whether it is an annual or biennial plant. All parts of the plant are medicinal, but the leaves and seeds are the parts usually employed; the former should be collected at the time of its flowering, and the latter when perfectly matured. The leaves of the second year's growth of the plant are reputed more active than those of the first year; when fresh they abound in a viscid juice, and when bruised have a nauseously rank, narcotic smell, and an acrid, oleaginous, disagreeable taste. Upon drying, the smell and taste are almost destroyed. The leaves impart their properties to diluted alcohol; water, alcohol, ether, fixed or volatile oils also take up a portion of their virtues. The aqueous infusion is tasteless, light-yellow, and has the taste and odor of the plant. The leaves should be kept in a dry situation on account of their tendency to absorb moisture.

Description.— HYOSCYAMUS (*U. S. P.*). "Leaves ovate, or ovate-oblong, up to 25 Cm. (10 inches) long and 10 Cm. (4 inches) broad; sinuate-toothed, the teeth large, oblong or triangular; grayish-green, and, particularly on the lower surface, glandular-hairy; midrib prominent; flowers nearly sessile, with an urn-shaped, 5-toothed calyx, and a light yellow, purple-veined corolla; odor heavy, narcotic; taste bitter and somewhat acrid"—(*U. S. P.*). For a microscopical examination of powdered hyoscyamus leaves, see Prof. S. E. Jeliffe, in *Druggists' Circular*, 1899, p. 74.

HYOSCYAMI SEMEN. *Hyoscyamus seeds.*—The seeds were official in the *U. S. P.*, 1870. They are employed for the production of the alkaloid, *hyoscyamine.* They are small, numerous, oval, obtuse, or somewhat reniform, compressed, finely dotted, of a yellowish-gray color, and having the same taste and odor as the leaves, but with oiliness. The interior is whitish, displaying within the albumen a figure 9-shaped embryo. The concavity of the seed is marked by the hilum.

Chemical Composition.—According to Morries, an empyreumatic and highly poisonous oil is obtainable by the destructive distillation of henbane (*Edin. Med. and Surg. Jour.*, Vol. XXXIX, p. 379), The chief constituents of hyoscyamus seeds, besides fixed oil and fatty matter, gum, starch, albuminous matter, etc., are two alkaloids, *hyoscyamine* and *hyoscine*, the latter having been recognized, in 1880, by Ladenburg (*Lieb. Ann.*, Vol. CCVI, p. 279), and previously (1876) observed by Buchheim, and called by him *sikeranine.* Mr. F. Mahla obtained nearly 2 per cent of nitrate of potassium from the leaves of henbane (*Amer. Jour. Pharm.*, 1859, p. 402).

HYOSCYAMINE ($C_{17}H_{23}NO_3$, Ladenburg), was found in henbane (impure) by Peschier (1821) and by Payen (1824), and subsequently purified by Geiger and Hesse (1833). It is more abundant in the seeds than in the herb, the latter when fresh, yielding 0.14 to 0.16 per cent; in the fresh seeds Wadgymar (*Proc. Amer. Pharm. Assoc.*, 1867, p. 404), found as high as 0.52 per cent of the alkaloid. (For a summary review of the various methods pursued in isolating hyoscyamine, see Husemann and Hilger, *Pflanzenstoffe*, p. 1181.) In purest form it is obtainable from its (purified) gold double chloride (Ladenburg). Pure *hyoscyamine* crystallizes in tufts or stellate, silky needles of an acrid, unpleasant taste; when impure it is an amorphous, deliquescent mass, having a nauseating, narcotic, tobacco-like smell. It dissolves sparingly in cold, more readily in hot water, is soluble in alcohol, ether, chloroform, benzol, and amyl alcohol. Its melting point is 108.5° C. (227.3° F.). *Hyoscyamine* is strongly basic and forms crystallizable salts with acids. In aqueous solution it is very unstable, being decomposed by heat, especially when heated with alkalies, ammonia then being liberated. Ladenburg proved it to be an isomer of *atropine* (which see), yielding the same decomposition products (*tropine* and *tropic acid*) as atropine when heated with diluted hydrochloric acid or baryta water. From solutions of its salts, hyoscyamine is but incompletely precipitated by caustic alkalies or carbonates; it forms precipitates with auric chloride, tincture of iodine, tannic acid, and other alkaloidal reagents. The platinic double chloride is more soluble than that of atropine. This behavior permits its isolation from commercial (impure) atropine. Hyoscyamine is identical with *duboisine* from *Duboisia myoporoides* (Ladenburg), and is likewise identical with *daturine* (see Merck's *Index*, 1896). Hyoscyamine is an active poison, as are its salts; a minute quantity of it placed within the eye, causes a persistent dilatation of the pupil.

Hyoscine ($C_{17}H_{21}NO_4$, O. Hesse and E. Schmidt). This base was obtained by Ladenburg from commercial semi-liquid brown hyoscyamine by dissolving it in water, precipitating with gold chloride, and recrystallizing from hot water, from which solution hyoscine gold chloride first precipitates, and the base is then easily regenerated. *Hyoscine* forms an amorphous, semi-liquid mass, not easily soluble in water, easily soluble in alcohol and ether. It yields crystallizable salts with acids, and on warming with baryta water at a temperature of 60° C. (140° F.) is decomposed into *tropic acid* ($C_9H_{10}O_3$), and *pseudo-tropine* ($C_8H_{15}NO$). A water soluble hyoscine was recently found by O. Hesse to be obtainable in comparatively large quantities from the flowers of *Datura alba*, an ornamental plant cultivated in southern Germany (*Druggists' Circular*, 1899, p. 85).

Action, Medical Uses, and Dosage.—Hyoscyamus is a powerful narcotic, and is dangerously poisonous, though fatalities from it or its alkaloids are rare. In fact, the physiological action of henbane and its bases scarcely differs from that of stramonium and belladonna and their alkaloids, except in degree. It produces the same dryness of the mouth, flushing of the face, pupillary dilatation, quickened cardiac and respiratory action, illusions, hallucinations, and delirium occasioned by belladonna, only in a lesser degree. No difference is observable in the action of hyoscyamine and atropine upon the mechanism of accommodation and upon the movements of the lungs and heart. Hyoscyamine is more hypnotic and less apt to cause delirium than atropine. The dilatation of the pupils, which, however, does not always take place under hyoscyamine, is caused by stimulation of the sympathetic nerves. When death occurs from hyoscyamus or its alkaloids it is due to respiratory paralysis. The alkaloids are eliminated by the kidneys. In large doses, but insufficient to produce death, the tendency of hyoscyamus is to produce general paralysis of the nervous structures. One patient lost her memory from being poisoned with it. Among the ill effects of hyoscyamus are: Deranged vision, dilatation of the pupils, giddiness, general excitation, fullness of pulse, flushing of the face, weight in the head, headache, loss of muscular control, with tremulousness, mental confusion, incoherency or loss of speech, somnolency, furious delirium, unconsciousness, coma, irresponsiveness of the pupils to light, cold sweat, small, frequent, and feeble pulse, and deep and labored respiration. Tetanic rigidity may be present a portion of the time and sometimes convulsions, as well as nausea, vomiting, and intestinal pain and purging. The treatment of poisoning by hyoscyamus is that indicated under *Belladonna*. Chloral is especially recommended for poisoning by hyoscine. Autopsies reveal gastro-intestinal inflammation from poisoning by this drug.

When $\frac{1}{15}$ of a grain of sulphate of hyoscyamine has been subcutaneously injected hyoscyamine has been detected in the urine 22 minutes afterward. If enough be injected to cause complete dryness of the tongue and hard and soft palates, the pulse will increase temporarily in frequency, volume, and power; if this effect upon the tongue is not produced, the pulse will be lessened in frequency without diminution of its volume and force, and giddiness, somnolency, and dilatation of the pupils will accompany, the patient frequently acting as if intoxicated (Harley). (Compare *Atropinæ Sulphas* and *Duboisia*.)

Hyoscyamus is a cerebro-spinal stimulant, or in the Eclectic meaning of the term, a cerebro-spinal sedative. It relieves pain and promotes sleep. *Nervous irritation*, without congestion, high fever, or disturbance of the circulation in the cerebrum is the key-note to its use. Functional disturbances are those best relieved by the smaller doses of hyoscyamus. In medicinal doses it is anodyne, hypnotic, calmative, and antispasmodic; allaying pain, soothing excitability, inducing sleep, and arresting spasm. It does not produce constipation like opium, but has a tendency to act as a laxative. Its sedative effect upon the sympathetic nervous system requires larger doses to produce, and it is more transient and less powerful than belladonna; its most prominent effects are excessive giddiness and somnolency, which is caused by belladonna in only a very secondary degree. Hyoscyamus is a far safer agent for children and old people than opium. It favors the restoration of the normal functions when impaired through nerve irritability or debility. In this way it often favors the action of the special sedatives. If there is irritation of the gastro-intestinal tract it improves the action of the bitter tonics. As a remedy for pain it is less efficient than opium, and usually requires larger doses. Unlike the latter, it does not restrain the secretions.

Hyoscyamus is usually given in cases where opium disagrees, or where constipation must be avoided; in *neuralgic* and all *spasmodic affections*, as *renal*, *uterine*, *hepatic* and *flatulent colic*, *asthma*, *gout*, *rheumatism*, *chronic cough*, *irritations of the urinary organs*, and *inflammatory cases* attended with nervous excitability and not with high fever. On account of not producing headache, it is preferred to opium in *hepatic* and *renal inflammations*, and to relieve pain and lessen cough in *pulmonic affections*. In *bronchitis* with short, dry, explosive cough, it is a very useful agent, and in *pneumonia* we have obtained prompt results from small doses, when a condition of sub-delirium with widely dilated pupils was present. Dry, irritative *cough* and the troublesome nervous cough, so-called, aggravated by lying down, are indications for hyoscyamus. As a cough remedy, it is frequently given with syrup of wild cherry, and in this form renders excellent service in *phthisis*. It often renders good service in *spasmodic asthma*, and it should be remembered as an important remedy in *whooping-cough*.

Hyoscyamus is a remedy for *spasm* and *pain*—particularly for *spasmodic pain*. When there is nervous irritation, feeble circulation, and tendency to mental aberrations, it is particularly useful in the *neuralgia of exhaustion*, *syphilitic bone-pains*, *dysmenorrhœa*, particularly when neuralgic, *menstrual headache*, *headache of debility*, and the *pains of herpes zoster*, *pains in the liver*, *kidneys*, *bladder*, *ovaries*, etc. All these cases when showing anemia and nervous depression, will yield to hyoscyamus or its alkaloids. *Great unrest*, with debility, is relieved by this drug. Hyoscyamus is an excellent agent in *irritable conditions of the bladder and urethra*, where nerve force is low, and should therefore find a place in urinal urging, tenesmic voiding, and in nocturnal as well as diurnal *incontinence*. It is a urethral sedative, and combined with camphor (pill) has long been employed to relieve *urethral irritation* after the passing of bougies, catheters, sounds, and divulsors. The pains of *hemorrhoids* are frequently relieved by this agent. Hyoscyamus is frequently combined with active cathartics, as scammony, colocynth, aloes, resin of podophyllin, etc., without impairing their energy, not only for preventing tormina, but because it renders their action more efficient.

The great field for hyoscyamus and its alkaloids is in *nervous affections*, and here its principal employment is to cause sleep, or remove irregular nervous action. They are useful in *irritable conditions of the brain* and *heart*, with palpitation, and in certain cases of *epilepsy*, *chorea*, *senile* and *mercurial tremors*, and *enuresis*. Brown-Sequard says that hyoscyamus should be used instead of belladonna or opium, in cases of *paraplegia*, with symptoms of irritation of the spinal cord, where sleeplessness is present. To force sleep in *insomnia*, narcotic doses are required, and, as a rule, such an action is undesirable, and other agents are better for this purpose. But to allay irritability, upon which sleeplessness often depends, or to relieve restlessness and dreaming during sleep, no drug is more efficient than hyoscyamus, in small doses. It is often useful in children's diseases for this purpose. In fractional doses, it is an excellent calmative in *typhomania of typhoid fever*. It is serviceable in *hysteria*, with frequent voiding of small quantities of urine. Fractional doses of hyoscyamus, frequently administered are useful in "*puerperal convulsions*, associated with a nervous condition bordering on mania" (Locke).

Few remedies have been more valued in the treatment of the various forms of *insanity* than hyoscyamus and its alkaloids. It is especially useful in *mania*, both acute and chronic, larger doses being usually required in the latter form. The cases most benefited are those exhibiting great excitation, with a tendency to destructiveness, *delusional insanity*, *epileptic mania*, and *recurrent mania*. Prof. Webster mentions as a strong indication for hyoscyamus the garrulousness and quarrelsomeness exhibited by the insane. Nervous disturbances manifested by low muttering delirium, or by singing and talkativeness during fevers, are frequently relieved by small doses of this agent. Hyoscyamus has been declared useless in *delirium tremens*, but there is abundant reliable evidence to prove that it is an exceedingly useful agent when that malady is not of the most active character, and the victim is given to low muttering delirium. Here stimulant doses sufficient to sustain the nervous system should be given.

Hyoscyamus should not be overlooked as a calmative in *nymphomania*, particularly if due to childbirth, when there is evidently more delirium than sexual passion; the circulation is feeble, the pulse quick and small, the brain active, and the patient may have been disturbed with unpleasant dreams. *Puerperal mania*, due to exhaustion and weakness, is often controlled by hyoscyamus. It acts well in the *insomnia* of exhaustion, where there is continual agitation and nervous unrest. Hyoscyamus is especially valuable to control the nervous phenomena following fevers and other exhausting diseases. Nervous heart action is amenable to it, as is also tumultuous heart-action, with valvular insufficiency.

Where the fresh leaves can be obtained, they are employed in fomentation, or bruised, as an external application to allay the *inflammatory* and *painful condition* of *ulcers* and *tumors*, as well as to relieve *nervous headache*, and the pain in *gouty*, *neuralgic*, *rheumatic*, and similar affections. An ointment of hyoscyamus extract (ʒj to petrolatum ℥j), is useful to relieve pain in *hemorrhoids*, *cancer*, etc. A liniment for *glandular swellings* may be made by mixing together, extract of henbane, 1 drachm; white soap, 4 drachms, and linseed oil, 12 fluid ounces; to be applied 2 or 3 times a day with considerable friction. Dose of the powdered leaves, from 2 to 10 grains; of the tincture, from 30 drops to 2 fluid drachms; and of the alcoholic extract, which is the only extract that should be used, from $\frac{1}{2}$ to 2 grains, which may be cautiously increased, according to its effects; of specific hyoscyamus, fraction of a drop to 20 drops. It should be remembered that the administration should begin with the smaller doses, and that patients become tolerant of its action so that enormous doses may be given. For the specific action, however, only small doses are required.

Hyoscyamine and Hyoscine (Scopolamine).—The two alkaloids of hyoscyamus—*hyoscyamine* and *hyoscine*—or their salts, chiefly the hydrobromates, are frequently given in the nervous disorders above mentioned, hyoscyamine salts being preferred to those of hyoscine, as the latter are said to sometimes produce mental excitation. From the fact that much of the so-called "amorphous hyoscyamine," the most active kind, is frequently largely contaminated with hyoscine it has been extremely difficult to determine the exact field of action of each, or the proper doses. Hyoscine is much more active than hyoscyamine, the ordinary hypodermatic dose ranging from $\frac{1}{300}$ to $\frac{1}{100}$ grain, though even in these doses it should be cautiously employed. The hydrobromate of hyoscyamine may be given in much larger doses. Hyoscine hydrobromate and hyoscyamine hydrobromate have been especially employed in *acute mania*, *epileptic mania*, *delusional insanity*, *chronic dementia*, *chronic alcoholism*, *paralysis agitans*, *sexual excitation* with *seminal emissions* ($\frac{1}{120}$ to $\frac{1}{80}$ grain at bedtime), *nymphomania*, *whooping-cough*, *enteralgia*, *spasmodic asthma*, *spasmodic torticollis*, *facial neuralgia*, *insomnia*, *profuse sweating*, *tetany*, *tetanus*, *neurasthenia of hypochondriasis*, etc. Hyoscine has been used to cure the *morphine habit*.

As a mydriatic, hyoscine is more powerful and more prompt than atropine, but the dilatation produced is less prolonged; accommodation, however, is slowly recovered. The hydrobromate is the form generally employed, being used in the cases in which atropine is apparently indicated, but when the latter gives rise to atropine irritation. The solutions generally employed are those containing from 2 to 4 to 8 grains to the ounce of distilled water. Scopolamine (see *Scopolia atropoides*), is now recognized as practically identical with hyoscine, the *German Pharmacopœia* having adopted the name *Scopolamin Hydrobromate* for hyoscine hydrobromate, from the fact that most of the hyoscine is now prepared from *Scopolia atropoides*, it yielding larger amounts than other hyoscine-yielding species. One drop of a 1 to 3000 aqueous solution of scopolamine hydrobromate produces complete dilatation of the pupils in $\frac{1}{4}$ hour, and maintains the dilatation for 2 days. A drop of 1 to 20,000 aqueous solution will produce a partial dilatation in 20 minutes (Murrell). Scopolamine may be employed for *accommodation paralysis* by applying 1 drop only by means of a glass rod. For examining for *errors of refraction* 1 drop of a solution of about $\frac{1}{4}$ grain to 1 fluid ounce of water is preferred. The lids should be rubbed outward to prevent the fluid from entering the ducts. Several cases of most profound poisoning have resulted from the use of even weak solutions of this mydriatic, therefore its action should be closely watched (Prof. W. B. Scudder, M. D.).

The leaves of hyoscyamus in infusion, or the extract dissolved in water, were formerly used locally to the eye before operating for *cataract*, in order to dilate the pupil, which is usually effected in 3 or 4 hours, without any subsequent injury to the eye. This was succeeded by the use of hyoscyamine and its salts, which have now given way to hyoscine hydrobromate; occasionally hyoscine hydriodate is used for the same purpose.

As to the dosage of the alkaloids, hyoscamine and hyoscine and their salts, there has been much variance, particularly in regard to the former, which in commerce is often of greatly variable strength. Hyoscyamine has been given in doses as large as 1 grain, but the ordinary commencing dose should not be larger than $\frac{1}{6}$ grain, gradually increased until the desired action is obtained. Hyoscyamine sulphate, $\frac{1}{130}$ to $\frac{1}{40}$ grain; by instillation into eye, $\frac{1}{40}$ to $\frac{1}{20}$ grain; hyoscyamine hydrobromate, $\frac{1}{150}$ to $\frac{1}{50}$ grain; by instillatiou into the eye, $\frac{1}{40}$ to $\frac{1}{20}$ grain; hyoscine hydrobromate, $\frac{1}{150}$ to $\frac{1}{80}$ grain; to eye, $\frac{1}{2}$ to 1 per cent solution; hypodermatically, $\frac{1}{300}$ to $\frac{1}{100}$ grain. As a general rule the hypodermatic dose of these salts is one-half or less than one-half as small as when given by mouth. Particularly should care be exercised in the case of the hyoscine salts, the preferred doses of of which are those of $\frac{1}{300}$ to $\frac{1}{100}$ grain.

Specific Indications and Uses.—Nervous irritability, with unrest and insomnia; face flushed and pupils dilated; fright, terror, restlessness in sleep; loquaciousness; busy delirium of a low muttering character, or with singing, talkativeness, amusing hallucinations and illusions, etc.; garrulousness; destructiveness; sharp, dry, nervous cough, worse upon assuming a recumbent position; muscular spasms; choking sensations; rapid and palpitating cardiac action.

Preparations Containing Hyoscyamus.—Balsamum Tranquillans. The *French Codex* has a preparation of the above name made by treating narcotic and aromatic plants with olive oil to extract their active constituents. It is used as a local application for *pain*. A modified preparation has been used in this country. Take 60 grains of each of the alcoholic extracts of belladonna, hyoscyamus, conium, and stramonium, and 24 grains of aqueous extract of opium. Add 2 fluid ounces of boiling water to soften the extracts, and add olive oil, 8 fluid ounces. Digest with moderate heat until the water is dissipated, and filter. Add to the filtrate 20 minims each of the essential oils of lavender, sage, peppermint, thyme, wormwood, and rue. It is a good application in *earache*, a few drops being introduced upon cotton into the external auditory meatus. Care should be observed in its use.

Oleum Hyoscyami Compositum (N. F.), *Compound oil of hyoscyamus, Balsamum tranquillans.*—"Oil of absinth, oil of lavender, oil of rosemary, oil of sage, oil of thyme, of each, 2 drops; infused oil of hyoscyamus (F. 279), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Mix them. *Note.*—Oil of absinth is the volatile oil of *Artemisia Absinthium*, Linné (wormwood), and oil of sage is the volatile oil of *Salvia officinalis*, Linne. Infused oil of hyoscyamus is the *Oleum Hyoscyami* of the *German Pharmacopœia*. The *Baume Tranquille* (*Balsamum Tranquillans*) of the *Codex* is a more complex preparation, not identical with the above, but possessing about the same properties" (*Nat. Form.*). This and the preceding preparation may be employed as embrocations for the relief of *neuralgic*, *myalgic* and *rheumatic pains*.

HYPERICUM.—ST. JOHN'S WORT.

The leaves and flowering tops of *Hypericum perforatum*, Linné.

Nat. Ord.—Hypericaceæ.

COMMON NAME: *St. John's wort.*

ILLUSTRATION: Johnson's *Med. Bot. of N. A.*, Fig. 112.

Fig. 140.

Hypericum perforatum.

Botanical Source.—This plant has a perennial, woody, tufted, fusiform, tortuous, somewhat creeping root. Its stem is 2-edged, branchiate, erect above, curved below, branched, and from 1 to 2 feet high. The leaves are very numerous, elliptical or ovate, obtuse, opposite, entire, marked with pellucid dots, of a pale-green color, from 6 to 10 lines long, one-third as wide, the ramial leaves being much smaller. The flowers are numerous, of a bright-yellow color, and borne in dense, forked, terminal panicles. The calyx is persistent; and the sepals are 5, acute, lanceolate, connected at the base, with 5 dark-colored glands. Petals 5, twice as long as the sepals, ovate, obtuse, yellow, dotted, and streaked with black or dark purple. Stamens numerous, united at base, divided into 3 sets, with small anthers. Styles 3, short, erect,; stigmas small. The capsule is roundish, 3-celled and 3-valved; the seeds numerous, small, and roundish. The whole herb is dark-green, with a powerful scent when rubbed, and stain the fingers dark-purple, from the great abundance of colored essential oil (L.—W.).

History and Chemical Composition.—St. John's wort is an herb abundantly growing in this country and Europe, and proving exceedingly annoying to farmers. The flowers appear from June to August. It has a peculiar, terebinthine odor, and a balsamic, bitterish, rather astringent taste. It imparts its properties to water, alcohol, ether, oils, or alkaline solutions. Other species of Hypericum are possessed of medicinal properties, notably the *Hypericum sarothra*, Michaux, *pine-weed* or *orange-grass*, growing in sands, which has aperient qualities. An allied plant, the *Ascyrum crux-Andreæ*, Linné, or *St. Andrew's cross*, has been locally applied to glandular indurations and swellings. Hypericum contains a volatile oil, a resin, tannic acid and coloring matter (Blair, *Amer. Jour. Pharm.*, Vol. II, p. 23). Pectin is also present. The red coloring principle is a resinous body known as *hypericum red*. The odor of this principle is similar to that of the flowers. Karl Dieterich (*Pharm. Centralh.*, 1891, p. 683) macerated the flowers with 90 per cent alcohol, and obtained a tincture of a rich red color, containing a mixture of two coloring matters, a yellow principle soluble in petroleum ether, and a red coloring matter, insoluble in this solvent. The red principle, in solid form, was a resinous mass of a green lustre, soluble in alcohol with red color, and resembling *carthamin red;* insoluble in fatty, but soluble in ethereal oils. Acids dissolve it with red, alkalies, chloroform, benzol and carbon disulphide with green color. The substance does not possess any advantage over other indicators in alkalimetry. When exposed to air in thin layers, it turns greenish at once. The aqueous extractive matter of the flowers contains calcium, magnesium, potassium, and oxalic, sulphuric and carbonic acids.

Action, Medical Uses, and Dosage.—Astringent, sedative, and diuretic. Used in *suppression of the urine*, *chronic urinary affections*, in *diarrhœa*, *dysentery*, *worms*, *jaundice*, *menorrhagia*, *hysteria*, *nervous affections* with depression, *hemoptysis*, and other *hemorrhages*. Hypericum has undoubted power over the nervous system, and particularly the spinal cord. Homœopathic physicians regard it as the arnica of that structure. It is used. in *injuries of the spine* and in lacerated and punctured *wounds* of the limbs to prevent tetanic complications and to relieve the excruciating pains of such injuries (Scudder). It is highly valued by Webster in *spinal irritation* when, upon gentle pressure upon the spinous processes of the vertebræ, burning pain is elicited. Throbbing of the whole body in nervous individuals, fever being absent, is said to be a good indication for hypericum. The usual method of administration is: ℞ Tincture of hypericum, gtt. x to xxx; aqua, fl℥iv. Mix. Sig. Teaspoonful every 1 or 2 hours. Externally, hypericum may be used in fomentation, or used as an ointment for dispelling hard *tumors, caked breasts, bruises, ecchymosis, swellings, ulcers*, etc. The blossoms, infused in sweet oil or bear's oil, by means of exposure to the sun, make a fine, red balsamic ointment for *wounds, ulcers, swellings, tumors*, etc. A very excellent ointment for *tumors, ecchymosed conditions*, etc., may be made by adding to 1 pound of lard, ½ pound of the recent tops and flowers of St. John's wort, and ½ pound of fresh stramonium leaves; bruise all together, expose to a gentle heat for an hour, and strain. Dose of the powder, from ½ to 2 drachms; of the infusion, from 1 to 2 fluid ounces. The dose of the strong tincture is from ½ to 10 minims. The saturated tincture of the fresh herb (℥viii to alcohol, 76 per cent, Oj) is nearly as valuable as that of arnica for *bruises*, etc., and may be substituted for it in many instances.

Specific Indications and Uses.—Spinal injuries, shocks, or concussions; throbbing of the whole body without fever; spinal irritation, eliciting tenderness and burning pain upon slight pressure; spinal injuries, and lacerated and punctured wounds of the extremities, with excruciating pain; hysteria; locally to wounds, contusions, etc.

HYSSOPUS.—HYSSOP.

The flowering tops and leaves of *Hyssopus officinalis*, Linné.

Nat. Ord.—Labiatæ.

COMMON NAME: *Hyssop*.

Botanical Source.—Hyssop is a perennial herb. Its stems are quadrangular, woody at the base, spreading, very much branched, and 1 foot or 2 in height; the branches are rod-like. The leaves are opposite, sessile, usually oblong-linear, or lanceolate, sometimes elliptical, sometimes narrower, acute, entire, punctate, green on each side, rather thick, and 1-ribbed underneath. The flowers are bluish-purple, seldom white, and borne in racemose, second whorls, consisting of from 6 to 15 flowers. The floral leaves are like those of the stem, but smaller. Outer bracts lanceolate-linear, acute, scarcely shorter than the calyx. Upper lip of the corolla erect, flat, emarginate; lower lip trifid, spreading, with the middle lobe larger. Stamens 4, protruding, and diverging; anthers with linear divaricating cells (L. W.).

History and Chemical Composition.—Hyssop inhabits Europe and this country, being raised principally in gardens. It flowers in July. The tops and leaves are the medicinal parts; their odor is pleasantly fragrant, and their taste hot, spicy and somewhat bitter, which properties are due to a volatile aromatic oil, which rises in distillation both with water and with alcohol.

This *oil of hyssop* is limpid, neutral, and of a pale yellow or greenish-yellow color, camphoraceous in taste, neutral in reaction, and in odor resembling hyssop. Alcohol freely dissolves it. Its specific gravity is 0.88 to 0.98. It is an oxygenated oil, or, according to Stenhouse, a mixture of several such oils (Husemann and Hilger). Trommsdorf has shown Herberger's (1829) *hyssopin* to be merely an impure sulphate of calcium. Hyssop also contains fat, tannin, resin, mucilage and sugar. Water, by infusion, or alcohol extracts the active virtues of hyssop. It is said to contain some bitter principle and sulphur. In Mexico the *Salvia axillaris*, Sesse, is called *hyssop*.

Action, Medical Uses, and Dosage.—Stimulant, aromatic, carminative and tonic. Principally used in *quinsy* and other *sore throats*, as a gargle, combined with sage and alum, in infusion sweetened with honey. Also recommended in *asthma, coughs*, and other affections of the chest, as an expectorant. The leaves, applied to *bruises*, speedily relieve the pain, and disperse every spot or mark from the parts affected. The infusion (herb, ʒiv to aqua Oj) may be given freely; the volatile oil, in doses of 1 or 2 drops.

ICHTHYOCOLLA (U. S. P.)—ISINGLASS.

"The swimming-bladder of *Acipenser Huso*, Linné, and of other species of *Acipenser*"—(*U. S. P.*).

Class: Pisces. *Order:* Sturiones.

Source and History.—Isinglass is an almost pure gelatin, being usually procured from the *air-bags*, *sounds*, or *swimming-bladders* of various fishes, chief among which are those furnishing *Russian isinglass.* These are mainly the *belugo* (*Acipenser Huso*, Linné), the *sterlet* (*Acipenser ruthenus*, Linné), the *osseter* (*Acipenser Güldenstädti*, Ratzeburg), and the *sewruga*, or *starred sturgeon* (*Acipenser stellatus*, Pallas). These sounds are membranous sacs situated under the spine, in the middle of the back, and above the center of gravity. In most fishes they connect with the stomach or œsophagus by the pneumatic duct; these sacs are filled with air, containing about 80 per cent of oxygen, and are composed of a firm, silvery external coat, and two thin and delicate internal coats. The sounds are removed from the fish, cut open, carefully washed, and then exposed to the air to dry; then, after being dampened to soften them, they are made into rolls about half an inch in diameter, and folded between three pegs, into the shape of a horseshoe, heart, or lyre (*long* and *short staple*), or folded in the manner book-binders fold printed sheets of paper (*book isinglass*), or dried in single sheets (*sheet isinglass*). When the sound is rolled out it is termed *ribbon isinglass.* The internal membrane of the sounds is thin and insoluble. Sometimes isinglass is reduced to small shreds, when it will be scarcely possible for the eye to distinguish the inferior from the finer kinds; the latter may be known by their whiteness, freedom from unpleasant fishy odor, solubility in water, and translucency of the jelly obtained on cooling from its hot solution. The above are the best forms; the sheet isinglass is superior to any; an ounce of water will dissolve 10 grains of it, leaving hardly any insoluble matter, and furnishing an excellent jelly.

There are other kinds of an inferior character, as the *cake isinglass,* which is in cakes or round pieces, having an unpleasant smell, and a tawny color, and which is principally used by artists. The *Samovey isinglass* is prepared in Russia from the *Silurus glanis*, but it is not so pure as those named above. Isinglass is also made in the eastern states, in this country, from the sounds of the *hake* (*Gadus merluccius*, Linné) and *cod* (*Gadus Morrhua* Linné, or *Morrhua americana*), and other fishes. It is in long, flat pieces, known as *ribbon isinglass*, is very pure, being almost wholly soluble in water, but its piscatory flavor is an objection to its use for domestic or pharmaceutical purposes. A very inferior isinglass is prepared in Brazil from the sounds of fish (*lump isinglass* and *honeycomb isinglass*), and in the East Indies (*purses* and *leaves*, P.) (*Amer. Jour. Pharm.*, Vol. XVIII, p. 54). A variety of fish glue, apparently procured from the natatory bladder of the yellow sturgeon, but unfit for pharmaceutical purposes, has been met with in commerce in France. It swells up in water and is only partially dissolved. Isinglass prepared from the air-bags of large fishes, when unopened, is known as *pipe* or *purse isinglass.*

When American isinglass, in solution, is thinly spread on cotton cloth, previously oiled and dried, it forms a very pure article, in clear, delicate laminæ, but having a piscatory smell, and is known as "*transparent* or *refined glass.*" The so-called *Chinese* or *Japanese isinglass* is the vegetable product of certain algæ (see *Agar Agar*).

Description and Chemical Composition.—"In separate sheets, sometimes rolled, of a horny or pearly appearance; whitish or yellowish, semi-transparent, iridescent, inodorous, insipid; almost entirely soluble in boiling water and in boiling diluted alcohol. A solution of isinglass in 24 parts of boiling water forms, on cooling, a transparent jelly"—(*U. S. P.*).

Isinglass is sometimes kept in thin, very fine cuttings, in which form it is more readily dissolved by boiling water. Isinglass is chiefly a very pure gelatin—that known as *glutin* (see *Gelatin*). The best kinds are white, transparent, glistening, odorless and tasteless; the poorer varieties are colored, opaque, and have either a fishy taste or smell. It is soluble in weak acidulous and alkaline liquids, and in water at 100° C. (212° F.), forming with the latter, when strained and cooled, a pure animal jelly. It is not dissolved by alcohol, ether, nor by water at 15.5° C. (60° F.), but with this latter it expands and becomes soft. Tannic acid added to its solution occasions a tough, gelatinous precipitate, tannate of gelatin. When boiled with caustic potash, or with concentrated mineral acids, it is decomposed, forming *sugar of gelatin* or *glycocoll* (*amido-acetic acid*), $C_2H_3(NH_2)O_2$, which is in large transparent crystals, very sweet, soluble in water, and forming beautifully crystallized salts with acids. John found 100 parts of the purest isinglass to consist of 70 parts of gelatin, 16 of *osmazome*,* 2.5 of membrane insoluble in boiling water, 4 of free organic acid salts of potassium, sodium and phosphate of calcium, and 7 parts of moisture. Mr. R. Baird (*Amer. Jour. Pharm.*, 1888, p. 608) found the ash in three samples of Russian isinglass to vary from 0.4 to 0.6 per cent, while in two specimens of American isinglass the ash amounted to 2.17 and 2.40 per cent. Prof. W. T. Wenzell (*Amer. Jour. Pharm.*, 1894, p. 447) recommends the use of American isinglass for the quantitative determination of tannin, in place of the hide-powder usually employed.

Action, Medical Uses, and Dosage.—Isinglass is seldom used in medicine, except as a nutritive. It is used as a diet, in the form of jelly, or added to other jellies, to give them a tremulous appearance. It has proved very useful for *scrofulous* and *consumptive patients.* I have used the following preparation in *incontinence of urine*, both in children and adults, in many instances, and have found it a useful as well as agreeable remedy, proving serviceable when other means had failed: Take of isinglass (*long staple*), 1 roll; boil it in 1 pint of water till it is dissolved, then strain, add 1 pint of sweet milk, put it again over the fire, and remove it just as ebullition commences; then sweeten with loaf sugar, and grate nutmeg upon it. When made it very much resembles custard. Of this, a tumblerful may be taken 3 or 4 times a day by an adult (K.). Isinglass is employed in the arts for various purposes, for clarifying or fining wines, beer, coffee, syrups, etc., and is a constituent of court-plaster. Three drachms form a proper jelly with a pint of water.

Cements.—An excellent cement, called ARMENIAN or DIAMOND CEMENT, is made with isinglass, which is valuable for mending glass, china, and porcelain vessels, which are not to be exposed to heat and moisture. It is made by sprinkling water upon 2 drachms of isinglass, allowing it to stand until softened, then adding as much proof-spirit as will rather more than cover it, then dissolving with a moderate heat. Have previously prepared, a solution made by dissolving 1 drachm of gum mastic in 2 or 3 fluid drachms of alcohol. Mix the two solutions, and stir in 1 drachm of gum ammoniacum, previously reduced to a fine powder, and rubbed down with a little water. Evaporate, if necessary, on a water-bath to a proper consistence. Keep the cement thus prepared in a vial. When required for use plunge the bottle in warm water, and keep it there until the cement becomes fluid; then apply it with a stick or small hard brush to the edges of the broken vessel, previously warmed. Compress the pieces firmly together until cold, taking care to make the contact perfect, and using a very thin layer of cement. When properly applied, the cement is almost, if not quite, as strong as the glass or china itself.

A cement for stoneware may be made by softening gelatin in cold water, warming and adding recently slaked lime enough to render the mass sufficiently thick for the purpose. A thin coating of this cement is to be spread while warm over the gently heated surfaces of fracture of the articles, and dried under strong pressure.

ICHTHYOLUM.—ICHTHYOL.

FORMULA: $C_{28}H_{36}S_3O_6(NH_4)_2$. MOLECULAR WEIGHT: 598.88.

SYNONYMS: *Ammonium ichthyol sulphonate, Ammonium ichthyol.*

Source and Preparation.—In the Tyrolese Mountains of Europe are found immense deposits of a bituminous mineral containing the fossilized remains of fishes and sea animals of a pre-historic period. If this mineral be subjected to destructive distillation, it yields a transparent, crude oil, of a brownish-yellow color, and a peculiar, penetrating, pungent odor. It has a density of 0.865 and boils between 100° C. and 255° C. (212° F. and 401° F.). The crude oil is mixed with strong sulphuric acid in excess, whereby it becomes ichthyolsulphonic acid When the reaction has ceased the mixture is treated repeatedly with a strong solution of common salt, to remove the remaining sulphuric and sulphurous acids, when the ichthyolsulphonic acid, in form of a dark mass, separates. If the acid be saturated with ammonia, ammonium ichthyolsulphonate is formed.

Ichthyol the ammonium salt), is a syrupy liquid of a reddish-brown color, and a bituminous taste and odor. It contains as much as 10 per cent of sulphur.

---

* *Osmazome*, according to Gmelin (*Handbook of Chemistry*, translated by Watts, London, 1871 Vol XVIII, p. 71), was obtained by Thenard by exhausting flesh with water, evaporating the extract, treating the residue with alcohol and evaporating the alcoholic liquid.

Water dissolves it, forming a clear, red-brown fluid, of faintly acid reaction. It is but partially soluble in ether or alcohol, but when these are mixed, volume for volume, complete solution is effected. The aqueous solution yields a tarry layer of the free acid upon the addition of hydrochloric acid. When dried by the heat of a water-bath, it loses nearly half (45 per cent) of its weight. Ichthyol puffs up when heated, and carbonizes, and if the heat be continued sufficiently long it completely volatilizes, leaving no residue. It mixes readily with fats and petrolatum in any proportion. (For a more detailed description of ichthyol and related preparations, see *Pharm. Centralhalle*, 1883, pp. 113 and 477; and 1886, p. 115.)

Action, Medical Uses, and Dosage.—Owing to the presence of the sulphur contained in it, several dermatologists were led to the use of ichthyol in *skin affections*. For a time it was extensively used in almost every form of skin disease, as well as applied to *wounds* and other accidental lesions. *Rheumatic joints, gouty conditions*, and *sprains* were treated with it, as were *tonsillar enlargements* and other *glandular hypertrophies*. Internally, it was employed for the relief of *throat disorders* and *digestive derangements*, particularly those of a fermentative type, but its intolerable odor and taste have led to its abandonment for the latter types of disease. Active germicidal properties are attributed to it, and its use is now largely confined to cutaneous maladies, in which it appears to be no more successful than other bodies of a like nature, the extraordinary properties first attributed to it being given but little credence at the present time. It appears, however, to give fair results in *erysipelas*. The chief skin diseases in which it has been employed are *ulcerations, chilblains, frost-bites, contusions, urticaria, burns, scalds, acne, eczema, psoriasis*, and *entertrigo*. A pomade of 1 part of ichthyol, 2 parts of lanolin, and 6 parts of sweet almond oil, is said to have been signally useful in *smallpox*. As an inhalation, a 25 per cent aqueous solution of ichthyol may be employed; internally, from 1 to 20 minims may be given in milk or capsules; as an ointment, it may be used with lanolin or petrolatum in strengths ranging from 22 to 50 per cent.

Related Compounds.—OTHER ICHTHYOLS. When the term *ichthyol* alone is used it refers to *ammonium ichthyol*. There are, however, several other compounds of *ichthyolsulphonic* (*sulphoichthyolic*) *acid*, known respectively as *sodium ichthyol, lithium ichthyol, zinc ichthyol, mercury ichthyol*, etc., prepared by saturation of the acid with either the oxides or carbonates of these elements. The sodium salt is the one prepared for pill administration. It dissolves in water, and is alkaline in character. These ichthyols are all tar-like, brown or black masses.

THIOLUM OR THIOL.—This drug, obtained by E. Jacobsen by a patented process, occurs in two forms, the dry, *thiolum siccum*, and the fluid, *thiolum liquidum*, the latter containing about 40 per cent of dry thiol. The latter is a deep-brown, syrupy preparation, really a neutral solution of thiol in water, It has a peculiar odor resembling that of so-called Russia leather. Its density is 1.080 to 1.081. It is freely soluble in water and glycerin, with the first forming a frothy solution when agitated. The dry form is prepared by evaporation of the liquid thiol. Pure thiol is a dark-brown, non-hygroscopic powder, soluble in water. This agent has been employed for precisely the same conditions as ichthyol, a solution, or ointment, or occasionally the dry powder being applied. The advantage claimed over the former is the absence of odor. From 5 to 10 drops of the fluid, or 1 to 2 grains of the powder have been administered in *rheumatic complaints*.

TUMENOLUM, TUMENOL.—Tumenol is a dark-colored, syrupy fluid obtained from the purified oils from bituminous shale, by acting upon them with strong sulphuric acid. It is a mixture of sulphonic acids and sulphones. *Tumenol oil* consists of the sulphones separated from a caustic soda solution of tumenol, by means of ether. It is a thick, deep-yellow fluid, soluble in benzol and ether, but does not dissolve in water, unless *tumenol sulphonic acid* be present. A caustic soda solution of tumenol precipitates, upon the addition of hydrochloric acid, a dark-colored, bitterish powder, *tumenol sulphonic acid*. *Crude tumenol* (*tumenol venale*), is a soft, tough, resinous mass of a brown color and without odor, composed of tumenolsulphonic acid and tumenol sulphone. A lotion containing 10 per cent of tumenol and equal quantities of glycerin (or water), alcohol, and ether, has been highly endorsed by Neisser (1891), to control the *itching of prurigo, eczema*, and *parasitic*, as well as other *affections of the skin*. *Eczematous forms of skin disorders* appear to be best influenced by it.

ICHTHALBIN, *Ichthyol albuminate*.—A form of ichthyol for internal use, prepared by precipitating ichthyol with fresh albumen. Prolonged heating or washing of the precipitate removes the ichthyol taste and odor. This is an odorless and nearly tasteless, grayish-brown powder, insoluble in water and acid media, but soluble in alkaline media. It is slowly dissolved by the intestinal secretions. Claimed to be more valuable than ichthyol for internal use, but can not supplant it as an external remedy. Said to disinfect and regulate the action of the bowels, improve the appetite, and increase assimilation. The dose ranges from 5 to 30 grains, directly before meals; for children, the smaller doses should be given, mixed with powdered chocolate. It has been used in *intestinal atony* and *catarrh, rachitis, scrofula, anemia*, etc.

IGNATIA.—IGNATIA.

The seed of *Strychnos Ignatia*, Lindley (*Ignatia amara*, Linne filius; *Strychnos Ignatii*, Bergius; *Strychnos philippensis*, Blanco; *Ignatiana philippinica*, Loureiro).

Nat. Ord.—Loganiaceæ.

COMMON NAMES AND SYNONYMS: *St. Ignatius bean, Bean of St. Ignatius; Faba Ignatii, Semen Ignatiæ.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 179.

Botanical Source.—*Strychnos Ignatia* of Lindley, is a branching tree, with long, tapering, smooth, scrambling branches. The leaves are ovate, acute, petiolate, veiny, smooth, and a span long. Hooks none. Panicles small, axillary, 3 to 5-flowered, with short, round, rigid pedicels. The flowers are very long, nodding, white, smelling like Jasmine. The fruit is smooth, pear-shaped, the size of an ordinary apple or a Bonchretien pear; seeds about 20, somewhat angular, about 12 lines long, and imbedded in a pulp (L.).

Fig. 141.

Bean of St. Ignatius; fruit of Strychnos Ignatia.

History and Description.—This tree is indigenous to the Philippine Islands. Its seeds, the St. Ignatius bean of commerce, are about the size of olives, rounded and convex on one side, and somewhat angular on the other, pale brownish externally, with a bluish-gray tint, greenish-brown internally. Their substance is hard, compact, and horn-like. They are inodorous and of an exceedingly bitter taste.

Chemical Composition.—The St. Ignatius bean yields its properties to water, but alcohol is its best solvent. Pelletier and Caventou, in 1818, found it to contain the constituents of nux vomica only in different proportions. These chemists found 1.2 per cent of strychnine and little brucine. On the other hand, however, F. F. Mayer, in New York (*Amer. Jour. Pharm.*, 1863, Vol. 36, p. 219), found it to yield twice to three times as much brucine as of strychnine. More recently, B. Sundblom, in Prof. Flückiger's laboratory (*Archiv der Pharm.*, 1889, Vol. 227, p. 145), obtained from the seeds 0.178 per cent of strychnine and 0.278 per cent of brucine. (For details regarding these alkaloids, see *Nux Vomica.*) The alkaloids were observed by Pelletier and Caventou to occur in natural combination with *igasuric acid*, a substance identified by Höhn (*Archiv der Pharm.*, 1873, Vol. CCII, p. 137) as an iron-greening tannic acid. Mr. Jas. M. Caldwell (*Amer. Jour. Pharm.*, 1857, Vol. XXIX, p. 294) notes the absence of starch from the seeds, while albuminous matter is present to the amount of about 10 per cent (*Pharmacographia*). Prof. Flückiger (*Archiv der Pharm.*, 1889), examining authentic specimens of other parts of the tree, found in the bark of the stem 0.52 per cent of total alkaloids, strychnine predominating, while in the wood of the stem brucine was in larger amount. The root contains considerably less alkaloid, while the leaves are free from it.

Action, Medical Uses, and Dosage.—The action and uses of ignatia are very similar to those of nux vomica, but more energetic. It appears also to possess an influence over the nervous system of a tonic and stimulating character, not belonging to nux vomica or strychnine. It is never a remedy for conditions of excitation of the nervous system, but its key-note is *atony;* it is the remedy for *nervous debility*, and all that that term implies, being one of the best of nerve stimulants and nerve tonics. It was early recognized in this work as a remedy for *nervous debility, amenorrhœa, chlorosis*, etc. As a rule, the dose of ignatia administered is too large, a depressing headache often resulting from its immoderate use. The preparation mostly employed in our school is specific ignatia, of which from 5 to 10 drops should be added to 4 fluid ounces of water, and the solution be administered in teaspoonful doses every 2 or 3 hours. Bearing in mind the condition of *nervous atony*, it may be successfully administered in *anemia*, where the patient is cold, and especially when coldness of the extremities is one of the distressing features of the menopause. It should be thought of in anemic states of the brain, and particularly in those cases where the patient exhibits *hysterical, melancholic*, or *hypochondriacal demonstrations*. It is a remedy for digestive disorders, such as *atonic dyspepsia* and *chronic catarrh of the stomach*, with atony, and *gastralgia* or *gastrodynia*. The *sick headache of debility* is relieved by it. Shifting, dragging, boring, or darting pains, deeply seated in the loins or lumbar region, are those benefited by ignatia. It is an important remedy in *atonic reproductive disorders*. Eclectics have not found it to be especially adapted to females only, as have the Homœopaths, who declare it the remedy for women, while nux and strychnine are remedies for men. *Sexual coldness* in both sexes, *impotence* in the male and *sterility* in the female are remedied many times by the judicious administration of ignatia. The deep-seated pelvic pains of women, particularly *ovarian pains* and *uterine colic* are especially relieved by ignatia, which is also indicated in *menstrual disorders* with colic-like pains, heavy dragging of the ovaries, and an abnormally large and heavy womb. If added to these pelvic weaknesses, the general nervous system is greatly debilitated, there are wandering pelvic pains or pain in the right hypochondrium with constipation, *neuralgia* in other parts of the body, twitching of the facial muscles, a tendency to paralysis, and choreic and epileptiform symptoms, associated with a disposition to grieve over one's condition, the indications for ignatia are still stronger. But to obtain beneficial effects the dose must be small.

Ignatia has shown itself useful in atonic states of the eyes and ears. *Atonic visual asthenopia* and *catarrhal conjunctivitis*, with palpebral twitchings and a sensation as of dust in the member, are relieved by doses of $\frac{1}{10}$ to $\frac{1}{6}$ drop of specific ignatia, while $\frac{1}{5}$-drop doses have proved useful in the *tinnitus* and *impaired hearing* depending upon general atony of the system (Foltz).

The dose of ignatia (powdered) may range from $\frac{1}{10}$ to $\frac{1}{2}$ grain; of the alcoholic extract, from $\frac{1}{20}$ to $\frac{1}{8}$ grain; of specific ignatia, from $\frac{1}{10}$ to $\frac{1}{5}$ drop; of the tincture, from $\frac{1}{5}$ to 2 minims. The treatment of poisoning by ignatia is identical with that of strychnine, which see.

Specific Indications and Uses.—General nervous atony; disposition to grieve; dull, deep-seated, dragging pain in loins, back, or right hypochondrium; hysterical, choreic, epileptoid, or hypochondriacal manifestation, due to debility; dysmenorrhœa, with colicky pains and heavy womb; sexual frigidity, impotence, and sterility; wandering pelvic pains; coldness of extremities; muscular twitchings, particularly of face and eyelids; dull hearing, due to general atony; nervous depression; burning of the soles of the feet; congestive headache.

ILEX OPACA.—AMERICAN HOLLY.

The leaves of *Ilex opaca*, Aiton.
Nat. Ord.—Aquifoliaceæ.
COMMON NAME: *American holly*.

Botanical Source.—This tree rises from 20 to 40 feet in height, having leaves which are alternate, coriaceous, evergreen, smooth, and shining, flat, oval, acute at the end, and the wavy margins armed with strong, scattered, spiny teeth. The flowers are small, greenish-white, arranged in scattered clusters along the base of the young branches, and borne from the axils of the leaves. The calyx is persistent; the calyx-teeth acute. The corolla is rotate, monopetalous, and 4-cleft; the stamens erect and alternate with the divisions. The ovary is globular, and 4-celled. Stigmas 4, subsessile, and obtuse. The fruit is a red, globular berry of 4 cells; the nutlets are 4 and striate (G.—W.).

Fig. 142.

Ilex opaca.

History and Chemical Composition.—The holly is found growing throughout the United States from Maine to Louisiana, in moist woodlands, and flowering in June. It is quite common to the Atlantic states, especially New Jersey. The viscid substance of the inner bark, like the mistletoe berry, furnishes an adhesive material known as *bird* The berries are about as large as a whortleberry, of a red color, and an acrid, bitterish taste. The leaves are the medicinal parts. They have a bitter, somewhat harsh taste, but no odor, and yield their virtues to water or alcohol. They are believed to contain *ilicin* (see *Related Species*), wax, gum, salts, etc. (For the preparation of Rousseau's *ilicin*, see this *Dispensatory*, last revision.) Mr. D. P. Pancoast (*Amer. Jour. Pharm.*, 1856, Vol. XXVIII, p. 315) prepared from the leaves of American holly an aqueous decoction from which the bitterness was removed by charcoal, and subsequently abstracted from the latter by alcohol. An amorphous, non-hygroscopic, intensely bitter mass resulted upon evaporation of the solvent, partially soluble in water, and completely soluble in alcohol and ether. It could not be obtained in the crystallized state. By the same process the author isolated from the berries a crystallizable, very bitter principle, soluble in ether, water, and alcohol. Acids precipitate it from aqueous solution. The fruit contains tannin. Mr. Walter A. Smith (*Amer. Jour. Pharm.*, 1887, p. 230) obtained from the leaves, by extraction with benzin, a volatile oil of an acrid, mustard-like odor, and also identified a glucosid. The leaves contained 4.5 per cent of ash.

Action, Medical Uses, and Dosage.—Holly leaves are tonic and febrifuge; said to be very efficient in the treatment of *intermittent fevers*, in doses of 60 grains of their powder administered 1 or 2 hours previous to the chill. The infusion has also proved beneficial in *icterus*, *pleuritis*. *catarrh*, *variola*, *arthritis*, etc. The berries are said to be emeto-cathartic and cholagogue; from 8 to 15 of them will act as a hydragogue. According to Dr. Rousseau, ilicin acts decidedly upon the spleen, liver, and pancreas, producing a sedative effect, and is a cheap substitute for quinine. Its dose is 10 grains in pill form, gradually increased to 30 grains.

Related Species.—*Ilex aquifolium*, Linné, *European holly*, together with several other species in this country, possess properties similar to those of American holly. Dr. F. Moldenhauer has found in the leaves a crystalline yellow coloring matter, which is scarce in the leaves when they are collected in January, but abundant when gathered in August. It is soluble in alcohol or hot water, but insoluble in ether or cold water, loses its color at 185° C. (365° F.), and fuses at 197.7° C. (388° F.), decomposing slightly above this temperature. He gave it the name *ilixanthin* ($C_{17}H_{22}O_{11}$). He also isolated from the aqueous extract the crystallizable calcium salt of a syrupy acid, *ilicic acid*. *Ilicin* is the bitter principle upon which the febrifuge properties of the leaves depend; it has not been obtained as yet in a pure state. The leaves have been used in *intermittent fevers* and *rheumatism*, and the berries in *dropsy*. The leaves produce gastric heat, nausea, and colic. The berries have emeto-cathartic properties.

Ilex Cassine, Walter (*Ilex vomitoria*, of Aiton), or *South Sea tea*, an evergreen shrub, growing in the southern states, is the *Cassine* of the Indians. It is also known as *Cassena*, *Yaupon*, or *Youpon*. A liquid, called *black drink*, is prepared by boiling the toasted leaves in water; in the performance of their religious rites, and on great occasions when in council, the men only are permitted to drink this, for the purpose of cleansing their systems. The leaves have a rough, aromatic taste, no odor, and in large doses their decoction causes active emesis, catharsis, and diuresis; in small quantity it greatly increases the urinary discharge. A few leaves of this plant lessen the injurious influence of saline water, and it is used for this purpose by persons along the sea shore in North Carolina. According to the analysis of Dr. F. P. Venable (*Amer. Jour. Pharm.*, 1885, p. 390), the dried leaves contain 0.32 per cent of *caffeine*, 7.39 per cent of tannin, and 5.75 per cent of ash. Mr. Henry M. Smith (*Amer. Jour. Pharm.*, 1872, p. 216) found 0.011 per cent of a volatile oil, 3.4 per cent of resin, and 0.122 per cent of caffeine. (For a detailed and exhaustive article on *Ilex Cassine* see monograph by Edwin M. Hale, M. D., *Bulletin No.* 14, Division of Botany, U. S. Department of Agriculture.)

Ilex glabra. *Ink berry*.—Sandy grounds from New England to Florida. Employed chiefly for ornamentation, and was at one time used in *intermittent fevers*.

Ilex Dahoon, Walter; *Dahoon holly*, and *Ilex myrtifolia*, Walter; both of southern states, are also known as *Cassena*.

Ilex paraguayensis, St. Hilaire; Argentine Republic, and Brazil.—This tree yields *Paraguay tea* or *Yerba maté*, *St. Bartholomew's tea* or *Jesuit's tea*, which is consumed in immense quantities in South America in place of Chinese tea. Its effects are said to more nearly resemble coca than tea. The plant grows along water courses, and from December to August collecting parties gather the leaves which, after a preparatory torrification to enhance their aroma, are powdered and enter into commerce and are sold to be prepared by infusion like common tea. Their chief constituent is caffeine, which exists in quantities varying from 0.2 per cent to 1.8 per cent, the average yield (Peckolt) being 0.64 per cent. Tannin (*matétannic acid*) is present in amounts of from 10 to 16 per cent (A. Robbins, *Amer. Jour. Pharm.*, 1878, p. 273). The leaves are most aromatic just before the fruit is ripe. Volatile oil, a stearopten, and a crystallizable acid, *mateviridic acid*, have also been obtained from the leaves. The infusion of Paraguay tea is diuretic and sudorific, and in excessive doses acts as a drastic purgative. For an interesting article on *maté* or Paraguay tea, see Th. Peckolt, *Amer. Jour. Pharm.*, 1883, p. 570.

Fig. 143.

Ilex glabra.

ILLICIUM (U. S. P.)—ILLICIUM.

The fruit of *Illicium verum*, Hooker.

Nat. Ord.—Magnoliaceæ.

Common Names and Synonyms: *Star-anise, Star-anise fruit, Chinese anise; Semen badiana, Anisi stellata fructus.*

Illustration: Bentley and Trimen, *Med. Plants*, 10.

Botanical Source and History.—The plant bearing star-anise is a small tree or shrub, indigenous to southwestern China, growing in the mountainous elevations of Yunnan. The shrub attains a height of from 8 to 12 feet, and has entire, lanceolate, evergreen leaves, which are pellucid-punctate. The flowers are polypetalous and of a greenish-yellow color. The fruit is described below. This plant was introduced into Japan by the followers of Buddha, and planted near their temples.

Description.—The *U. S. P.* describes star-anise of commerce as follows, giving also the distinctive differences between it and the poisonous fruit of *Illicium anisatum*, Linné: "The fruit is pedunculate and consists of 8 stellately-arranged carpels, which are boat-shaped, about 10 Mm. ($\frac{3}{8}$ inch) long, rather woody, wrinkled, straight-beaked, brown, dehiscent on the upper suture, internally reddish-brown, glossy, and containing a single, flattish, oval, glossy, brownish-yellow seed; odor anise-like; taste of the carpels sweet and aromatic, and of the seeds oily. Star-anise should not be confounded with the very similar but poisonous fruit of *Illicium anisatum*, Linné (*Illicium religiosum*, Siebold), the carpels of which are more woody, shriveled, and have a thin, mostly curved beak, a faint, clove-like odor, and an unpleasant taste"—(*U. S. P.*). This last poisonous fruit is sometimes found as a dangerous admixture to true star-anise.

Chemical Composition.—The seeds contain, according to Meissner (1818), some volatile oil, resin, and a large amount of fixed oil. The fruit (without the seeds) contains volatile oil, resin, fat, tannin, pectin and mucilage. The volatile oil (*oil of star-anise*), amounts to about 4 to 5 per cent, and is almost identical with *oil of anise* (from *Pimpinella Anisum*, Linné). Star-anise oil (from Chinese fruit) according to Schimmel & Co.'s *Semi-annual Report* (October, 1893), has the specific gravity at 15° C. (59° F.), of 0.980 to 0.990, and its known constituents are *pinene, anethol, phellandrene, safrol*, and *hydro-quinone-ethyl-ether*, while only *anethol* ($C_6H_4[OCH_3][CH:CHCH_3]$) and *pinene* ($[C_{10}H_{16}]$) (Fluckiger, *Pharmacognosie*, 1891) are given as the constituents of *anise oil*, which has the same density as *star-anise oil*. J. F. Eykmann (1888) detected the poisonous *sikimin* in the fruit, while Schlegel found a crystalline principle of a pronounced odor of musk. He also found *saponin* in the watery extract (*Amer. Jour. Pharm.*, 1885, p. 426).

Action, Medical Uses, and Dosage.—Both the seeds and oil of star-anise possess the stimulant, diuretic, carminative, and slightly anodyne properties of anise. Locally applied and internally administered, they have been used for *abdominal pains*, particularly when associated with flatus, and in *bronchitis*, and locally alone in *earache* and *rheumatic complaints*. The dose of the powder is from 10 to 20 grains; of the oil, from 1 to 10 drops. Oil of star-anise is largely employed to impart a flavor to spirits, especially in France, Germany and Italy.

Related Species.—*Illicium anisatum*, Linné (*Illicium religiosum*, Siebold). This fruit was until quite recently (1880) considered identical with the preceding, the shrub bearing which was also known as *Illicium anisatum*, Loureiro, until it was determined by Hooker (1888) to be a distinct species, to which the name *Illicium verum*, Hooker, was applied. *Illicium religiosum* is indigenous to the eastern portion of Asia, and is cultivated in Japan, where the plant is known as *sikimi* (*shikimi*). Eykmann found in the seeds a crystalline, poisonous, non-glucosidal, non-alkaloidal body, *sikimin*, soluble in hot water, alcohol, and chloroform. For an account of the analysis, see *Amer. Jour. Pharm.*, 1881, p. 407. The volatile oil (*oil of star-anise*, from Japanese fruit), according to Schimmel & Co., contains *safrol*, and has a density of 0.984 to 0.994 at 15° C. (59° F.). The fruit is described above. It is highly poisonous, and attention was drawn to this fruit through cases of poisoning which occurred in the Netherlands, in 1880, as also in Japan, their native country. Fatalities in children have resulted from the ingestion of the seeds, the toxic symptoms being vomiting, convulsions resembling those of epilepsy, with frothing at the mouth, loss of consciousness, dilated pupils, and the face excessively cyanotic.

Illicium parviflorum, Michaux.—Georgia, Florida, and Carolina, in the hill districts. This species has yellow blossoms, the fruit is 8-carpelled, and has the taste of sassafras. They are poisonous. Barral *Amer. Jour. Pharm.*, 1890, p. 330), isolated a toxic glucosid from the seeds. The properties are thought to resemble those of *shikimi* (*Illicium religiosum*, Siebold).

Illicium floridanum, Ellis; *Stink-bush*, *Poison-bay.*—An evergreen shrub, growing from Florida along the Gulf of Mexico coast to Louisiana, and bearing purple flowers. The fruit is 13-carpelled, and has a disagreeable, anise odor resembling somewhat that of turpentine. Both fruit and leaves are poisonous. The fruit, leaves, and bark of this species are aromatic, the first being occasionally substituted for anise, the last for cascarilla. (See Henry C. C. Maisch, *Amer. Jour. Pharm.*, 1885, pp. 228 and 278, for a histological and chemical study of this plant.

Illicium majus, Hooker filius et Thomson.—Malay Peninsula. Fruit 11 or 13-carpelled, blackish-brown in color, and has a taste like mace.

Illicium Griffithii, Hooker filius et Thomson.—Bengal. Fruit 13-carpelled. Taste bitter and acrid, like bay-leaves and cubebs.

IMPATIENS.—JEWELWEED.

The plants *Impatiens pallida*, Nuttall, and *Impatiens fulva*, Nuttall.

Nat. Ord.—Geraniaceæ.

Common Names: I. (*Impatiens pallida*), *Balsam jewelweed*, *Balsam weed*, *Pale touch-me-not.* II. (*Impatiens fulva*), *Speckled jewels*, *Spotted touch-me-not.*

Botanical Source.—*Impatiens pallida* is an indigenous annual plant having a smooth, succulent, tender, subpellucid, branching stem, with tumid joints, growing from 2 to 4 feet in height. The leaves are oblong-ovate, coarsely and obtusely serrate, teeth mucronate, from 2 to 5 inches long, petiolate, and about two-thirds as wide. The flowers are large, pale-yellow, sparingly maculate, and mostly in pairs; the peduncles, 2 to 4-flowered and elongated. The sepals are apparparently but 4, the 2 upper united, the lowest gibbous, dilated-conical, broader than long, with a very short, recurved spur. The petals are apparently 2, unequal-sided and 2-lobed, each consisting of a pair united. Stamens 5, short; anthers opening on the inner face, connivent over the stigma. Ovary 5-celled; stigma sessile. Capsules oblong-cylindric, an inch long, 5-valved, bursting at the slightest touch when ripe, and scattering the anatropous seeds (W.—G.).

Fig. 144.

Impatiens pallida.

Impatiens fulva is the most common variety; its leaves are rhombic-ovate, obtusish, coarsely and obtusely serrate, with teeth mucronate. The flowers are smaller than in the previous one, deep-orange, maculate, with many brown spots; lower gibbous sepals acutely conical, longer than broad, with an elongated, recurved spur.

Impatiens balsamina, the *Garden balsam*, or *Ladies' slippers*, is spontaneous about gardens; its leaves are lanceolate, serrate, upper ones alternate; peduncles clustered and 1-flowered; spur shorter than the flowers. The flowers are red, white, purple, pink, flesh-color, and scarlet; sometimes they are double. This is an exotic plant, a native of the East Indies, and cultivated as a beautiful garden annual. Its height is from 1 to 5 feet (W.—G.).

Fig. 145.

Impatiens fulva.

History.—These plants grow throughout the United States, in moist, shady places, and along rills, in rich soil, flowering from July to September. The *I. pallida* is most common northward and westward, and the *I. fulva* southward. Both plants possess similar properties. The leaves are astringent. The whole plants are used medicinally, and impart their virtues to water. They contain a yellow coloring matter, but have not been chemically studied.

Action, Medical Uses, and Dosage.—They are aperient and diuretic; a decoction is recommended in *jaundice*, *hepatitis*, and *dropsy*. The juice is said to remove *warts*, cure *ringworms*, *salt-rheum*, etc., and to cleanse foul *ulcers;* or it may be applied for these purposes in the form of a poultice boiled in milk. The bruised plants or the juice applied to parts *poisoned by rhus*, give prompt relief. It also gives relief from the effects of stinging nettle. The recent plant boiled in lard, forms an excellent ointment for *piles*.

INDIGO.—INDIGO.

A blue dye-stuff obtained from several species of *Indigofera*.

Nat. Ord.—Leguminosæ.

SYNONYMS: *Indicum, Pigmentum indicum.*

Source and History.—The plants furnishing indigo are quite numerous; chief among them are *Indigofera tinctoria*, Linné, cultivated in India and the East India Islands; *Indigofera Anil*, Linné, growing in the West Indies, Central and South America, and *Indigofera argentea*, Linné, cultivated in Egypt and the French colonies in Africa. To these sources is to be added the commercial product called *Woad*, prepared from the leaves of *Isatis tinctoria* and *I. lusitanica* (*Nat. Ord.*—Cruciferæ), plants which were formerly much cultivated in France and Germany, and supplied the demand for indigo before it was introduced into Europe from foreign countries.

Indigo-blue does not pre-exist as such in these plants. . It is developed by the decomposition of the bitter glucosid *indican* ($C_{26}H_{31}NO_{17}$), a colorless chromogene existing therein. This substance also occurs sometimes in pathological urine. When acted upon by diluted acids or ferments, it is said to absorb water and to be hydrolyzed into *indigo-blue* ($C_{16}H_{10}N_2O_2$), and a saccharine principle *indiglucin* ($C_6H_{10}O_6$), which undergoes further decomposition by fermentation. However, oxidation also plays an important part in the production of indigo-blue. The plants are collected during the flowering season, and are kept immersed in water in soaking vats or cisterns. At a temperature of about 30° C. (86° F.), fermentation soon sets in, lasting from 12 to 15 hours. When the liquid becomes of a yellowish-green color, it is drawn off and stirred briskly for about 3 hours. The liquid now turns deep blue, and the indigo, being insoluble in water, and of a greater specific gravity, soon falls to the bottom. The supernatant liquid is removed, the thick indigo sediment is heated to the boiling point of water to prevent further fermentation, then strained, pressed, and cut into cubical blocks and carefully dried. Three hundred kilograms of the indigo plant yield about 1 kilogram of indigo (S. P. Sadtler, *Handbook of Industrial Organic Chemistry*, 2d ed., 1895).

Description and Chemical Composition.—Commercial indigo occurs in hard, porous, brittle lumps or cubes of a dark-blue color and devoid of taste or odor. Indigo which is firm, dense, not easily broken, and which has a dull or greenish or grayish hue, is of inferior quality. Its specific gravity varies between 1.32 and 1.45. Commercial indigo contains from 20 to 80 per cent of *indigo-blue*, the average being about 45 per cent; the remainder consists of *indigo-brown*, *indigo-red*, *indigo-gluten*, water, and varying quantities of mineral matters. The ash should not amount to more than 8 per cent. When indigo is rubbed with a hard and smooth body, the surface of friction assumes a copper-like lustre. Heated to 287.7° C. (550° F.), indigo sublimes as a violet-colored vapor, although not without decomposition, and condenses on cool surfaces in the form of small, acicular crystals of a copper hue. Indigo-blue is not affected by the ordinary solvents, such as water, alcohol, ether, diluted acids and alkalies. It can be crystallized, however, from aniline and oil of turpentine, and is also soluble in chloroform, glacial acetic acid, paraffine, castor oil, nitrobenzene, phenol, and similar solvents. Concentrated, especially fuming sulphuric acid, readily dissolves indigo, forming deep-blue solutions. According to the relative quantities of indigo and sulphuric acid, and the temperature maintained in the reaction, either *indigo-monosulphonic* (*sulpho-purpuric*) *acid* ($C_{16}H_9[SO_3H]N_2O_2$), or *indigo-disulphonic* (*sulphindigotic*) *acid* ($C_{16}H_8[SO_3H]_2N_2O_2$), may be obtained. The *monosulphonic acid* is insoluble in water; its sodium salt is soluble, and is called *indigo-purple* or *red-indigo carmine*. The *disulphonic acid* is soluble in water, and is the substance commercially termed *Saxony blue* or *Chemnitz blue*. The sodium or potassium salt of this acid is the true *indigo-carmine* or *soluble indigo* of commerce, and occurs in the form of a pasty mass or as a powder; in the latter case it obtains the commercial name *indigotine* (S. P. Sadtler, *Handbook*, 1895, p. 447). The name *indigotin* is also often given in text-books to the pure *indigo-blue* ($C_{16}H_{10}N_2O_2$).

Indigo-blue is converted by oxidizers, *e. g.*, nitric acid, into yellow-red, crystallizable *isatin* ($C_{16}H_{10}N_2O_4$), which, when distilled with caustic potash, yields *aniline*

($C_6H_5NH_2$). When indigo is acted upon by reducing agents in alkaline solution, *e. g.*, by dextrose, or sulphurous acid, or hydrogen sulphide, zinc, etc., a solution of a yellow color is yielded, containing alkali-soluble *indigo-white* ($C_{16}H\ N\ O$). This solution, exposed to the air, precipitates *indigo-blue* again. This reaction is made use of in dyeing; the cloth, being saturated with the alkaline solution containing *indigo-white*, is exposed to the air, whereby the indigo-blue formed is firmly fixed in the fiber.

Action, Medical Uses, and Dosage.—Indigo and its preparations when administered, have imparted a blue color to the cutaneous and renal secretions. Large doses cause gastro-intestinal irritation, debility, and nervous derangements. The sulphate is reputed an active emmenagogue, and indigo was several years ago tested as a remedy for *epilepsy*, but has been abandoned as inefficient and even detrimental. The dose may be stated at from 1 to 20 grains.

Synthetical Indigo.—Within the last 20 years, several syntheses of indigo-blue and its derivatives have been accomplished. An important stepping-stone to this feat was the synthesis of *Indol* (C_8H_7N) (the skeleton substance of indigo), by Baeyer and Emmerling, in 1869. The first synthesis of indigo by Baeyer (*Ber. d. Deutsch. Chem. Ges.*, 1880, p. 2254), was accomplished by converting *ortho-nitro-cinnamic acid* ($C_6H_4NO_2.CH{:}CH.COOH$) into *ortho-nitro phenyl propiolic acid* ($C_6H_4[NO_2].CC{:}COOH.$), and this into *indigo-blue* through the reducing agency of sugar in alkaline solution. The graphic formula of *indigo-blue* ($C_6H_4.NH.CO{:}C-C{:}CO.NH.C_6H_4$), elucidated by the researches of Prof. Baeyer and his co workers, suggests to him an analogy with that of the *Azo dyes* (which see). More recently additional syntheses of indigo were effected simultaneously by L. Lederer and K. Heumann (see *Chemiker Zeitung*, 1890, Oct. 1st and Oct. 8th; also see *Amer. Jour. Pharm.*, 1890, p. 614); likewise some methods for the direct synthesis of *indigo-carmine* are on record (see A. Haas, in *Amer. Jour. Pharm.*, 1891, p. 406, and B. Heymann, in Prof. Sadtler's *Handbook*, 1895, p. 452).

Related Species and Product.—In addition to the plants above mentioned, indigo is probably yielded also by the following plants: *Gymnema tingens*, Sprengel, Hindustan; *Polygonum tinctorium*, Linné, China; *Wrightia tinctoria*, Robert Brown, Hindustan; and *Galega tinctoria*. Prof. H. Molisch (*Amer. Jour. Pharm.*, 1893, p. 494), detects the presence of *indican* in plants by boiling some fragments of the latter in a test-tube with a diluted solution of aqua ammoniæ, and in another experiment with diluted hydrochloric acid, filtering, cooling, and agitating with chloroform, which assumes a blue color if indican is present.

Crescentia cujete.—South America. The fruit of this plant contains a blue body resembling indigo, and *crescentinic acid* (G. Peckolt, *Pharm. Rundschau*, 1884).

INFUSA.—INFUSIONS.

Infusions are solutions of vegetable principles in water. The addition of any alcoholic mixture is only made in cases where the medicinal action of the liquor itself is desired, or to act as a preservative. Clear, soft water, as river, rain, or distilled water should be used in the preparation of infusions; hard, or limestone water, from springs or wells, or water holding saline substances in solution, is unfit for this purpose, as such water is apt to occasion precipitates. Drugs containing volatile active constituents, or which are deteriorated by a temperature somewhat elevated, or which contain a principle not desired, and which is not readily dissolved by water at a low degree of heat, are better made into infusions by cold instead of hot water.

Infusions form a very expeditious and convenient mode of exhibiting many medicines, as the most of them readily yield their active constituents in this way without requiring to be very finely divided. The principal objection to them is the difficulty of keeping them for any length of time, in consequence of which they require to be prepared off-handed, and in limited quantity at a time. Mugs containing a movable diaphragm are now much in use for the preparation of infusions. The diaphragm extends to one-third or one-half of the depth of the mug, and contains the vegetable remedy, while the jar is filled with hot or cold water as may be required. A constant circulation is kept up in the fluid by the increased density of the impregnated water carrying it to the bottom, while its place is occupied by the less impregnated fluid, and this continues until the remedy is exhausted of its active soluble principles.

In making infusions with boiling water, starch and other principles are often taken up, whose presence disposes to acidity or moldiness, or perhaps favors reactions which materially impair the infusions; on this account percolation by cold water is often preferable, as it avoids these inconveniences, beside which these infusions have a less tendency to spoil than those made at a boiling temperature. The process of percolation or displacement by cold water, affords infusions of very great strength, and is preferred to any other mode; it requires, however, that the articles should be more finely powdered, as a general thing, than is customary in preparing infusions in the ordinary way. When of too great strength, the infusion may be reduced by dilution with water. Very excellent infusions may be prepared with many medicinal herbs, roots, or barks, by percolating with a fluid composed of 3 parts of water and 1 part of glycerin.

Infusions are better when prepared in glazed earthenware or porcelain vessels fitted with covers, than when prepared in metallic vessels, on account of a liability to chemical alteration from metallic influence, and which frequently impairs the preparation. Infusions containing acids, or saline substances, should always be prepared and kept in glass or china vessels.

In the preparation of infusions, the reactions of agents should always be kept in view. Thus, infusion of *chamomile flowers* yields precipitates with nitrate of silver, sulphate of iron, gelatin, yellow Peruvian bark, tincture of chloride of iron, corrosive sublimate, and the acetates of lead. Infusion of *horseradish* undergoes rapid decomposition, and is precipitated with acetate of lead, infusion of galls, nitrate of silver, corrosive sublimate, and the alkaline carbonates. Infusion of *cloves* is precipitated by the soluble salts of antimony, zinc, iron, silver, lead, and by lime-water. Infusion of *cascarilla* is precipitated by infusion of galls, acetates of lead, sulphates of zinc and iron, nitrate of silver, and lime-water. Infusion of *yellow Peruvian bark* is incompatible with potassium, sodium, and ammonium hydroxides and carbonates, lime, magnesia, tannic and gallic acids, and vegetables containing these acids, tartaric acid, oxalic acid, and the soluble tartrates and oxalates. It also affords precipitates with other agents, which, however, do not always injure its efficiency or active principle, as corrosive sublimate, arsenous acid, tartar emetic, gelatinous solutions, soluble salts of iron, silver, and zinc, and many vegetable solutions, as those of cloves, chamomile, calumba, cascarilla, galls, horseradish, catechu, digitalis, senna, orange-peel, rhubarb, valerian, and simaruba. Infusions of *senna*, *gentian*, *rhubarb*, and *calumba*, are better made with cold water. When boiling water is added to *calumba* it takes up the starch, and the infusion spoils rapidly. It should be made with cold water, then boiled, and filtered to separate albuminous matter. Infusion of *digitalis* is precipitated by acetate of lead, sulphate of iron, and infusion of cinchona (*Lond.*—Phillips, *Pharm. Jour. and Trans.*, 1855, Vol. XIV, pp. 339, 438, 439, 403, 486).

As nearly all vegetable medicines are occasionally administered in the form of infusion, it would be useless to enter into an especial relation of them, further than already explained in the above general rules. They are more commonly prescribed as secondary or auxiliary measures, and are left for the nurse or family to prepare. However, there are a few compound infusions, some of which are of a spiritous nature, which it may be advisable to describe on account of their extensive employment and superior efficiency in the diseases for which they are recommended.

The *U. S. P.* general method is as follows: "An ordinary infusion, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula: Take of the substance, coarsely comminuted, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; boiling water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Put the substance into a suitable vessel provided with a cover, pour upon it the boiling water, cover the vessel tightly, and let it stand for half an hour. Then strain, and pass enough water through the strainer to make the infusion measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Caution.*—The strength of infusions of energetic or powerful substances should be specially prescribed by the physician"—(*U. S. P.*).

We give place to formulas for several infusions according to the *British Pharmacopœia*, and a number official in the *U. S. P.*, 1870.

INFUSUM EUPATORII (*U. S. P.*, 1870), *Infusion of thoroughwort.*—Dried boneset, or thoroughwort, 1 troy ounce; boiling water, 1 pint. Macerate 2 hours. Strain. Dose, as an emetic, take freely in tepid condition; as a tonic, use cold in 1 or 2 fluid-ounce doses.

Infusum Picis Liquidæ (*U. S. P.*, 1870), *Infusion of tar, Tar water.*—Tar, 1 pint; water, 4 pints. Mix, agitate frequently throughout 24 hours, pour off infusion, and filter. Dose, as a diuretic, 1 or 2 pints daily. Locally, as a lotion in *skin diseases*, and as a bladder-wash in *chronic cystitis*.

Infusum Spigeliæ (*U. S. P.*, 1870), *Infusion of spigelia.*—Spigelia, ½ troy ounce; boiling water, 1 pint. Macerate 2 hours. Strain. Dose, for young child, ½ to 1 fluid ounce, night and morning; for adult, 2 to 6 fluid ounces.

Infusum Salviæ (*U. S. P.*, 1870), *Infusion of sage.*—Sage, ½ troy ounce; boiling water, 1 pint. Macerate ½ hour. Strain. Dose, 1 fluid ounce. Valuable in *spermatorrhœa* and *night-sweats*. Locally, as a mouth-wash, or vehicle for other topical agents.

INFUSUM ANTHEMIDIS.—INFUSION OF CHAMOMILE.

Synonym: *Infusum chamomillæ romanæ.*

Preparation.—Infuse, in a closed vessel for 15 minutes, ½ ounce (av.) of chamomile flowers in 10 fluid ounces (Imp.) of boiling distilled water. Strain. This accords with the *Br. Pharm.*, 1885.

Action, Medical Uses, and Dosage.—(See *Anthemis.*) A useful preparation in the *bowel troubles of dentition*. Dose, ½ to 2 fluid ounces, smaller doses being given to children. It is emetic when warm; tonic and nervine when cold.

INFUSUM APII COMPOSITUM.—COMPOUND INFUSION OF PARSLEY.

Preparation.—Take of parsley roots and seeds, coarsely bruised, carbonate of iron, each, 4 ounces; horseradish root, in small pieces, 2 ounces; juniper berries, squill, white mustard seed, mandrake root, and queen of the meadow, of each, finely bruised, 1 ounce; good cider, 6 quarts. Boil the cider and pour it on the rest of the articles mixed together in an earthen vessel; cover the vessel, and digest with a gentle heat for 24 hours.

The cider should not be hard, nor too new, but sparkling and pleasantly tart, and, after digestion by heat, it should be allowed to remain upon the articles without straining it off. By this course, the liquid becomes still further impregnated with the properties of the medicines.

Action, Medical Uses, and Dosage.—This is a most excellent preparation in several varieties of *dropsy*, for which alone it is used. It increases the action of the kidneys, regulates the bowels, improves the digestive functions, and promotes activity of the absorbent vessels. The dose is 1 or 2 fluid ounces, 3 times a day. In the summer season, half the above quantity may be made at one time, as otherwise it becomes very sour and moldy. It should always be used immediately after its preparation (J. King).

INFUSUM AURANTII COMPOSITUM.—COMPOUND INFUSION OF ORANGE PEEL.

Preparation.—Infuse, in a closed vessel for 15 minutes, ¼ ounce (av.) of bitter orange peel (cut small); 56 grains of fresh lemon peel (cut small), and 28 grains of bruised cloves, in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—Used chiefly as a carminative. Dose, ½ to 2 fluid ounces.

INFUSUM BUCHU.—INFUSION OF BUCHU.

Synonyms: *Infusum diosmæ, Infusum barosmæ.*

Preparation.—Infuse, in a closed vessel, for 30 minutes, ½ ounce (av.) of bruised buchu leaves, in 10 fluid ounces (Imp.) of boiling water. Strain.

Action, Medical Uses, and Dosage.—(See *Buchu.*) One of the best forms in which to employ buchu. Dose, ½ to 2 fluid ounces.

INFUSUM CALUMBÆ.—INFUSION OF CALUMBA.

SYNONYM: *Infusion of columbo.*

Preparation.—Macerate, in a closed vessel, for 30 minutes, ½ ounce (av.) of calumba root (cut small), in 10 fluid ounces (Imp.) of cold water. Strain. When made with boiling water the preparation is mucilaginous, and is not believed to keep so well. T. Greenish, however, states that the contrary is true, and directs that cold water be first used, thus getting rid of the starch, and afterward bringing the infusion to the boiling point, by means of which the albumen is coagulated. Greenish's views are not generally accepted, for according to the weight of evidence, the infusion made by means of cold water is most permanent.

Action, Medical Uses, and Dosage.—(See *Calumba.*) Dose, 1 to 2 fluid ounces, before meals.

INFUSUM CARYOPHYLLI.—INFUSION OF CLOVES.

Preparation.—Macerate, in a closed vessel, for 30 minutes, ¼ ounce (av.) of bruised cloves in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—(See *Caryophyllus.*) Carminative. Used chiefly in the *nausea of debility*, and in pains induced by *flatulence.*

INFUSUM CATECHU.—INFUSION OF CATECHU.

SYNONYMS: *Compound infusion of catechu*, *Infusum catechu compositum* (*U. S. P.*, 1870).

Preparation.—Infuse, in a closed vessel, for 30 minutes, 160 grains (av.) of coarsely powdered catechu, and 30 grains (av.) of bruised cinnamon bark, in 10 fluid ounces (Imp.) of boiling distilled water. Strain. This accords with the *Br. Pharm.*

Action, Medical Uses, and Dosage.—(See *Catechu.*) Used chiefly in *non-irritant diarrhœa.* Dose, 1 to 3 fluid ounces.

INFUSUM CINCHONÆ (U. S. P.)—INFUSION OF CINCHONA.

SYNONYM: *Acid infusion of cinchona.*

Preparation.—"Cinchona, in No. 40 powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; aromatic sulphuric acid, ten cubic centimeters (10 Cc.) [162 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the acid with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, and moisten the powder with thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of the mixture; pack it firmly in a conical glass percolator, and gradually pour upon it, first, the remainder of the mixture, and afterward water, until the infusion measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

The *Br. Pharm.* directs red cinchona bark. Yellow bark is preferable for this preparation, although the *U. S. P.* permits any good cinchona. This preparation represents a solution of the cinchona alkaloids in the form of sulphates, and is an efficient preparation.

Action, Medical Uses, and Dosage.—(See *Cinchona.*) Used mostly as a tonic. Dose, 2 fluid ounces, 3 times a day.

INFUSUM CUSSO.—INFUSION OF KOUSSO.

SYNONYMS: *Infusum brayeræ* (*U. S. P.*, 1880), *Infusion of brayera.*

Preparation.—Infuse, in a closed vessel for 15 minutes, ½ ounce of coarsely powdered kousso in 8 fluid ounces (Imp.) of boiling distilled water. Do not strain. This accords with the *Br. Pharm.*

The *U. S. P.*, 1870, directed brayera, No. 20 powder, 6 parts; boiling water, 100 parts. The *National Formulary* directs as follows:

INFUSUM BRAYERÆ (N. F.) (*U. S. P.*, 1880), *Infusion of brayera.—Formulary number*, 191: "Brayera, in No. 20 powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; boiling water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour the boiling water upon the brayera, and let it macerate in a covered vessel until cool. The infusion should be dispensed without straining"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—As a vermifuge, this infusion should be taken fasting, one-half the quantity being given an hour before the second portion, the flowers being swallowed with the infusion. This is the original Abyssinian method of administering cusso.

INFUSUM DIGITALIS (U. S. P.)—INFUSION OF DIGITALIS.

Preparation.—"Digitalis, bruised, fifteen grammes (15 Gm.) [232 grs.]; alcohol, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; cinnamon water, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; boiling water, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; cold water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Upon the digitalis, contained in a suitable vessel, pour the boiling water, and allow it to macerate until the mixture is cold. Then strain, add the alcohol and cinnamon water to the strained liquid, and pass enough cold water through the residue on the strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

The cinnamon in this preparation is merely added to flavor the infusion, while the alcohol tends to preserve it. Infusion of digitalis throws down a precipitate on standing several hours.

Action, Medical Uses, and Dosage.—(See *Digitalis.*) Infusion of digitalis is the most efficient preparation of foxglove, and is particularly applicable when a diuretic action is desired. It should be remembered that digitalis acts slowly and the infusion should not be pushed too fast, lest an over action result from it a day or two after its administration. Dose, 1 to 4 fluid drachms, 3 times a day, carefully watching its action.

INFUSUM EPIGÆÆ COMPOSITUM.—COMPOUND INFUSION OF TRAILING ARBUTUS.

SYNONYM: *Diuretic compound.*

Preparation.—Take of trailing arbutus, queen of the meadow root, dwarf-elder bark, marshmallow root, each, coarsely bruised, ½ ounce; boiling water, good Holland gin, of each, 1 pint; honey, a sufficient quantity. Pour the boiling water and gin on the plants, and digest them with gentle heat, in a close-covered vessel, for 6 hours; then remove from the fire, strain, and add sufficient honey to render it pleasantly sweet.

Action, Medical Uses, and Dosage.—This is a very valuable remedy in *gravel*, in *chronic catarrh of the bladder*, *suppression of urine*, *high colored* or *scalding urine*, *inflammation of the urethra*, and other *disorders of the urinary organs*. In *oxalic deposits*, however, it is of no utility. The dose is about 2 fluid ounces, 3 or 4 times a day; in severe cases, this dose may be given every hour until relief is obtained, after which every 3 or 4 hours. In cases of gravel, a corresponding quantity of wild carrot root and seed may be advantageously added to the articles (J. King

INFUSUM ERGOTÆ.—INFUSION OF ERGOT.

Preparation.—Infuse, in a closed vessel for 30 minutes, ¼ ounce (av.) of coarsely powdered ergot in 10 fluid ounces (Imp.) of boiling distilled water. Strain—*Br. Pharm.*

Action, Medical Uses, and Dosage.—About 10 grains of ergot are contained in a fluid ounce of this infusion, the dose of which is from 1 to 2 fluid ounces. It is used as a parturient.

INFUSUM GENTIANÆ COMPOSITUM.—COMPOUND INFUSION OF GENTIAN.

Preparation.—"Gentian, in moderately coarse powder, ½ troy ounce; bitter orange peel, in moderately coarse powder, coriander, in moderately coarse powder, of each, 60 grains; alcohol, 2 fluid ounces; water, a sufficient quantity. Mix the alcohol with 14 fluid ounces of water, and, having moistened the mixed powders with 3 fluid drachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them, first, the remainder of the menstruum, and afterward water, until the filtered liquid measures a pint"—(*U. S. P.*, 1870).

The following accords with the *Br. Pharm.:* Infuse, in a closed vessel for 30 minutes, 55 grains each of sliced gentian root and bitter orange peel (cut small), and ¼ ounce (av.) of fresh lemon peel (cut small) in 10 fluid ounces (Imp.) of boiling distilled water. Strain.

The formula of the *U. S. P.*, 1870, is to be preferred to that of the latter, as it is a more efficient product, and, on account of the alcohol it contains, is much more easily preserved.

Action, Medical Uses, and Dosage.—Stomachic and tonic. Dose, ½ to 1 fluid ounce, 3 times a day.

Related Infusion.—INFUSUM GENTIANÆ COMPOSITUM FORTIUS (N. F.), *Stronger compound infusion of gentian. Formulary number*, 192: "Gentian, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; coriander, thirty-five grammes (35 Gm.) [1 oz. av., 93 grs.]; bitter orange peel, thirty-five grammes (35 Gm.) [1 oz. av., 93 grs.]; diluted alcohol (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Reduce the drugs to a moderately coarse (No. 40) powder, moisten it with diluted alcohol, pack it in a percolator, and percolate with diluted alcohol, until one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] are obtained. *Note.*—When *Infusum gentianæ compositum* is prescribed, mix 1 volume of this preparation with 3 volumes of water"—(*Nat. Form.*).

INFUSUM GERANII COMPOSITUM.—COMPOUND INFUSION OF CRANESBILL.

Preparation.—Take of cranesbill, witch-hazel, black cohosh, and golden seal, each, coarsely bruised, ½ ounce; boiling water, 2 pints. Mix the articles together, and digest with a gentle heat, in a closed vessel, for 2 hours; remove from the fire and strain. If required, alum, 1 drachm, may be added.

Action, Medical Uses, and Dosage.—This forms an efficient astringent wash in aphthous and other *diseases of the mouth and throat*, when unaccompanied with inflammation; and is also useful as an injection in *leucorrhœa*, *prolapsus ani*, and *prolapsus uteri*. Without the alum, this infusion may be administered internally in doses of from 1 fluid drachm to ½ fluid ounce, repeated 3 or 4 times a day, and will prove efficient in *chronic diarrhœa* and *dysentery*, in *passive hemorrhages*, in *hemorrhoids*, and in *debilitated conditions of the venous system* (J. King).

INFUSUM HYDRASTIS COMPOSITUM.—COMPOUND INFUSION OF GOLDEN SEAL.

Preparation.—Take of golden seal, blue cohosh, witch-hazel, of each, in powder, ½ ounce; boiling water, 1 pint; pulverized alum, 1 drachm; honey, a sufficient quantity. Add the plants to the boiling water, and digest with a gentle heat, in a closed vessel, for ½ hour, remove from the fire, strain, add the alum, and sufficient honey to thoroughly sweeten the infusion.

Action, Medical Uses, and Dosage.—This infusion is very valuable as a wash or gargle in various forms of *sore mouth* and *ulcerated sore throat*. Without the alum, it may also be employed internally in the same cases as named in the preceding article (J. King). Dose, ½ to 1 fluid ounce.

INFUSUM JABORANDI.—INFUSION OF JABORANDI.

Preparation.—Infuse, in a closed vessel, for 30 minutes, ½ ounce (av.) of jaborandi (cut small), in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—(See *Pilocarpus.*) The large doses necessary render this infusion somewhat apt to provoke nausea and vomiting, though it well represents the virtues of jaborandi. Dose, ½ to 2 fluid ounces.

INFUSUM KRAMERIÆ.—INFUSION OF RHATANY.

Preparation.—Infuse, in a closed vessel, for 30 minutes, ½ ounce (av.) of rhatany-root (No. 40 powder), in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*). Each fluid ounce contains 23 grains; that of the *U. S. P.*, 1870, contained 30 grains.

Action, Medical Uses, and Dosage.—(See *Krameria.*) Useful in *passive hemorrhages* and *mucous profluvia.* Dose, ½ to 2 fluid ounces.

INFUSUM LINI.—INFUSION OF LINSEED.

SYNONYMS: *Infusum lini compositum* (*U. S. P.*, 1870), *Infusion of flaxseed.*

Preparation.—Infuse, in a closed vessel, for 2 hours, 150 grains (av.) of linseed (whole), and 50 grains (av.) of liquorice-root (No. 20 powder), in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*). The *U. S. P.*, 1870, process directed flaxseed, ½ troy ounce; bruised liquorice-root, 120 grains, and boiling water, 1 pint. Macerate 2 hours and strain. The linseed should not be bruised, else the swelling of the seed will prevent straining, and as the mucilage is in the testa of the seed, bruising is wholly unnecessary.

Action, Medical Uses, and Dosage.—(See *Lini Farina.*) Useful in *acute respiratory disorders*, but the liquorice impairs its usefulness in intestinal inflammations. It may be freely used for the administration of magnesium sulphate and quinine salts, though it is employed chiefly for coloring and flavoring purposes. *Buccal and faucial inflammations* and *ulcerations* may be washed with it, and given internally, through the sulphuric acid contained in it, it exerts some control over *colliquative sweats.* Dose, 1 to 4 fluid ounces.

Related Preparation.—INFUSUM ROSÆ COMPOSITUM (N. F.), *Compound infusion of rose. Formulary number*, 193: "Red rose, thirteen grammes (13 Gm.) [201 grs.]; diluted sulphuric acid (*U. S. P.*), nine cubic centimeters (9 Cc.) [146 ♏]; sugar, forty grammes (40 Gm.) [1 oz av., 180 grs.]; boiling water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour the boiling water upon the rose, in a glass or porcelain vessel, add the acid, cover the vessel, and macerate for an hour. Then dissolve the sugar in the liquid and strain.

INFUSUM LUPULI.—INFUSION OF HOP.

SYNONYM: *Infusum humuli* (*U. S. P.*, 1870).

Preparation.—Infuse, in a closed vessel, for 1 hour, ½ ounce (av.) of hops i 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*).

Action, Medical Uses, and Dosage.—(See *Humulus.*) An efficient form for the administration of hops. Dose, ½ to 2 fluid ounces.

INFUSUM PRUNI VIRGINIANÆ (U. S. P.)—INFUSION OF WILD CHERRY.

Preparation.—"Wild cherry, in No. 20 powder, forty grammes (40 Gm.) [1 oz av., 180 grs.]; water, a sufficient quantity to make one thousand cubic centimeters

(1000 Cc.) [33 fl℥, 391 ♏]. Moisten the powder with sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏] of water, and macerate for 1 hour; then pack it firmly in a conical glass percolator, and gradually pour water upon it until the infusion measures one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*

On account of the volatile character of the active constituents of wild cherry, cold water only should be used in preparing an infusion of it. A transparent, wine-colored infusion, pleasantly bitter, and possessing the well-known flavor of bitter almonds.

Action, Medical Uses, and Dosage.—(See *Prunus virginiana.*) Sedative and tonic. Dose, 1 to 3 fluid ounces, 3 or 4 times a day.

INFUSUM QUASSIÆ.—INFUSION OF QUASSIA.

Preparation.—Macerate, in a closed vessel for 30 minutes, 55 grains of quassia wood (in chips) in 10 fluid ounces of cold distilled water. Strain—(*Br. Pharm.*). Warm water is equally or more effective for the preparation of this infusion. The above process of the *Br. Pharm.* yields an infusion of only one-fourth of the strength which might be had by employing the *U. S. P.* general method.

Action, Medical Uses, and Dosage.—A pure, bitter stomachic tonic. Dose, ½ to 2 fluid ounces.

INFUSUM SALVIÆ COMPOSITUM.—COMPOUND INFUSION OF SAGE.

Preparation.—Take of sage leaves, hyssop leaves, of each, 1 ounce; boiling water, 2 pints; pulverized borax, 1 drachm. Place the herbs in the boiling water, allow them to digest for ½ hour, then strain and add the borax.

Action and Medical Uses.—This infusion is employed as a wash and gargle in *aphthæ*, *sore throat*, and *quinsy*, when accompanied with inflammation.

INFUSUM SENNÆ.—INFUSION OF SENNA.

Preparation.—Infuse, in a closed vessel for 30 minutes, 1 ounce (av.) of senna and 28 grains of sliced ginger in 10 fluid ounces (Imp.) of boiling distilled water. Strain—(*Br. Pharm.*). The *U. S. P.*, 1870, directed senna, 1 troy ounce; bruised coriander, 60 grains; boiling water, 1 pint. Macerate 1 hour. Strain. Infusion of senna, when exposed to the atmosphere, precipitates a yellow deposit, which is said to increase its tendency to gripe.

Action, Medical Uses, and Dosage.—(See *Senna.*) Dose, 1 to 4 fluid ounces.

INFUSUM SENNÆ COMPOSITUM (U. S. P.)—COMPOUND INFUSION OF SENNA.

SYNONYM: *Black draught.*

Preparation.—"Senna, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; manna, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; magnesium sulphate, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs]; fennel, bruised, twenty grammes (20 Gm.) [309 grs.]; boiling water, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]; cold water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Upon the senna and fennel, contained in a suitable vessel, pour the boiling water, and macerate until the mixture is cold. Then strain with expression, dissolve in the infusion the magnesium sulphate and manna, and again strain. Lastly, add enough cold water through the strainer containing the senna and fennel to make the infusion measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

This is the famous *black draught*, and should not be confounded with *black drop*, or vinegar of opium (*Acetum Opii*). These names should be dropped from medical literature, as much harm has and may still result from confusing the one with the other. The infusion should not be allowed to macerate too long, lest an increased griping result from its use. The addition of the fennel is for the purpose of lessening its tendency to gripe.

Action, Medical Uses, and Dosage.—(See *Senna*.) Purgative. Dose, 1 to 4 fluid ounces every 1 or 2 hours until catharsis occurs.

INFUSUM VALERIANÆ. INFUSION OF VALERIAN.

Preparation.—Infuse in a closed vessel for 1 hour, ¼ ounce (av.) of bruised valerian rhizome in 10 fluid drachms (Imp.) of boiling distilled water. Strain —*Br. Pharm.*

Action, Medical Uses, and Dosage.—(See *Valeriana*.) Dose, ½ to 2 fluid ounces.

INJECTIO APOMORPHINÆ HYPODERMICA.—HYPODERMIC INJECTION OF APOMORPHINE.

Preparation.—"Take of apomorphine hydrochlorate, 2 grains; camphor water, 100 minims. Dissolve and filter. The solution should be made as required for use. Dose, by subcutaneous injection, 2 to 8 minims"—(*Br. Pharm.*). Equal to about 1/25 to 1/6 grain of apomorphine hydrochlorate.

INJECTIO ERGOTINI HYPODERMICA.—HYPODERMIC INJECTION OF ERGOTIN.

Preparation.—"Take of ergotin, 100 grains (or 1 part); camphor water, 200 fluid grains (or 2 fluid parts). Dissolve by stirring them together. The solution should be made as required for use. Dose, by subcutaneous injection, 3 to 10 minims"—(*Br. Pharm.*). Equal to about 1 to 3½ grains of ergotin.

INJECTIO MORPHINÆ HYPODERMICA.—HYPODERMIC INJECTION OF MORPHINE.

Preparation.—"Take of hydrochlorate of morphine, 92 grains; solution of ammonia, acetic acid, distilled water, of each, a sufficiency. Dissolve the hydrochlorate of morphine in 2 ounces of distilled water, aiding the solution by gently heating; then add solution of ammonia so as to precipitate the morphine, and render the liquid slightly alkaline; allow it to cool; collect the precipitate on a filter, wash it with distilled water, and allow it to drain; then transfer the morphine to a small porcelain dish with about an ounce of distilled water, apply heat gently, and carefully add acetic acid until the morphine is dissolved, and a very slightly acid solution is formed. Add now sufficient distilled water to make the solution measure exactly 2 fluid ounces. Filter and preserve the product in a stoppered bottle excluded from the light"—(*Br. Pharm.*).

Description. This is a slightly acid, clear solution, free from any solid particles when freshly prepared. When kept, it slowly disintegrates, acquiring a brownish color, crystals of morphine being gradually deposited. To prevent this change, Squibb recommended 1/6 per cent of pure carbolic acid; Johnson, sulphurous acid (5 drops to the fluid ounce, Jennings); and Limousin, 1/5 per cent of salicylic acid. "A fluid drachm of it, rendered slightly alkaline by the addition of solution of ammonia, yields a precipitate of morphine which, after being washed and dried, should weigh 4.25 grains, corresponding to 6 grains of acetate of morphine"—(*Br. Pharm.*).

Dose, by subcutaneous injection, from 1 to 6 minims (1/12 to ½ grain) beginning with the smaller doses.

INULA (U. S. P.)—INULA.

"The root of *Inula Helenium*, Linné"—(*U. S. P.*) (*Corvisartia Helenium*, Mérat). *Nat. Ord.*—Compositæ.

Common Names: *Elecampane*, *Scabwort*.

Illustrations: Millspaugh, *Amer. Med. Plants*, Pl. 81; Bentley and Trimen, *Med. Plants*, 150; Woodville, *Med. Bot.*, 26.

Botanical Source.—Elecampane has a thick, tap-shaped, branching, aromatic, and perennial root, with a thick, leafy, round, furrowed, solid stem, from 4 to 6 feet high, branched and downy above. The leaves are large, ovate, serrate, veiny, smooth, of a dark-green color above, downy and hoary beneath, with a fleshy midrib; radical ones petiolated, from 1 to 3 feet in length, by 6 or 12 inches wide; cauline ones sessile and amplexicaul. The flower-heads are large, radiated, solitary at the downy summits of the branches, 2 inches broad, and of a bright-yellow color. The involucre is hemispherical; the outer scales broad, recurved, leafy, and finely downy on both sides; the inner ones linear. The florets of the ray are numerous, pistillate, long, and narrow, in 1 row, and terminate in 3 unequal teeth; the disk-florets are numerous, perfect, tubular, and 5-toothed, and the anthers have 2 bristles at the base. Ovary oblong. Achenia quadrangular and smooth; pappus simple and roughish. The receptacle is reticulated, and not quite smooth or naked (L.—W.—G.—T.).

Fig. 146.

Inula Helenium, with root.

History and Description—Elecampane is common to Europe, and cultivated in this country, growing in pastures, along roadsides, etc., flowering from July to September. The root, which is the part used, should be gathered in the second year of its development, and during the fall months. When recent it is quite thick, spindle-shaped, dividing, with many delicate fibers; its color is yellowish-gray externally. Iodine colors the root brown, and the infusion is changed to a green color by the addition of ferric chloride. The *U. S. P.* describes *Inula* as follows: "In transverse, concave slices or longitudinal sections, with overlapping bark, externally wrinkled and brown; flexible in damp weather; when dry, breaking with a short fracture; internally grayish, fleshy, slightly radiate, and dotted with numerous shining, yellowish-brown resin-cells; free from starch; odor peculiar, aromatic; taste bitter and pungent"—(*U. S. P.*).

Chemical Composition.—The following percentage composition of inula is recorded in Hager's *Handbuch der Pharm. Praxis*, Vol. II, 1886. p. 76: "*Inulin*, 30 to 40; a trace of volatile oil; *inula* (*alant*) *camphor*, or *helenin*, a crystallizable, volatile substance, 0.5; wax, 0.3; acrid soft resin, 2; glutinous bitter extractive, 33; protein bodies, 12.5; cellulose, 9.6; potassium and calcium salts. *Inulin* ($6C_6H_{10}O_5 + H_2O$, Kiliani, 1881), an isomer of starch, was discovered in elecampane by Val. Rose, in 1804, and was called by him *alantin*. Sometimes it is also termed *helenin*. It is a fine, white, starchy powder, very hygroscopic, tasteless, and inodorous; its specific gravity is 1.356. Iodine gives it a yellow color, which distinguishes it from starch, and also renders it insoluble in water. It is soluble in boiling water, from which it is deposited as the solution cools. It is insoluble in alcohol. Diluted acids, upon heating, transform it into *lævulose*, the intermediary products, *metinulin* and *lævulin* ($C_6H_{10}O_5$), being formed. Ferments, *e. g.*, diastase, yeast, emulsin, saliva, have but a slight sugar-forming effect upon inulin (Dragendorff, 1870; also see Husemann and Hilger, *Pflanzenstoffe*, 1882, Vol. I, p. 142). The researches of Kiliani made it probable that inulin is chemically the anhydride of lævulose (see *Amer. Jour. Pharm.*, 1881, pp. 188 and 469). Its solution in boiling water produces left-handed rotation upon a ray of polarized light. It melts near 165° C. (229° F.), gives off water, and leaves a scaly, sweetish, gummy mass.

readily soluble in water. Concentrated nitric acid, heated with it, converts it into oxalic acid. Diluted nitric acid, by oxidation, changes it into formic, oxalic glycolic, and racemic acids. Inulin does not reduce Fehling's solution, nor does it undergo fermentation. It may be prepared in abundance also from dandelion roots, and those of the dahlia and other roots of the *Compositæ*, when dug up in the autumn. Roots dug in the autumn yield over twice the amount (44 per cent, Dragendorff) yielded by spring roots. In the spring of the year a portion of the inulin seems to have been changed into lævulin, mucilage, sugar, and several glucosids.

Alant camphor (*helenin*) was observed in the root of elecampane as early as 1760, by Léfebure and others (see Husemann and Hilger), as it sometimes crystallizes on old roots. J. Kalien (*Ber. d. Deutsch. Chem. Ges.*, 1873 and 1876), has shown this volatile substance, which he obtained by distillation of the root with water, to be composed of needle-like crystals of *alantic anhydride* ($C_{15}H_{20}O_2$), melting at 66° C. (150.8° F.); *alantol* ($C_{10}H_{16}O$), an aromatic liquid; *alant camphor* proper ($C_{10}H_{16}O$), the latter a white substance melting at 64° C. (147.2° F.), of a mint-like, aromatic odor; and *helenin* (C_6H_8O), an odorless, bitterish, crystallizable principle, with melting point at 110° C. (230° F.).

Action, Medical Uses, and Dosage.—Elecampane is an aromatic stimulant and tonic, and is said to be expectorant, emmenagogue, diuretic, and diaphoretic. It is much used in *chronic pulmonary affections*, *weakness of the digestive organs*, *hepatic torpor*, *atonic dyspepsia*, with flatus, and internally and externally in *tetter*, *itch*, and other *cutaneous diseases*. When added to the compound syrup of spikenard, it should be exhausted by boiling alcohol, and the tincture added to the syrup, instead of boiling it with the other articles, as is usually done. The alcoholic extract, combined with powdered extract of liquorice, benzoic acid, sanguinaria, and morphine, forms a lozenge or pill very valuable in *chronic catarrhal*, *bronchial*, and all *pulmonary irritations*. One drop of the oil of stillingia may be added to each lozenge for *bronchial and laryngeal affections*. *Night-sweats* are relieved by inula, as are some cases of *humid asthma*, and, by its tonic properties, it tends to sustain the strength of the patient in chronic disorders of the respiratory tract. Helenin is accredited with a fatal action upon the tubercle bacillus by Korab, Blocq, and others. Inula is somewhat slow in action, and should be used for quite a time to get its full action. That it is an important remedy in irritation of the trachea and bronchiæ is now well established. It is adapted to cases with free and abundant expectoration, teasing cough, and pain beneath the sternum, conditions frequent in *la grippe*, and the severer forms of *colds*.

An efficient preparation is that recommended by Prof. Locke (*Syllab. of Mat. Med.*): ℞ Elecampane, ℥i; boiling water, 1 pint. Boil until but 8 ounces remain; add ½ pound of white sugar. *Chronic vesical catarrh* has yielded to the kindly action of elecampane. Both acute and chronic disorders may be treated with inula. It is also useful in *leucorrhœa*, and is especially effective in *catarrhal endometritis*, with discharge of glairy mucus. Dose of the powder, from 20 grains to 1 drachm; of the infusion, from 1 to 2 fluid ounces; syrup, 1 to 4 fluid drachms; specific inula, 5 to 40 drops; fluid extract, 10 to 60 drops; helenin, $\frac{1}{12}$ to ¼ grain. Elecampane should be restudied in reference to its action in catarrhal affections of the respiratory organs, and especially in relation to the kind of cough which is mentioned above.

Specific Indications and Uses.—Cough, of a teasing, persistent character, accompanied with substernal pain, and profuse secretion; atony of abdominal viscera, with engorgement and relaxation; catarrhal discharges.

Related Species. *Inula squarrosa*, Bernhardi *Inula Conyza*, De Candolle; *Conyza squarrosa*, Linné). Herb used in Europe. Diuretic and emmenagogue, and, when charred, employed as an insecticide.

Pulicaria dysenterica, Gaertner (*Inula dysenterica*, Linné), *Fleawort.*—Properties like those of the preceding species.

Carlina acaulis, Linné. *Carline thistle.*—Europe. The root, which is unpleasant in odor, and sweet, hot, and finally bitter to the taste, is the part employed. It contains volatile oil and resin. Diuretic and emmenagogue; large doses cathartic. The decoction or powder has been used in *amenorrhœa*, *impotence*, *glossal paralysis*, and in *typhoid states* of acute maladies. Dose of powdered root, from 10 to 20 grains, best administered in decoction. It appears to strongly influence the sexual organs of both male and female.

IODOFORMUM (U. S. P.)—IODOFORM.

FORMULA: CHI_3. MOLECULAR WEIGHT: 392.56.

"Iodoform should be kept in well-stoppered bottles, in a cool and dark place"—(*U. S. P.*).

History and Preparation.—Iodoform was discovered, in 1822, by Serullas, and introduced into medicine by Glover and Bouchardat, in 1837. Its composition was determined by Dumas (1834). It is formed when iodine, in the presence of caustic alkalies, or alkaline carbonates, acts upon a variety of substances, such as alcohol or acetone, aldehyde, lactic acid, acetic ether, and other readily saponifiable ethers. Gum, dextrin, and sugars, in aqueous solution, as well as albumen, casein, fibrin, and other proteid compounds in alkaline solutions, also give rise to iodoform when properly acted upon by iodine.

Iodoform may be prepared by heating an alcoholic solution of iodide of potassium to 40° C. (104° F.), then adding and stirring in successive quantities of chlorinated lime, until the dark-red color of the liquid is removed. On standing, crystals of iodoform and iodate of calcium are precipitated. Treat these with boiling alcohol of 90 per cent; the iodoform only is dissolved, and is deposited in crystals as the solution cools.

Suillot and Raynaud (1889) devised a process now largely employed in France, and by which an exceptionally pure product (the "*absolute iodoform*" of Casthélaz) is produced. It is prepared directly from *kelp* (ash of sea weeds), which is lixiviated; a definite quantity of potassium or sodium iodide prepared therefrom (say 25 parts); and acetone (3 parts), and caustic soda (1 part), both in solution in water (500 to 1000 parts), are added. Sodium hypochlorite solution is then added, drop by drop, as long as a precipitate of iodoform occurs. Filhol's method is favorably received, and gives a large yield (72 per cent). It is essentially as follows: Into a long-necked flask, with a long supply tube are introduced crystallized sodium carbonate (2 parts), water (10 parts), and alcohol (1 part). The mixture is then gradually and slowly heated to between 60° and 80° C. (140° to 176° F.). Then iodine (1 part) is added in fractional portions until the color is discharged. The solution is allowed to cool and the crystals collected upon a filter. The filtrate is then warmed, sodium carbonate (2 parts) and alcohol (1 part) added, and chlorine gas passed rapidly into the solution as long as iodoform is precipitated. More iodoform may be obtained by repeating this treatment of the filtrate. (For a review of some of the earlier methods of preparing iodoform, see *Pharm. Centralhalle*, 1882, p. 419.)

Description and Tests.—Iodoform is officially described as occurring in "small, lemon-yellow, lustrous crystals of the hexagonal system, having a peculiar, very penetrating and persistent odor, somewhat resembling that of saffron and iodine, and an unpleasant, slightly sweetish, and iodine-like taste. Specific gravity 2.000, at 15° C. (59° F.). Very slightly soluble in water, to which it, however, imparts its odor and taste. Soluble in about 52 parts of alcohol at 15° C. (59° F.), in about 12 parts of boiling alcohol, and in 5.2 parts of ether. Very soluble in chloroform, benzin, and fixed and volatile oils. Iodoform is slightly volatile even at ordinary temperatures, and in boiling water distills slowly over with its vapor. At about 115° C. (239° F.), it melts to a brown liquid, and at a higher temperature emits vapors of iodine, leaving behind a carbonaceous mass, which, upon full combustion, should be completely dissipated (absence of fixed impurities). On digesting about 0.1 Gm. of iodoform with 5 Cc. of a 5 per cent solution of potassium hydrate in alcohol, and then slightly supersaturating with diluted nitric acid, the liquid will be rendered blue by starch T.S. The solutions in neutral solvents are neutral to litmus paper. If 2 Gm. of iodoform be thoroughly shaken with 10 Cc. of water, the filtrate should be colorless and free from bitter taste (absence of soluble yellow coloring matters, picric acid, etc.), should not affect the color of litmus paper (absence of free acids), and should remain unaffected by silver nitrate T.S. (absence of soluble iodides)"—(*U. S. P.*).

Iodoform is somewhat unctuous to the touch. The aromatic oils of peppermint, anise, fennel, and others, as well as balsam of Peru and coumarin, have been said to mask its unpleasant odor, from 3 to 5 drops of oil of peppermint being recommended to disguise an ounce of iodoform in ointments or mixtures. Our experience is to the effect that none of them accomplish the purpose. Even though they cover the odor in mass, on exposure the rank odor of iodoform asserts itself. In this connection it may be said that Johnson and Johnson have introduced an *iodurct of carbon*, under the name *iodoform odorless*, which is claimed to be fully as efficient as ordinary iodoform, and free from all odor. Analysis by Prof. S. P. Sadtler gave 95.20 per cent iodine. To remove the odor from the hands, utensils, and instruments, first apply a few drops of oil of turpentine, and afterward thorougly wash with water and soap (see also *Iodoformum Aromatisatum*). Iodoform solutions, when exposed to sunlight, liberate iodine. The latter is contained in iodoform to the extent of 98.69 per cent. Gentle heat decomposes it into iodine and hydriodic acid. It is partially decomposed when boiled with solution of potassa, yielding iodide and formate of potassium. It is not likely to contain many impurities. Its chemical decomposition is analogous to that of chloroform.

Action, Medical Uses, and Dosage.—Ordinarily iodoform, when applied to the sound or broken skin, wounds, ulcers, and mucous membranes, is non-irritating, and acts as a topical anæsthetic. Occasionally, however, serious poisoning occurs from its absorption, and death has been known to result from such applications. Among the symptoms thus produced are drowsiness and stupor, meningitis, delirium, progressive emaciation, high fever, sphincter paralysis, and death. Occasionally an eczematous eruption is caused by it, or an erythema or papular eruption may appear. In one case under our treatment, after the removal of an encysted bullet from the knee, and the dressing of the wound with a 10 per cent iodoform gauze of standard make, an erythematous redness followed in 24 hours, succeeded in 2 days by an extensive and painful eruption of vesicles, filled with a deep, orange-colored serum. Considerable constitutional infection accompanied, with a rise in the temperature of 2 degrees. The whole knee was involved, and had the appearance of a large, rough-skinned orange. The lesion spread rapidly wherever the viscid serum touched the sound surface. It resisted ordinary treatment with sodium bicarbonate, borax, etc., until dusted with bismuth subnitrate, when healing took place rapidly. Applied to the rectum in suppository, iodoform so far blunts sensibility as to allow unconscious defecation. Iodoform, when employed in large quantities for packing, may become an encapsulated foreign body, and eventually gives rise to an iodoform "abscess," the contents of which are iodoform and mucus (Murrell). Chorea, suicidal mania, and profuse diarrhœa have followed the local use of iodoform. Internally, small doses (5 or 6 grains, or less) improve the appetite, and iodine quickly appears in the urine and saliva, escaping from the former as an iodide of sodium with a small portion of iodate. The symptoms produced by toxic doses are the following: Faintness, giddiness, headache, mental confusion, drowsiness, burning gastric pain, delirium, convulsions, unconsciousness, a quickened or slowed, small pulse, cold, livid skin with profuse perspiration, and general paralysis (Taylor, *Med. Juris.*, from *Br. Med. Jour.*, 1882).

In iodoform poisoning, the use of the drug should be stopped and the alkaline carbonates employed locally and internally together with the internal administration of bromide of potassium, acetate of potassium, or lemonade. As a rule, iodoform should not be used in conjunction with carbolic acid. Fatty degeneration of the kidneys, liver, and heart has been found after death from iodoform.

Iodoform has been used to some extent as an internal medicine. M. Righini (1862) stated that the inhalation of its ethereal solution is of great service in retarding the progress of phthisis. Foxwell, of Birmingham, England, now regards it as almost specific in the treatment of *phthisis.* From 1-grain pills, 6 times a day, he claims greater results than from any drug or combination he has employed. He has administered as high as 50 grains per day for long periods without ill results. The effects reported by Foxwell are: Soothing of nervous erethism, lessening of cough and expectoration, increased nutrition, and improvement of physical signs. Murrell, who endorses Foxwell's treatment in the main, in *phthisis* and *winter-cough*, found that in some cases the large doses had to be abandoned on account of the strong odor imparted to the breath, and the nausea and vomiting induced (Murrell, *Mat. Med.*, 1896). It is said to be very efficient in checking *pulmonary hemorrhage* in *tuberculosis of the lungs.* Internally, in the dose of 1 to 3 grains, 3 times a day, in pill form, it was formerly regarded useful in *goitre, scrofula. rachitis, glandular tumors, menstrual derangements, affections of the bladder*, etc, but is now seldom employed for these affections. It is, however, valued by some as an alterative in the same-sized doses, in *syphilis* and in *syphilitic neuralgia*.

Iodoform is best known as an antiseptic surgical dressing for use in *operations*, and as an application in various forms of *ulcerations*, syphilitic and otherwise. Few agents are more useful in the treatment of ulcerated, granulated, or abraded surfaces, than a solution of 1 part of iodoform in 4 parts of glycerin (Locke). In venereal diseases, barring its odor, which may be masked, however, it is one of the most useful of applications. *Soft chancres* readily yield to it, as do many painful *phagedenic ulcers*. For these purposes, the pure iodoform in small amount may be dusted upon the ulcers, or the powder proposed by Prof. Locke may be employed. It is composed of iodoform, 100 parts; thymol, 1 part, and sugar of milk, 200 parts. It is exceedingly useful in *syphilitic fissure of the tongue, syphilitic pharyngeal ulcers*, and *simple* or *syphilitic ozena*. It is without a superior in *hospital gangrene, gangrenous vulvitis, aphthous vulvitis* of debilitated children, and in ointment, to temporarily relieve *pruritis vulvæ*. It forms the chief application to *suppurating buboes*. A good form of exhibition is that given by Murrell: R Iodoform, ʒj; oil of eucalyptus, fl℥j; soft and hard petrolatum, of each, ℥ijss. Mix. In venereal diseases, the more irritable and painful the lesions, the more effectual is iodoform. *Gonorrhœa* and *gleet* may be well treated with iodoform, bougies containing that drug and oil of eucalyptus, being the preferable form for use. It is better adapted to *gonorrhœa of the female*. However, iodoform is less effectual in this class of diseases than other forms of treatment. *Chordee* is palliated by it. A 20 per cent ointment is reported to have subdued pain and swelling in *acute orchitis*. *Vaginismus* and other forms of *vaginal hyperæsthesia* are relieved by iodoform.

An ointment of 30 to 60 grains of iodoform to an ounce of lard or petrolatum, has been successfully applied to *tumors* and in certain dry forms of *skin diseases*, and especially of syphilitic origin. *Ringworm* is said to be cured by it. In suppository form with cacao butter (iodoform, grs. xxx; cacao butter, ℥j. Mix. Make 6 suppositories), it has proved beneficial in *cancer of the uterus*. *Cancer of the breast* and other *carcinomata* are also benefited by it. Its advantages are that it relieves pain, corrects the offensive odor, retards destruction of tissues, and conserves the strength of the patient. It does not arrest the secretions as does opium. An ointment (1 part to 15 of petrolatum) forms a good application in *cracked nipples*. The parts, however, should be thoroughly washed before suckling the child. *Painful chronic ulcers* should be first destroyed with nitric acid, and then treated with iodoform. Iodoform in ointment or suppository is exceedingly useful to subdue pain and promote healing in *rectal ulcers, hemorrhoids*, and *painful anal fissures*. It aids greatly by rendering defecation painless. Iodoform forms a good dressing after the opening of *boils* and *carbuncles*. The latter are said to have been aborted by the injection of an ethereal solution of iodoform.

An emulsion of iodoform has been employed for injecting *cold abscesses* and *tubercular caries* (Billroth), and in the treatment of *cystitis*. A solution of iodoform in ether or glycerin has been lauded by some as an injection for *empyema, abscesses*, and *joint affections*, all of *tuberculous character*. A collodion solution has been employed topically to *inflammatory swellings, chronic arthritis, localized neuralgias, goitre, swollen cervical*, and other *lymphatic glands*, and for the absorption of *peritoneal, pleuritic*, and *pericardial effusions*. A saturated chloroformic solution gives relief in various *superficial neuralgias*. A turpentine solution (4 per cent), inhaling from 3 to 5 drops, has been advised in *bronchiectasis* and in *laryngeal* and *pulmonic tuberculosis*. Murrell recommends the following powder for insufflation in *laryngeal phthisis:* R Iodoform, boric acid, aa ʒij; menthol, grs. x; phosphate of calcium, q. s., ℥j. All in fine powder. Mix.

Iodoform is largely used in the treatment of *simple, surgical, gunshot*, and *infected wounds*. For such purposes, the powder or the gauze are generally preferred. It relieves pain and promotes healing. As little should be used as will accomplish the desired purpose, and never should more than 30 grains be used at one dressing. Neither should its application be too frequent. Good drainage should be insured, and the parts should not be too snugly bandaged. Iodoform gauze should be preferred in *operations upon the intestines*, and *peritoneal* and other *cavities*.

Iodoform is an important agent in *nasal*, *ocular*, and *aural diseases*. As an insufflation powder, a combination of iodoform and tannic acid is effectual in *ozena*, *post-nasal catarrh*, and in *soft nasal hypertrophies*. A first decimal trituration dusted upon the lids with a soft brush, is useful in *granular conjunctivitis* (Locke). In eye disorders a 5 to 10 per cent ointment or an impalpable powder should be employed. Aged persons are sometimes toxically impressed by its application in ocular affections. Iodoform may be used after *operations upon the eye* or *appendages*, in *ciliary blepharitis*, *simple* and *serpiginous corneal ulcers*, *hypopyon keratitis*, *purulent conjunctivitis*, *pannus*, *ophthalmia neonatorum*, *phlyctenular conjunctivitis*, *palpebral ulcers*, and *conjunctival gumma*. Iodoform is employed in *suppurative ear affections*, particularly after the active phases have passed. The powder or gauze may be used after *operations upon the aural canal*. Foltz (*Dynam. Therap.*) declares the "pale mucous membrane" the indication for iodoform, and in *suppurative otitis media* prefers a mixture of equal parts of boric acid and iodoform. If eye or ear disorders are of syphilitic origin its use is particularly commended.

Various combinations of iodoform are employed locally, besides those already mentioned. The following are useful forms: (1) ANTISEPTIC POWDER: Iodoform 11 parts, bismuth subnitrate 4, salicylic acid 4, camphor 1 (Cavazini). (2) ANTISEPTIC PASTE: Iodoform 1 part, oil of camphor 4, salicylic acid 4, starch, a sufficient quantity to form a stiff paste. (3) INHALANT: Iodoform 1 part, oil of turpentine 8. (4) EMULSION: Iodoform 10 parts, glycerin 8, distilled water 2, tragacanth 5. This may be shaken with water in any quantity desired.

Ointments of iodoform (with petrolatum), usually contain from 5 to 10 per cent of the drug. With it may be incorporated some of the deodorants mentioned, particularly oil of camphor or eucalyptus. Glycerin solutions contain from 5 to 30 per cent; ether solutions, from 5 to 25 per cent; oleaginous solutions (olive oil), 10 to 25 per cent; flexible collodion solutions, 5 to 10 per cent; iodoform gauze, from 10 to 50 per cent, the former being generally preferred; trituration in milk sugar, 10 per cent. The dose of iodoform ranges from ½ grain to 3 grains, in pill.

Other Iodoform Preparations.—CARBASUS IODOFORMATA (N. F.), *Iodoform gauze. Formulary number*, 18: "Iodoform, ten grammes (10 Gm.) [154 grs.]; ether (*U. S. P.*), forty grammes (40 Gm.) [1 oz. av., 180 grs.]; alcohol, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; tincture of benzoin (*U. S. P.*), five grammes (5 Gm.) [77 grs.]; glycerin, five grammes (5 Gm.) [77 grs.]; gauze muslin, a sufficient quantity. Dissolve the iodoform in the ether, then add the alcohol, tincture of benzoin, and glycerin. Immerse in a weighed quantity of this solution, contained in a suitable vessel, the exact amount of gauze muslin required to absorb the whole of it, to produce a product of a prescribed percentage of iodoform, work it about with a pestle so as to impregnate it uniformly; then take it out, and hang it up to dry, in a horizontal position, and in a dark place. Lastly, wrap it in paraffin paper and preserve it in air-tight receptacles. *Note.*—To calculate the amount of muslin and of iodoform solution required to obtain a product approximately of any required percentage of iodoform, let x denote this required percentage. Then take of the above iodoform solution ten (10) times this quantity (or 10 x). Also multiply the required percentage (x) by three (3), divide the resulting product by two (2), and subtract the quotient from one hundred (100). The remainder represents the number of parts by weight of gauze muslin to be used. Regarding the most suitable kind of gauze muslin, see note to *Carbasus Carbolata* (F. 17)"—(*Nat. Form.*).

IODOFORMUM AROMATISATUM (N. F.), *Aromatized iodoform, Deodorized iodoform.*—"Iodoform, 25 parts; cumarin, 1 part. Mix them intimately by trituration. *Note.*—Should cumarin not be available, or should it be objectionable to the patient, the odor of iodoform may also be more or less masked by many essential oils, for instance those of peppermint, cloves, cinnamon, citronella, bergamot, sassafras, eucalyptus, etc. Another efficient covering agent is freshly roasted and powdered coffee. The odor of iodoform may be removed from the hands or any utensil which it has come in contact with, by washing them with an aqueous solution of tannic acid"—(*Nat. Form.*, 1st ed.).

Related Compounds.—ARISTOL, *Annidalin*, *Dithymol diiodide* ($C_{20}H_{24}O_2I_2$). An iodoform substitute preferred on account of its comparative lack of odor. It contains 45.8 per cent of iodine. It is a bulky, deep reddish-brown, amorphous powder, without taste, but having a peculiar and slightly aromatic odor, suggestive of iodine. Water and glycerin do not dissolve it, but it is readily dissolved by chloroform, ether, and collodion. Alcohol dissolves it with difficulty. Caustic alkalies do not effect its solution, though it is taken up by the fixed and essential oils, vaseline, petrolatum, etc. Sulphuric acid, heat, and light decompose it. Aristol is produced by the interaction of a solution of thymol in caustic soda solution and a solution of iodine in an aqueous solution of potassium iodide. Mr. George M. Beringer (*Amer. Jour. Pharm.*, 1891, p. 175) found commercial aristol to conform to the following formula, $C_{20}H_{24}I_2O_2 \, 2H_2O$, thus holding 6.14 per cent of water. Annidalin was originally one of the names applied to aristol, but it is chemically a dithymol diiodide. Aristol is employed as a cicatrizant and substitute for iodoform, consequently the conditions requiring its use need not be repeated. Some prefer it to iodoform. Foltz speaks highly of aristol, in dry powder, in *acute, subacute,* and *chronic suppurative otitis media,* and in *moist eczema of the external auditory canal,* with great itching. An ointment of aristol may be used upon *corneal ulcers,* after active inflammation has been subdued; and in *interstitial keratitis,* after subsidence of the acute phases it assists in clearing the cornea. In powder and ointment it has given good results in *phlyctenular conjunctivitis.* A 1 per cent solution in almond oil has been used by injection with apparently good results in *pulmonary tuberculosis.*

Carvacrol Iodide ($C_{13}H_{13}OI$).—A yellow-brown powder, which decomposes above the boiling point of water. It results when, in the manufacture of aristol, carvacrol is substituted for thymol.

Xeroform, *Tribromphenol-bismuth* ($C_6H_2Br_3O—Bi—O$).—A new substitute for iodoform, greater efficiency being claimed for it, besides its comparative lack of odor and the capability of being sterilized without decomposition at 110° C. (230° F.). (For its preparation, see *Pharm. Centralhalle,* 1895, p. 309.) It is a neutral, greenish-yellow, fine powder, tasteless, and having but a faint carbolic acid odor. It is not decomposed by light. Acids and bases decompose it, especially when heated. The claims made for it are: It is antibacterial, rendering poisonous toxines and ptomaines innocuous, and being itself non-poisonous; it limits and prevents the secretion of pus. It is desiccant, deodorant, analgesic, hemostatic, and promotes granulation and cicatrization. Bulk for bulk, it has greater covering power than iodoform. Having first thoroughly cleansed the parts, it should be applied exactly like iodoform. It is particularly claimed of value in *moist eczemas,* even when produced by iodoform. Success has been reported from its use in *fresh* and *infected wounds, old ulcerations, varicose ulcerations, suppurating buboes, abscesses, burns, chancroids, paronychiæ, boils, sycosis, pruritic affections, impetigo, nasal* and *aural diseases, antral disease,* and in *gynæcological disorders.* Its application is sometimes irritating at first, but this is said soon to pass off.

Europhen, *Diisobutyl-ortho-cresol-iodide* ($C_{22}H_{31}O_2I$).—Prepared like aristol, the thymol being substituted by isobutyl-ortho-cresol. A soft, fine, and light, non-crystalline, yellow powder, having a feeble, saffron-like odor, but no taste. Alcohol, chloroform, ether, collodion, and the fixed oils dissolve it, while in glycerin and water it is insoluble. It is much lighter than iodoform, being five times as bulky. When heated to 110° C. (230° F.), it yields a transparent, brown liquid. When dry, it is permanent. When moistened, it splits into iodine, and an iodine compound, which is soluble. Iodine is also set free by the alkalies and their carbonates. Light and heat decompose its solutions. Europhen contains 27.9 per cent of iodine. The general applications of this body are those of iodoform, being regarded by some as superior in certain *eye, ear,* and *nose affections,* and in various forms of *skin diseases, wounds,* and in *specific* and *non-specific ulcerations.*

Antiseptin, *Boro-thymol-zinc-iodide.*—Radlauer, who introduced this remedy, claimed it to be a definite chemical compound, but, according to F. Goldmann (*Pharm. Centralhalle,* 1891, p. 499), it is a mixture of zinc sulphate (85 parts), boric acid (10 parts), thymol (2.5 parts), and zinc iodide (2.5 parts).

Antiseptol, *Cinchonine iodosulphate,* or *Cinchonine herapathite.*—A compound of varying composition, according to methods of preparation. Usually a reddish-brown, light powder, containing 50 per cent of iodine, soluble in chloroform and alcohol, but not in water. It is prepared by precipitating cinchonine sulphate by means of solution of iodine in potassium iodide (Yvon, *Amer. Jour. Pharm.,* 1890, p. 493). Solutions of it are employed upon *wounds, ulcers,* and *hemorrhoids.*

Iodol, *Tetraiodo-pyrrol, Pyrrol tetriodide* (C_4I_4NH).—Introduced, in 1885, by Ciamician and Silber. Iodine is allowed to react with pyrrol in alcoholic (or methyl alcohol) solution. Upon the addition of water, iodol separates in crystalline, yellow flocculi. It may also be obtained as directed for aristol, substituting pyrrol for thymol. A bulky, pale-yellow, shining, crystalline powder, without odor or taste when pure. It contains 88.97 per cent of iodine. Water scarcely dissolves it, diluted alcohol but slightly, ether, alcohol, and the fixed oils freely dissolve it. Its solution in alcohol is miscible with glycerin. At the temperature of boiling water, it remains permanent, but at and above 145° C. (293° F.), decomposition takes place, iodine is given off, and the iodol burns without leaving a residue. Upon treatment with sulphuric acid, iodol turns green (see *Amer. Jour. Pharm.,* 1885, p. 605). It should not be confounded with *Iodal,* a substance resembling chloral in its action upon animals (Rabuteau), and prepared by acting upon a mixture of nitric acid and alcohol with iodine. Iodal is decomposed by alkalies, yielding formic acid and iodoform. Iodol is antiseptic and a substitute for iodoform. Its external use is reported to have produced toxic symptoms. Internally, in 2 or 3-grain doses, it has been employed in *diabetes mellitus, scrofula,* and *syphilis.* Applied locally, to *wounds, chancroids, ulcers, condylomata,* and *fungous growths;* and, by insufflation, in *laryngeal tuberculosis* and atrophic forms of *nasal* and *pharyngeal catarrh.*

Iodol has also been employed in *catarrhal eye affections,* but is said to be undesirable in *phlyctenular conjunctivitis.* It is more irritating in traumatic and ulcerated ear affections than iodoform. According to Foltz, it does not produce healthy granulations, and he declares it less efficient than boric acid in *purulent inflammation of the middle ear.* It is, however, said to be useful in *carious suppuration of the external auditory canal.* Dose, 2 to 20 grains.

Losophan (Losophane), *Tri-iodo-metacresol* ($C_6HI_3OH.CH_3$).—This body was introduced in 1892, and contains 78.39 per cent of iodine. It is prepared by the action of iodine upon meta-oxy-toluic acid ($C_6H_3.OH.CH_3.COOH$) in the presence of the calculated quantity of caustic alkali or alkaline carbonate. It forms white or colorless needles, without odor, and melting at 121.5° C. (250.7° F.). Ether, chloroform, benzol, and the fixed oils, when warmed to 60° C. (140° F.), dissolve it. Alcohol dissolves it with difficulty; in water it is insoluble. It is used for the same purposes as iodoform.

SOZOIODOLE, *Sozoiodol*, *Sozoiodolic acid*, *Diiodo-para-phenol sulphonic acid* ($C_6H_2.OH.I_2.SO_3H.+3H_2O$).—A compound containing 52.8 per cent of iodine. The potassium salt is prepared by the action of concentrated sulphuric acid upon phenol (carbolic acid), *para-phenol sulphonic acid* being formed. This is converted into the potassium salt, and the calculated amount of iodo-chloride is added, whereby the *sozoiodole-potassium* is precipitated as a crystalline substance, soluble with difficulty in water. It is then purified by recrystallization (Ostermayer, *Pharm. Centralhalle*, 1888, p. 534). Sozoiodolic acid occurs in small, prismatic needle-crystals, easily soluble in water, alcohol, or glycerin. With metallic bases it forms acid and neutral salts, the former of which constitute the medicinal salts generally employed. The four which have come into more prominent use are the following: (1) *Sozoiodole-sodium* (*Sodium sozoiodolate*), in colorless, inodorous, astringent-sweetish needles, soluble in water (1 in 20) in alcohol, and warm glycerin. This is the preparation known simply as SOZOIODOLE. It is non-toxic, antiseptic, and desiccant, and has a wide application in *venereal disorders*, in *ophthalmology*, in *affections of the nose and throat*, and in all cases requiring antiseptic treatment. It is used in powder of 1 to 10, or pure; and in solutions of 1 to 12 to 1 to 50 of solvent. (2) *Sozoiodole-potassium* (*Potassium sozoiodolate*), a white, light, inodorous powder, hardly soluble in warm alcohol, but soluble in water (1 in 100). Properties similar to the sodium compound; unlike the latter, it swells up when heated on platinum foil, similar to the phenomenon known as the "Pharaoh's Serpent." (3) *Sozoiodole-zinc* (*Zinc sozoiodolate*). Delicate, prismatic needle-crystals, colorless, odorless, soluble in glycerin and alcohol, and in 25 parts of water. More astringent than the preceding, and being more irritant and liable to prove escharotic in concentration, must be used in greater dilution. Specially applicable in *gonorrhœa*. Employed in powder, salve, or solution of strength ranging from 1 to 5 to 1 to 100. (4) *Sozoiodole mercury* (*Mercury sozoiodolate*). Very fine, orange-yellow powder, insoluble in water or alcohol, but dissolving in water (1 in 200) upon the addition of salt or hydrochloric acid. Caustic in concentrated form, and the only poisonous salt of the group. Employed like other mercury compounds, and as a general antiseptic like iodoform. Used in strengths of from 1 to 200 to pure, in powder, salve, or solution. These salts are odorless, non-toxic (except the mercury salt), soluble in one or more of the common solvents, non-decomposable by light, and in from 10 to 25 per cent triturations are claimed to have about the same power as pure iodoform. (For their detailed description, see *Pharm. Centralhalle*, 1890, p. 335.)

SOZAL, *Aluminum paraphenylsulphonate* (*Sozonate*) ($[C_6H_4[OH]SO_3]_6Al_2$).—Formed by double decomposition between barium paraphenolsulphonate and aluminum sulphate, or by dissolving aluminum hydrate in paraphenolsulphonic acid. It forms astringent, crystalline granules having a faint phenol odor. It is quite stable and forms permanent solutions with water, alcohol, or glycerin. It is one of the proposed antiseptic substitutes for iodoform.

SULPHAMINOL, *Thioxydiphenylamine* ($C_{12}H_9OS_2N$). *Metaoxydiphenylamine*, boiled with caustic soda solution and sulphur, filtered, and treated with ammonium chloride, yields a precipitate of sulphaminol. It is a light-yellow powder, tasteless and odorless, easily soluble in alcohol, glacial acetic acid, and alkali solutions, insoluble in water. Combined in solution with guaiacol, menthol, eucalyptol, and creosote, under the names of sulphaminol guaiacol, sulphaminol menthol, etc., it has been employed in *tubercular affections of the larynx*.

THIOPHENE (C_4H_4S).—An oily, colorless, mobile liquid, boiling at 84° C. (183.2° F.), a regular constituent of commercial coal-tar benzol (Victor Meyer, 1883), and isolated therefrom by agitation with strong sulphuric acid. It does not mix with water. Two of its compounds have been medicinally employed. Sodium thiophene sulphonate ($C_4H_3S.NaSO_3$) is a crystalline white powder containing of sulphur about 34 per cent. Thiophene diiodide ($C_4H_2I_2S.$) contains 9.5 per cent of sulphur and 75.6 per cent of iodine, and forms plate-like crystals soluble in the common solvents except water. It is volatile, and melts at 40.5° C. (104° F.). It is proposed as an iodoform substitute.

NOSOPHEN, *Tetraiodophenolphthalein* ($[C_6H_2I_2.OH]_2$:C:C_6H_4CO.O or $C_{20}H_{10}I_4O_4$).—This is an odorless iodine compound intended chiefly as an antiseptic powder—a substitute for iodoform. It has greater covering power than the latter. It is a tasteless, pale, yellowish-gray powder, containing 61.8 per cent of iodine. Nosophen is insoluble in water and acids, and feebly soluble in alcohol, while chloroform and ether dissolve it freely. Heating with strong sulphuric or hydrochloric acid decomposes it, iodine being liberated. Concentrated alkalies and diluted acids, however, do not decompose it, even upon boiling. It forms salts with sodium (antinosine), bismuth (eudoxine), mercury, zinc, etc. It is non-poisonous, possesses bactericidal, anæsthetic, antihemorrhagic, and desiccating properties, and may be used in a great variety of troubles, both locally and internally, in which iodoform is employed. It is used chiefly, however, in powder, as a topical agent. The dose is $\frac{1}{8}$ grain to 8 grains, but the bismuth salt (eudoxine) is preferred for internal administration.

ANTINOSINE is the sodium salt of nosophen, and is used chiefly in 1 to 5 per cent solutions, in antiseptic irrigations. It is a dark-blue amorphous powder, freely soluble in water and alcohol; also soluble in glycerin. It is not permanent, like nosophen, owing to the action of the atmospheric carbon dioxide. It has no odor, and is said to be non-irritant and non-poisonous.

EUDOXINE is the bismuth salt of nosophen. It is a tasteless and odorless, reddish-brown powder, containing 52.9 per cent of iodine and 14.5 per cent of bismuth. It is insoluble and non-poisonous. Alkalies decompose it, nosophen and bismuth oxide resulting. It has been recommended in the *bowel disorders of infants.* Eudoxine is the salt of tetra-iodo-phenol-phtalein, and is preferred for internal administration. Dose, ⅛ grain (very young infants), to 8 grains, 3 times a day.

IODUM (U. S. P.)—IODINE.

SYMBOL: I. ATOMIC WEIGHT: 126.53.

A non-metallic element obtained from *kelp,* and as a by-product from the mother liquor of Chili saltpeter. It should "be kept in glass-stoppered bottles, in a cool place"—(*U. S. P.*).

History and Source.—Iodine was discovered, in 1812, by M. Courtois, a saltpeter manufacturer of Paris; and, in 1820, its medicinal virtues were first made known by Dr. Coindet, Sr., of Geneva. It is prepared from the ashes of sea weeds, occurring on the coasts of France, Ireland, Scotland, Japan, etc. The ashes are of a dark color, and are known by the name of *kelp.* They contain about 0.2 per cent of iodine. It also occurs in sponge. The amount of iodine present in the different algæ varies according to the species. Mr. James Wheeler (1882) found comparatively large amounts of iodine in *Laminaria flexicaulis* and *L. saccharina.* According to L. Van Itallie (1889) about 0.01 per cent of iodine is contained in *Fucus vesiculosus* and *Chondrus crispus.* The occurrence of iodine in the beds of Chili saltpeter is also traceable to a probable marine origin.

Probably all varieties of *Gadus* (codfish) contain it in their livers—a maximum of 1 part in 60,000 (Mitchell Bird, 1882)—and the liver of *Raja clavata* and *R. batis* are said to contain even more than the cod-liver. Traces of iodine have been found in the liquids of *Julus fœtidissimus,* crabs, starfish, salted herrings, etc.

Its presence in minerals and natural waters is frequent. It has been found combined with mercury and silver, in the *cerussite* of Catorce, Mexico; in very small quantity in Silesian zinc ore; in the salt of Hall, Tyrol; in native nitrate of sodium; in Silesian coal; in the distillation products of coal; in the Jura limestones near Lyons and Montpellier; in clay, vegetable mold, sulphur, cinnabar, iron, and manganese minerals, gypsum, white chalk, etc. It has likewise been detected in rain and fresh water, and in various mineral waters, in different parts of the globe. The salt brines, left in the manufacture of salt and of bromine in West Virginia, were shown by Prof. Mallet (see *Amer. Jour. Pharm.*, 1881, p. 606) to contain considerable quantities of iodine.

Preparation.—Iodine is commonly prepared from kelp, which is lixiviated in water, the solution concentrated by evaporation, and the various salts of sodium and potassium deposited, whereby a dark-colored mother liquor is left, called *iodine lye.* Sulphuric acid is added to this to acidulate it, and to liberate carbonic acid, sulphurous acid, and hydrogen sulphide gas, while sulphur is deposited, and hydriodic acid is formed in solution. The acidulated lye is now introduced into a leaden still, and heated to 60° C. (140° F.) when manganese dioxide is gradually added; a leaden head is then adapted, heat is applied, iodine is evolved, and is collected into a series of glass receivers, on the inner surface of which it condenses. The following reaction takes place: $2IH+MnO_2+H_2SO_4 = MnSO_4+2H_2O+I_2$.

Soubeiran states that iodine may also be obtained from the mother liquor by the following process: Add sulphate of copper to the mother water so long as a white precipitate of cuprous iodide (Cu_2I_2) is thrown down, while part of the iodine remains in the fluid. Then treat the supernatant liquid with more of the sulphate, together with iron filings. The iron, taking the place of the copper in the solution, sets that metal free, and the metal, in the act of evolution, unites with the iodine in the fluid, so that more iodide of copper is formed. When this iodide is mixed with dioxide of manganese and sulphuric acid, a moderate heat decomposes it, and iodine is sublimed.

The crude iodine is purified to some extent by resublimation, but must undergo additional purification to get rid of traces of iodine chloride, bromide, or cyanide. For this purpose it is recommended by F. Musset (1890) to melt it under a concentrated layer of potassium iodide solution, allowing to cool, and washing out the iodine cake with water. Another method, that of Stas, to obtain pure iodine from potassium iodide solution, is to oxidize part of the iodide to iodate in such proportion that upon subsequent acidulation with sulphuric acid, iodine is precipitated according to the following equation: $KIO_3 + {}_5KI + {}_3H_2SO_4$ ${}_3K_2SO_4 + {}_3H_2O + I_6$. According to C. Meineke (*Chemiker Zeitung*, 1892, p. 1219 and 1230), an exceptionally pure iodine is yielded by this method. This author prefers the use of potassium permanganate as an oxidizer.

Description.—Iodine is usually sold in small scales, or rhombic plates; occasionally in solid masses. It is heavy, friable, dry, grayish-black or bluish-black in color, has a shining appearance, a peculiar, unpleasant, and irritating odor, and a sharp, acrid taste. It is brittle and easily pulverized, fuses at 114° C. (237.2° F.), boils at 175° C. (347° F.), though its vapor rises with that of boiling water. "As it fuses it is gradually dissipated in the form of a purplish vapor, leaving no residue"—(*U. S. P.*). At common temperatures it slowly evaporates. Its specific gravity is 4.948 at 17° C. (62.6° F.)—(*U. S. P.*). It stains the skin a deep brown, which slowly disappears, and, if the contact be prolonged, will destroy the soft textures of the body. Vegetable colors are slowly discharged by it. "Soluble in about 5000 parts of water, and in 10 parts of alcohol at 15° C. (59° F.) with a brown color; also freely soluble in ether, and in a solution of potassium iodide with a brown color; and in chloroform or carbon disulphide with a violet color"—(*U. S. P.*). According to W. Duncan (*Amer. Jour. Pharm.*, 1892, p. 100), the solubility of iodine in chloroform is limited to 1:56.6 at 10° C. F. Dietze (*Amer. Jour. Pharm.*, 1898, p. 574) states that its solubility in water is (on the average) 1:3600 at ordinary temperature, and 1:2200 at 30° C. (86° F.). It is soluble in water containing syrup of orange, and 6 ounces of water to which 2 grains of tannic acid are added, will dissolve 10 grains of iodine. In saline solutions it is much more soluble, and freely so in solutions of chloride of sodium, nitrate of ammonium, or iodide of potassium. It is very soluble in benzene, glycerin, or the volatile oils, but with some of them, especially those from the coniferous tribe of plants, considerable heat is evolved, brisk effervescence ensues, and much of the iodine is discharged in vapor. With castor oil, a 20 per cent solution of iodine may be obtained, which has the advantage of being miscible with alcohol (*Amer. Jour. Pharm.*, 1885, p. 435).

Iodized oil of juniper (iodine, ½ drachm, oil of juniper, 1 ounce, the iodine to be added gradually until the whole is added) possesses all the properties of the tincture of iodine, and its use is not attended with discoloration of the cuticle. Iodine unites with oxygen or hydrogen to form acids, also with sulphur, phosphorus, carbon, chlorine, etc., and readily unites with metals, such as copper, iron, silver, etc. Its characteristic reaction is that with starch. This substance, if converted by boiling with water into soluble starch, forms a blue precipitate with it, of such intensity that iodine may easily be detected in 450,000 parts of water. To effect this the iodine must be free, which may be obtained by adding a little nitric acid to the suspected solutions, and the solutions must be cold (see also *Amylum*). Iodine is easily mixed with fatty substances; it is apt to escape from the surface of ointments, unless united with iodide of potassium, which impedes this result. The combination of iodine with hydrogen forms a gaseous acid, called *hydriodic acid* (IH), and that with oxygen forms two acids, the *iodic* (IO_3H) and *per-iodic acids* (IO_4H). The preparation known as *colorless tincture of iodine* is a solution of iodine in combination, and will be considered in its proper place.

Tests.—"With starch T.S. it produces a dark-blue color. A solution of iodine in chloroform should be perfectly clear and limpid (absence of moisture). To determine the presence of cyanogen, chlorine, or bromine, proceed as follows: Triturate 0.5 Gm. of finely powdered iodine with 20 Cc. of water, and filter off the solution. To one-half of this solution, in a test-tube, carefully add decinormal sodium hyposulphite V.S., until the solution is just decolorized. Then add a few drops of ferrous sulphate T.S., and subsequently a little sodium hydrate T.S., and heat the mixture gently. On now adding a slight excess of hydrochloric acid, the liquid should not assume a blue color (absence of iodine cyanide). To the other half of the aqueous filtrate, in a test-tube, add a slight excess of silver nitrate T.S., shake actively, allow the precipitate to subside, and, having poured off the clear, supernatant liquid completely, shake the precipitate with a mixture of 1 Cc. of ammonia water and 9 Cc. of water, and filter. Upon the addition of a slight excess of nitric acid to the filtrate, not more than a slight opalescence should make its appearance (limit of chlorine or bromine). If 0.32 Gm. of iodine, together with 1 Gm. of potassium iodide, be dissolved in 20 Cc. of water, and the solution mixed with a few drops of starch T.S., it should require not less than 25 Cc. of decinormal sodium hyposulphite T.S. to discharge the blue or greenish color of the liquid (corresponding to at least 98.85 per cent of pure iodine)"—(*U. S. P.*). (For a detailed list of tests and the mode of their application, see this *Dispensatory*, preceding edition.)

Action, Medical Uses, and Dosage.—In large doses, iodine is an irritant and corrosive poison, stimulating the mucous membranes, liver, and absorbent glands, exciting the sexual organs, and producing debility of the digestive functions, muscular weakness, and emaciation. This influence upon the system, in which its poisonous effects are developed, is termed *iodism*. Its symptoms are fever, violent vomiting and purging, great thirst, palpitation, extreme restlessness, rapid emaciation, acute, epigastric pain, cramps, small and frequent pulse, violent priapism, trembling, occasional syncope, etc. These symptoms vary in different persons, and have even terminated fatally. From 4 to 6 grains have produced these symptoms, hence it should never be administered in large doses, and when these effects appear, the medicine should at once be stopped. (For further consideration of iodism, see *Potassii Iodidum.*)

In small, or medicinal doses, iodine is a stimulant, tonic, alterative, diuretic, emmenagogue, and diaphoretic. It affects especially the absorbent and glandular system, and its results vary according to the dose, combination, etc. It has been detected in the urine soon after being swallowed, also in the saliva, perspiration, milk, and blood, and always in the form of hydriodic acid, or an iodide. It is supposed to undergo conversion in the stomach into hydriodic acid, and is thus absorbed. In proper doses, iodine improves the appetite and digestion, stimulates to some extent excretion and secretion, proves diuretic, and increases strength. It probably does not stimulate blood-making nor nutrition, but it materially assists in the removal of worn-out tissues—in fact, increases retrograde metamorphosis. There is a difference of action in preparations of iodine; those which act especially by iodine in a free state, or in which it is readily set free, are not eliminated from the economy, as tincture of iodine, iodide of iron, and iodide of calcium, and should be administered in small doses. On the other hand, those which are eliminated, as iodide of potassium, or of sodium, may be given in large doses. These not only convey into the excretions metallic substances that may have been in the system for a long time, but, as with iodide of potassium, they produce the influences peculiar to the base; with the iodide of potassium we observe the diuretic and sialagogue influence of the alkali (Bouchardat's *Ann. de Thérap.*, 1869, p. 184). Iodine and some of its preparations will occasionally produce salivation, soreness of the mouth, coryza, and often pustular eruptions. Under its influence, *enlarged glands* are brought to their normal size, and *strumous ulcers* gradually healed. Occasionally it has caused a rapid and permanent wasting away of the mammæ or testicles, and again, after a lapse of time, these organs have recovered their original development.

Iodine is employed medicinally in various forms of disease, in some of which it produces astonishingly beneficial results, this being especially true in diseases involving the lymphatic structures. The diseases in which it appears to be more generally efficient are *bronchocele*, *glandular obstructions*, *scrofula*, *syphilis*, *mercurio-syphilis*, *strumous ophthalmia*, *ozena*, *ulcers of the teguments*, *enlargement of the external absorbent glands*, *chronic enlargement of the liver and spleen*, *mamma*, *testes*, and *uterus*, *ovarian tumors*, *leucorrhœa*, *amenorrhœa*, *dysmenorrhœa*, *caries*, *paralysis*, *chorea*, *rheumatism*, and, in fact, the majority of *diseases of a hypertrophical*, *strumous*, or *cachectic character*. In *bronchocele*, it is most serviceable in the early congestive stage, or in the middle stage of gelatiniform effusion; in the indurated stage of the thyroid gland it is of little benefit. In this affection its use should be continued uninterruptedly for at least five weeks, and if no good effects appear, it may be laid aside. The compound solution of iodine is generally preferred in doses of 5 to 10 drops, 3 times a day. Iodine has been injected into the gland with apparent benefit, but this practice is not generally commended. Prof. J. M. Scudder (*Spec. Med.*) advised small doses of iodine in *sexual debility:* ℞ Tincture of iodine, gtt. xx; simple syrup, fl℥iv. Dose, 1 teaspoonful 4 times a day, preferably after meals and at bedtime.

Iodine is not a cumulative medicine, like lead, digitalis, etc., hence, whenever its effects approach iodism, a suspension of its use will gradually remove them; however, at the present time, these effects are not so often observed as among its early investigators. Yet, as some persons are very susceptible to its influence, the approach of iodism should be carefully watched, and its symptoms checked. In *chronic diarrhœa* and *dysentery*, *cholera infantum*, *colliquative diarrhœa of phthisis*, and *scrofulous diseases*, Prof. King found the following a superior remedy: Take of iodine, $1\frac{1}{2}$ grains; sulphate of morphine, $\frac{1}{8}$ grain; extract of geranium, 20 grains; triturate thoroughly together in a mortar, form into a pill-mass with simple syrup or extract of liquorice, and divide into 10 pills; of these 1 pill may be given every 1 or 2 hours to an adult. In *hepatic* and *splenic affections*, dried extract of leptandra may be substituted for the extract of geranium. In the *Mexican diarrhœa*, he succeeded in curing every case in which the following preparation was employed: Take of iodine, $1\frac{1}{2}$ grains; tannic acid, 10 grains; distilled water, 5 fluid drachms. Mix together. For an adult, give 1 fluid drachm every 2 hours, in syrup of ginger, or cinnamon water, to be continued daily. Iodine is contraindicated in cerebral congestion and tendency to apoplexy, in menorrhagia, in disordered stomach or bowels, or wherever local diseases become attended with symptomatic fever, or with incidental febrile affections.

Externally, iodine is used in the form of ointment for *strumous ulcers*, *ophthalmia*, and some *cutaneous diseases*, as *lupus*, *favus*, *acne*, *psoriasis*, etc. With collodion it forms a good application for *frost-bites*. Subcutaneous injections of iodine around the wound, have been found successful in *bites of some snakes* and other *poisonous wounds*. A *caustic iodine solution* (Lugol's) is recommended as an application to stimulate or destroy *soft* and *fungous granulations*, and as a remedy for *noli-me-tangere*. (See *Lugol's Solution*.)

Drs. R. Druitt and B. W. Richardson recommended the vapor from iodine as a deodorizer and disinfectant. Powdered iodine, or a strong tincture of iodine is placed in open vessels in various parts of a room, so that the air therein becomes impregnated with the vapor. This is recommended in cases of *smallpox*, *typhoid* and other *fevers*, or wherever the atmosphere of a room requires purification, as where there are sinks, sick-chairs, closets, etc. The air thus purified becomes fresh and agreeable to the sense of smell. Inhalations of vapor from iodine have been highly spoken of in the treatment of *phthisis* (palliative only), *chronic laryngitis* and *bronchitis*, and in *aphonia;* the atmosphere of the patient's room to be impregnated with the vapor, so that it can be constantly inhaled day and night. Dr. J. Waring Curran, in the treatment of *diphtheria*, recommended a fluid drachm, of a compound composed of iodine, iodide of potassium, each, 4 grains; alcohol, 4 fluid drachms; water, 4 fluid drachms—which he adds to a pint of vinegar in which a handful of sage has been boiled; this is placed in a teapot or an inhaler, and kept hot over a spirit lamp, and the vapor is inhaled 10 or 12 times a day, for 10 or 12 minutes each time. The dose of the iodine solution must be steadily increased until it reaches $\frac{1}{2}$ fluid ounce for each inhalation. The tincture, in 2 or 3-drop doses, in syrup of lemon, is said to improve the condition in *diphtheria*. In *erysipelatous inflammations* it has been advised to paint the inflamed surface with a strong tincture; likewise, in *chilblains* and *cutaneous scrofula*. *Boils* may be aborted by painting with tincture of iodine, which application is also useful in *carbuncles*, though a dilution (1 part to 3 or 4 of water) is less painful, arrests destruction of tissues, and removes the decayed parts. Locally, iodine is useful in *chronic uterine engorgement*, *chronic indurations of the cervix uteri*, *uterine ulcerations*, *leucorrhœa*, *nævi*, *pharyngeal granulations* and *ulcers*, *spina bifida*, and the tincture or compound tincture gives relief in *laryngeal ulcerations*, for which the vapor has been less efficiently employed. The topical application of iodine is frequently resorted to in *chronic rheumatism* and *neuralgia*, and applied to the chest in *chronic pleurisy* to promote the absorption of plastic exudations. An ointment of iodine is of value in *hydrarthrosis*. Applied in *smallpox* it is said to prevent in a measure the full development of the pustules, and thereby prevent extensive pitting. Iodine is an excellent application to *buboes*, and if applied early may abort them; it is likewise of value in *syphilitic ulcerations of the tonsils and fauces*, and *in swelling of the gums* and *loosening of the teeth*. *Ringworm*, *corns*, and *felons* are often benefited by iodine

A solution of iodine (grs. j), in glycerin (fl℥j), forms a good application in *purulent nasal discharges*, as *ozena.* The tincture, diluted with three times its volume of water, has been recommended as an injection in *hydrocele*, after removal of the effused fluid, to stimulate the tunica vaginalis to adhesive inflammation. These injections have also been advised in *ovarian cysts*, *dropsy of the joints*, *hernia*, *indolent abscess*, *cavities*, *sinuses*, *fistula in ano*, etc.

Iodine in strong solution has been successfully employed in *blepharitis ciliaris* and in *conjunctivitis*. An adhesive iodine paint is used at Moorfield's Ophthalmic Hospital, as an application to *chronic inflammations of the eyelids;* the mastic prevents the paint from spreading on the more delicate structures in the neighborhood; take of alcohol, 2 fluid drachms; spirit of nitric ether, 4 fluid drachms; mastic, ½ drachm; iodine to saturation. Mix. The vapor of tincture of iodine with camphor, applied by Politzer's method, is said to improve *non suppurative otitis media*. Occasionally painting the tincture on the mastoid region relieves in *mastoid disease*, and the same applied to the attic of the tympanum checks suppurative action in those parts. The compound tincture is applied after opening the sac of *hematoma auris*, and according to Foltz (*Dynam. Therap.*, p. 628), a mixture of glycerin 10 parts, and iodine 1 part, is excellent for the cure of that morbid action giving rise in the canal and fundus of the ear to *aggregations of epithelium and pus* of a tenacious character.

Iodine may be kept in a state of solution when added to mixtures in the form of tincture, by the addition of syrup of orange peel, or a few grains of tannic acid. When given internally to females it is apt to increase the quantity of the menstrual discharge and sometimes to multiply the periods of its appearance; if the symptoms are not very severe or alarming, but little interference will be required, as they will cease after a short time; where this is demanded, a cessation of the use of the remedy will most generally suffice. In the employment of iodine, if the urine is passed in quantity, and on examination is found to contain iodine, and the strength and appetite of the patient gradually return, it may be considered indicative of a beneficial therapeutic influence, and its use should be continued. Dose of iodine, in substance, ½ grain, 2 or 3 times a day, in pill form; of the tincture, from 5 to 15 drops, twice a day. The best forms for internal use are the compound tincture and compound solution. Some prefer the 3 x trituration. When given in powder, it should be united with opium or hyoscyamus, and formed into a pill with the extract of liquorice. In poisoning by iodine, first evacuate the stomach, by giving an emetic in starch water, and afterward administer freely starch water, starch paste, flour, or arrow-root in water.

Related Preparations.—Iodized Phenol. Dr. Percy Boulton introduced to the profession a colorless solution of iodine and carbolic acid, as possessing stimulant and antiseptic properties in a marked degree. It has been found useful as a local application (by injection, gargle, lotion, or spray inhalation), in *sore throat*, *diphtheria*, *ozena*, *otorrhœa*, *purulent ophthalmia*, *foul* and *indolent ulcers*, *leucorrhœa*, *ulceration of the cervix uteri*, *internal hemorrhoids*, *laryngeal*, and *bronchial affections*, etc. In some instances it will require to be diluted with water, and when the spray is to be inhaled, the glycerin may be omitted, and the mixture be diluted to the required extent with water. Its formula is as follows: Take of compound tincture of iodine, 45 minims; crystals of carbolic acid (liquefied), 6 minims; glycerin, 8 fluid drachms; distilled water, 5 fluid ounces. Mix. The color disappears in from 8 hours to 10 days, depending upon the temperature; the mixture should be kept in a dark place. See also formula of *Acidum Carbolicum Iodatum* [*Nat. Form.*], p. 41, which preparation has similar uses to the preceding.

Methynol.—This agent was introduced by Prof. J. A. Jeançon, M. D., according to whom it is "a compound of the sodium salts of a systematic series of iodo-phenol acids, in which the hydrogen of iodo-phenol is progressively substituted with iodine, carboxyl, and hydrocarbon groups, and in which the iodine preponderates. The use of methynol is indicated in all forms of *venous congestion* of the skin or of the mucous membranes of the body; in all forms of *ulceration*, of whatever origin; in infiltrated states of the tissues, whether due to stoppage of the venous current and dilation of the lymphatic vessels, or to local obstruction by *tumoral masses*, etc. In action this substance is highly stimulating to vascular activity without having the least effect on the heart. It acts also as an antiseptic and powerful germicide, its two qualities combining to produce healthy circulation and absorption of infiltrated substances, also destroying the more or less noxious matter, formed in the stagnant, unhealthy tissues. The use of methynol promptly produces healthy granulations in *indolent ulcers*, checking suppuration and invigorating the enfeebled tissues; new and invigorating substance is the result. In *piles*, *condylomata*, *pruritis ani* (itching piles), it is equally efficient. In *vulvar* or *vaginal hypersecretions*, in *catarrhal states of the primæ viæ*, as well as in that of the uterine cervix, its action is both prompt and effective. *Old sore shins* are readily healed by daily applications of methynol. In *pruritis vulvæ* and *prurigo*, *porrigo*, and *intertrigo*, the itching gives way after several applications of this drug; and most of the squamous and nodular affections of the skin are removed by it. Methynol can be applied with a soft sponge, or with a camel's hair pencil, after the affected surfaces have first been cleaned with castile soap or borax water. Cavities lined with diseased mucous membranes have to be treated with proper-sized cotton tampons, which are allowed to remain 1 or 2 hours, as the case requires. There is very seldom any pain produced by the application of the drug. Should the affected surface be too irritable, methynol should be applied only after the parts have been first treated with a solution of cocaine hydrochlorate. As the drug is not poisonous, it can be safely used (properly diluted) upon the buccal, nasal, pharyngeal, and laryngeal mucous membranes. In *tumors* or *tumoral masses*, it may be injected without producing any harm; beginning with 5 drops of the methynol mixed with about 1 drachm of castor oil or almond oil, as an injection, and gradually increasing the quantity of the drug. An ointment of methynol with petrolatum or kindred substances, can readily be formed by mixing the ingredients in the proportion desired. The following is a desirable prescription: R Methynol, 1 ounce; petrolatum, 3 ounces. Mix together by rubbing in a mortar, or on a pill slab, with a spatula" (Prof. J. A. Jeançon, M. D.).

IPECACUANHA (U. S. P.)—IPECAC.

"The root of *Cephaëlis Ipecacuanha* (Brotero) A. Richard"—(*U. S. P.*). *Cephaëlis emetica*, Persoon; *Callicocca Ipecacuanha*, Brotero; *Uragoga Ipecacuanha*, Baillon; *Psychotria Ipecacuanha*, Müller-Argoviensis.

Nat. Ord.—Rubiaceæ.

COMMON NAMES: *Ipecac, Ipecacuanha.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 145.

Botanical Source—Cephaëlis Ipecacuanha is a small plant, with a perennial root, descending obliquely into the ground, from 4 to 6 inches long, simple, or divided into a few diverging branches, about as thick as a goose-quill, ringed, when fresh pale-brown, when dry umber-colored, blackish-umber-colored, or grayish brown; the cortical integument with a reddish, resinous, glittering fracture, and readily separating from a central woody axis. The stem is suffruticose, from 2 to 3 feet long, ascending, often rooting near the ground, smooth and cinereous at the base, and downy and green near the apex. The leaves are rarely more than 4 or 6 on a stem, oblong-ovate, acute, roughish with hairs, from 3 to 4 inches long, from 1 to 2 broad; those at the top of the stem are opposite, those toward the base alternate. Petioles short and downy. Stipules erect, appressed, membranous, deciduous, and 4 to 6-cleft. Peduncles solitary, axillary, downy, erect when in flower, reflexed when in fruit, and about 1½ inches long. The flowers are small, white, in semiglobose heads, of 8, 12, or more; the involucre is 1-leaved, spreading, deeply 4 to 6-parted, with obovate, acuminate, ciliated segments. Bracts to each flower 1, obovate-oblong, acute, and downy. Calyx minute, obovate, whitish, adhering to the ovary, with 5 bluntish, short teeth. The corolla is white, funnel-shaped, the tube cylindrical, downy on the outside and at the orifice, the limb shorter than the tube, with 5 ovate, reflexed segments. Stamens 5; filaments filiform, white and smooth; anthers linear, longer than the filaments, projecting a little beyond the corolla. Ovary with a fleshy disc at the apex; style filiform; stigmas 2, linear The berry is ovate, obtuse, about the size of a kidney-bean, at first purple, afterward violet-black, 2-celled, 2-seeded, with a longitudinal, fleshy partition. Nucules plano-convex and furrowed on the flat side (L.).

Fig. 147.

Cephaëlis Ipecacuanha, with root

History.—Ipecacuanha inhabits Brazil, in moist, shady situations, and is also found in other sections of South America, generally between 7° and 20° south latitude (*Ed.*), flowering from December to March, and maturing in fruit between April and June. The root, which is the official part, is gathered by the natives from January to April, who, after removing the stem from it, wash it and dry it by exposure to the sun's rays. (For details regarding its cultivation and collection, see article in *Western Druggist*, 1897, p. 346.) It is principally imported from

Rio Janeiro, in barrels, seroons, and large packages. The bark of the root is its most active part.

Description.—"About 10 Cm. (4 inches) long, and 4 or 5 Mm. (⅙ to ⅕ inch) thick; mostly simple, contorted, dull grayish-brown or blackish, finely wrinkled; closely and irregularly annulated, and often transversely fissured; bark thick, brittle, brownish, easily separated from the thin, whitish, tough, ligneous portion; odor slight, peculiar, nauseous; taste bitterish, acrid, nauseating. When ipecac is sound and free from moldiness, its quality is proportionate to the thickness of the bark, and the thinness of the ligneous portion"—(*U. S. P.*). Commercial ipecacuanha roots are sometimes distinguished as the grayish-black, the grayish-red, and the grayish-white varieties. The true variety is called *Rio ipecac* commercially.

Ipecacuanha root, when whole, is so characteristic, that it is hardly liable to adulteration. A variety known as the *Carthagena*, *New Granada*, or *Columbian ipecac* (*Cephaëlis acuminata*, Karsten), is larger, less markedly annulated, and shows a larger number of more conspicuous medullary rays than the ordinary drug. The name *radix antidysenterica*, was formerly applied to ipecacuanha root. The powder of the genuine article is of a grayish-yellow color, with a faint, bitterish, obscurely acrid taste, and a weak, musty, peculiar odor, which becomes stronger and nauseating during the process of pulverization; in some persons it excites sternutation, in others a difficulty of breathing resembling asthma. It yields its properties to water, and still better to alcohol, spirits, or wines. Boiling impairs its virtues. As regards the detection of adulterants of ipecacuanha, see article on the microscopic examination of ipecac root and its possible adulterants in powder form, by Dr. Alfred Schneider (*Amer. Druggist*, 1897, p. 3). Likewise, some microscopical and chemical criteria for true ipecac root were laid down by Prof. Tschirch and F. Lüdtke (*Archiv der Pharm.*, 1888, p. 441).

Chemical Composition.—While the root of the ipecacuanha plant is the only official part, its active, emetic principle has been shown to exist also in other parts of the plant, *e. g.*, the stems and the leaves (Hooper, 1892), but not in the seeds (Flückiger, *Pharmacognosie*, 1891). In 1817 Pelletier and Magendie isolated from true ipecac root an alkaloid which they called *emetine*, but the fact that they obtained 16 per cent of this principle demonstrates their product to have been merely a concentrated extract. Upon further experimentation, however, Pelletier succeeded in obtaining a pure alkaloidal product in the amount of 60 grains to the pound, which corresponds to somewhat less than 1 per cent. Subsequently, the chemistry of ipecacuanha root was elaborated by Reich (1863), Lefort (1869), Podwissotzky (1879), and others. H. Kunz, in 1887 (*Jahresb. der Pharm.*, 1887, p. 416), found for emetine the formula $C_{30}H_{40}N_2O_5$, which is now generally adopted as correct. Kunz also established the dyad nature of the alkaloid *emetine* in its saturation power with acids, which in 1890 was confirmed by Blunt (*Pharm. Jour. Trans.*, 1890, Vol. XX, p. 809), and W. Simonson (*Proc. Amer. Pharm. Assoc.*, 1890, p. 188); hence the statement in Flückiger (*loc. cit.*), that emetine is a monad base, requires correction. Kunz also found *cholin* ($C_2H_4OH.N[CH_3]_3OH$), to be present in ipecac root.

Pure *emetine* forms a white, non-crystallizable powder which turns brown by exposure to light and air. It is very slightly soluble in water; the solution tastes bitter and is alkaline to litmus paper. It dissolves readily in diluted acids, as well as in chloroform, alcohol, warm benzin, and ether, and is also soluble in fixed oils and benzol, but insoluble in caustic alkalies and in essential oils. With acids, *emetine* forms neutral, soluble, bitter, acrid, and for the most part uncrystallizable salts. Flückiger obtained the hydrochlorate in crystalline form (*Pharmacognosie*, 1891). The nitrate dissolves in water with difficulty. The solutions of the salts are precipitated by gallic and tannic acids. Flückiger (*loc. cit.*), gives the following test for *emetine* in ipecac root: Shake the root with five times its weight of cold hydrochloric acid (sp. gr. 1.12), filter, and sprinkle some chlorinated lime upon the liquid. If emetine is present, a characteristic fire-red color is produced. By this reaction, the absence of emetine from the wood of the root is established.

In 1894 and 1895 Paul and Cownley (*Jahresb. der Pharm.*, 1894, p. 523, and 1895, p. 163), discovered another alkaloid in ipecac root which they called *cephaëline*.

This is distinguished from emetine principally by its being soluble in caustic alkalies, and by its melting point, which is 102° C. (215.6° F.), while for *emetine* they found 68° C. (154.4° F.). Pelletier also had observed that emetine was naturally combined with what he took to be gallic acid, but which was recognized later by Willigk as a new substance, and by him called *ipecacuanhic acid*. Reich subsequently found it to be a glucosid. *Starch* is present in ipecac root in large amounts, and a trace of a nauseating *ethereal oil* is also present. In some allied species *sugar* abounds.

Literature concerning the assay of ipecacuanha is abundant and often discordant, although a satisfactory solution of the ipecac problem seems to have been reached. The proportions of total alkaloids observed by different authors generally range from 1 to 3 per cent. C. C. Keller thinks that 2½ per cent may not be too excessive a standard of alkaloidal strength (*Proc. Amer. Pharm. Assoc.*, 1893, p. 400). Dr. A. R. L. Dohme (*Proc. Amer. Pharm. Assoc.*, 1895, p. 269), has found that the part of the root where it merges into the stem (*wiry root*) is at least as rich in alkaloid as the rest of the root (*fancy root*), and that the part of the stem adjacent to the root still contains considerable quantities of emetine. (Adapted in part from an article on ipecacuanha in the *Western Druggist*, 1897, p. 346. Tannic acid, all astringents containing tannic or gallic acids, iodine, salts of iron, and acetate of lead, are incompatible with ipecacuanha.

Action, Medical Uses, and Dosage.—Ipecac, in material amounts, is irritant to the cutaneous and mucous surfaces. Applied to the skin by inunction it excites irritation, and produces vesicular, pustular, and sometimes ulcerative effects. It is exceedingly irritating to the Schneiderian membrane, causing heat and violent sneezing. In some individuals, the inhalation of the powdered drug provokes decided paroxysms, closely resembling spasmodic asthmatic attacks—the chief symptoms being great dyspnœa, with marked anxiety and prostration, and wheezing respiration and cough. This is often accompanied with violent and prolonged sneezing and spitting of blood. Such attacks are usually followed by a free expectoration of mucus. Ipecac, in doses of less than 1 grain, acts as a gastric tonic and hepatic stimulant, but large doses prove emetic. When it fails to produce emesis, catharsis usually results, though both effects may take place from its employment. The stools produced by this agent are of the so-called bilious type, and have been denominated "ipecacuanha stools." A state of tolerance may be established from the prolonged use of ipecac. Ipecac produces a relaxation of the skin and consequent diaphoresis, and it increases the broncho-pulmonic secretions. Physiologically speaking, ipecacuanha is said to scarcely affect the circulation, but there is no doubt that in minute doses in disease, it stimulates the circulatory apparatus, acting thereby as a *special sedative*, as that term is employed in Eclectic therapy. Its therapeutic action upon the circulation is well shown in its effects upon *hemorrhage;* and in *acute* disorders of the stomach, bowels, and breathing organs. The alkaloid, emetine, the active principle of ipecac, is so severe and uncertain in its action that it is seldom used in medicine. Two grains of it have killed a large dog, and $\frac{1}{16}$ grain vomited an old man severely. Observations upon the lower animals prove that death takes place from cardiac paralysis. The post-mortem lesions are: Gastro-intestinal irritation, and sometimes swollen, red, blood-stained, and ecchymosed patches are seen, similar to those produced by some of the metals; the lungs are hyperemic, though occasionally anemic: and hepatized patches are observable. Emetine is eliminated by the way of the bowels.

Therapeutically, ipecac is a very important remedy. It has three chief fields of operation: (1) In large doses it provokes emesis, and for this purpose it may be employed as suggested below; (2) it checks active hemorrhages; (3) it relieves gastro-intestinal and broncho-pulmonic irritation and inflammations. Its specific use, in small doses, is to relieve *irritation*, no matter what the disease may be. The specific action of ipecac is best observed in acute affections, when there is hyperemia, capillary engorgements, and hypersecretion. Ipecac is often employed to assist the action of other agents, particularly agents to act upon the bowels, and with other agents which control irritation.

The dose of ipecac largely controls its uses. In doses of ¼ to ½ grain, it acts as a tonic, improving digestion, increasing the appetite, and is valuable in *irritative* *dyspepsia.* In doses of ½ to 2 grains, administered every 3 or 4 hours, it produces perspiration, and is beneficial in *febrile* and *inflammatory diseases;* combined with opium its diaphoretic influence is greatly augmented, as seen in the *powder of ipecacuanha and opium.*

Half-grain doses are expectorant. From 3 to 10 grains will produce nausea, which may be continued for any length of time, and which is attended with more or less depression of the pulse, languor, moisture of the skin, and an increased mucous discharge from all the mucous tissues of the system, which renders it very useful in *pulmonary* and *hepatic diseases.* It has been found very useful in *typhoid pneumonia* in combination with sulphate of quinine. In doses of from ¼ to 1 grain, rubbed up with sugar to render it pleasant, it has proved efficient in the *pneumonia* of children. Doses of from 5 to 15 grains have a tendency to move the bowels, while doses of 20 grains or more act as an emetic. It is stated that an infusion of 2 drachms of ipecacuanha in a gill of hot water and strained, will, if drank warm, prove emetic; then if the same quantity of hot water is again added to the residue, strained and drank cold, it will prove purgative; and the same process repeated the third time, and used cold, becomes a valuable tonic. This, however, requires confirmation.

Ipecac is a specific emetic, and the mildest of its class. As such, in 20-grain doses, it operates actively, causing much nausea and continued muscular straining, with a free secretion of mucus; vomiting, however, seldom takes place until 15 or 20 minutes after its administration. It is inferior to no other emetic, being safe even in large doses, seldom producing painful spasms of the stomach or bowels, and causing less prostration of the vital forces than tartar-emetic and similar drugs. It is best employed in combination with other emetics, as in the *compound powder of lobelia*, which is much used by practitioners, and is preferred to any other emetic in the early stage of *febrile diseases*, and in other instances where a severe succussion of the system is indicated. Ipecac is the best emetic for the purpose of unloading the stomach of undigested aliment, and "*acute indigestion*, *bilious attacks*, accompanied with *sick headache*, and other forms of headache, depending upon difficult digestion, may be cut short with an emetic dose of the powdered drug" (Locke, *Syllab. of Mat. Med.*, p. 24). "In *nausea*, with a broad, flabby, and slimy tongue, give ipecac in full emetic doses" (*ibid*). Repeated doses of the powder in sweetened warm water, until emesis takes place, are useful in the *convulsions* of children, *cramps*, *colic*, etc., arising from intestinal irritation, though it is less effectual than lobelia and gelsemium combined. Small doses of ipecac may follow to relieve irritation. In *intermittent fever*, and particularly in *chronic ague*, where quinine is ineffectual, the system may be gradually brought under the emetic action of ipecac, after which the quinine will give better results, and may even not be needed. Ipecac is less useful than zinc sulphate, or, preferably, apomorphine hydrochlorate, hypodermatically, in *narcotic poisoning*, for which it has been recommended. This is due to the fact that, being a specific emetic chiefly, it must be absorbed before it exerts its emetic effect. In *croup* and *membranous croup*, when the secretions are well loosened, ipecac is a useful emetic. In *spasmodic asthma* (less valuable than lobelia), *hysteria*, *pertussis*, *sore throat*, *common catarrh*, and *stricture of the chest* common in *phthisis*, ipecacuanha, as an emetic, will sometimes be found very beneficial. In *menorrhagia*, 20 grains of the powder at bedtime, followed by a saline cathartic in the morning, has, in the hands of several practitioners, promptly checked the discharge. As a rule, however, its emetic action is not required, as hemorrhage is best checked with smaller doses. *Bronchitis* in children, with dry, hoarse, croupal cough, is often cut short by the emetic action of ipecac.

While ipecac is an emetic, it has long been well-known as a remedy to check *nausea* and *vomiting.* This is best accomplished by it when the tongue is red and pointed, and shows evidence of irritation. If the condition depends upon foul accumulations within the stomach, the emetic action will be first required, after which the small doses may be continued to control irritation, if present.

The specific use of ipecac, as before stated, is to relieve *irritation*, no matter what organ is affected. With this may be vascular excitation. This is probably due to the irritated condition of the sympathetic. The patient may be irritable mentally, easily disturbed by noises, and the skin is heightened in color. Fits of weeping are not uncommon. Its beneficial effects are particularly noticeable in *acute* irritative and inflammatory disorders of the stomach and bowels. It should be said here that in these, as well as in other troubles of a similar nature, the special sedatives—aconite, veratrum, gelsemium, and rhus, and such other irritation-relieving remedies, as matricaria, amygdalus, epilobium, bismuth, magnesium sulphate (small doses), collinsonia, hydrastis, and bryonia, may be indicated with ipecac. In fact, where the indications below given for ipecac are present, it will materially aid the action of these remedies, one or more of which are usually necessary, as ipecac seldom covers the whole range of symptoms present in these cases. The chief indications pointing to the sole or associate use of ipecac, in stomach and bowel disorders, are the elongated and pointed tongue, with reddened tip and edges, with large papillæ, or effacement of the papillæ; tenderness on pressure; contraction of tissues; pinched countenance, white line around the mouth; tendency to nausea and vomiting, with or without eructations; and marked hyperæsthesia. There is evidence of hypersecretion, sympathetic irritation and capillary engorgement, and the cases are acute. With these indications well in hand, it will be found of great service in *gastric irritability, nausea*, and *vomiting* (if not from organic stomach lesions), and *acute mucous diarrhœa*. In the *diarrhœa of teething*, with tongue coated white, and stools green, bloody, and offensive, and associated with nausea, ipecac serves a useful purpose. For the offensive element chlorate of potassium may be associated with it, and for the peevishness and fretfullness usually present, matricaria. In *simple diarrhœa*, due to undigested and irritating food, an emetic or cathartic is preferable to small doses of ipecac, though the latter should be given to control after-irritation. It is a valuable remedy in *muco-enteritis*. It should be associated with aconite or epilobium. In *acute cholera infantum*, with small and frequent mucoid passages, it should be given early. It is of less value where the stools are profuse and watery, Though less valuable in chronic than in acute diseases, it is applicable in *chronic cholera infantum*, with pallid tongue, nausea, vomiting, abdominal pain, and pallid or yellowish face. But in this case nux vomica should be given with it (Scudder). In simple *irritative diarrhœa*, nux should be given with it when the preceding symptoms are present. No remedy, with the exception of magnesium sulphate, gives better results in *acute dysentery*. Combined with proper diet and absolute rest upon the back, the following may be given: R Specific aconite, gtt. v; specific ipecac, gtt. x to xv; magnesium sulphate, ʒi; aqua, fl℥iv. Mix. Dose, 1 teaspoonful every hour. Small doses of diaphoretic powder (containing ipecac) are also useful in dysentery. Ipecac is specially adapted to cases of *sporadic dysentery*, and is less effectual in zymotic cases, unless associated with antizymotic treatment. Dysentery has been treated with large doses of the powdered drug, sufficient to produce catharsis, but this method is less efficient than that indicated above. Formerly, 1 grain each of dried extract of leptandra and ipecacuanha, and ½ grain of resin of podophyllum, given every 3 hours until it operated freely, was considered an excellent remedy for *dysentery*.

Ipecac is a remedy of first importance in many respiratory disorders. These conditions are similar to those indicating its employment in gastro-intestinal diseases, viz., irritation, capillary engorgement, and hypersecretion. Thus, associated with the special sedatives and asclepias and bryonia, if necessary, it is a very valuable agent, in *hoarseness* or *congestion of the vocal cords, broncho-pulmonary congestion* from *colds, irritable and spasmodic coughs*, and in the early stage of *acute catarrhal affections, dyspnœa of pregnancy*, and *pertussis*. In *colds, capillary bronchitis, acute bronchitis*, and *pneumonia*, particularly of children, it has an important place. It acts chiefly on the bronchioles and the parenchyma of the lungs, allaying irritation, relieving cough, and diminishing expectoration when profuse (stimulant doses), and aiding expectoration when scanty (nauseant doses). It also answers well in subacute cases. The use of ipecac (emetic doses) in *croup* has already been referred to. It is also of value in small doses in *mucous croup;* it should be combined with aconite. In *membranous croup* it has been recommended with bryonia. In dry forms of *cough* it may be given in nauseant doses; in hypersecretion, in small or stimulant doses; in spasmodic cough, with bloody expectoration, frequently repeated doses short of nausea. It relieves *irritative conditions* arising from too frequent or violent use of the voice.

Owing to its evident action upon the capillaries, it is a valuable agent in *active hemorrhages—post-partum, hemoptysis, hematemesis, hematuria, epistaxis*, and *hemorrhages from the bowels.* The cases calling for it are usually those of nervous individuals, with marked irritability and vascular excitation. Under similar conditions it is of value in *menorrhagia* and *metrorrhagia.* It is sometimes of value in *hemorrhoids,* especially when of the bleeding variety. It may be associated with hamamelis, æsculus, or collinsonia as indicated.

In *fevers* and *inflammatory affections*, small diaphoretic doses of ipecac have been highly beneficial. Its action in these cases is also beneficial upon the nervous system and mucous membranes. Excitability and suppressed secretions being symptoms, it acts favorably in the *eruptive fevers.* Both *Dover's Powder* and the *Diaphoretic Powder* are often indicated in *inflammatory* and *febrile disorders.* Both are very efficient in the *night-sweats of consumption.* Doses of from $\frac{1}{10}$ to $\frac{1}{2}$ drop of specific ipecac give prompt relief in the majority of cases of *phlyctenular diseases of the eye* with photophobia, the latter symptom being quickly subdued by it (Webster's *Dynam. Therap.*, p. 588). It will likewise act as a sedative in many local inflammatory diseases, and will be found extremely valuable in *peritonitis.* even the worst form occurring in puerperal women. It is also of value in *acute rheumatism, gout, jaundice* from biliary catarrh, and to relax the parts in the passage of small *biliary calculi.*

A liniment of ipecac (℞ Powd. ipecacuanha, sweet oil, of each, ʒij; lard, ℥ss: mix well together), to be used with friction, 3 or 4 times a day, afterward covering the parts with flannel until an eruption was produced, was formerly used in the treatment of *incipient phthisis*, certain *rheumatic affections, chronic hydrocephalus, chronic inflammation of the synovial membrane of the knee*, and *infantile convulsions.* It has, however, but little to recommend it. In all cases where this drug as an emetic, can not be given by the mouth, it may be used in injection, adding 2 drachms of the powder to 1 pint of warm water, for an adult—it will operate kindly and thoroughly as an emetic.

The doses of ipecac, for its various uses, have been sufficiently indicated above. However, the range of dosage is from the fraction of a grain to 20 grains; specific ipecac, the fraction of a drop to 20 drops. The usual prescription for specific purposes is ℞ Specific ipecac, gtt. v to xx; aqua, fl℥iv. Dose, 1 teaspoonful every 1 or 2 hours. It must be remembered that sometimes powdered ipecac will do that which no fluid preparation of ipecacuanha can accomplish.

Specific Indications and Uses.—An emetic for overloaded or foul conditions of the stomach, and other conditions indicating emesis; *irritation*, whether of stomach, bowels, nervous system, or pulmonary tissues; active hemorrhages; irritative diarrhœa; acute bowel disorders with irritation; long, pointed tongue, with reddened tip and edges, accompanied with nausea and vomiting, and with or without fever; dyspnœa; irritative cough; hoarseness from cold; hypersecretion, with mucous rales (small doses); diminished expectoration (nauseant doses).

False Ipecacs and Related Species.—Several emetic roots of the natural orders *Rubiaceæ, Polygalæ*, and *Violaceæ*, have been at times thrown upon the market as varieties of Ipecacuanha. They are all known in Brazil as *poaya*, or in the remaining parts of South America as *Ipecacuanha.* These are:

LARGE STRIATED IPECACUANHA.—Derived from the *Psychotria emetica*, Mutis (*Nat. Ord* Rubiaceæ), New Granada. This is also known as *Violet striated ipecacuanha, Ipecacuanha of St. Martha*, etc. It is larger than ipecac-root, and is marked by longitudinal grooves. The thick, brown bark has constrictions, but is not, like ipecac, annulated. It is tough under the knife, exhibiting a violet-cut surface, and is *moist and soft*, even when many years old, this being its chief distinguishing feature. It has a sweet taste, due to sugar. It contains no starch (*Pharmacographia*).

SMALL STRIATED IPECACUANHA.—This is thought by Planchon to come from a species of *Richardsonia.* It is known also as *Black ipecacuanha, Striated brittle ipecacuanha, Black striated ipecacuanha*, etc. It resembles the foregoing, but is smaller, and usually tapering at the extremities. It differs in color (being black-brown), and in being *brittle.* Starch cells are prominent, and the taste is acrid, not sweet.

UNDULATED IPECACUANHA.—*Farinaceous, Amylaceous*, or *White ipecacuanha.* The root of *Richardia scabra*, Linné (*Richardsonia scabra*, St. Hilaire), *Nat. Ord.*—Rubiaceæ; Brazil. The fresh root is white; the dried, iron-gray. It is sinuous or undulated, appearing knotty, and is alternately fissured on the sides. Its bark is thick, brittle, white, and starchy, enclosing a strong, slender, flexible, ligneous portion. It contains no emetine.

Indian Ipecacuanha.—Another asclepiadaceous plant, the *Tylophora asthmatica*, Wight et Arnott (*Asclepias emetica*, Linné), furnishes an emetic root. Indian ipecac is a twining, shrubby species, a native of the Indian Peninsula, Ceylon, and the Moluccas. The root has long been used by the Hindus as a medicine; and, in small doses, is cathartic—in large doses, emetic. In consequence of its use as a substitute for ipecac, in India, the plant has acquired the name "*Indian ipecac.*" It has been successfully employed as a remedy for *epidemic dysentery*, and has also been recommended in *humoral asthma*. Kilpatrick reports the administration of the leaves, in a great number of cases, with entire satisfaction. The dose of the powdered leaves, as an emetic, is 25 or 30 grains; as a diaphoretic and expectorant, from 3 to 5 grains. *Tylophorine*, an alkaloid, was obtained from it, in 1891, by Mr. D. Hooper.

The other species yielding emetic roots are as follows: *Ionidium Ipecacuanha*, Ventenat. *Nat. Ord.*—Violaceæ. So-called *White ligneous ipecacuanha*. Brazil. *Solea verticillata*, Sprengel, and *Ionidium polygalæfolium*, Ventenat, have been employed by the Mexicans.

Asclepias curassavica, Linné, is known as *Bastard ipecacuanha*. A Senegambian plant furnishes a root known as *Batatior*, having properties like those of ipecac. A species of *Ionidium*, variously determined as *I. marcucci*, *I. parviflorum*, and *I. microphyllum*, yields an emeto-purgative root known in South America as *cuichunchulli*. It has been used in *elephantiasis*. *Gardenia campanulata*, Roxburgh (*Nat. Ord.*—Rubiaceæ), of India, yields a purgative and anthelmintic berry.

Naregamia alata, Wight and Arnott. *Nat. Ord.*—Meliaceæ. *Naregamia*, *Tinapani*, *Goanese ipecacuanha*. Western Indis. This root contains wax, oxidizable fixed oil, and *naregamine*, an alkaloid (D. Hooper). *Asparagine* is also thought to be present. It is reputed an expectorant, hepatic stimulant, and emetic. Small doses of it are given in India in bronchitis, fulfilling the indications for ipecac and senega. The natives of Malabar employ it in emetic doses in *dysentery*, *bronchitis*, *rheumatism*, and *bilious* and *dyspeptic states*. The ordinary dose of a strong tincture (1 in 4) is from 5 to 10 drops; as an emetic, 15 to 30 drops.

Cocillana.—Cocillana bark is derived from a Bolivian tree, the *Sycocarpus Rusbyi*. Its activity is due to a principle regarded by Rusby as an alkaloid; by Eckfeldt, a glucosid. Its action closely resembles that of ipecacuanha, vomiting, heavy headache, sneezing, coryza, depression, and purging having been produced by from 20 to 50 grains. As an expectorant it is reputed more stimulating than ipecac, and in doses of 10 to 20 drops of the fluid extract, it has been employed in *bronchial affections*, both acute and chronic, and in *pulmonary consumption*, with reputed success.

Cyperus articulatus, *Adrue*, *Guinea rush.*—Antiemetic. Tonic. Dose of fluid extract, 30 drops.

Petiveria hexaglochin, *Pipi root.*—Reputed diaphoretic and a stimulant expectorant.

IRIS (U. S. P.)—IRIS.

"The rhizome and roots of *Iris versicolor*, Linné"—(*U. S. P.*).

Nat. Ord.—Irideæ.

Common Names: *Blue flag*, etc. (see below).

Illustrations: Meehan, *Native Flowers and Ferns*, I, 141; Bigelow, *American Medical Botany*, I, 155; Millspaugh, *American Medicinal Plants*, 173.

Botanical Source.—Iris versicolor is an indigenous plant, with a fleshy, horizontal root or rhizome. Its stem is 2 or 3 feet in height, terete, flexuous, round on one side, acute on the other, and frequently branched. The leaves are about 1 foot long, ½ to 1 inch wide, ensiform, striated, erect, and sheathing at the base. Bracts scarious. The flowers are from 2 to 6 in number, generally blue or purple. The ovary is obtusely 3-cornered. The peduncles are of different lengths, and flattened on the inside. The sepals are spatulate, beardless, the border purple, the claw variegated with green, yellow, and white, and veined with purple. The petals are erect, varying in shape from spatulate to lanceolate, usually paler than the outer, entire, or emarginate. The stigmas are 3, petaloid, purple, or violet, bifid, crenate, and more or less reflexed at the point. Stamens 3, concealed under the stigmas, with oblong-linear anthers. Capsule 3-celled, 3-valved, when ripe oblong, turgid, 3-sided, with roundish angles. The seeds are numerous and flat (L.—B.—W.).

History and Description.—Iris versicolor has been designated by various names, as *Blue flag*, *Flag lily*, *Water flag*, *Liver lily*, *Snake lily*, *Flower de luce*, *Poison flag* in contradistinction to Sweet flag (*Acorus Calamus*), and *Larger blue flag* to distinguish it from the other species of this genus. The name *Iris*, from a Greek word meaning "the rainbow deified," was given it by the ancients on account of the brilliancy and diversity of color in its blossoms.

Blue flag is one of our most beautiful and interesting common wild flowers, growing throughout the United States in wet, marshy localities, blooming in May and June. The flowers, from 2 to 6 in number, are large and showy, of a purplish, or violet-blue color, variegated with white and greenish-yellow, interspersed with purple veins. The plant grows from 1 to 3 feet high, having a stout, sometimes branching stem, angled on one side. The leaves are sword-shaped, from 6 to 8 inches long, and ¾ of an inch wide. The root, which resembles that of *Acorus Calamus*, is the part officially used. It has a peculiar odor, augmented by rubbing and pulverizing. The *U. S. P.* thus describes iris: "Rhizome of horizontal growth, consisting of joints, 5 to 10 Cm. (2 to 4 inches) long, cylindrical in the lower half, flattish near the upper extremity, and terminated by a circular scar, annulated from the leaf-sheaths, grayish-brown; roots long, simple, crowded near the broad end; odor slight; taste acrid and nauseous"—(*U. S. P.*). The recently dried root varies from a light, pinkish-brown internally, studded over with minute white dots, somewhat resembling in color very light sandstone, to a dark red-brown—the latter being unfit for pharmaceutical uses. Care should be exercised as to the locality in which the plant grows. We recently rejected a large lot, more than 2000 pounds, extra fine in external appearance, that came from the South, and was of a dark, red-brown internally, but almost destitute of oleoresin, which principle had been replaced by a red, astringent tannate. Our experience is to the effect that the Ohio raised iris is superior to that of any other locality known to us, and in collecting the drug, for specific iris, many times the market price is paid for the rhizome from one locality in the state.

The active properties of iris are taken up by boiling water in infusion, and by alcohol or ether; and its acridity, as well as its medicinal virtues are diminished by age. The fresh root, sliced transversely, dried in an atmosphere not exceeding 39.4° C. (103° F.), pulverized, and then placed in darkened and well-closed vessels to protect it from the action of light and air, will have its medicinal virtues preserved for a great length of time.

Chemical Composition.—The fresh rhizome of iris, when distilled with water, yields an opalescent distillate, from which a white, camphoraceous substance separates, soluble in alcohol, and having a faint odor (C. H. Marquardt, 1876). The rhizome furthermore contains starch, gum, tannin, sugar, oil, and resin. The *resin* is of a light-brown color, of a faint odor, and of a taste resembling that of the root; when perfectly freed from oil it is whitish-yellow. Its therapeutic influences are not positively known. It is soluble in chloroform, ether, and boiling alkaline solution, from which acids precipitate it. The *oil* possesses in a high degree the taste and smell of the root, and is the principle to which it owes its medicinal activity. Cressler (*Amer. Jour. Pharm.*, 1881, p. 602) found indications of an alkaloid, obtainable by extracting the alcoholic extract of iris with acetic acid, removing fat by means of ether, and abstracting the alkaloidal substance by means of amylic alcohol after rendering the fluid alkaline.

As early as 1844, Prof. John King prepared and introduced to the profession the *oleoresin of iris*—about the same time that he discovered the resins of cimicifuga and podophyllum. The name, oleoresin of iris—a trade name being *iridin*—was applied to this substance 50 years ago. It is but little used at present, except in combination with other hepatics, in pill form, in the treatment of chronic diseases of the liver. The preparation upon the market known as *irisin*, though commonly spoken of by medical writers as iridin, or oleoresin, is a mixture of the oleoresin, with a sufficient amount of the root to stiffen it and render it pulverizable. It may be stated here that the watery fluid preparations of iris are very unreliable. Fluid preparations should be made only from recent rhizomes, presenting internally a very light pinkish-brown color, studded with minute white dots. Those having a brown-red color throughout, should be rejected. When dropped into water the preparation should give an opalescent, milky appearance, and when in large amount should precipitate oleoresin. The odor of iris should also be perceptibly increased when its preparations are added to water, being to most people a disagreeable, nauseous, fatty odor.

Medical History.—This plant was highly esteemed by our American Indians, who used it in gastric affections, and it was also a popular domestic remedy when it was thought necessary to produce salivation without resorting to mercurials—hence it is sometimes called "*vegetable mercury*." Bigelow, Smith, and Thacher wrote regarding its cathartic properties, but on account of its unpleasant effects, when given in purgative doses, it did not come into general use until taken up by our school, where it is not used as a cathartic.

The blue flag is one of our most valued of early Eclectic medicines, having been used almost exclusively by our practitioners, until of late years, when it found quite a prominent place in the therapeutics of both Allopathic and Homœopathic practice.

Action, Medical Uses, and Dosage.—Physiologically, iris acts upon the gastro-intestinal canal, and the glandular and nervous systems. It powerfully excites the biliary, salivary, and pancreatic secretions. Upon the gastro-intestinal tract it acts violently, causing acid vomiting, frequent, hydragogue catharsis, with intestinal burning and severe colic. A writer says: "The root of the blue flag extends its influence through every part of the system in small doses, and repeated at short intervals. It seems to act more particularly on the glandular system, exciting them to a discharge of their respective offices. In large doses it evacuates and exhausts the system, acting on the liver, and the alimentary canal throughout." Animals, after death from its ingestion, show marked congestion of the gastric and intestinal tissues. By its action upon the nervous system, it has produced neuralgia of the face, head, and extremities. Iris salivates, but without injury to the gums and teeth. In general practice salivation is not, as a common rule, desired for the cure of disease, yet we have many articles which produce it, and often without the practitioners being aware of the fact, and hence, when it does occur, the cry is at once raised that mercury is used. Salivation caused by vegetable agents may be known from that by mercury, by the absence of mercurial fetor, and no sponginess of the gums or loosening of the teeth.

Therapeutically, this agent is alterative and cholagogue. It is one of our best agents to influence the process of waste and repair. It exerts a powerful catalytic action upon the lymphatic glandular system, and the ductless glands, as well as upon the liver, pancreas, and kidneys. In *cachectic states* of the system, *bad blood*, *scrofula*, and "*mercurial diseases*," it does excellent service, and in *secondary syphilis*, with cerebral disturbances, and copper-colored dermal pigmentation, it is one of the best drugs we possess.

Upon the liver, its action is marked. In that unpleasant condition known as "*biliousness*," it is prompt and efficient, and as a remedy for *bilious headache*, accompanied by nausea and vomiting of bitter ingesta, or in *sick headache*, dependent upon *indigestion*, it is unsurpassed. In *chronic hepatitis*, and other hepatic disorders, with *constipation*, and sharp, cutting pains, increased by motion, iris may be given alone or may be advantageously combined with other hepatics. *Duodenal catarrh*, with jaundice, and clay-colored stools, indicating a lack of biliary secretion, is cured by iris, and it is likewise valuable in *constipation*, dependent upon biliary and intestinal torpor. Minute doses of iris allay *gastric irritation*, being valuable in *cholera infantum* and *cholera morbus*. ℞ Specific iris, gtt. v; aqua, fl℥iv. Mix. Dose, 1 teaspoonful every hour. In *diarrhœa* and *dysentery*, with large, slimy evacuations: ℞ Specific iris, gtt. xv; aqua, fl℥iv. Mix. Dose, 1 teaspoonful every hour. Iris, in small doses, is often valuable in *gastric irritation*, associated with sickness at the stomach and vomiting, and in *gastralgia*. It is not without good results in burning aphthous states of the oral cavity. From 1 to 5 drops should be used in the latter case. *Reflex muscular pains*, dependent upon gastro-intestinal and pancreatic disorders, are relieved by it, and especially when the muscular coats of the viscera are involved. *Pectoral pains* and distressing sensations beneath the scapula are also relieved by iris in doses of from 1 to 5 drops.

Iris is specifically indicated in *soft glandular enlargements*. It is one of the very few reliable drugs used for the cure of *goitre*, or *enlarged thyroid*. Indeed, for this condition it is our most direct and effectual remedy, whether the enlargement be constant, or whether it be simply a fullness due to menstrual irregularities. This use was early pointed out by Prof. King. Further, it has a marked influence for good on the *ovarian and uterine disturbances* giving rise to this fullness. In goitre, apply a cotton cloth saturated with specific iris, and give internally a teaspoonful, 3 times a day, of a mixture of specific iris, flℨss; aqua, fl℥iv. *Basedow's disease—exophthalmic goitre*—in the early stage, has been cured by iris; *Addison's disease* of the suprarenal capsules has been greatly improved, though not cured by it. In *chronic affections of the pancreas*, with a sodden, leaden-colored tongue, and in *chronic splenic disease*, when the skin is blanched—as in *leucocythæmia*—this drug is indicated. *Chronic renal diseases*, *ascites*, *anasarca*, *hydrothorax*, and *hydropericardium* have yielded to its curative powers. In *dropsy*, it is administered in cathartic doses. It is seldom used at present as a cathartic, but when so used its harsh effects may be somewhat overcome by combining it with ginger, piperin, or camphor.

As a remedy for *uterine hypertrophy*, *enlarged ovaries*, *ulcerated os and cervix uteri*, *uterine leucorrhœa*, and *dysmenorrhœa:* ℞ Specific iris, gtt. x to xx; aqua, fl℥iv. Mix. Dose, 1 teaspoonful every hour in acute troubles, and 4 times a day in chronic affections. It is all the more strongly indicated in these conditions, if there be impaired general health, with mental depression, and when the skin presents abnormal pigmentation.

This drug has been successfully used in *chronic rheumatism*, *syphilitic rheumatism*, *gonorrhœa*, *spermatorrhœa*, and *prostatorrhœa*. Specific iris, in doses of from 1 to 5 drops, every 4 or 5 hours, in a fluid ounce of water, will be found very useful in those *prostatic discharges* and *nocturnal emissions*, the result of masturbation, and which are accompanied with considerable debility, mental uneasiness, and more or less irritation of the nervous centers. Prof. Scudder, in his "Practice," states that he has for years placed great reliance on iris in treating *syphilitic iritis*. It is very efficient in *malarial jaundice*, and *intermittent* and *bilious remittent fevers*. It is rendered more efficient in malarial disorders, when combined with euonymus, or alstonia constricta. Iridin, in 3-grain pill, every night, followed by a saline cathartic in the morning, was quite popular among Edinburgh physicians some years ago as a remedy for the *vomiting of pregnancy*.

Iris is of great utility in dermal practice, given alone or associated with other indicated remedies. It seems to have a better action in chronic conditions. It is particularly adapted to diseases involving the sebaceous glands, and is especially useful in *comedones*, and other eruptions common to youth. It is indicated by rough, greasy, discolored conditions of the skin, and in those cases where pustular eruption seems to be associated with functional disturbances of the reproductive apparatus; also when associated with thyroid fullness in the female. It is valuable in *syphilitic skin diseases*. We have used it beneficially in *eczema rubrum* of children, and in cases of *eczema of the scalp* in adults. Some cases are benefited only, not cured by it. In one case of 13 years' standing, the unpleasant symptoms were subdued as long as the patient took the drug; as soon as the iris was withdrawn the unpleasantness returned, though the general health of the man was much improved by its administration. *Herpes zoster* and *herpes præputialis* usually call for iris and rhus. *Rupia* and *impetigo* have been cured by it when associated with sulphur, or Fowler's solution. *Persistent prurigo*, *psoriasis*, and *acne indurata* will usually present conditions calling for iris. For *lepra:* ℞ Specific iris, flʒi to flʒii; aqua, fl℥iv. Mix. Teaspoonful 4 times a day.

The system should first be prepared by sulphur, or the sulphites, compound tonic mixture, or acid solution of iron, if debilitated. Other remedies may be associated with iris in chronic skin diseases when indicated, as alnus, apis, phytolacca, or rhus tox. *Pustules* upon the scalp and face in children are benefited by the minute dose of iris.

The dose of iris depends largely upon the effect desired. If a pronounced action upon the gastro-intestinal and glandular secretions is desired, from 5 to 20 grains of the powder, or 10 to 60 minims of the strong tincture, or 5 to 20 drops of specific iris may be used. In some persons, and when exhibited in large doses, it is apt to occasion much distressing nausea, with considerable prostration; these effects may be obviated or mitigated by combining it with a few grains of capsicum, or ginger, a grain of camphor, or 4 or 5 grains of resin of blue cohosh (*caulophyllin*). For its specific uses, however, the specific iris, in doses of from $\frac{1}{20}$ to 5 drops, is preferred. Like all representative fluid preparations of iris, specific iris is liable to decompose and gelatinize, and is then useless as a medicine. The remedy is not appreciated as it should be, but it is safe to say that with a reliable preparation it will grow in favor the more it is employed.

Specific Indications and Uses.—The specific indications for iris may be stated as fullness of thyroid gland; enlarged spleen; chronic hepatic complaints, with sharp, cutting pain, aggravated by motion; nausea and vomiting of sour liquids, or regurgitation of food, especially after eating rich pastry or fats; watery, burning bowel discharges; enlarged lymphatics, soft and yielding; rough, greasy conditions of the skin; disorders of sebaceous follicles; abnormal dermal pigmentation; menstrual wrongs, with thyroid fullness; unilateral facial neuralgia; muscular atrophy and other wastings of the tissues; bad blood.

Related Species.—There are several species of iris, as *I. virginica*, Linné, *Boston iris* *I. lacustris*, Nuttall; *Iris verna*, Linné, or *Dwarf iris*, etc., which are often collected and mixed with the official article. *Iris florentina*, or *Florentine orris*, is said to be emetic, cathartic, and diuretic, but it is seldom employed except in the composition of tooth powders, and to conceal an *offensive breath* (see *Iris florentina*).

IRIS FLORENTINA.—FLORENTINE ORRIS.

The rhizome of *Iris germanica*, Linné; *Iris florentina*, Linné, and *Iris pallida*, Lamarck.

Nat. Ord.—Iridaceæ.

Common Names: *Florentine orris*, *Orris-root.*

Botanical Source and History.—Three species of iris furnish the orris-root of commerce, the *Iris germanica*, or *Blue flag;* the *Iris pallida*, or *Pale flag*, and the *Iris florentina*, or *White flag*. The first is indigenous to south Europe, and found likewise in Morocco and northern India, and is cultivated near Florence and Lucca, besides being a common flower in London gardens. All three species have the general characteristics of the order, but differ in the color of the flower. The *Iris germanica* has large, handsome, dark-blue flowers. *Iris pallida* has flowers of a delicate, pale-blue hue. Though not indigenous, it grows plentifully about Florence and Lucca, and wild in the stony regions of Istria. Its stem is much taller than that of the *I. germanica*. The two preceding varieties furnish the bulk of commercial orris-root, the *Iris florentina* furnishing but little. The latter is closely related to *Iris pallida*, but has large, beautiful white flowers, marked with yellow and brown. They are sweet-scented. The rhizomes of all these species are indiscriminately collected, and are termed by the Tuscan peasants *Giaggiolo*. They are gathered in August, peeled, and dried by solar heat. The larger sections are replanted. The peasants divide the drug into several grades, as *selected*, *sorts*, *raspings*, *powder*, and that made into *orris peas*. *Irisia*, of the Indian bazaars, which is brought into commerce unpeeled, is believed by the authors of *Pharmacographia* to be the product of *Iris germanica*. The same source is attributed to an inferior grade from Morocco. The fresh root-stock is jointed, branching, and fleshy. Externally it is yellowish-brown, internally juicy and white. Its taste is acrid, and its odor at first earthy, becoming, as it dries, of a pleasant, violet-like fragrance, which is said to be not fully developed until the root has been dried for two years. The rhizomes of the three species all resemble each other.

Fig. 148.

Iris florentina.

Description.—Dried orris-root comes in sections from 2 to 4 inches in length, and from 1 to 1½ inches in width, being broadest at the apex. The pieces are made up of an elongated portion which is irregularly subconical, and sends off at its broader extremity 1, 2, and occasionally 3, branches, and these, having been cut short in trimming, give them the appearance of small cones attached to the main portion by their apices. The rhizome is somewhat bent into an arch, flattened, shrunken, grooved, and contorted. Where the small rootlets have been attached to the under surface, little circular scars may be seen. The bark is usually absent, leaving a dull, white, heavy, compact texture, which fractures irregularly. Its taste is at first bitterish and aromatic, and finally acrid; its odor suggestive of the violet. Under the microscope the drug exhibits crystals of calcium oxalate. Orris-root is sometimes adulterated with other species of orris, but they lack its peculiar fragrance. The various starches used to adulterate the powder may be detected under the lens.

Chemical Composition.—Orris-root contains a large amount of starch, a small quantity of a crystalline, volatile substance (Dumas), a brownish, soft, acrid resin, and a small proportion of tannin, which strikes green with ferric salts. By distillation with water from 0.60 to 0.80 per cent of a crystalline *orris camphor* floats upon the surface of the distillate. Flückiger (*Pharmacographia*), has proved this to be chiefly *myristic acid* ($C_{14}H_{28}O_2$), intermingled with a small amount of volatile oil, which develops in the drying of the drug. This *orris camphor*, sometimes called *oil of orris-root*, has the persistent violet fragrance of the drug. The so-called *liquid oil of orris-root* is said to be prepared by digesting crushed orris-root in oil of cedar-wood, and finally distilling with steam.

Iridin ($C_{24}H_{26}O_{13}$) is a glucosid obtained from orris-root by G. De Laire and F. Tiemann (*Jahresb. der Pharm.*, 1893, p. 548; also see *Amer. Jour. Pharm.*, 1894. p. 32). It must not be confused with the Eclectic *Iridin* (see Iris versicolor), which for half a century has been an article of commerce. It forms white needles slightly soluble in water (1 to 500), and acetone (1 to 33), insoluble in ether, chloroform, benzol, etc., soluble in hot alcohol. Dilute alcoholic sulphuric acid decomposes it, near the temperature of boiling water, into dextrose and crystallizable *irigenin* ($C_8H_{16}O_8$), having the character of a phenol and producing with ferric chloride a deep violet color. *Irigenin*, when heated with concentrated alkali, is decomposed into *formic acid*, *iridic acid* ($C_{10}H_{12}O_5$), (which is an aromatic oxy-acid , and *iretol* ($C_7H_8O_4$), a phenol. Heated above its melting point, 180° C. (356° F.), *iridic acid* is decomposed into carbonic acid and a phenol, *iridol* ($C_7H_5[OCH_3]_2OH$). The synthesis of all these bodies was effected by the authors.

Action, Medical Uses, and Dosage.—Active irritant qualities are ascribed to orris-root, abdominal pain and emeto-catharsis being among its effects. These properties are dissipated upon drying the rhizome, when it becomes merely a gastric stimulant. The salivary flow and renal secretion are augmented by it while sneezing and increased pituitary secretion results from its use as a sternutatory. About the only use now made of orris-root is as an ingredient of breath perfumes and dentifrices, it not only giving a pleasant flavor, but acting beneficially on the gums. It was formerly used as a diuretic, expectorant, and remedy for *chronic diarrhœa*. From 5 to 15 grains constitutes a dose of the powdered root.

JACARANDA.—JACARANDA.

The leaves of *Jacaranda procera*, Sprengel (*Jacaranda Caroba*, De Candolle; *Bignonia Caroba*, Velloso; *Bignonia Copaia*, Aublet; *Karadelestris syphilitica*, Arruda da Camara).

Nat. Ord.—Bignoniaceæ.

COMMON NAMES: *Carob-tree*, *Caroba*, *Caaroba*.

Botanical Source.—The caroba tree grows in Guiana and Brazil, and attains a height of 30 or 40 feet. The tree is much branched, and luxuriantly crowned with a foliage of beautiful deep-green, compound leaves. These are abruptly bipinnatifid, dividing into 3 or 4 pairs of pinnæ, each having from 8 to 12 elliptical, nearly sessile leaflets, subacute at each extremity, and covered underneath with a woolly pubescence, due to the abundance of long, empty hairs. The flowers are borne in terminal cymes, are white and red and showy, and exhale a honey-like perfume. The fruit is a woody, many-seeded capsule. The root of the tree is deep-red externally, and yellow-white internally. The bark of the tree is of an ashen hue.

Fig. 149.

Leaves of Jacaranda procera.

Description and History.—The leaves are the medicinal parts. They are somewhat coriaceous, from 1 to 2 inches long, entire or nearly so, elliptic, lance-oblong, or oblong; either oblique at base, or subacute at both extremities, smooth, and dark-brown on upper surface, lighter beneath, strongly nerved, and velvety-woolly. The surfaces are beset with oil-glands. Odor slight; taste bitter-astringent.

The *Jacaranda procera* is one of the many trees known in Brazil as *Caroba* or *Carobinha*, others being *Jacaranda oxyphylla*, Chamisso; *Jacaranda brancha*, Sprengel; *Jacaranda subrhombea*, De Candolle; *Caroba de flor verde*, Sprengel; *Bignonia nodosa*, Manso; *Sparottosperma lithontripticum*, Martius; *Cybistax antisyphilitica*, Martius—all of them having uses similar to jacaranda in their native country.

Chemical Composition. A detailed analysis of the leaves and bark of *Jacaranda procera*, by Th. Peckolt (*Zeitschr. d. Oesterr. Apoth. Ver.*, 1881, Nos. 30 and 31), is abstracted in *Amer. Jour. Pharm.*, 1882, p. 135. The leaves contain *carobin* (0.16 per cent), a crystallizable, faintly bitterish, inodorous principle, soluble in boiling water and alcohol, insoluble in ether, precipitated from aqueous solution by tartar emetic; with acetic acid it yields a crystallizable compound. *Carobic acid* (0.05 per cent) crystallizes in needles of aromatic odor and acid taste; is soluble in water and diluted alcohol; *steocarobic acid* (0.10 per cent), pale-brown, of a tonka-like odor, soluble in cold absolute alcohol and ether; *carobone* (2.66 per cent), a balsamic, resinous acid, greenish, soluble in alcohol (sp. gr., 0.815) and caustic alkalies; *caroba resin* (3.33 per cent), inodorous and tasteless; *caroba balsam* (1.44 per cent), dark brown, syrupy, of tonka-like odor; *caroba tannin* (0.44 per cent), and a *bitter* principle (2.88 per cent); albumen, starch, etc. The bark contains *carobin* (0.3 per cent), *caroba resin* (0.5 per cent), the *bitter* principle (0.28 per cent), and in addition *carobaretic acid* (0.2 per cent), devoid of odor. According to Hesse (1880), no alkaloid is present.

Action, Medical Uses, and Dosage.—This agent has been used in its native country as an antisyphilitic, and was introduced into general medicine for the treatment of *venereal disorders*. If useful at all in *syphilis*, it appears to be endorsed as a remedy for secondary manifestations, and is used both locally and internally in *syphilitic ulcerations*. It has not been generally used by Eclectics for this purpose. It seems to have been successful in *cystic disorders* with pus-bearing and fetid urine, and in *gonorrhœa*. *Carobin*, which resembles the active constituent of sarsaparilla, has been used in doses of 1 grain in *syphilis* and *scrofula* (Peckolt). Dr. Lyman Watkins (*Ec. Med. Jour.*), treated successfully with jacaranda a case of *epilepsy* at the Eclectic Medical Institute Clinic. The disease was of fourteen years duration, and averaged from 7 to 10 convulsions in a day. From the very outset, through the 3 months during which the patient was treated, not a convulsive attack was experienced. Jacaranda undoubtedly has an influence upon the nervous structures. Epileptic disorders relieved by it are those superinduced by sexual indiscretions. It is recommended for those of feeble mentality though well-nourished in body, with voracious appetite and addicted to masturbation. The usual manner of exhibiting the remedy is as follows: ℞ Specific jacaranda, fl℥i or fl℥ii; aqua, fl℥iv. Mix. Sig. Teaspoonful every 4 hours. Fluid extract of jacaranda is given in doses of from 15 to 30 minims, 4 times a day; carobin, in 1-grain doses. For local use, ℞ Jacaranda leaves (powdered), ʒi to ʒii; petrolatum, ℥i.

Specific Indications and Uses.—Mental enfeeblement, voracious appetite, and epilepsy, particularly of masturbators; secondary syphilis and syphilitic ulcers.

JALAPA (U. S. P.)—JALAP.

"The tuberous root of *Ipomœa jalapa*, Nuttall"—(*U. S. P.*); (*Ipomœa purga*, Hayne; *Ipomœa Schiedeana*, Zuccarini; *Exogonium jalapa*, Baillon; *Exogonium purga*, Bentham; *Convolvulus jalapa*, Linné; *Convolvulus purga*, Wenderoth).

Nat. Ord.—Convolvulaceæ.

COMMON NAME: *Jalap*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 186; *Bot. Magazine*, Vol. 73, Plate 4280.

Botanical Source.—Jalap has a fleshy, tuberous, pyriform root, with numerous roundish tubercles. The stems are several, smooth, brownish, very slightly rough, with a tendency to twist, twining about surrounding bodies. The leaves are long petioled, the first hastate, the succeeding ones cordate, acuminate, mucronate, smooth, deeply incised at base, and conspicuously veined beneath. Peduncles axillary, 2-flowered, rarely 3, twisted, as long as the petioles. Calyx has no bracts; composed of 5 smooth, obtuse, mucronate sepals. The corolla is funnel-shaped, purple, with a long, somewhat clavate tube, and an undulated limb, with 5 plaits. Stamens 5; filaments smooth, unequal, and longer than the corolla tube; anthers white, oblong-linear, and projecting. Ovary slender, and 2-celled; stigma simple, capitate, and deeply furrowed. Capsule 2-celled; cells 2-seeded; seeds unknown (L.—N.).

Fig. 150.

Ipomœa jalapa.

History.—It is only within comparatively recent years that any certainty has existed in relation to the plant from which jalap root is obtained. It was first spoken of in 1609, as *Bryonia mechoacana nigricans*, then it was regarded by Ray as *Convolvulus Americanus jalapium dictus*, after which Tournefort, being deceived by persons who asserted that they had seen the plant growing, referred it to a species of *Mirabilis*. Balfour placed it as the *Exogonium purga*, and Linnæus named it *Convolvulus jalapa*, and thus much difference of opinion existed until, in 1827, when Dr. J. R. Coxe, of Philadelphia, succeeded in obtaining perfect flowers from roots of the true plant furnished to him from their native soils, and thus first made its true character known to the scientific world. The name of *Ipomœa purga* was bestowed upon the plant by Wenderoth and Hayne, but as the authorities of this country have, undoubtedly, the first claim, it may be viewed as fixed that *I. jalapa*, the name originally given to it by Nuttall, is the official plant.

The jalap plant is found in a deep, rich, vegetable soil, at an elevation of nearly 6000 feet above the level of the sea, growing in Mexico, near Chicanquiaco and Xalapa, from which last named place it is usually exported, and from which it has also obtained its name. It is generally imported in bags, containing 100 or 200 pounds. The root is the official part, and is gathered in all seasons, but principally in March and April, when the young shoots are appearing. The plant may be cultivated in the southern parts of the United States. In 1866, Dr. D. Hanbury planted a root or tuber of jalap in a garden, near London, and obtained promising results. It is now successfully grown in Jamaica and in India, especially in the Nilgherry hills of that country. According to Warden (1887), the jalap tubers of India are not of first quality. Jalap is a very variable drug, much of it being of an inferior quality. The best kind is that known as the Vera Cruz variety. Several related, and often inferior drugs, *e. g.*, Tampico jalap, have appeared on the market (see *Related Species*).

Description.—When fresh, the root is black externally, white and milky within, and varies in size according to its age, from that of a walnut to that of a moderate-sized turnip. It is dried in net bags over the fire, sometimes entire, and sometimes in sections. It is often preyed upon by insects which, however, leave its active part untouched, rendering it consequently more energetic. Jalap thus preyed upon is used for procuring the resin, but should not be given internally, except in much smaller doses than for the ordinary root. Jalap is rather difficult to pulverize, but if triturated with cream of tartar, sugar of milk, or other hard salt, the process of pulverization is facilitated, and the powder rendered much finer. When in powder, the color is a pale grayish-brown, and when in contact with the mucous membrane of the air-tube, causes coughing and sternutation, with an increased discharge of saliva. Its solvents are water, alcohol, or spirits. Water takes up a small portion of its cathartic principle, but considerable of an amylaceous and mucilaginous extractive matter. Alcohol dissolves the resin, on which its cathartic virtues depend. Ether only partially dissolves it. Diluted alcohol completely extracts its active properties.

The *U. S. P.* thus describes good jalap, and gives the method of valuation of same: "Napiform, pyriform, or oblong, varying in size, the large roots incised, more or less wrinkled, dark-brown, with lighter-colored spots, and short, transverse ridges; hard, compact, internally pale, grayish-brown, with numerous concentric circles composed of small resin cells; fracture resinous, not fibrous; odor slight, but peculiar, smoky, and sweetish; taste sweetish and acrid. On exhausting 100 parts of jalap with alcohol, concentrating the tincture to 40 parts, and pouring it into water, a precipitate of resin should be obtained, which, when washed with water, and dried, should weigh not less than 12 parts, and of which not over 10 per cent should be soluble in ether" (*U. S. P.*).

Jalap root is seldom adulterated; if light, whitish internally, spongy, friable, and of a dull fracture, it should be rejected. The resin of jalap, met with in commerce, however, is subject to falsification, being adulterated sometimes with guaiac, colophony, and various inert substances. In the case of colophony, freshly rectified oil of turpentine will dissolve out this adulteration, while jalap resin is insoluble in this medium (Tromsdorff).

Chemical Composition. Analysis of commercial jalap shows the presence of starch, uncrystallizable sugar (19 per cent, Guibourt), gum, coloring matter, a resin, soluble in alcohol, and a soft resin, soluble in ether. From 12 to 18 per cent is the average yield of resin (*Pharmacographia*), though as high as 22 per cent has been obtained. As stated above, the *U. S. P.* demands 12 per cent of total resin, including not more than 1.2 per cent of ether-soluble resin. The resin of jalap may be obtained by treating the coarsely-chopped roots with water, which removes such constituents as sugar, gum, and coloring matter, and extracting the resin from the roots by means of boiling alcohol, specific gravity 0.880. This resin consists of two distinct resins. One of these, having the odor and acrid taste of jalap, is soft, of acid reaction, and soluble in ether as well as in alkaline solutions; from the latter it is reprecipitated by acids. Prof. Maisch (*Amer. Jour. Pharm.*, 1887, p. 326) considers it a mixture of resins, not deserving a special name until better investigated. The other resin, insoluble in ether, is the purging principle (*jalapurgin*, Maisch, 1887; *convolvulin*, $C_{31}H_{50}O_{16}$, Wm. Mayer, 1856; or $C_{61}H_{108}O_{27}$, A. Kromer, 1894; *rhodeoretin*, of G. A. Kayser, 1844; and *jalapin*, of Buchner and Herberger, 1831). It is hard, white, odorless, and tasteless, while in alcoholic solution it is nauseously acrid. The latter solution is optically lævo-rotatory. *Convolvulin* (as it is mostly called) is insoluble, or nearly so, in water, ether, chloroform, carbon disulphide, petroleum benzin, oil of turpentine, etc., but dissolves readily in alcohol, acetic acid, acetic ether, in cold nitric acid, and in alkalies; in the case of ammonia being used, the heat of the water-bath effects solution. Upon again acidulating the alkaline solution, no precipitate is formed, owing to the conversion of *convolvulin* into *convolvulic* (*convolvulinic*) *acid* ($C_{62}H_{106}O_{35}$, Mayer), an amorphous, white, hygroscopic powder, soluble in water and alcohol, and insoluble in ether. Of this substance convolvulin is the anhydride. *Convolvulin*, as well as *convolvulic acid*, are glucosids (Kayser). When *convolvulic acid* ($C_{28}H_{52}O_{14}$, A. Kromer. *Amer. Jour. Pharm.*, 1894, p. 197) is treated with the ferment *emulsin*, or with warm diluted acids, it is decomposed into 2 molecules of sugar ($C_6H_{12}O_6$), and crystallizable *convolvulinolic acid* ($C_{16}H_{30}O_3$, Kromer). The latter is insoluble in water and melts at 46° C. (114.8° F.). *Convolvulin*, treated with the same agents, decomposes into glucose, volatile *methyl-ethyl-acetic acid*, and *convolvulinolic acid*; with alkalies, 1 molecule of *methyl-ethyl-acetic* and 2 molecules of *convolvulinic* acids are formed. Höhnel (1896), by the same agents, obtained 2 glucosid acids, *convolvulinic* and *purginic acids* (see *Jahresb. der Pharm.*, 1896, p. 511). Strong nitric acid oxidizes *convolvulin* to carbonic and oxalic acids, and a small quantity of *sebacic* (*ipomic*) *acid* ($C_8H_{16}[COOH]_2$), a substance which is also one of the products of the dry distillation of oleic fats.

Action, Medical Uses, and Dosage.—Jalap is an irritant and cathartic, operating energetically, occasioning profuse liquid stools with griping, and sometimes sickness at stomach, or even vomiting. Large doses produce violent hypercatharsis, sometimes terminating fatally. When applied to a wound, it is said to induce purgation. Notwithstanding its activity, it is a safe and convenient purgative, much in use among the profession, and is useful in all cases where it is desirable to produce an energetic influence on the bowels, or to obtain large evacuations. In intestinal inflammations it should not be used. United with the bitartrate of potassium, its hydragogue properties are much increased, and thus it proves beneficial in *dropsies*, as well as in some forms of *scrofula*. Jalap, however, is suitable for excitable, active conditions, and may be used where a cooling effect is desired, as when it is necessary to evacuate the bowels in *febrile disorders*. *Inflammatory conditions of the biliary apparatus* are exceptions to the rule that it should not be used in gastro-intestinal inflammations. When the rectum is impacted with a hard, fecal mass, the expulsion of the latter is facilitated by the purgative action of jalap, which greatly augments the intestinal secretions; all cases of *constipation*, due to dryness of the mucous membranes, through inactivity of the intestinal glands, are relieved by jalap. The dose for this latter purpose may be 5 grains in the morning, repeated for several days. When a stimulating laxative can not be used in *hemorrhoids*, jalap may be employed, and it is likewise efficient as a derivative in *cerebral disorders*. The *antibilious physic* (which see), or the following modifications (Locke) of it are very useful preparations: (1) R Powdered jalap, ℥viii; powdered senna, ℥xvi; powdered ginger, ℥i. Mix. Dose, a full teaspoonful in sweetened water; (2) R Jalap, ℥iij; potassium bitartrate, ℥vj; ginger, ʒii. Mix. Dose, 30 to 60 grains, in water, every 3 hours, as a hydragogue cathartic.

It is stated that the aqueous extract of jalap, the root having been previously exhausted of its resin by alcohol, will exert no cathartic influence, but will operate as a powerful diuretic, but I have not been able to procure this effect, though having made a trial in several cases (King). Three grains of jalap, taken an hour before each meal, act as a slight nauseant, destroying a desire for food among persons who are apt to eat too freely. If jalap is digested in ether, its nauseous taste and smell will be wholly removed without lessening its cathartic power. A biscuit is sometimes made for those to whom it is extremely nauseous and disagreeable; 5 drachms of jalap, 30 of sugar, and 4 ounces of flour, are made into 15 biscuits after the usual mode; 1 biscuit is a dose. The tendency of jalap to gripe and nauseate, may be obviated by adding to the dose 1 or 2 grains of camphor, or 3 grains of cloves. The dose of powdered jalap is from 10 to 30 grains (the aqueous extract ought not to be used, except as a diuretic); of the tincture, from 1 to 4 fluid drachms; the resin, or alcoholic extract, is given in from 2 to 8-grain doses, being usually rubbed up with sugar, or in emulsion, for the purpose of lessening its disposition to produce painful irritation of the intestinal mucous membrane. As a hydragogue, 2 drachms of the bitartrate of potassium are added to 10 or 30 grains of pulverized jalap. *Convolvulin* (*rhodeoretin*) purges violently in 3 or 4-grain doses, and appears to be the active principle of jalap. Specific jalap, 10 to 20 drops every 4 hours for its specific uses. Though not an anthelmintic, jalap is often given to hasten the expulsion of *worms*, after agents have been given for their stupefaction or destruction.

Specific Indications and Uses.—Constipation from deficient secretion of intestinal glands; pain and griping in lower bowel; colic, with stercoraceous vomiting; general gastro-intestinal torpor.

Related Species and Drugs.—Several related convolvulaceous tubers of Mexico and Brazil have been employed as purgatives. They are not, however, articles of general commerce.

TAMPICO JALAP.—This is the Mexican *Purga de Sierra Gorda*, and is derived from the *Ipomœa simulans*, Hanbury. It much resembles the jalap tuber in appearance, odor and taste. While it is difficult to distinguish some of the tubers from those of true jalap, most of the Tampico tubers are smaller and more elongated, more corky and shrivelled, and show an absence of little scars crosswise the roots so noticeable in true jalap (*Pharmacographia*). It yields a resin (10 to 15 per cent). Flückiger obtained 10 per cent of it. It is completely soluble in ether. Spirgatis (1870) named the resin *tampicin* ($C_{68}H_{10}O_{28}$). It is converted into *tampicic acid* ($C_{68}H_{120}O_{34}$) by means of concentrated alkalies. Acids resolve it into sugar and *tampicolic acid* ($C_{32}H_{64}O_{6}$), thus showing its glucosidal character, analogously to that of *convolvulin*. It has purgative properties.

Mirabilis jalapa, Linné; *Four o'clock.*—The tubers of this species, which somewhat resemble jalap, may be distinguished by the presence of needle-like raphides of calcium oxalate.

Ipomœa turpethum, R. Brown; *Turpeth root.*—This is the *Turbith végétal* of the *French Codex*. It is not very similar in appearance to jalap. It contains a resin (4 per cent), of which *turpethin*, the ether-soluble portion, a glucosid, behaves like resin of jalap in relation to acids and alkalies. Bases convert it into *turpethic acid*, *methyl-crotonic acid*, traces of formic, and *methyl-ethyl-acetic acids*, etc. (see articles by N. Kromer, *Oesterr. Zschr. f. Pharmacie*, 1895, Nos. 18 to 24).

Ipomœa nil, Roth (*Convolvulus nil*, Linné; *Pharbitis nil*, Choisy).—Tropical regions and southern United States. Seeds called *kaladana* in India, and are slightly purgative. They are black, triangular, with a rounded back, and have a sweetish taste, followed by an acrid sensation. They yield *pharbitisin* (identical with *convolvulin*) and a volatile oil. The seeds are roasted and given in powder.

Ipomœa triloba (*Pharbitis triloba*, *Ipomœa hederacea*). The seeds of the Japanese plant known as *kengashi*, yield *convolvulin*, and are employed like *kaladana*.

Mechoacan. This product, probably of a convolvulaceous plant, comes in gray or whitish circular sections or fragments, somewhat farinaceous, and destitute of the circles of resinous cells. It sometimes occurs as an adulterant of jalap, but its detection is not difficult. It is feebly cathartic.

Orizaba Root. This is variously known as *Woody*, *Light*, or *Fusiform jalap*, *Male jalap*, *Jalap tops* or *stalks*, and is the Mexican *Purgo macho*. It is derived from the *Ipomœa orizabensis*, Ledanois. This root is fusiform, and sometimes occurs in commerce in transverse slices, but more frequently in rectangular blocks. Its longitudinal wrinkles are deeper than those of jalap. Its color is also lighter. From the latter it may be known by the radiations on transverse section, and by leaving, when fractured, projecting bundles of fibrous vessels. Chemically, it closely resembles jalap. Its chief constituent is *jalapin* ($C_{34}H_{56}O_{16}$, or $C_{68}H_{112}O_{32}$, Poleck), so named by Mayer (*para-rhodeoretin* of Kayser), and should not be confounded with the *jalapin* of Buchner and Herberger, which is convolvulin. Mayer's jalapin differs from convolvulin in that ether and acetone freely dissolve it. Poleck (1892) proposes for it the name *orizabin*, as Prof. Maisch has done in 1887. Alkalies change it into water-soluble *jalapic acid* ($C_{68}H_{118}O_{35}$, or $H_2C_{17}H_{28}O_9$, Poleck). Diluted acids convert it into sugar and *jalapinol* ($C_{32}H_{62}O_7$), insoluble in water; probably identical with *jalapinolic acid* ($C_{32}H_{60}O_6$, or $C_{16}H_{30}O_3$, Poleck, 1892), obtainable from scammony resin. *Jalapin* (*orizabin*) is oxidized by nitric acid to carbonic, isobutyric, and *ipomic acid*, the latter an isomer of sebacic acid (compare *convolvulin*). *Jalapin* (Mayer's) has been shown by Spirgatis to be identical with *scammonin* both in chemical and purgative qualities, a fact more recently confirmed by Th. Poleck (see *Jahresb. der Pharm.*, 1892, p. 80).

Ipomœa pandurata, Meyer (*Convolvulus panduratus*, Linné); *Wild potato*.—This plant, likewise known as *Wild jalap*, *Man in the Ground*, *Mechameck*, *Man of the Earth*, etc., has a perennial, very large, tapering root, with several stems from the same root, from 4 to 8 feet long, round, slender, purplish, smooth or nearly so, trailing or twining. Leaves 2 or 3 inches long, about the same width, broadly cordate at base, acuminate, entire, or wavy, alternate, sometimes panduriform, smooth, deep-green above, paler beneath, on long petioles. Flowers white, dull-purple toward the base, large, opening in the forenoon; peduncles axillary, longer than the petioles, cymose, branching at the top, several-flowered. Corolla large, campanulate, 2 or 3 inches long. Calyx smooth, 5-parted, naked; sepals ovate-oblong, stamens white, the length of the tube; anthers oblong. Style white, thread-like; stigma capitate, bilobed. Capsule oblong, 2-celled, 4-seeded, without intermediate partitions (L.—W.—G.).

Wild potato is indigenous to the United States, growing in light and sandy soils, from Connecticut and west New York, southward and westward, and flowering from June to August; it rarely grows North, but is found in some parts of South America. The root is the medicinal part; it is very large, being from 2 to 8 feet in length, and from 2 to 4 or 5 inches in diameter, branched at the bottom, brownish-yellow externally, whitish and lactescent internally, furrowed lengthwise, and of a disagreeable odor and bitter, rather acrid taste; about 75 per cent in weight is lost in drying. It is generally met with in transverse, circular sections, which are somewhat tawny externally, whitish with diverging lines internally, and not readily powdered; the powder is somewhat grayish. Water or alcohol extracts its active properties, but diluted alcohol or spirits are its best solvents. It contains resin, bitter extractive, sugar, starch, gum, a body resembling tannic acid, etc. The resin is purgative. It consists of an acid, and a non-acid portion. It is a glucosid, and exists to the extent of 1.5 per cent.

The active principles of this plant are unknown. It possesses mild cathartic properties, acting gently in doses of from 40 to 60 grains of the powdered root. The infusion taken in wineglassful doses every hour, has been effective in *dropsy*, *strangury*, and *calculous affections*. It seems also to exert an influence over the lungs, liver, and kidneys, without excessive diuresis or catharsis. The saturated tincture is more energetic than the powdered root, decoction, or extract. It is asserted that the Indians can handle rattlesnakes with impunity after wetting their hands with the milky juice of this root.

JEFFERSONIA.—TWINLEAF.

The rhizome of *Jeffersonia diphylla*, Barton.

Nat. Ord.—Berberidaceæ.

Common Names: *Twinleaf*, *Rheumatism-root*, *Ground-squirrel pea*.

Botanical Source.—This is an indigenous, perennial plant, sometimes known as Ground-squirrel pea, and Rheumatism-root. Its rhizome is horizontal, with matted fibrous radicles; the scape or stem is simple, naked, 1-flowered, and from 8 to 14 inches in height. The leaves are in pairs, binate, placed base to base, oval, broader than long, ending in an obtuse point, smooth, glaucous beneath, and borne on petioles as long as the scape, which arise from the rhizome. The flowers are large, regular, and white. The calyx consists of 4 colored, deciduous sepals. The corolla is composed of 8 flat, oblong, spreading, incurved petals. Stamens 8, with oblong-linear anthers, on slender filaments. Ovary ovoid, soon gibbous, pointed;

stigma 2-lobed. The capsule is obovate, or somewhat pear-shaped, stipitate, and 1-celled, opening half-way round horizontally, making a persistent lid. The seeds are many on the lateral placenta, with a fleshy lacerate aril on one side and oblong (W.—G.).

History and Description.—This plant is found from New York to Maryland and Virginia, and in many parts of the western states, growing in limestone soil, in woods and near streams and rivers, and flowering in April and May. The part used is a thick, knotty rhizome, from which long, fibrous roots proceed, and is of a brownish-yellow color. It is used as an adulterant of hydrastis, and is often artfully mixed therewith. In cases that have come under our observation, this root has been chopped so as to bring it to about the size of hydrastis. In other instances it has been matted together inside of bunches of hydrastis, and in still others the rootlets have been removed, chopped, and mixed with hydrastis. The epidermis is somewhat corrugated, and in some specimens transversely cracked. The bark is resinous, and contains the active principle of the roots. The central portion is ligneous, of a light straw color, and is easily separated by bruising the root. The root has an odor similar to that of *podophyllum*, and a bitter, mucilaginous taste at first, followed by a pungent, nauseous, and acrid taste. Water or alcohol extracts its virtues.

Chemical Composition.—An analysis by Prof. E. S. Wayne, showed this plant to contain tannic acid, gum, starch, sugar, mineral matters, considerable pectin, fatty resin, a bitter substance, an acrid and nauseous matter somewhat similar to polygalic acid, which occasioned vomiting with persistent nausea (see *Amer. Jour. Pharm.*, Vol. XXVII, p. 1). Prof. F. F. Mayer states that the pectin of Prof. Wayne, in the above analysis, is *saponin;* also that the root contains a large proportion of a white alkaloid, and a small quantity of *berberine* (*Amer. Jour. Pharm.*, 1863, p. 99). A. W. Flexer (*Amer. Druggist*, 1884, p. 227), denies the existence of berberine in Jeffersonia.

Action, Medical Uses, and Dosage.—Diuretic, alterative, antispasmodic, and a stimulating diaphoretic. Successfully used in *chronic rheumatism*, as a tonic in *secondary* or *mercurio-syphilis;* also used with advantage in *dropsy*, in many *nervous affections*, *spasms*, *cramps*, *nervous excitability*, and even during *pregnancy*. In *syphilitic diseases* it has been combined with corydalis, but I have been unable to determine any other than a tonic influence, with evident improvement in nutrition, whether it be administered alone in this malady, or combined as just stated (King). As a gargle it has been beneficial in *diseases of the throat*, *ulcers* about the fauces, *scarlatina*, *ophthalmia*, and *indolent ulcers*. It is administered in decoction and saturated tincture. Dose of the decoction, from 2 to 4 fluid ounces, 3 times a day; of the tincture, from 1 to 3 fluid drachms, 3 times a day. Some practitioners substitute this plant for senega, as an expectorant and emetic.

Specific Indications and Uses.—Pain in the head with dizziness and sensation of tension (Watkins, *Compendium of Eclectic Practice*).

JUGLANS (U. S. P.)—JUGLANS.

"The bark of the root of *Juglans cinerea*, Linné, collected in autumn"—(*U. S. P.*). (*Juglans oblonga*, Miller; *Juglans cathartica*, Michaux). The leaves are also employed.

Nat. Ord.—Juglandaceæ.

COMMON NAMES: *Butternut*, *White walnut*, *Oil nut.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 247.

Botanical Source.—This tree is indigenous, and grows to a height of from 30 to 50 feet, with a trunk about 4 feet in diameter, at some 4 or 6 feet from the ground, and which, at 8 or 10 feet from its base, divides into numerous, nearly horizontal, wide-spreading branches, with a smooth gray bark, and forming a large tufted head, giving to the tree a peculiar appearance. The leaves are alternate, from 12 to 20 inches long, consisting of 7 or 8 pairs of leaflets, which are 2 or 3 inches in length, oblong-lanceolate, rounded at the base, acuminate, finely serrate, and downy, with the petioles and branchlets downy with clammy hairs

Male and female flowers distinct upon the same tree, the former in large aments, 4 or 5 inches long, hanging from the sides of the last year's shoots, near their extremities. The scales which compose them, oblong and deeply cleft on each side into about 3 teeth or segments. Anthers about 8 or 10 in number, oblong, and nearly sessile. The fertile flowers grow in a short spike at the end of the new shoot; are sessile, universally pubescent, and viscid; when fully grown they seem to consist of a large oblong ovary, and a forked feathery style. The top of the ovary, however, presents an obscurely 4-toothed calyx. Within this is a corolla of four narrow lanceolate petals growing to the sides of the style; the style divides into 2 large, diverging, feathery, rose-colored stigmas, nearly as long as the ovary. The fruit is sometimes single, suspended by a thin, pliable, peduncle; sometimes several are together on the sides and extremity of the same peduncle. It is of a green color, brown when ripe, oblong-oval, obtusely pointed, hairy, and extremely viscid. The nut or nucleus is dark-colored, hard, oblong, pointed, carinated on both sides, and its whole surface roughened by deep indentures and sharp prominences. The kernel is oily, pleasant-flavored, and edible (L.—W.—B.).

Fig. 151.

Juglans cinerea.

History and Description.—This tree and the *Juglans nigra* or Black walnut are common to North America. The *J. cinerea* is found throughout the New England, Middle, and Western states, and Canada, growing in rich woods, on elevated river banks, and on cold, uneven, rocky soils, flowering in April and May, and maturing its fruit during the middle of autumn. A saccharine juice, said to furnish a good sugar, is obtained by tapping the trees early in the spring. Butternut wood is light, of a reddish hue, not apt to become worm-eaten, and is frequently used in paneling and for ornamental work. The fruit collected sometime previous to its ripening is used in the form of pickles by many persons; the bark and shells of the nut furnish a dye of a chocolate color, for woolen goods, but as a dye, the bark of the black walnut is preferable. In the recent state, butternut bark is acrid, and when rubbed upon the surface of the body, occasions redness and sometimes blisters. The medicinal parts are its leaves and the inner bark of the root, the latter of which is best when gathered from April to July. The bark of the root is official, and this, the Pharmacopœia directs, should be gathered in the autumn. The official description of the bark is as follows: "In flat or curved pieces, about 5 Mm. (⅕ inch) thick; the outer surface dark-gray and nearly smooth, or deprived of the soft cork and deep-brown; the inner surface smooth and striate; transverse fracture short, delicately checkered, whitish, and brown; odor feeble; taste bitter and somewhat acrid"—(*U. S. P.*). Its original whiteness soon begins to alter upon exposure to the air, changing from a yellow to a dark-brown color. Water at 100° C. (212° F.), takes up all its active poperties.

Chemical Composition.—In the bark of *Juglans cinerea*, (Butternut tree), C. O. Thiebaud found (*Amer. Jour. Pharm.*, 1872, p. 253), bitter extractive, much oil, crystallizable, orange-yellow *juglandic acid*, soluble in benzol, alcohol, and ether, but hardly soluble in water, and probably related to chrysophanic acid; a crystallizable, colorless acid, and a volatile acid, but no tannin, although ferric chloride gave a dark-colored precipitate. Mr. E. S. Dawson (1874), however, established the presence of tannin in the bark, when rapidly and immediately dried after collection. The bark stains the skin persistently brown. A quantitative and comparative analysis of the bark of the root and trunk by E. D. Truman is recorded in *Amer. Jour. Pharm.*, 1893, p. 426. *Juglandic acid* was obtained by the author in orange-red crystals from the alcohol extract when this was treated with water and the solution abstracted with ether. The crystals turn deep-violet with alkalies, and decompose very readily, resinous products insoluble in water being formed. Perhaps *juglandic acid* is identical with *nucin* or *juglon*, obtainable from the green leaves and pericarps of the *Juglans regia*, Linné, or European walnut (see *Related Species*).

JUGLANDIN is a name once given to a dried extract from the *J. cinerea*. It was a member of the class of preparations introduced and used about 50 years ago by the Eclectics under the name *resinoids* or *concentrations* (see *Leptandrin* and *Podophyllin* for special remarks concerning this class).

Action, Medical Uses, and Dosage.—Butternut in small doses is a mild stimulant to the intestinal tract, proving laxative and in larger doses is a gentle and agreeable cathartic, causing no griping, nor subsequent weakness of the intestines. It resembles rhubarb in its effect, but without inducing constipation after its action. It is very valuable in cases of *habitual constipation*, *colorectitis*, and several other *intestinal diseases*. It is generally used in the form of an extract, in doses of 1 to 30 grains. An excellent combination for chronic constipation is the following: ℞ Ext. butternut, ʒj; ext. nux vomica, grs. v. Mix. Ft. Pil. No. 40. Sig. Two pills, 3 times a day (Locke). The same pill is very efficient in deficient gastric secretion, in *atonic dyspepsia*, and in *indigestion* accompanied with gastric irritation, sour eructations, and flatulent distension of the stomach. Administer 1 pill a day. Juglans is useful in tenesmic, burning, fetid *diarrhœa* and *dysentery*, and should be remembered in *intestinal dyspepsia* with irritation. The specific juglans may be given in from 1 to 10-drop doses. The same doses of the same preparation act as an efficient alterative in *chronic skin affections* and *scrofula*, being particularly indicated in those skin affections exhibiting vesicles or pustules. Webster believes it effectual in all skin diseases except those presenting parasitic, scrofulous, or syphilitic manifestations. Juglans is an efficient cathartic to use when a free action of the bowels is demanded in *rheumatism* and *chronic respiratory affections*. A strong decoction of it is much employed in some sections of the country, as a domestic remedy in rheumatism affecting the muscles of the back, and in *intermittent* and *remittent fevers*, as well as in other diseases attended with congestion of the abdominal viscera; it is also reputed efficient in murrain of cattle, and yellow water in horses. It was used with great advantage in the treatment of *dysentery* and *diarrhœa* occurring among our soldiers in the Civil War. Dose of the extract, from 1 to 30 grains, usually from 1 to 5 grains; specific juglans, 1 to 20 drops, the smaller doses being preferred for its specific action.

Specific Indications and Uses.—Chronic constipation; gastro-intestinal irritability, with sour eructations, flatulence, and either diarrhœa or constipation dependent thereon; diarrhœa and dysentery with tenesmus and burning and fetid discharges; torpid liver; chronic skin affections of a pustular or vesicular character, discharging freely; eczematous affections.

Related Species.—*Juglans nigra*, or *Black walnut* grows from 60 to 90 feet high, with a diameter of from 3 to 6 feet, with a brown bark. Leaflets numerous, 7 to 10 or 11 pairs, ovate-lanceolate, serrate, subcordate at base, taper-pointed at the apex, smooth above, the lower surface and the petioles minutely downy. Fruit globose, with scabrous punctures; nut corrugated, kernel sweet, more pleasant tasted and less oily than the butternut, but greatly inferior to the European walnut, *Juglans regia* (W.—G.). *Juglans nigra* is rarely found in the northern states, but is more common to the middle and western. It flowers and ripens its fruit at the same time with the butternut. The duramen of its wood is compact and heavy, of a deep-violet color, surrounded with a white alburnum. It is extensively used in building and for cabinet work (G.—W.). The leaves of *Juglans nigra* were analyzed by Lillie J. Martin (*Amer. Jour. Pharm.*, 1886, p. 468), and contained tannin as the dominant principle; volatile oil, a volatile acid, resin, wax, gum, and a crystallizable substance, probably a glucosid. The ash constituted 8.5 per cent, and the absence of aluminum in the ash was established. The juice of the rind of black walnut is said to cure *herpes*, *eczema*, *porrigo*, etc., and a decoction has been used to remove *worms*. The bark is very astringent and acrimonious, and is employed in dyeing.

Juglans regia, Linné; *English*, or *European walnut*.—The leaves and green pericarp of the fruit of this species have an astringent, bitter taste and a characteristic odor. They are known in European pharmacy respectively as the *Folia juglandis* and *Cortex fructus juglandis*. The kernels of the ripe fruit, as well as those of the black walnut, butternut, pecan-nut (*Carya olivæformis*, Nuttall), and the hickory nuts (species of Carya) yield a fixed oil known as *nut oil*. It is one of the drying oils, and is bland, of a greenish or light-yellow color, and becomes of the consistence of lard at near —18° C. (0° F.). It has a specific gravity of 0.928, and, according to Mulder (1865), contains linoleic, myristic, and lauric acids. A volatile oil was obtained from the leaves (0.029 per cent), by distillation with water. It has the flavor of tea, and solidifies at 15° C. (59° F.) (Schimmel's *Report*, 1890).

Juglon ($C_{10}H_6O_3$, *Oxy-alpha-naphtho-quinone*, Bernthsen and Lemper, 1885; *Nucin*, of Vogel and Reischauer, 1856 and 1858; *Regianin*, of Phipson, 1896), occurs in the green pericarps of the European walnut, and is obtainable by extraction with carbon disulphide, ether, etc. According to Bernthsen and Lemper, it is an oxidation product of *hydrojuglon*, which exists in the husks, and can be abstracted therefrom with ether. The ethereal solution shaken with diluted chromic acid, converts it by oxidation into yellow, crystallizable *juglon*, soluble in chloroform and concentrated sulphuric acid with blood-red color, hardly soluble in cold alcohol and ether. Crystals of *juglon* are sublimable, and are decomposed by hot water, a brown coloring matter resulting. *Juglon* stains the skin brown. Diluted alkalies dissolve *juglon* with an evanescent purple color. The pericarp of the immature fruit contains large quantities of tannic acid (*nucitannic acid*, of Phipson), but the ripe husk is entirely free from this principle (C. Hartwich, *Archiv der Pharm.*, 1887, p. 333).

A crystallizable alkaloid, *juglandin*, was isolated from the leaves in 1876, by Tanret; it turns black upon exposure to the air. *Nucit* ($C_6H_{12}O_6 + {}_2H_2O$), a non-fermentable sugar occurring in the leaves, was found by Tanret and Villiers (1878) to be identical with *inosit*. Sestini obtained from the root of juglans considerable quantities of *glycyrrhizin* in the form of potassium and calcium salts.

The European walnut has been found by Prof. Negrier, of Angers, to be very efficient in *scrofula*. To children laboring under this disease he administered a strong infusion of the leaves in teacupful doses, or the aqueous extract in doses of 6 grains, or a proportionate dose of a syrup prepared with 8 grains of the extract to 10 drachms of syrup, repeating the dose from 2 to 5 times a day. All the *ulcers* and *sore eyes* were washed with a strong decoction of the leaves, and the ulcers covered with linen compresses steeped in this decoction, or poultices made with flour and the decoction. No injury followed its long-continued administration. The above American species would probably answer as good a purpose.

JUJUBA.—JUJUBE-BERRIES.

The fruit of *Zizyphus vulgaris*, Lamarck, and *Zizyphus Lotus*, Lamarck.

Nat. Ord.—Rhamnaceæ.

COMMON NAME: *Jujube-berries.*

Botanical Source and History.—The shrubs bearing jujube-berries are cultivated in Spain, Italy, and France, and along the Mediterranean. The first species is indigenous to Syria and Asia Minor, the second grows in the northern part of Africa. Jujube plants are shrubs, sometimes arborescent, and have alternate, serrated, ovate leaves, which are 3-nerved and armed at the base with prickly and spinous stipules. By abortion the fruit is 1-celled and 1-seeded, but it usually has 2 cells and 2 seeds.

Description and Chemical Composition.—Jujube-berries are roundish-oval or oblong drupes, about the size of an olive. The skin is vivid-red when fresh, but when dried becomes brownish-red, and is leathery, thin, and wrinkled. The pulp is soft, yellowish, mucilaginous, sweet, and acidulous, and encloses the ovate, pointed stone. The drupe of the *Z. Lotus* is smaller (about $\frac{3}{5}$ inch) and subglobular. The fruit of an East Indian species, *Zizyphus jujuba*, Lamarck, possesses like properties, and the shrub gives a stick-lac from which a portion of the shellac of commerce is prepared (see *Amer. Jour. Pharm.*, 1886, p. 307). Chemically, jujube-berries contain sugar and mucilage, while tannin is a constituent of the bark. (2.8 per cent, D. Hooper, 1894). The fruits of the first two species constitute an article of food in their native countries, being employed like raisins, figs, etc.

Preparation.—JUJUBE PASTE. *Massa de jujubis.* With sufficient water extract jujube-berries, 5 parts, to obtain of the infusion, 35 parts; add sugar, 20 parts; acacia, 30 parts. Evaporate, add orange-flower water, 2 parts; boil slowly for 12 hours, and run into molds. This is in accordance with the *French Codex.* Jujube paste (in the United States), seldom contains jujube.

Action and Medical Uses.—Jujube decoction is employed in some countries as a demulcent pectoral, and like other acidulous and sweet fruits, jujube enters into the composition of tisanes for the relief of *throat* and *broncho-pulmonic irritations.* Jujube paste is demulcent, but seldom met with in this country.

JUNIPERUS.—JUNIPER.

The fruit (berries) of *Juniperus communis*, Linne.

Nat. Ord.—Coniferæ.

COMMON NAME: *Juniper berries.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 255.

Botanical Source.—This is a small evergreen shrub, never attaining the height of a tree, with many very close branches, the extremities of which are smooth and angular. The leaves are attached to the stem or branches in threes, in a verticillate manner, linear-acerose, sharply mucronate, entire, shining-green on their lower surface, and channeled and glaucous along the center of their upper surface; they are always resupinate, and turn their upper surface toward the ground. The flowers are diœcious, the males in small axillary aments, with roundish, acute, stipitate scales, inclosing several anthers. The female flowers are on a separate shrub, having a small, 3-parted involucre growing to the scales, which are 3 in number. The fruit is fleshy, roundish-oblong, berried, of a dark-purplish color, formed of the confluent, succulent scales, marked with 3 prominences, or vesicles at top, ripening the second year from the flower, and containing 3 bony, angular seeds (L.).

History and Description.—Juniper is common to Europe and this country, growing in dry woods and hills, and flowering in May. The fruit or berries are the medicinal parts; those which are imported from the southern parts of Europe are the best. The American berries possess less medicinal virtue, and are seldom employed. Juniper berries are about the size of currants, of a purplish-black color, shrunken, marked at the top with a triradiate groove, and at the base with the bracteal scales; they contain 3 seeds. Their odor is peculiar, terebinthine, and aromatic, and their taste terebinthine and sweetish, succeeded by some bitterness; these qualities are due to an essential oil, which may be obtained by distillation with water. They yield their properties to hot water or alcohol. An empyreumatic oil—*oil of cade* (see *Oleum Cadinum*), or *huile de cade*, is obtained in France by dry distillation of the wood of *Juniperus Oxycedrus*, Linné.

Chemical Composition.—According to Schimmel & Co., juniper berries contain 1.2 per cent of essential oil in Hungarian, and only 0.7 per cent in German fruit (Flückiger, *Pharmacognosie*, 1891). (Also see *Oleum Juniperi*.) Steer (1856) isolated from the berries a yellow coloring matter which he called *juniperin*. It is soluble in 60 parts of water, also soluble in ether, alcohol, sulphuric acid, and in ammonia with golden-yellow color. Two analyses by Ritthausen and Donath (*Jahresb. der Pharm.*, 1877, p. 62), gave the following percentage composition: Moisture 10.77 (recent), 29.44 (dry); ash 3.37 (R.), 2.33 (D.); dextrose 14.36 (R.), 29.65 (D.); water-soluble matter, consisting of formic, acetic, and malic acids and a bitter substance 11.7 (R.), 3.41 (D.); fat, resin, and volatile oil, 12.24 (R.), 11.33 (D.); protein bodies, 5.41 (R.), 4.45 (D.); cellulose, 31.6 (R.), 15.83 (D.); nitrogen-free matter soluble in sulphuric acid and caustic potash (pectin, Donath) 10.55 (R.), 0.73 (D.).

Action, Medical Uses, and Dosage.—Both the berries and oil are stimulating, carminative, and diuretic. The oil is said to act like copaiba in arresting mucous discharges, especially from the urethra. It is contained in the spiritous liquor called Hollands, one of its best forms as a diuretic. Five minims of the oil, with 1 fluid drachm of nitrous ether, given 3 times a day in any common vehicle, produces diuresis in *dropsy* when other means fail. Combined with an equal part of watermelon seeds, and made into an infusion, I have cured several cases of *ascites* occurring in children, having them to make free use of it (King). The berries are employed principally as an adjunct to other diuretics, and have been found efficient in *gonorrhœa, gleet, leucorrhœa, cystirrhœa, affections of the skin, scorbutic diseases*, etc. *Pyelitis, pyelo-nephritis*, and *cystitis* when chronic, and particularly when in old people, are relieved by juniper. Uncomplicated *renal hyperemia* is cured by it. The indications are a persistent weight or dragging in lumbar region. Dose of the berries, from 1 to 2 drachms; of the oil, from 4 to 20 minims. The infusion (berries, ℥i; aqua, Oj), may be given in wineglassful doses, a pint being taken in a day. It is very useful in the *dropsy* following *scarlatina*, and other infectious diseases, and may be combined with acetate or bitartrate of potassium if desired. OIL OF CADE has been successfully employed in *parasitic skin diseases, moist eczema*, and *psoriasis*.

Preparation of Juniper.—HOWE'S JUNIPER POMADE. This preparation is a compound of lard, oil of juniper and Fowler's solution, the proportions of which have been published in the *Eclectic Medical Journal*. Much pharmaceutical skill is required to blend the ingredients so as to prevent subsequent separation. Juniper pomade is useful in "all forms of *eczema* or *tetter*. It allays the itching and destroys the vesicles and scales. The unguent may be used upon all parts of the body, though sparingly upon mucous surfaces. It is employed in the nasal cavities with a camel's hair brush to mitigate the symptoms of *catarrh*, to arrest *hay-fever*, to heal *nasal ulcers*, to arrest *ringing in the ears*, and to improve states of *deafness* depending upon thickening of the linings of the Eustachian tubes. Juniper pomade softens the scaly patches on the face which are often *epitheliomatous*. It has proved an excellent dressing for *tetter of the edges of the eyelids*, which leads to '*wild hairs*,' and *induration of the tarsal borders*. The pomade is reliable in the treatment of *sore nipples* in nursing women; and it will cure *chapped hands*" (Prof. A. J. Howe, M. D.).

KALMIA.—MOUNTAIN LAUREL.

The leaves of *Kalmia latifolia*, Linne.

Nat. Ord. Ericaceæ.

Common Names: *Mountain laurel*, *Laurel*, *Sheep laurel*, etc. (see below).

Botanical Source and Description.—This plant is known by various names in different sections of the country, as *Laurel*, *Lambkill*, *Ivy*, *Big-leaved ivy*, *Spoonwood*, *Calico-bush*, *Mountain laurel*, etc. It is a beautiful shrub, from 4 to 8 feet high, sometimes attaining the height of a small tree, with crooked stems and a rough bark. The leaves are irregularly alternate and ternate, evergreen, coriaceous, very smooth, with under side somewhat paler, ovate-lanceolate, acute at each end, entire, on long petioles at the ends of the branches, from 2 to 3 inches long. The flowers are numerous, white or variously tinged with red, very showy, clammy, in splendid terminal, viscid-pubescent, simple or compound corymbs, with opposite branches. The pedicels are glutinous and pubescent, with ovate, acuminate bracts. Calyx small, 5-parted, and persistent, with oval acute segments. The corolla is large, monopetalous, with a conical tube, a cyathiform limb, and an erect, shallowy, 5-lobed margin; at the circumference of the limb, on the inside, are 10 niches or pits, accompanied with corresponding prominences on the outside; in these depressions the anthers are found lodged at the time when the flower expands. The stamens are 10, hypogynous, bent outwardly so as to lodge their anthers in the niches of the corolla, but liberating them during the period of flowering and striking against the sides of the stigma; anthers 2-celled with 2 terminal pores. The ovary is roundish, supporting a slender, declinate style longer than the corolla; stigma obtuse. The fruit is a dry capsule, which is roundish, depressed, 5-celled, 5-valved, the valves alternating with the divisions of the calyx. The seeds are numerous, and minute (L.—W.—B.—R.).

Fig. 152.

Kalmia latifolia.

Fig. 153.

Single flower of Kalmia latifolia.

History.—Sheep laurel, or more properly Mountain laurel, inhabits most parts of the United States, on rocky hills and elevated grounds, and in damp soil, sometimes forming a dense thicket, with a profusion of beautiful rose-colored flowers which appear in June and July, forming a contrast with its dark, glossy, green leaves. The leaves are reputed to be poisonous to sheep and several other animals, killing them; while others again, as deer, goats, and partridges, feed upon them without any unpleasant consequences. When partridges, which have eaten the laurel leaves, have themselves been cooked and eaten, they are said to have occasioned sickness at stomach, headache, impaired vision, difficult breathing, coldness of the surface and extremities, and other symptoms similar to those caused when putrid meats are eaten. An emetic of mustard with warm water has relieved some of the above symptoms by removing the poison from the stomach. It is very doubtful, however, whether these symptoms were caused by the poisoned flesh of the birds, as numerous persons eat partridges that have fed on these leaves, without the least inconvenience. The Indians are said to have used the expressed juice of the leaves, or a strong decoction, for the purpose of committing suicide. They also made spoons of the wood, hence the name spoonwood. The leaves, which are astringent and bitter (*described above*), are the medicinal parts, and yield their virtues to alcohol or water.

Chemical Composition.—The leaves contain, according to Mr. C. Bullock, fatty matter, resin, tannic acid, gum, a body somewhat like mannit, chlorophyll, wax, albumen, an acrid substance, extractive, yellow coloring matter, and various salts (*Amer. Jour. Pharm.*, Vol. XX, p. 264). Mr. G. W. Kennedy (1875) isolated *arbutin* in small quantity. The poisonous principle is *andromedotoxin* ($C_{31}H_{51}O_{10}$), a neutral body, found by Prof. Plugge in several poisonous, ericaceous plants (see also investigation by A. J. M. Lasché, *Pharm. Rundschau*, 1889, p. 208). It is soluble in water (1 in 35), chloroform (1 in 400), alcohol (1 in 9), and almost insoluble in ether (1 in 1400). The diluted mineral acids, when warm, impart to it a beautiful red color. Miss De Graffe (*Amer. Jour. Pharm.*, 1896, p. 321), found tannin resembling oak-tannin in the stems and leaves of mountain laurel. Mr. Harry Matusow (*Amer. Jour. Pharm.*, 1897, p. 341) analyzed the root of Kalmia latifolia, which contained 11.4 per cent of starch, 1.24 per cent of ash, tannin resembling oak-tannin, etc. The ether extract contained a substance which gave reactions for *andromedotoxin*.

Action, Medical Uses, and Dosage.—In immoderate doses, sheep laurel is a poisonous narcotic, producing the symptoms above named, with diminished circulation. In medicinal doses, it is antisyphilitic, sedative to the heart, and somewhat astringent. Internally, either in powder, decoction, or tincture, it is an efficient remedy in primary or secondary *syphilis*, and will likewise be found invaluable in *febrile and inflammatory diseases* and *hypertrophy of the heart*, allaying all febrile and inflammatory action, and lessening the action of the heart. In *active hemorrhages, diarrhœa*, and *flux*, it has been employed with excellent effect. and will be found useful in overcoming *obstinate chronic irritation of mucous surfaces*. I have extensively used this agent, and regard it as one of our most efficient agents in *syphilis;* and have likewise found it very valuable in *inflammatory fevers, jaundice*, and *ophthalmic neuralgia* and *inflammation*. The remedy must always be used with prudence; and should any of the above mentioned symptoms appear, the dose must be diminished, or its use suspended for a few days. In cases of poisoning by this article, stimulants, as brandy, whiskey, etc., must be given, with counter-irritation to the spine and extremities. Sheep poisoned by eating the leaves, have been saved by administering 1 or 2 gills of whiskey to them (King). Scudder (*Spec. Med.*), states that he has employed it with marked advantage in *secondary syphilis* and *atonic chronic inflammations*. For the treatment of aching pains in the muscles of the face, *muscular rheumatism* with shifting pains, and in the early stage of *rheumatism of the heart*, success has been claimed for this drug, the specific medicine being used in from 1 to 5-drop doses. *Bright's disease(?)* is asserted to have been benefited by its use. Pain in the back during the menstrual period, and pain upon moving the eyes are said to be relieved by kalmia. Externally, the fresh leaves stewed in lard, or the dried leaves in powder mixed with lard to form an ointment, are said to be beneficial in *tinea capitis, psora*, and other *cutaneous affections*. "Some time since I treated a case of syphilis of five weeks' standing, which had not received any kind of treatment during that period. The patient, at the time I first saw him, had several chancres, the surface of the body and head was covered with small red pimples, elevated above a jaundiced skin, and he was in a very debilitated condition. I administered a saturated tincture of the leaves of kalmia, and touched the chancres with a tincture of chloride of iron, and effected a cure in 4 weeks, removing the jaundice at the same time" (King). The saturated tincture of the leaves or specific kalmia, are the best forms of administration; they may be given in doses of from 10 to 20 drops every 2 or 3 hours; the decoction may be given in doses of from ½ to 1 fluid ounce; and of the powdered leaves, from 10 to 30 grains. For acute disorders, particularly affections of the heart, from 5 to 20 drops of specific kalmia may be added to 4 fluid ounces of water, and the dilution administered in teaspoonful doses every hour. A salve made of the juice of the plant, forms an efficient local application for *rheumatism*. This remedy was a great favorite with Prof. King, especially for troubles depending primarily upon syphilitic infection.

Specific Indications and Uses.—Syphilis with excitation of the heart and circulation; rheumatism with shifting pains; cardiac excitation; cardiac palpitation excited reflexly from gastro-intestinal irritation; pain upon movement of the eyes.

Related Species and Derivative.—There are other species of Kalmia, as *Kalmia glauca*, Aiton, or *Swamp* or *Pale laurel*, and *Kalmia angustifolia*, Linné, or *Narrow-leaved laurel*, which possess similar properties. The *K. angustifolia* is supposed by some to be the best of the species for medicinal use. Lasché, in 1889, found *andromedotoxin* in the leaves and twigs of the latter plant, as well as the berries of *Kalmia latifolia*. This plant is used by the Cree Indians as a tonic and remedy for *intestinal irregularities*.

Laurotetanine.—M. Greshoff has found in a number of Laurel species a crystalline, toxic alkaloid (*laurotetanine*), soluble in an excess of alkali. It closely resembles strychnine in its action upon the spinal cord (*Pharm. Jour. Trans.*, 1891, Vol. XXI, p. 662).

KAMALA (U. S. P.)—KAMALA.

"The glands and hairs from the capsules of *Mallotus philippiensis* (Lamarck), Müller Arg."—(*U. S. P.*); (*Echinus philippinensis*, Baillon; *Rottlera tinctoria*, Roxburgh; *Croton philippensis*, Lamarck).

Nat. Ord.—Euphorbiaceæ.

Common Names: *Rottlera* (*U. S. P.*, 1870), *Kamala*, *Kameela*, *Spoonwood*.

Illustration: Bentley and Trimen, *Med. Plants*, 236.

Botanical Source and History.—This is a small tree or arborescent shrub, found in the hilly parts of India, along the base of the Himalaya mountains from Assam to near Perhawur, in Mysore, and near Bombay, in Australia, China, Abyssinia, etc., and growing from 15 to 30 feet high. It was formerly known as *Rottlera tinctoria*. Its leaves are entire, petiolate, ovate, and acute. The fruit of this plant is about the size of a hazel-nut, tricoccous, with its external covering trifurrowed, and thickly covered with glands of a pulverulent appearance, and a reddish color. These glands are the parts used, and are obtained by simply brushing them off from the ripe capsule, which usually ripens between the last of January and the first of April. In Hindustan this powder, under the name of *wurrus* (see *Related Drugs*), has been extensively employed as a dyeing agent.

Description.—Kamala, when recent, has a peculiar, heavy odor (inodorous, *U. S. P.*), increased on being rubbed between the fingers, or upon being warmed, but which diminishes with age. In the mouth it is gritty and has a somewhat acrid taste. When exposed to a temperature of 93.3° to 100° C. (200° to 212° F.) it undergoes no apparent alteration; when a small portion is dropped into a flame it flashes up instantaneously. Its best solvents are alcohol, ether, and solutions of alkalies, from which it is precipitated by water or acid, in the form of a resinous substance.

The *U. S. P.* thus describes the official drug: "A granular, mobile, brick-red or brownish-red powder, inodorous, and nearly tasteless, imparting a deep-red color to alkaline liquids, alcohol, ether, or chloroform, and a pale-yellow tinge to boiling water. Under the microscope it is seen to consist of stellately arranged, colorless hairs, mixed with depressed-globular glands, containing numerous red, club-shaped vesicles. Upon ignition it should leave not more than 8 per cent of ash"—(*U. S. P.*). Dr. F. A. Flückiger states that if the glands are caused to roll under water or glycerin, they all ultimately show, to the observer, under the microscope their flat side. In its center we find a very short stalk-cell, from which a certain number of small clavate cells radiate in different directions, thus constituting the somewhat globular form of the gland, which is covered by a weak integument. The thicker ends of the small clavate cells within appear at the outside as soft protuberances, upon which partly depends the irregularity of the nearly globular form of the glands. The radiate cells in question are arranged around the center of the flat side to the number of from 9 to 30. If only the basal side is examined, they will be seen to be filled with a dark-brown or brownish-red resin, the intermediate spaces and the outer membrane being of a light-yellow color. The outline of that side, which is always turned to the observer, forms thus an undulated circle or ellipsis, the diameter of which varies from 70 to 120 micromillimeters (thousandth parts of a millimeter), the height of the whole gland being always considerably less. The kamala glands are always accompanied by a tolerable amount of characteristic, stellate, colorless, or brownish hairs, belonging equally to the fruits of *Mallotus*, and some fragments of the latter, and inorganic impurities (*Pharm. Jour.*, Dec., 1867, p. 279).

Chemical Composition.—Kamala contains a small amount of moisture (0.5 to 3.5 per cent), starch, tannin, gummy extractive, citric and oxalic acids, volatile oil, and ash, but consists chiefly (to 80 per cent) of a red-colored resin, which is soluble in ether, alcohol, carbon disulphide, amyl alcohol, glacial acetic acid; also in alkalies, imparting to the latter a beautiful red color. Leube (1860) differentiated the ether-soluble part of kamala into a resin freely soluble in alcohol, fusing at 80° C. (176° F.), and another, less soluble, fusing at 191° C. (375.8° F.). Anderson (1855) observed a yellowish-brown crystalline sediment in an ethereal solution of the resin, and named it *rottlerin* ($C_{22}H_{20}O_6$). By fusion with caustic potash, Flückiger obtained from this substance *para-oxy-benzoic acid*. *Rottlerin* (or *kamalin* of Merck; see Flückiger, *Pharmacognosie*, 1891, p. 261), is probably the same substance as *malloloxin* ($C_{18}H_{16}O_5$, or $C_{11}H_{10}O_3$), obtained in flesh-colored needles from kamala by A. G. and W. H. Perkin (1886), and by Jawein (1887), the latter observing its melting point at 200° C. (392° F.). Acids reprecipitate this substance from its solution in alkalies. The ash of kamala was found by Flückiger and Hanbury not to exceed 3 per cent in a good grade; the *U. S. P.* allows 8 per cent. A red color of the ash points to the presence of ferric oxide. H. G. Greenish (*Amer. Jour. Pharm.*, 1893, p. 193) calls attention to a *false kamala* observed by him in trade, and which consisted mainly of powdered safflower, carelessly collected and badly preserved.

Action, Medical Uses, and Dosage.—This article has been known as a remedy for *tapeworm* among European and American physicians, for only a few years, though long known and employed for this purpose in India. Dr. C. Mackinnon, a surgeon in the English army in India, first made its properties known to the profession, he having been almost invariably successful with it. Since then other practitioners have employed it with equal success. In doses of from 2 to 4 drachms it purges, often with griping, or nausea and vomiting, and producing from 4 to 10 or 15 stools. The worm is usually expelled entire, but often without the head, in the third or fourth stool, after 3 drachms of the powder have been administered. A strong alcoholic tincture acts more mildly and with more uniform effects. *Round* and *seat worms* are also said to be expelled by it. The dose of the powder for an adult is from 2½ to 3 drachms, given in mucilage, syrup, or other vehicle; of the tincture, made in the proportion of 3 ounces to ½ pint of alcohol, ½ fluid ounce. The dose to be repeated, if necessary. Dose of specific kameela, as a tænifuge, 30 to 60 drops, every 3 hours, until 5 or 6 doses have been taken. Externally, its employment is stated to be efficient in certain cutaneous affections, particularly *scabies* and *herpetic ringworm*.

Related Drug.—WARS, WURRAS, or WARRAS. This term properly signifies saffron, but has been applied not only to kamala, but more especially to a certain powder, the botanical source of which is not definitely known, though thought to come from *Flemingia Grahamiana*. This is the substance referred to and beautifully illustrated in the paper from which the above quotation (see *Kamala, description*) is extracted. Dr. Flückiger therein refers to a new kind of kamala, which he thinks must belong to another plant. It is darker colored, more free from earthy impurities, and its grains are all larger than those of the old or true kamala, and instead of being globular they are cylindrical or nearly conical; its cells are not clavate, but simply subcylindrical, and not radiate, and the hairs with which it is mixed are nearly colorless, and not stellate or tufted, as in the true kamala, but quite simple. When exposed to a temperature of 93.3° to 100° C. (200° to 212° F.), the new kamala becomes intensely black. Its alcoholic tincture, slowly evaporated, leaves microscopic crystals, probably the *rottlerin* of Dr. Anderson. It is imported from Aden. (For interesting details regarding wars, see Flückiger, *Pharmacognosie*, 2d ed., 1883, p. 236).

Other Tæniafuges.—*Embelia ribes*, Burmann. *Nat. Ord.*—Myrsineæ. India. The berries of this tree are aromatic, and have been used to adulterate pepper. The color is dull-red. The stalk and 5-parted calyx are often attached; the apex is beaked; and the surface striated. The taste is pleasantly astringent and feebly aromatic. It is tæniacide. The natives of India attribute tonic, alterative, and especially anthelmintic properties to it. It is said to cause the death of the worm. It enters into the local applications for skin diseases, especially [illegible], and has some reputation as a carminative stomachic in *dyspepsia*. The natives further believe that its use, with licorice, tends to strengthen the body, and prevent the ill-effects of old age (Dymock, *Mat. Med. Western India*). Warden (1888) isolated from it golden-yellow crystals of *embelic acid* ($C_9H_{14}O_2$). It is soluble in alcohol and chloroform, but not in water. For *tapeworm*, *Embelia ribes* is given in powder (ʒi to ʒiii) with milk, upon an empty stomach, and followed with a purgative.

MUSENNA, MESENNA, BISINNA, or BUSSENA. The bark of *Acacia anthelmintica*, Baillon. *Nat. Ord.*—Leguminosæ. An acrid drug containing, according to Thiel (1862), bitter and sweet principles, besides *musenin*, an amorphous, saponin-like principle. An Abyssinian remedy for *tapeworm*, taken in doses of 2 or 3 ounces of the powder, followed after some time with a purgative. It is said to cause nausea, and the worm is expelled in a pulpy condition.

Kossala is a remedy employed by the Abyssinians for the removal of *tapeworm*.

Ophioxylon serpentinum.—East India. The root contains an essential oil and *ophioxylin* $C_{16}H_{12}O_6$, a yellow, crystalline body. The root is used by the natives as an anthelmintic and cathartic.

Saoria.—Fruit of *Mæsa lanceolata*, Forskal. *Nat. Ord.*—Myrsineæ. Abyssinia. A brown-green, resinous drupe, having a bitter, acrid, pungent taste, and sometimes causing nausea, emesis, and catharsis. It contains, according to Apoiger (1857), pectin, an iron-greening tannin, fatty and volatile oil, and an acrid body. Wittstein and Apoiger (*Amer. Jour. Pharm.*, 1858, p. 159) established the remarkable occurrence of *boric acid* among the mineral constituents of this plant. Reputed an effective tæniacide. Administered in powder. It is said to impart a violet hue to the urine.

Tatzé, or Satzé.—A disagreeable fruit, of a red-brown color, derived from the *Myrsine africana*, Schimper. Tæniacide. Dose, 4 to 6 drachms.

KINO (U. S. P.)—KINO.

"The inspissated juice of *Pterocarpus Marsupium*, Roxburgh"—(*U. S. P.*).

Nat. Ord.—Leguminosæ.

Common Name: *Gummi kino*, *Resina kino*, *Buja* (Bengalese).

Illustration (of tree): Bentley and Trimen, *Med. Plants*, 81.

Botanical Source.—For a long time the origin of kino was unknown. It has been ascertained to be the product of a lofty tree, growing upon the mountains of the Malabar coast of Hindustan, named *Pterocarpus Marsupium*, belonging to the *Nat. Ord.* Leguminosæ. It has an erect, very high trunk, rarely straight. The outer layer of the bark is brown and spongy, falling off in flakes; the inner red, fibrous, and astringent; branches spreading, horizontal, numerous, and far-extending. The leaves are sub-farious, alternate, pinnate with an odd one, 8 or 9 inches long; leaflets 5, 6, or 7, alternate, elliptic, emarginate, firm, deep-green, and shining above, less so below, from 3 to 5 inches long, and 2 or 3 broad. The petioles are round, smooth, waved from leaflet to leaflet, 5 or 6 inches long, stipules none. Panicles terminal, very large; ramifications bifarious, like the leaves. Peduncles and pedicels round, a little downy. Bracts small, caducous, solitary below each division and subdivision of the panicle. The flowers are very numerous, white, with a small tinge of yellow. Vexillum with a long, slender claw, very broad; sides reflexed, waved, curled, and veined; keel 2-petaled, adhering slightly for a little way near the middle, waved, etc., same as the vexillum. Stamens 10, united near the base, but soon dividing into 2 parcels of 5 each; anthers globose, 2-lobed. Ovary oblong, pedicelled, hairy, generally 2-celled; cells transverse, 1-seeded. Style ascending. The legume, which is borne on a long petiole, is three-fourths orbicular, the upper remainder, which extends from the pedicel to the remainder of the style, is straight, the whole surrounded with a waved, veiny, downy, membranous wing, swelled, rugose, woody in the center, where the seed is lodged, not opening; generally 1, but sometimes 2-celled. Seeds single and reniform (L.).

History and Description.—Kino is the juice of the tree obtained by making longitudinal incisions in the bark; it flows abundantly, has a red color, and by drying in the sun, cracks into irregular, angular masses, which are then placed into wooden boxes for exportation. It usually reaches this country by way of England, being originally imported from Bombay or Tellicherry. East India (or Malabar) kino is that recognized by the *U. S. P.*, which describes it as follows:

"Small, angular, dark, brownish-red, shining pieces, brittle, in thin layers ruby-red and transparent, inodorous, very astringent and sweetish, tinging the saliva deep-red. Soluble in alcohol, nearly insoluble in ether, and only slightly soluble in cold water"—(*U. S. P.*). Kino burns without fusion or softening, with but little flame and frothing, leaving a scanty gray ash. Boiling water dissolves a large proportion of it, forming, when cold, a permanent, intense, blood-red solution, which yields with ferric chloride a dark-green, coarsely flocculent precipitate, which is so abundant as to render the whole liquid gelatinous. Acetate of lead produces a gray precipitate, and tartar emetic gradually a lake-red, muddy jelly. Cold water, which partly dissolves it, forms with it a clear, cherry red solution, leaving a crumbly, grayish residuum. Alcohol dissolves about two-thirds of it, and forms a deep, brownish-red tincture, which is not disturbed by water. By long standing the tincture gelatinizes, and becomes less astringent. Proof-spirit is a less complete solvent, but the tincture is less apt to gelatinize. Its solubility in water is facilitated by alkalies, but its astringency is thereby lost, and its general characters changed.

Chemical Composition.—The chief constituent of kino is *kino-tannic* (*coccotannic*) *acid*, which is present in the amount of from 45 to 55 per cent (F. E. Mafat, *Pharm. Jour. Trans.*, 1892, Vol. XXIII, p. 146). It is closely related to the tannin from catechu; its non-glucosidal nature was established by Bergholz (*Dissert. Dorpat*, 1884). Unlike catechu, however, kino yields to ether no *catechin* (*catechuic acid*). This solvent, according to Eissfeldt (1854), abstracts from kino only traces of *pyrocatechin* ($C_6H_4[OH]_2$). On continued boiling of an aqueous solution of kino or *kino-tannic acid*, an insoluble, red phlobaphene, *kino-red*, is precipitated. This substance is also formed gradually by prolonged exposure of solutions of kino at ordinary temperature (Gerding, 1851). By fusion with caustic potash, Hlasiwetz (1865) obtained from kino 9 per cent of *phloroglucin* ($C_6H_3[OH]_3$); *protocatechuic acid* ($C_6H_3[OH]_2.COOH$) has also been observed in this reaction (Stenhouse). *Kinoïn* ($C_{14}H_{12}O_6$) is a crystallizable substance obtained by Etti (1878 from Malabar kino, by boiling this with diluted hydrochloric acid, decanting from the *kino-red* formed, and abstracting the aqueous solution with ether (see *Jahresb. der Pharm.*, 1878, p. 190).

The yield of *kinoïn* is 1.5 per cent. Etti found this substance to be decomposable by hydrochloric acid into *gallic acid* ($C_6H_2[OH]_3.COOH$), *pyrocatechin*, and *methyl chloride*. Heated to 130° C. (266° F.), it loses water and is converted into *kino-red* ($C_{28}H_{22}O_{11}$). *Kinoïn* is soluble in alcohol and boiling water, little soluble in ether; its solutions produce with ferric chloride a red coloration, and are not precipitated by gelatin. *Kino-red* is hardly soluble in water, soluble in alcohol and alkalies; its solutions are precipitated by gelatin, and colored green by ferric chloride. A. Kremel was unable to obtain *kinoïn* by Etti's method; in its place he invariably found *protocatechuic acid* (see *Jahresb. der Pharm.*, 1884, p. 281). Good kino leaves about 1.5 per cent of ash.

Action, Medical Uses, and Dosage.—Kino is a pure and energetic astringent, and may be used to fulfil all the indications for which catechu is employed. It is not considered so efficient in *chronic dysentery* as catechu, but is preferred internally in *menorrhagia*, and as a topical application in *leucorrhœa*, *relaxed sore throat*, and *aphthæ* of the mouth or fauces. An infusion thrown into the nostril has suppressed *hemorrhage* from the Schneiderian membrane; and the powder on lint has suppressed a hemorrhage from a wound in the palate. Dose of the powder, from 10 to 30 grains; of the tincture, from ½ to 2 fluid drachms.

Related Drugs.—There are many other exudations known in commerce as *Kino*, partly derived from plants belonging to entirely different natural orders, *e. g.*, many species of *Eucalyptus*, *Myristica*, etc. Among the most important are the *African kino*, *Dhak-tree kino*, *Botany Bay kino*, *Jamaica kino*, and *South American kino*.

African Kino, *Gambia kino*, until within recent years was very rarely seen in commerce; from specimens received from Mungo Park, when on his last journey, it was decided to be an exudation from the *Pterocarpus erinaceus*, Poiret, a tree growing in many districts of the Senegal, Nunez, and along the banks of the Gambia and other streams of West Africa. Its behavior is similar to that of ordinary kino. According to Th. Christy, of London, this tree yields the genuine kino that was first introduced into medicine by Dr. Fothergill. An authentic commercial specimen left 1.75 per cent of ash, and contained 52 per cent of tannin, while other commercial species yielded from 2.6 to 7 per cent ash, and from 14 to 39 per cent tannin.

Dhak-tree Kino, *Butea kino*, *Bengal kino*, *Butea gum*, *Palas kino*, *Pilas kino*, *Gum of the Palas* (*Dhak-tree*), is the product of the *Butea frondosa*, Roxburgh, a magnificent leguminous tree of the East Indies. *Butea superba*, Roxburgh, and *Butea parviflora*, Roxburgh, exude a similar product. The juice naturally exudes from fissures in the branches of the tree, and concretes into red tears which become black under the action of the sun. They are irregularly angular, seldom so large as a grain of barley, apparently black and opaque, but really of an intense garnet-red color, transparent in thin pieces, and frequently have fibers of bark adhering to one of their faces. Their taste is very astringent, brittle when chewed, without adhering to the teeth, and they tinge the saliva lake-red. Their chemical reactions and solubilities are similar to those of the East India variety. They contain from 73 to 90 per cent of tannic acid, and might be safely substituted for ordinary kino. It rarely reaches England, and has not been imported to America. It is termed *Gum butea*.

BOTANY BAY KINO, *Australian kino*, or *Eucalyptus kino*, first described by White and Smith, in 1790, was believed to be the astringent inspissated juice of the brown gum tree of New Holland (the *Eucalyptus resinifera*), a fine tall tree belonging to the *Nat. Ord.*—Myrtaceæ, and was stated to yield a red juice so profusely from incisions that 60 gallons might be collected from one tree. According to J. H. Maiden (*Pharm. Jour. Trans.*, Vol. XX, 1889, pp. 221 and 321), these statements are considerably overdrawn, and the peculiar *Eucalyptus resinifera* botanically described by Smith, can not now be identified, as the majority of Australian eucalyptus species are resin-bearing plants. Only one species, however, is of commercial value (although Maiden recommends several others), viz., *Eucalyptus rostrata*, Schlecht., growing in enormous quantities along the Murray River, in Australia; it yields the *Murray red-gum*, or *Red-gum kino*. The product obtained from all other species is sparingly soluble in water and alcohol and therefore commercially unsuitable, but this is probaly due to prolonged exposure of the resin to the air before it is gathered. This inferior grade has been used as an adulterant of the better grades of kino. Mr. Joseph Bosisto (*Amer. Jour. Pharm.*, 1897, p. 533), states that the *red-gum* of *E. rostrata* lodges itself in the ducts between the bark and the wood, and when tapped it can be obtained in rather large quantities. J. H. Maiden (*Amer. Jour. Pharm.*, 1897, p. 1) gives the highest yield at 4 gallons, the average being 1 quart from one tree. On evaporating the juice in a vacuum pan a ruby-red gum is obtained, entirely soluble in water and alcohol. Commercial specimens yielded about 47 per cent of tannic acid. The turbidity observed with some of the kinos from Australian eucalyptus (including *E. rostrata*), when dissolved in alcohol or water, is due to the presence of two crystallizable substances, *eudesmin* and *aromadendrin*. (For details regarding the chemistry of these substances, see Henry G. Smith, *Amer. Jour. Pharm.*, 1896, p. 679).

JAMAICA, or WEST INDIAN KINO, is obtained from the *Sea-side grape* (*Coccoloba uvifera*, Linné), a tree belonging to the *Nat. Ord.*—Polygonaceæ. The tree inhabits the seacoast of the West India Islands and the adjoining coast of America. A decoction is prepared from the leaves, wood, and bark, which are excessively astringent, then evaporated, and the thick fluid poured into vessels, in which it solidifies upon cooling. Upon extracting it from the vessels containing it, it is readily reduced to pieces varying in size, generally about as large as a small cherry, and with a disposition to the orthogonal form. They are ligliter colored, and less shining than the ordinary kino, are impervious to light in bulk, but garnet-red and semi-transparent in thin fragments; are brittle and pulverable, forming a paler-colored powder than the commercial drug. They are inodorous, amarous, and excessively astringent, impart a red hue to the saliva when masticated, and contain about 41 per cent of tannic acid. Cold water, and alcohol, dissolve nearly the whole of West Indian kino, about 6 to 11 per cent remaining undissolved.

SOUTH AMERICAN, COLUMBIA, or CARACAS KINO, is probably furnished by the same tree as the West Indian, and is likewise probably derived from the *Coccoloba uvifera*, Linne. It is imported in heavy masses, and closely resembles the Jamaica kino in its several properties, excepting that it is equally soluble in cold water and alcohol, is more free from any tenacious substance interfering with the filtration of its watery solution, and contains no resinous body. It is rarely seen in America.

MYRISTICA KINO (*Kat jadikai*) is an extract resembling official kino, obtained as an exudation upon making incisions into the bark of *Myristica malabarica*, Lamarck, a tree growing in southern India. The product was studied in recent years by Prof. Ed. Schaer (*Amer. Jour. Pharm.*, 1896, p. 546), who found that the myristica kino agrees in all characteristics with true kino, except that no *pyrocatechin* could be abstracted with ether. A characteristic constituent of *Myristica kino*, however, was found both in a dry specimen obtained from the Kew Gardens, and a semi-liquid extract prepared for the author in the Buitenzorg (Java) Botanical Garden, namely, crystals of *calcium tartrate*, the presence of which, therefore, seems to indicate *Myristica kino*, and to distinguish it from the official kino. *Myristica succedanea* seems to yield most of these crystals.

Pterocarpus indicus, Willdenow.—Philippine Islands and South India. This species yields a red kino of a fetid character, known as *Sang dragon*.

CERATOPETALUM.—A kino-like gum. Is said to be obtained from a plant of this genus growing in New South Wales.

KOLA.—KOLA.

The seeds of *Sterculia acuminata*, Palisot de Beauvais (*Cola acuminata*, Robert Brown). It has many other synonyms. (See *Kola*, Monograph No. 5, of Frederick Stearns & Co.)

Nat. Ord.—Sterculiaceæ.

COMMON NAMES: *Kola, Kola nut, Female kola, Cola* (*Bissy-bissy, Guru*, Vernacular).

ILLUSTRATIONS: *Kola*, Monograph No. 5, of Frederick Stearns & Co., Figs. 3, 5, 6 and 11; *Kola Illustrated*, by Johnson & Johnson.

Botanical Source.—This is a tree from 40 to 60 feet high, somewhat resembling the common chestnut tree. The trunk is erect, smooth, and cylindrical. The bark is green and thick. The leaves are alternate, entire, slightly revolute, smooth, green, and oblong-acuminate, from 8 to 6 inches long by 1 to 2 inches broad. They are borne on petioles from 1 to 3 inches long. The younger leaves are pubescent. The flowers are polygamous, and borne in both terminal and axillary cymose panicles, beset with stellate hairs. The flowers are greenish-yellow or white and purple at the margins of the petals. The fruit is composed of follicles, containing from 1 to 10 oblong, obtuse seeds, with a cartilaginous, purplish testa. The cotyledons are generally 2 in number (may be 3 to 5), red or greenish-yellow, flatly ovate, or auriculate, compressed, and thick.

Fig. 154.

Sterculia acuminata.

History.—The kola tree grows in a somewhat limited locality, comprising that portion of western Africa between Sierra Leone and the Congo and Lower Guinea. It thrives at about or a little higher than the sea level, in hot and moist situations. When conditions of soil and climate are favorable, it grows inland from the points mentioned 500 or 600 miles. It has been found elsewhere, though undoubtedly introduced, as in Jamaica, where it was distributed by slave traders. The English and French have introduced it into many of their possessions, and the gulf and Pacific coast districts of the United States are said to possess the required climate and soil for its growth in this country. The travels of Leo Africanus (in the 16th century) referred to this tree as the Gora or Guru, and he wrote concerning its bitter nut. Clusius (1591) described and illustrated the seeds. J. Bauhin first referred to its medicinal use, noting its employment by the natives in fevers. Kola seeds have been used by the African natives from time immemorial as a necessity and a luxury. It figured as an indispensable necessity in many ceremonials—social, political, and religious. It was used as a declaration of war (red nut), and as a symbol of peace (white nut). It figured in courtship and marriage, compacts of friendship, as a mark of hospitality, and was put into the graves of the dead to nourish them on their long journey. The natives masticated kola to allay hunger, prevent thirst, promote digestion, and sustain strength. Like the so-called Indian clearing nut, it was accredited with the property of purifying and sweetening water. The natives prefer it over tea and coffee, and innumerable are the fabulous virtues ascribed to it. In civilized countries kola was known chiefly as a curiosity until quite recently. In 1883, Heckel and Schlagdenhauffen published a detailed monograph concerning it, entitled "*Sur les Kolas Africains.*" It now has an extensive commerce in this country. (For exhaustive and instructive matter concerning kola consult "*Kola,*" by Frederick Stearns & Co., and *Kola Illustrated*, by Johnson & Johnson; see also an interesting illustrated paper by F. B. Kilmer, on *Bissy nuts*, the *Kola* of the West Indies, in *Amer. Drug.*, 1894, p. 356.)

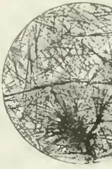
Description.—Kola nuts, so-called, are the cotyledons of the seeds, deprived of their purplish, cartilaginous testa. The irregular seeds, owing to close nesting in the follicle, have a compressed, somewhat triangular and subtetragonal shape, and bear considerable resemblance to the horse-chestnut. The cotyledons, which may number from 2 to 5, are fleshy and thick, and about 1 inch in length. They have, when fresh, a bitterish, somewhat astringent taste. When dried, however, they possess a mild and faintly aromatic taste, and an odor that has been compared to that of nutmegs. There are two varieties of kola nut—the *white kola*, which is more nearly "a pale greenish-yellow," and the *red kola*—both being yielded by the same species, and often occurring in the same pod.

Chemical History and Composition.—O. Dapper, in his description of Africa (Amsterdam, 1670), states that the kola nut, "as experience teacheth, eaten in the evening, hindereth sleep" (J. O. Schlotterbeck, in "*Kola,*" published by F. Stearns

& Co.). That this effect was due to the presence of *theine* (*caffeine*), was ascertained, in 1864, by Dr. Daniell, a noted traveller in West Africa, who also supplied Dr. Attfield with the drug for the purpose of analysis. Beside *theine* (*caffeine*) (2.13 per cent), starch (42.5 per cent), ash (3.20 per cent), volatile oil, fat, albuminoids, gum, and sugar were found by the latter chemist (*Pharm. Jour. Trans.*, 1864, Vol. VI, p. 450).

More recently, Heckel and Schlagdenhauffen (*Sur les Kolas Africains*, 1883), discovered, in addition, small quantities of *theobromine* ($C_7H_8N_4O_2$, the chief alkaloidal principle of cacao (*Theobroma Cacao*); *tannin*, a substance not recorded by Attfield; and a residual, peculiar and physiologically active substance, called *kola-red*. E. Knebel, in 1892, concluded that the kola-red of these French chemists was an impure glucosid, to which, in its pure form, he gave the name *kolanin*. According to Knebel, *kolanin* is a combination of equal molecules of *caffeine*, glucose, and *kola-red* proper, a body closely allied to the tannins. It is decomposed into its constituents by drying the drug, or by the action of diluted acids, or a certain diastatic ferment, which he succeeded in isolating. The gradual decomposition and consequent liberation of caffeine would account for discrepancies observed in the analyses on record. In this connection, see an interesting paper on *kola* and *kolanin*, by F. B. Kilmer, in *Amer. Jour. Pharm.*, 1896, p. 96. The recent exhaustive researches of James W. T. Knox and A. B. Prescott (*Proc. Amer. Pharm. Assoc.*, 1896, p. 136; and 1897, p. 131) have shown, however, that the caffeine compound, called by Knebel *kolanin*, is simply a *kolatannate of caffeine*, the *kolatannic acid* itself being free from sugar, thus differing from *caffeotannic acid*.

Fig. 155.



Crystals of Caffeine.

Kolatannic acid (*kolatannin*) exists in kola both free and in combination with caffeine, and was obtained in pure form by abstracting it by repeated shakings with acetic ether, after removing the alkaloids with chloroform. (For the details of this painstaking process, as well as the description of its acetyl and bromine derivatives, prepared in order to clear up the constitution of this compound, consult the original paper.) The formula for *kolatannin* is $C_{20}H_{10}O_8$. It is completely soluble in water, alcohol, acetone ethyl ether; sparingly so in ether; and insoluble in chloroform and benzin. Fusion with caustic potash yields *protocatechuic acid* ($C_6H_3[OH]_2.COOH$) and *phloroglucin* ($C_6H_3[OH]_3$). Boiling with diluted acids converts it into an insoluble *red body* of variable composition; the filtrate yields to ether *protocatechuic acid*. *Kolatannin* is to be classed with the oak tannin group, as contradistinguished from the gall tannin group (Trimble), the former group yielding with ferric salts a green (the latter a blue) solution and precipitate, with calcium hydroxide a light-pink precipitate, turning red, then brown (the gallotannic group forming a white precipitate, turning blue), and with bromine water a yellow precipitate, turning brown, while the latter group yields no precipitate.

The question of assay methods seems to be still a matter of some controversy. For a resume of the methods of J. Jean (1896), F. Carles (1896), and the method of Knox and Prescott (1897), see the paper of these chemists herein referred to; also see K. Dieterich, *Pharm. Centralhalle*, 1897, p. 675.

A. R. L. Dohme and H. Engelhardt (1896) found specimens of African kola to yield more caffeine (2.24 per cent) than Jamaica kola (1.93 per cent).

Action, Medical Uses, and Dosage.—The action of kola has been compared to that of coffee and cocoa, but it differs even from these, and from that of the two principles—caffeine and theobromine—contained in it. Upon the stomach it appears to exert a tonic influence, improving digestion. This it does either by increasing secretion or by acting upon the circular fibers of the stomach (Monnet). It increases the functions of the cerebro-spinal system and sympathetic system. This is the effect of small and medium doses, rendering one capable of severe mental exertion, overcoming mental depression, and the tendency to somnolency. Large doses produce overstimulation, and thus tend to destroy the usefulness of the drug when given in proper doses. Physical strength is augmented and sustained by kola, its action upon the muscular system, increasing contractility, being pronounced. It must not be forgotten, however, that while kola has considerable power in warding off physical and mental depression and exhaustion, that statements regarding its action in this respect are largely overdrawn. Kola is a tonic to the heart, regulating its contractions and increasing its power. Under a weakened state of the heart, kola causes the pulsations to become fuller and less frequent. Arterial tension is increased by the drug, diuresis augmented, an especial increase of the watery portion of the urine having been observed. Tissue waste is retarded under its administration, the excretion of urea being diminished.

Kola is undoubtedly of value in certain conditions, hinging chiefly on *nervous depression*. *Hysteria* and *neurasthenia*, with mental gloominess and forebodings, have been relieved by it. In *melancholia* it appears sometimes useful, particularly if that condition be associated with *phthisis*. The neurasthenic conditions following exhaustive discharges, or following typhoid and other fevers, is a field for its exhibition. It is very useful in *cerebral anemia*. The guiding symptoms, after protracted illness, are mental depression, tendency to faintness, marked nervous irritability, poor appetite and digestion, and great muscular debility. To these may be added the *diarrhœa of debility*. It has been administered in *pneumonia* and *typhoid fever*, when great nervous irritability was present. Its reputation as a remedy for the *alcohol habit* has not been sustained, though there is good reason to credit the statement that it quickly overcomes *acute alcoholism*. Evidence is not wanting that it sustains the nervous system in one attempting to break from the *tobacco habit*. C. W. Hamilton, M. D. (*Brit. Med. Jour.*, 1890. Vol. I, p. 1067), claims it an effective remedy in *sea sickness*. Certain forms of *atonic dyspepsia* are benefited by it, while for the cure of obstinate *chronic diarrhœas*, it has long had a reputation. It has been asserted that its action in this respect can not be well understood, as the amount of tannin in the drug is so small. May it not be due to relieving irritation, and not to its astringent action? That form of dyspepsia, attended with pyrosis, eructations, and sick headache, is amenable to kola. The *vomiting of pregnancy* is said to be arrested by it. It has also appeared useful to check Asiatic *cholera*, and has been used in the various forms of diarrhœa prevalent in the tropics.

Kola may be used in feeble conditions of the heart, especially *cardiac irritability*, the cases being those in which caffeine is useful. Difficult breathing, irregular action, and valvular deficiency are the indications for its use. It forms a good vehicle for the exhibition of other cardiac stimulants. It is said to be of marked value in *smoker's heart*. Kola has given good results in *migraine*, and in those forms of *neuralgia of debility* in which caffeine and like agents have proven useful. Dose of powdered nut, 5 to 30 grains; fluid extract, 5 to 30 drops; solid extract, 1 to 6 grains. Various proprietary fluid preparations are upon the market. The best form for administration is kola in bulk, the drug to be slowly masticated and the salivary solution swallowed.

Substitutes and Adulterations.—The seeds of several plants have been used either wholly as a substitute for, or as adulterants of, true kola. All of these, however, are wholly destitute of the characteristic principles of that drug. Among these plants may be mentioned the following:

Garcinia Kola, Heckel. *Nat. Ord.*—Guttiferæ. The fruit of this plant is rarely found as an adulterant of kola, as their external features are entirely different. However, it bears the names of *False kola*, *Male kola*, and *Bitter kola*. False kola does not enter commerce, but it is highly esteemed by the natives of Africa, though devoid of marked stimulant properties. Aphrodisiac effects are accredited the seeds by the Negroes, and, as a masticatory, they employ them in *common colds*. They contain tannin, coloring matter, and a brown and a yellowish-white resin, but no alkaloids (see also *Garcinia Mangostana*).

Heritiera littoralis, Aiton. *Nat. Ord.*—Sterculiaceæ. An orbicular-shaped seed of a chocolate color, which ought not to be mistaken for kola, its characteristics being sufficiently different. Admixture with the smaller seeds of kola is possible. This plant grows in India, Africa, Australia, and the Philippines. It contains none of the characteristic principles of kola, excepting a tannin similar to kolatannic acid. It contains, however, 10 times as much fat.

Pentadesma butyraceæ, Don. *Nat. Ord.*—Clusinceæ. *Kanya.* Tree growing along west coast of Africa. Found by Heckel and Schlagdenhauffen as a frequent adulterant of kola, which it closely resembles in appearance and color, and from which its differentiation is difficult. No starch or alkaloids are present, but the seeds contain an abundance of fat—*kanya butter*—and a peculiar, odorless, and tasteless resin, of a yellowish color, and possessing toxic properties.

Sapolema imperialis, Beauvais.—The reniform, reddish seeds of this species constitute a false kola, which has a taste closely resembling that of true kola. The external appearances, however, are entirely different. *Saponin* is present in large amounts, according to Heckel and Schlagdenhauffen.

Lucuma mammosa, Griesebach. *Sapote*. *Nat. Ord.*—Sapotaceæ. According to Helbing the seeds of this plant have been offered as kola. The dried seeds are said to evolve a strong odor of prussic acid. On account of their aroma, the seeds, which contain a large quantity of fatty oil, are said to be used as a condiment by the natives of the West Indies.

Dimorphandra Mora (*Mora excelsa*) a leguminous tree, is the probable source of a false kola, from St. Domingo (West Indies), which was offered in 1896 in the English market. It appears to contain no caffeine (*Pharm. Jour. Trans.*, 1898, p. 287).

Related Species.—*Abroma augusta*, Linné. *Nat. Ord.* Sterculiaceæ. A common shrub in Bengal, where it is known as *Ulat kambal*, and cultivated as *Olak-tambol* in Bombay gardens. The shrub has velvety branches, and the flowers are of a handsome red color. The leaves are ovate-oblong, and the seeds are contained in a cottony envelope. Sircar (*Ind. Med. Gaz.*, 1872) announced the bark of the root as an efficient emmenagogue. It is also reputed serviceable in *dysmenorrhœa*, particularly when accompanied with congestion or with neuralgic pain. One-half drachm of the white, viscid juice found in the bark of the root is administered in combination with black pepper (see Dymock. *Mat. Med. Western India*).

KRAMERIA (U. S. P.)—KRAMERIA.

"The root of *Krameria triandra*, Ruiz et Pavon, and of *Krameria Ixina*, Linne"—(*U. S. P.*).

Nat. Ord.—Polygaleæ.

COMMON NAMES: *Rhatany*, *Ratanhia*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 30 and 31.

Botanical Source.—KRAMERIA TRIANDRA. This is a suffruticose plant, with a horizontal, very long, and branched root, with a thick bark, reddish-brown externally, and red internally. The stem is round, procumbent, much branched, and tapering; the branches are 2 or 3 feet long, and when young white and silky; when old, dark and naked. The leaves are alternate, sessile, oblong, and obovate, acuminate, entire, and hoary on each side. Flowers red, solitary, and axillary, on short stalks. Calyx of 4 sepals, the inferior largest, silky externally, smooth and shining inside, of the color of lac. The corolla consists of 4 petals, the 2 upper separate, spatulate, the two lateral roundish and concave. Stamens 3, hypogenous; anthers small, urceolate, with 2 openings at top; ovary ovate; style red, and terminal; stigma simple. The fruit is a dry, hairy drupe, burred with dull red hooks; seeds 1 or 2 (L.).

KRAMERIA IXINA, Linné, differs in having 5 unlike petals in its flowers which are red, and borne in terminal, loose racemes. Its leaves are petiolate and longer than those of the preceding species.

History and Description.—The root of *Krameria triandra* is known as Payta or Peruvian rhatany; that of *K. Ixina* as New Granada or Savanilla rhatany. The latter is found growing from North Brazil to Mexico, and in the West Indies. The former plant grows upon the dry, gravelly, and sandy hills in Peru and Bolivia flowering all the year round. The natives had used it as a strong astringent long before its discovery by Ruiz, in 1780. The root is the official part; it is dug up in large quantities after the rains, and after being well dried is exported. In Portugal it has been employed to adulterate red wines. Sometimes an extract is prepared from it, which is exported and used in a similar manner. The *U. S. P.* thus describes rhatany: "From 1 to 3 Cm. ($\frac{2}{5}$ to 1$\frac{1}{5}$ inch) thick, knotty, and several-headed above, branched below, the branches long; bark smooth, or in the thinner pieces, scaly, deep, rust-brown, 1 to 2 Mm. ($\frac{1}{25}$ to $\frac{1}{12}$ inch) thick, very astringent, inodorous; wood pale brownish-red, tough, with fine medullary rays, nearly tasteless. The root of *Krameria Ixina* (Savanilla rhatany) is less knotty and more slender, and has a dark purplish-brown bark, about 3 Mm. ($\frac{1}{8}$ inch) thick"—(*U. S. P.*). Cold water or diluted alcohol readily extracts its active constituents. In powder it is of a reddish color. The bark contains more of the medicinal virtues than the ligneous or woody part. If the root be macerated in water at 100° C. (212° F.), its medicinal properties will be extracted, but as a little starch and some colored extractive will also be dissolved, the infusion, when cool, will become muddy, and after a time the above inert substance will be deposited.

Boiling will extract still more of this matter, and the tannic acid of the root being oxidized by the action of the air, loses all its therapeutical influences. A cold infusion, or an extract from the cold infusion, are the best forms for use. By placing the powdered root in a percolator, and passing water through it, a brick-red, aqueous solution is obtained, possessing all the medicinal qualities of the root. and from which an excellent extract may be procured by a quick, but cautiously conducted evaporation.

Chemical Composition.—Wittstein (*Vierteljahrsschrift*, 1854, Vol. III, pp. 348 and 485), found the freshly peeled root-bark of rhatany to contain an iron-greening tannic acid, and a red decomposition product of the latter, analogous to *chinova-red;* gummy matter, wax, sugar, starch, calcium oxalate, etc. No gallic acid is present. The tannin of rhatany, called *ratanhia-tannic* (*krameria-tannic acid*, is the most important constituent. It is a red amorphous powder. Nearly 18 per cent was obtained from the Payta variety by Wittstein (1854), while R. G. Dunwody (*Amer. Jour. Pharm.*, 1890, p. 166) found in the commercial drug considerably less tannin, viz., 8.4 per cent. Tartar emetic causes no precipitate with it; with gelatin a flesh-colored precipitate is obtained. *Pyrocatechin* is produced as a decomposition product in dry distillation; fused with potassium hydroxide it yields *phloroglucin* and *protocatechuic acid;* and diluted acids acting upon it produce sugar and *ratanhia-red* ($C_{26}H_{22}O_{11}$), a product similar in composition to one yielded by hippocastanum and tormentil. The dry extract of rhatany formerly imported from South America yielded to Wittstein a crystalline principle which he believed to be identical with *tyrosin* ($C_9H_{11}NO_3$), an amido acid; this principle is not contained in ratanhia root. Ruge and Städeler (1862) found it to have the formula $C_{10}H_{13}NO_3$, and pronounced it to be *methyl-tyrosin*, and also named it *ratanhin*. Ruge obtained 1.26 per cent of this substance. Gintl (see *Jahresb. der Pharm.*, 1869, p. 165), showed it to be identical with *angelin*, first obtained by Peckolt in the quantity of more than 86 per cent from the *Resina d' angelim pedra*, a natural exudate from the Brazilian tree *Ferreira spectabilis*, Allemao. It is probable that the South American ratanhia extract in question was derived from this tree and not from krameria. O. Hiller-Bombien (*Archiv der Pharm.*, 1892, pp. 513–548). confirmed the identity of *ratanhin* with *methyl-tyrosin* and *angelin*, and also with the alkaloid *surinamine*, obtained in 1824 by Hüttenschmid from *Geoffroya surinamensis*, and proposed for it the name *andirin*, on account of its probable occurrence in all species of *Andira*.

Action, Medical Uses, and Dosage.—Rhatany is a powerful astringent, with some slight tonic virtues. Constipation with slight dyspeptic symptoms may be induced by immoderate doses. It may be employed internally with advantage in *menorrhagia, hematemesis, passive hemorrhages, chronic diarrhœa, leucorrhœa, chronic mucous discharges, colliquative perspiration*, and *incontinence of urine.* Internally in small doses, Prof. J. M. Scudder (*Spec. Med.*) recommends it in "*gastric catarrh, dyspepsia*, with full, relaxed skin, *incontinence of urine, gleet, prostatorrhœa, leucorrhœa*, and in some cases of *catarrh*" (p. 164). It is also used as an energetic styptic in *epistaxis, hemorrhage* from the cavity of an extracted tooth, or the surface of a wound, and as a local application to *prolapsus ani, fissure of the anus, fissured nipples*, and *leucorrhœa.* As an application to *spongy and bleeding gums*, to redden and consolidate them, as well as to preserve the teeth, the following paste will be found unsurpassed: Take of prepared chalk and powdered cinchona, of each, equal parts; combine them with a sufficient quantity of equal parts of the tinctures of rhatany and myrrh, to form a paste. Use daily with a brush. Dose of the powdered rhatany, from 10 to 30 grains; of the tincture, from 1 to 4 fluid drachms; of the infusion, from 1 to 4 fluid ounces; of the extract, from 10 to 20 grains.

Related Drugs.—BRAZILIAN (PARA or CEARA) RHATANY is referred by Fluckiger and Hanbury to *Krameria argentea*, Martius, of Brazil. *Krameria cistoidea*, Hooker, of Chili, furnishes a rhatany closely resembling the Payta product, while *Texas rhatany* is yielded by the *Krameria secundiflora* of De Candolle. *Krameria lanceolata*, Torrey, of North America, is richer in tannin and extract than the official product. A false rhatany has been met with, the source of which is unknown; compared with true rhatany, its twigs are smoother and slightly sl[illegible]ing, having also deeper furrows and transverse depressions of an annular form. It is not so tough, breaks more easily and with a short fracture; its bark is thicker and adheres firmly to the wood, is lighter-colored on its inner surface, and has a glistening aspect when cut with a sharp knife. The center, when cut through, is of a dull, pale-red color, and without the dark points met with in the true root. It is inodorous, more strongly astringent in taste than the genuine rhatany, and gives more abundant precipitate with chemical reagents (*Pharm. Jour. and Trans.*).

LABURNUM.—LABURNUM.

The seeds of *Cytisus Laburnum*, Linne.

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Bean-trefoil*, *Golden chain*.

ILLUSTRATION: *Botanical Magazine*, Plate 176.

Botanical Source and History.—Laburnum is an unarmed shrub or small tree, native of the mountainous portions of southern Europe, and frequently found in cultivation, especially in Great Britian. The leaves are petiolate and trifoliate, with ovate lanceolate leaflets, pubescent underneath. The golden-yellow flowers, which appear from May to June, are very showy, and are disposed in loose, pendulous racemes. The calyx is campanulate and two-lipped; the upper lip is entire, the lower one three-toothed. The corolla is papilionaceous, with a large vexillum. The fruit is a brown legume, containing many seeds, and is attenuate at the base. The genus Cytisus is almost exclusively European, and there is no indigenous species in the United States. *Cytisus Scoparius*, Link, or "common broom," a very abundant shrub in Great Britain, is extensively used as a diuretic.

Chemical Composition.—The ripe seeds of *Cytisus Laburnum*, as well as other species of Cytisus, contain an alkaloid *cytisine*, discovered and obtained pure in 1864, by Husemann and Marmé. It also occurs in other genera of plants, and was established by A. Partheil (*Archiv der Pharm.*, 1892, p. 470), to be identical with *ulexin*, discovered by A. W. Gerrard (*Pharm. Jour. Trans.*, 1886, Vol. XVIII, p. 101), in the seeds of *Ulex europæus*. More recently, K. Gorter (*Archiv der Pharm.*, 1897, p. 321), proved its identity with *baptitoxine*, the alkaloid of the root of *Baptisia tinctoria* (which see). Prof. Plugge (1891) also believes it to be the same substance as *sophorin*, from *Sophora tomentosa*. *Cytisine* (*Ulexine*, *Baptitoxine*) has the formula $C_{11}H_{14}N_2O$ (Partheil, 1892; Gorter, 1897), and when pure crystallizes in large colorless prisms, soluble in water, alcohol, chloroform, and acetic ether; less soluble in benzol, amyl alcohol, and acetone; insoluble in petroleum ether, carbon disulphide, and absolute ether. It melts at 152° to 153° C. (305.6° to 307.4° F.), and can be sublimed by heating *in vacuo*. It is a dyad base, forming two series of salts with acids. The nitrate ($C_{11}H_{14}N_2O.HNO_3+H_2O$) forms large crystals. Partheil obtained 1.5 per cent of cytisine from laburnum. In the mother liquors he observed the presence of *cholin*.

Action, Medical Uses, and Dosage.—Administered to certain animals, as the dog, cat, etc., even in small doses, M. Chevallier found laburnum to occasion emesis, muscular debility, increased pulse, accelerated respiration, somnolence, spasms, and finally death. With man, according to Dr. T. S. Gray, Popham, Clout, and others, the bark, the flowers, or the seeds, in large doses, produce a sense of indisposition, drowsiness, followed by vomiting, vertigo, cold sweats, dryness and constriction of the throat, gastric pain, pallor, purging, accelerated respiration, strong contraction of the features, dilatation of the pupils, muscular contractions, quick and agitated pulse, and other symptoms of narcotism. Recovery from these symptoms occurs more or less speedily, and no case is recorded in which death was the result. In cases of poisoning by laburnum, Dr. Gray has advised the use of charcoal, though in many severe cases, persons who have suffered severely from the symptoms named, have promptly recovered without the aid of any antidote. Chevallier, who, having taken 6 or 8 grains of cytisine, found himself threatened with severe symptoms, drank quite freely of lemonade, and thereby checked their further progress. In medicinal doses, Dr. Gray recommends the use of the active principles of laburnum in the treatment of *dyspepsia* attended with vomitings of bile-matters and alternate attacks of diarrhœa and constipation; likewise to check the *vomiting of children* who eject their food soon after its ingestion; to relieve *bronchial cough*, and mitigate the severity of the paroxysms of *pertussis* and *asthma*, and to prevent the sympathetic *vomiting of pregnancy;* however, these recommendations have not been supported by subsequent trials. Prof.

J. M. Scudder (*Spec. Med.*), suggests the small dose (teaspoonful of the solution of 10 drops of a tincture of the recent bark, made with 98 per cent alcohol, in 4 ounces of water), every 1 to 3 hours in *irritation of mucous tissues* occurring in *nervous dyspepsia*, in the *restlessness* and uneasiness which follows mental overwork, and in the excitation of the gastric and hepatic nerves giving rise to frequent and easily excited *vomiting*. The dose of a decoction, of sp. gr. 1.034, is from 2 to 30 minims; of cytisine, from $\frac{1}{8}$ grain to 2 grains (hypodermatically $\frac{1}{10}$ to $\frac{1}{4}$ grain); of laburnine, from 2 to 10 grains. In a case where poisoning occurs, the best course to pursue is to remove the contents of the stomach as speedily as possible by means of an emetic well diluted with warm water, and then to administer ammonia, whiskey, or other diffusible stimulants.

LAC.—MILK.

"The fresh milk of the cow, *Bos Taurus*, Linné"—(*Br. Pharm.*, 1885).

Class: Mammalia. *Order:* Ruminantia.

Description.—Cow's milk was official in the former *British Pharmacopœias*, being used in the preparation of *Mistura Scammonii*. It is a white, opaque fluid, having a density of near 1.030. Its taste is sweet, bland, and to most individuals agreeable; its odor slight and peculiar and its reaction feebly alkaline or neutral. Under the microscope it appears as a transparent fluid in which are imbedded minute globules or corpuscles of a fatty nature, which give to the liquid its opacity and whiteness. According to some observers, these globules are surrounded by an albuminous envelope. The globules being somewhat lighter than the medium in which they are suspended, rise to the surface and constitute what is familiarly known as *cream*. This yellowish-white stratum, which contains also some of the serum and casein, constitutes about 5 per cent of the fluid. When the cream is removed or skimmed off, skim-milk remains, containing enough of the globules to give it opacity and a bluish whiteness. If the cream be agitated for a time, as in churning, the fat globules aggregate, or as some contend, the envelope is ruptured, and *butter* is produced. The serum which remains upon removing the butter, contains some butter and casein, saline matter, and *milk sugar* in solution, and is the well-known *buttermilk*. The pleasantly acid taste of buttermilk is due to *lactic acid* formed by the fermentation of some of the milk sugar. If milk be allowed to stand it will become soured on account of the formation of *lactic acid*, and forms *curds* or *clabber*, due to the precipitation of the *casein*. The latter substance is the material which forms cheese. Acids and rennet produce the same effects. The curds are suspended in a thin fluid and can be readily separated by straining. The separated fluid is then known as *whey*, and is chiefly a solution of salts and *sugar of milk* (*saccharum lactis*) and some albumen, coagulable by heat. When the casein is precipitated by rennet, *sweet whey* is obtained, while when precipitated by spontaneous souring, *sour whey* results. According to C. Arnold (*Archiv der Pharm.*, 1881, p. 41), fresh milk that has not been boiled may be recognized by the guaiacum test, producing with tincture of guaiacum a blue color; if, however, an alkali or an acid has been added, or the milk heated to 80° C. (176° F.), no such coloration takes place (also see *Guaiaci Resina*). Benzin, ether, alcohol, chloroform, and carbon disulphide yield with milk permanent emulsions. This behavior prevents the elaboration of a method to determine the total solids in milk by taking its specific gravity after removing the fat by means of immiscible solvents (Gustavus Pile, *Amer. Jour. Pharm.*, 1883, p. 244).

Chemical Composition.—The milk of all mammals has the same composition qualitatively; the ingredients differ only in their relative quantities. Even in one and the same species of animals, there is a marked diversity in the composition of the milk, according to the breed of the animal, the quality and quantity of its food, according to whether the animal is at rest or active, or on the proximity to a birth. For cow's milk, Wagner (*Handbuch der Chem. Technologie*, 1889, p. 953) gives the following limits in the percentage of its constituents: Total solids, 6.8 to 17.1 (water, 92.2 to 82.9); fat, 1.4 to 7.2; nitrogenous matter, 2.2 to 6.2; milk sugar, 1 to 5.2; salts, 0.1 to 1.7. The following table compiled from data given by J. König (*Die Menschl. Nahrungs und Genussmittel*, 3d ed., 1893), illustrates the comparative average composition of a great number of samples of milk from various sources:

	Woman.	Cow.	Goat.	Sheep.	Ass.	Mare
Water	87.41	87.17	85.71	80.82	89.64	90.78
Casein	1.03	3.02	3.20	4.97	0.67	1.24
Albumin	1.26	0.53	1.09	1.55	1.55	0.75
Total nitrogenous matter	2.29	3.55	4.29	6.52	2.22	1.99
Fat	3.78	3.69	4.78	6.86	1.64	1.21
Sugar of milk	6.21	4.88	4.46	4.91	5.99	5.67
Salts	0.31	0.71	0.76	0.89	0.51	0.35

It is evident from this table that cow's milk and woman's milk differs in some respects. Woman's milk is richer in milk sugar, but poorer in salts. Woman's milk also contains more albumin and less casein than cow's milk. The deficiency in the salt contents in woman's milk is probably the cause why its casein is precipitated by the acid of the gastric juice in the unusual form of fine flakes which are more readily digestible than the more lumpy casein precipitate of cow's milk (A. Dogiel, in J. König, *loc. cit.*). Even richer in salts than cow's milk is the milk of goats and sheep. Much fat (butter) and nitrogenous matter characterize that of the goat and sheep. The milk of the mare and ass, on the other hand, show a marked deficiency in butter and albuminoids, and a relatively larger amount of sugar of milk. They approach woman's milk in composition.

The nitrogenous portion of milk is chiefly composed of *casein* and *albumin*. The latter is coagulable by heat in the presence of acids. Besides, there are small quantities of pepton-like bodies present, probably originating in the decomposition of casein or albumin. One of these substances is called *lacto-protein*, which is not precipitated by acids, or heat or rennet, but is thrown from solution by alcohol or tannic acid. *Casein*, which is held in solution probably as a calcium compound (W. Eugling, 1885), differs from albumin in not being coagulable by heat, but being coagulated by the action of inorganic and organic acids, and by certain ferments, especially a peculiar *enzyme* (unorganized ferment) contained in rennet, a membrane obtained from the fourth stomach of the calf. The separation of casein also takes place spontaneously at ordinary temperatures upon standing, the process being greatly favored by warmth, and being due to the formation of lactic acid. (For Duclaux's views regarding the properties of the protein matters of milk, see *Amer. Jour. Pharm.*, 1884, p. 591.)

The fatty matter in milk is the butter, which is a rather complex body. The fats are glycerides of butyric, capronic, caprinic, stearic, oleic, palmitic, and myristic acids. *Rancid butter* is due to the decomposition of the glycerides containing the lower fatty acids, and the liberation of the free fatty acids, especially butyric acid, in fluid form. Besides the fats, an odorous substance in small quantity and *lactin* (sugar of milk), salts, casein, and water are present in butter. The salts contained in milk are chiefly phosphates and chlorides of calcium, magnesium, potassium, and sodium, all being inorganic bodies necessary to the sustenance of life. Th. Henkel (1888) has found citric acid to be a normal constituent (0.1 per cent) of cow's milk; woman's milk does not contain it.

Preservation.—Boiled milk may be preserved in open air longer than raw milk. To preserve milk for journeys the simplest method is to sterilize it by placing the fresh milk in a proper container, well filled, immersing in a boiling water-bath for a time, closing the container tightly, and taking proper measures to prevent the access of air. It is also recommended to place the milk in a well-annealed glass container, to add sodium bicarbonate (about 5½ grains to the quart), cork the bottle tightly, place in water-bath at 90° C. (194° F.), for 4 hours, remove the container, and varnish the cork. Boric acid (1 to 1000) and salicylic acid (1 to 5000) will prevent for a time the formation of lactic acid in milk. However, preserved milk, even if kept in well-sealed bottles, is liable to decomposition and to become intensely bitter, if it is not heated to a sufficiently high temperature or for a sufficient length of time (C. Naegeli). This observation is confirmed by Meissl (1882), who found the milk, after a lapse of one year, to have a somewhat bitterish taste; the fat being somewhat rancid and bleached, the milk sugar (4 to 5 per cent) unaltered, the nitrogenous matter peptonized, and small quantities of leucin, tyrosin, and ammonia were present, but no organized ferment. O. Loew (*Berichte*, 1882; also see *Amer. Jour. Pharm.*, 1883, p. 102), found that milk heated to 120° C. (248° F.) will keep for a number of years, while another specimen that was kept for 8 years after having been heated to 101° C. (213.8° F.) for 40 minutes, was intensely bitter, the milk sugar being decomposed into lactose and dextrose, and casein and albumin into peptones, etc.

Condensed, or Concentrated Milk is now largely used in place of preserved milk. This, as usually found upon the market, appears as a pasty mass, of yellowish-white color and somewhat translucent. When diluted with about 5 parts of water (by weight), it will appear like ordinary milk. There are various brands, and all are prepared by varying methods and require different amounts of diluent. The above-mentioned dilution applies to a condensed milk prepared essentially as follows: Milk is poured to a depth of about 2 inches into a flat-bottomed, shallow boiler, and heated by means of a water-bath. Cane sugar is added in the proportion of 1 ounce to the pint of milk. Heat is continued and evaporation favored by constantly stirring the mixture, which is reduced in volume four-fifths, when it is poured into cans and these are hermetically sealed. The cans are then arranged in a boiler and subjected to a steam heat a little above the boiling point of water. The process is then completed (Lignac). On a manufacturing scale, milk is condensed by evaporation in vacuum apparatus. Sugar is added to the original milk as a preservative. Evaporation can also be carried to dryness, producing "*milk powder*." (See tabulated results of 21 analyses of condensed milk in *Jour. Amer. Chem. Soc.*, 1899, p. 444.)

Adulteration and Detection.—Watered milk may be known by its relatively low specific gravity, that of milk being 1.030. Skim-milk has a higher specific gravity. To detect adulterations it is first necessary to carefully evaporate the fluid to dryness; the loss will represent the water, the residue the solids. To ascertain the amount of fats, extract the residue with benzin or ether; incineration of the residue now remaining will indicate the amount of salts in ash, while the nitrogenous matter and sugar are represented by what is lost in incineration. Another method is to treat with alcohol and water the ether-insoluble residue, whereby the salts and sugar are dissolved and the casein remains as residue. Special instruments have been devised for the rapid determination of the amount of cream, butter, and the density and degree of opacity of milk. These are known as *lactometers* (*creamometers*), and *lactoscopes*. The following process for the determination of fat in milk is recommended in *Pharm. Centralhalle* (1899, p. 274) as giving exact results: In a glass cylinder 40 Cm. long, provided with a graduation between 15 and 20 Cc. and at 70 Cc., place 10 Cc. of milk, 1 Cc. of 20 per cent ammonia water, and 10 Cc. of 95 per cent alcohol. Add 25 Cc. of ether, shake and add 25 Cc. of petroleum ether, shake again. Allow the ether—petroleum ether solution to separate, measure its volume, evaporate an aliquot part of it to dryness. Dry the residual fat at 100° Cc. (212° F.) for 2 hours, and weigh.

The presence of *salicylic acid* in milk can easily be recognized by abstracting milk diluted with its own volume of water, treating with a few drops of acetic acid, and filtering with ether, evaporating this solvent, and observing the violet coloration with a 1 per cent solution of ferric chloride (see *Amer. Jour. Pharm.*, 1882, p. 358). (For details regarding milk analysis see J. König [*loc. cit.*]; also Prof. Sadtler's *Handbook of Industrial Organic Chemistry*, 1885, p. 264, and special literature there indicated.)

Action, Medical Uses, and Dosage.—The use of milk as a beverage and food are too well-known to require comment. Suffice to say that in *acute diseases*, with high temperature and rapid burning of the tissues, hot milk, salted or unsalted, is the best food for administration, being easily digested and sustaining the nutrition of the body. It is specially of value in most *wasting conditions*, and, when modified, forms the best *substitute for mother's milk*. Occasionally, some individuals can not partake of milk, claiming that it renders them bilious. This effect is undoubtedly more largely due to a faulty condition of the digestive tract, rendering the digestion of cream difficult. In such cases skimmed milk has the advantage over whole milk. Milk is frequently of great advantage in *digestive derangements*, particularly in chronic affections, relieving *gastro-intestinal irritation*, *uneasiness*, *unrest*, and *insomnia*. Sour or coagulated milk is an excellent agent to meet the indications alluded to under *Acidum Lacticum*.

The so-called "milk cure" has given excellent results in many disorders, chiefly of a chronic character. In certain European centers milk cures have been established, and, while to the fresh milk must be attributed great good, there is no doubt but that hygienic attention, climate, and sanitary surroundings contribute much toward a cure. The plan is usually to place the patient upon an exclusive milk diet for at least 3 weeks, from 1 to 2 quarts of milk being consumed in a day. This treatment requires great fortitude on part of the patient. Upon taking this treatment, but a short time elapses before a repugnance for milk comes upon the patient, the appetite fails, there is a distressing sense of goneness and emptiness in the stomach, the tongue becomes pasty and furred and tastes badly, and constipation and great weakness ensue. The body steadily loses weight until a certain point is reached, and there it is maintained. Constipation, with dry, scybalous, practically inodorous, and yellowish stools is the rule.

The urinary flow is increased, and the quantity of urea greatly lessened. After the third week it is customary to allow a little bread, and then meat, and so on, for a continued period, the chief part of the diet, however, still consisting of milk. Sometimes it is necessary to skim the milk or to boil it, or to add to it lime-water or some of the carbonated alkalies, but where possible the pure milk alone is to be preferred. Coffee, mineral waters, and laxatives are sometimes required to overcome the constipation. The "milk cure" has been signally effective in certain *obstinate stomach and bowel affections*, as *chronic dyspepsia*, *gastric ulcers*, *gastric catarrh*, *gastralgia*, *chronic diarrhœa*, *chronic dysentery*, *persistent enteralgia*, *intestinal indigestion*, *ascites*, *diabetes*, and *desquamative nephritis*, with *albuminuria*. *Gout* and *eczema* are also said to have been cured by an exclusively milk diet. Milk is one of the most soothing of substances for *gastric cancer*, and sustains the strength of the patient.

CONDENSED MILK is stated by Dr. Richard Neale to be of great medicinal value to infants at times, but it should not be given to them as food, as it does not sufficiently support vitality (see *Amer. Jour. Pharm.*, 1883, p. 472). Similar experience is recorded by Dr. Edmund Owen (*Amer. Jour. Pharm.*, 1884, p. 278). It is evident that if too much sugar has been added considerable dilution with water is necessary, which renders the milk too weak in nutritive constituents.

BUTTERMILK is signally effective in many cases of *stomach and bowel disorders;* and in *diabetes* and *albuminuria*. (For indications, see *Acidum Lacticum*.)

SWEET WHEY forms an excellent diet drink in *acute diseases*, *fevers*, and *inflammations*. The pale tongue indicates it.

SOUR WHEY should be given when the tongue is red.

KOUMYS is useful in many constitutional and exhausting diseases, as *chronic bronchitis*, *phthisis pulmonalis*, *scrofula*, *low fevers*, *chronic diarrhœa* and *dysentery*, *dyspepsia*, *neurasthenia*, *gastric cancer* and *gastric ulcer*, *summer bowel disorders of children*, and in many *adynamic states* requiring food and an alcoholic stimulant. It should be borne in mind, however, that on account of the amount of alcohol present, an intemperate habit may be formed or fostered by the continued use of koumys. Under favorable conditions, as under the koumys treatment in the steppes of Russia and in Asia, consumptives are reported to have been cured by this beverage.

KEFIR is very similar in its effects to koumys, though less stimulating, and may be used in the affections for which the latter is useful. The amount of these two beverages to be consumed will be regulated according to the effect desired or produced.

Milk is one of the substances usually administered in *poisoning by the corrosive poisons*, particularly those with which it may combine chemically, as with mercuric chloride; even when not antidotal it forms a soothing agent in the after treatment. A bread and sweet milk poultice is in frequent use to hasten suppuration in *boils*, *abscesses*, etc., and milk has been employed as a lenitive in several skin diseases, particularly in cases of *sunburn*, and as an application in *ophthalmia* and *otorrhœa*. The practice of milking mother's milk into the eyes of the newborn is to be condemned.

Milk Preparations.—Koumys (*kumiss*), a fermented beverage and medicine, prepared and used by certain nomadic tribes of Russia and the inhabitants of Tartary, is produced by fermenting fresh mare's milk with yeast. When about 12 hours old it is known as *staumgal* or *ssaumal*. Upon standing a few days it becomes much more energetic, acquires a stronger acid taste, and becomes well charged with carbonic acid gas, which renders it sparkling. Even when well secured in bottles, and at a low temperature, fermentation having once begun will continue, with an increase of lactic acid, carbon dioxide, and alcohol. The Tartars are said to prepare koumys also by adding $\frac{1}{10}$ part of koumys to fresh milk, stirring frequently, and, at the end of 3 or 4 hours, removing the mixture from the tall vessels employed and putting it into champagne bottles, placing them into a cool place for a period of about a week. The product acquires thereby a peculiar, sweet, acidulous taste. Cow's milk is free from the unpleasant odor and taste of mare's milk, and is, therefore, to be preferred in preparing koumys. Dr. L. Wolff recommends as follows: Take $\frac{1}{2}$ ounce of grape sugar, dissolve it in 4 ounces of water in a quart champagne bottle, and add to the mixture a solution of 20 grains of compressed yeast (Fleischmann's), or well-washed and pressed brewer's yeast; finally, to the whole add good cow's milk sufficient to almost fill the bottle. Place the cork and wire it. Put the bottle in a cool place at 10° C. (50° F.), or lower, shake 3 times a day, and allow fermentation to proceed about 3 or 4 days. It is then ready for use, and will keep 4 or 5 days. The kumyss of the *National Formulary* is prepared as follows:

Lac Fermentatum (N. F.), *Fermented milk, Kumyss.*—"Cow's milk, fresh, 32 fluid ounces; yeast, semiliquid, 60 minims; sugar, 1 troy ounce. Dissolve the sugar in the milk contained in a strong bottle, add the yeast, cork the bottle securely, and keep it at a temperature between 25° and 32° C. (75° to 90° F.) for 6 hours, then transfer to a cold place"—(*Nat. Form.*, 1st ed.).

Kefir, or Kephir.—A milk-wine, prepared by certain tribes of the Caucasus from goat's and sheep's milk by fermentation, in a leather bag, with yeast and a peculiar bacterium or fungus. A goat-skin bag is filled with milk, and to it is added "*kefir seed*," a tenacious, dark-brown, dry, earthy mass, the origin of which is kept secret, and which contains, according to Kern, the bacterium *Dispora caucasica*, Kern, with some *Saccharomyces cerevisiæ*, or yeast fungus. The properties of this "seed" are retained for a long period after drying. It is an article of commerce, and is used in the preparation of kefir from cow's milk, which is preferably sterilized by heat before the adding of the kefir seeds (B. Niederstadt, 1890). Fermentation ensues in a few hours after adding the ferment. The changes which take place are chiefly in the casein. Prepared from cow's milk, it is less acid and not so alcoholic as koumys, but contains more albumin, and, by some, is preferred to the koumys preparation. For directions to prepare kefir without the "kefir seeds," see Dr. Kogelmann, *Amer. Jour. Pharm.*, 1886, pp. 295 and 388.) The comparative percentage composition of cow's milk, koumiss and kefir, is stated as follows *Amer. Jour. Pharm.*, 1887, p. 515):

	Cow's Milk.	Koumiss.	Kefir.
Albumin	4.8	1.12	3.8
Butter	3.8	2.05	2.0
Sugar of milk	4.1	2.20	2.0
Lactic acid	....	1.15	0.9
Alcohol	....	1.65	0.8
Water and salts	87.3	91.83	90.5

Serum Lactis Dulce, *Whey.*—With 200 parts of fresh cow's milk mix 1 part of rennet-wine; warm to 35° to 40° C. (95° to 104° F.), when coagulation takes place, and the whey may be strained from the curd.

Serum Lactis, or *Serum lactis acidum, Acid whey.*—Heat 100 parts of fresh, or skim milk, to boiling, and add 1 part of vinegar, or 0.1 part of citric acid, in 1 part of water. When coagulation is complete strain, mix the strained fluid with the white of 1 egg, heat to the boiling point, and filter.

Serum Lactis Tamarindinatum, *Tamarind whey.*—A brownish whey, obtained by heating together 4 parts of tamarinds and 100 parts of milk, and straining.

Serum Aluminatum, *Alum whey.*—Obtained by heating to boiling 1 part of powdered alum and 100 parts of milk. Strain.

LACCA.—LAC.

A resinous exudate produced through the puncture of several trees by the hemipterous insect, *Coccus lacca*, Kerr.

Source.—Lacca is collected from the branches of several trees, most of them lac-bearing, found chiefly in the East Indies. Several American plants are also said to yield the product, these being the *Larrea mexicana*, Moricand (*Larrea glutinosa*, Engelmann), the *Stinkweed* or *Creasote-bush*, and the *Acacia Greggii*, Gray, both growing in Arizona, west Texas, Mexico, and southern California. The East India trees yielding it are said to be the following: *Aleurites laccifera*, Willdenow (*Croton* *lacciferum*, Linné [Euphorbiaceæ]; *Ficus indica*, Roxburgh; *Ficus religiosa*, Linne, *Ficus bengalensis*, Linne; *Ficus Tsjela*, Hamilton [Urticaceæ]; *Butea frondosa*, Roxburgh [Leguminosæ]; *Schleichera trijuga*, Willdenow [Sapindaceæ]; and *Zizyphus jujuba* [Rhamnaceæ]).

Large numbers of the insects (*Coccus lacca*) congregate upon the smaller and tender branches of these trees. The female insect punctures the limb and becomes surrounded by the exuding resinous matter. The imbedded insects swell up and form a cell containing a red-coloring matter (yielding *lac-dye*), which gives to the lac containing it a superior value. The young larvæ are developed in the exudation, which gradually becomes hard, and, boring their way out, make their escape.

History and Description.—The principal grades of lacca are *stick-lac*, *grain-lac* (*seed-lac*), *shell-lac* (*shellac*), and *lump-lac* (*grape-lac*). The thickly beset resin-nodules enclosing the twigs constitute *stick-lac*. This contains about 10 per cent of red coloring matter. When these nodules are detached from the branchlets, and for the most part deprived of their coloring matter by a washing process, they form the *seed* or *grain-lac*. The individual tears of the first variety are reddish-brown and contain in their central portion a deep, blackish-red substance. The taste is subastringent and slightly bitterish. When the young insect has made its escape the exudation is brown. The second variety consists of more or less shiny, small fragments, of a yellowish or reddish color, and are almost tasteless. *Shell-lac* is the product of the preceding varieties after they have been boiled in water and partially deprived of coloring matter, fused, and congealed upon a polished surface. Or, the crude seed-lac is put into a narrow, sausage-like cloth bag, heated over a charcoal fire, and the cloth slightly twisted until the melted lac appears on the outside; the bag is then removed from the fire, and the lac scraped off by means of an aloe leaf. The scrapings at once harden, and constitute what is known as shellac (see interesting article on shellac, by Jos. Bosisto, in *Amer. Jour. Pharm.*, 1886, p. 307). *Lump-lac* is the same as stick-lac, yet deprived of the woody portion and melted together. Seed-lac, in agglutinated masses, is sometimes known as *grape-lac*. If stick-lac be chewed, it becomes soft, and a beautiful, purple-red hue is imparted to the saliva. Red stick-lac boiled in water, imparts to it its coloring matter. This, when precipitated by alum, and pressed into cakes, constitutes what is known as *lac-dye*—a purple coloring body. Lime-water likewise precipitates the coloring matter. Caustic soda and potash, sodium biborate, acetic and hydrochloric acids dissolve shellac, also hot alcohol, while cold alcohol dissolves about 90 per cent, leaving a wax-like body undissolved. With aqua ammoniæ, if digested in a closed container, it forms a gelatinous magma. Acids reprecipitate shellac from its solution in alkali. *Bleached shellac* is obtained by acting with chlorine gas upon shellac in alkaline solution. This yields a product insoluble in alcohol. Alcohol-soluble bleached shellac is obtained by digesting an alcoholic solution of it with animal charcoal.

Chemical Composition.—Unverdorben found lac to be a complex material consisting of at least five resins (separable by their behavior toward ether, alcohol, or alkalies), fat, wax, and coloring matter. According to Hatchet, shellac contains about 90 per cent resin and 4 per cent wax, while scarcely seven-tenths of resin and 10 per cent of coloring matter, also wax, etc., is contained in stick-lac (see Hager, *Handbuch der Pharm. Praxis*, 1886, Vol. II, p. 330). Shellac contains but little if any coloring matter. The coloring body has been more recently examined by R. E. Schmidt (1887), who gives it the formula $C_{16}H_{12}O_8$, and names it *laccaic acid*. It closely resembles the coloring matter of cochineal, *carminic acid*, although they are not identical. It forms brown-red, crystalline crusts, is slowly soluble in alcohol, easily soluble in amyl alcohol, acetone, and glacial acetic acid; also somewhat soluble in water, and insoluble in ether. It forms colored solutions with alkalies.

Action and Medical Uses.—Lacca is slightly astringent, besides possessing some of the properties common to the resins, on which account it was formerly used as a dressing for *wounds* and *ulcers*. It is not now used medicinally. Surgical splints are sometimes prepared from it (see below).

Shell-lac Splints.—Take of finely pulverized shell-lac, 1 pound; alcohol (90 per cent), 1 quart; mix, and expose it to a moderate heat in a loosely-stopped bottle, for 48 hours, when the shell-lac will be dissolved. With this solution saturate woolen cloth, and allow it to dry. To apply and fit the cloth to any part, cut it into the proper shape, and then hold it near a fire or hot stove, or dip it into boiling water, when it will become soft and pliable. As soon as it has cooled so as not to burn the patient, apply it to the part, and by holding it for a few minutes, or by the application of the bandage while it is yet pliable, it will assume any form desired, and on cooling, it becomes hard and retains its form exactly. If it is desirable to strengthen the splint, take two pieces of the saturated cloth, spread one side of each with a thick coat of the solution, by means of a common paint brush, allow the alcohol to evaporate, and then, placing these two coated sides together, press them with a hot flat-iron until they have become perfectly cemented. This operation may be repeated several times. if it is necessary to increase the strength of the cloth or splint.

Related Products.—Xanthorrhœa Resins, *Gum acaroides, Gum acroides, Grass-tree gum.* Different species of Xanthorrhœa in Australia have yielded resinous balsams, the chief of which are the yellow balsam from *Xanthorrhœa hastilis*, and the red, from *X. australis*. They contain *cinnamic* and *benzoic acids*, and when heated evolve a tolu-like odor. Heated with nitric acid they are converted into picric acid. Medicinally they resemble tolu and storax, and have been used in the treatment of *diarrhœa*. The supply is inexhaustible, and the resin has been used like shellac for varnishing cabinet work, but is much inferior to that product.

Sonora Gum.—An acidulous gum-resin, said to be the exudate of the branches of *Larrea mexicana*, Moricand. It is employed by brewers, and is said to be identical with Arizona shellac.

LACHNANTHES.—LACHNANTHES.

The whole plant *Lachnanthes tinctoria*, Elliott.

Nat. Ord.—Hæmodoraceæ.

Common Names: *Red root, Spirit weed.*

Botanical Source.—This is a perennial plant, introduced into practice by the Homœopaths. It has a red fibrous root, and an erect stem, strict. 18 to 24 inches high, clothed with white wool above. The leaves are mostly radical, fleshy, equitant, sword-shaped, 3 to 4 inches wide, and nearly as high as the stem; the cauline leaves remote and bract-like. The corymb is terminal, close, 15 to 30-flowered; the flowers densely clothed with white wool outside, glabrous and yellow within. Perianth woolly outside, 6-parted down to the adherent ovary. Calyx lobes exterior, of 3 linear sepals, as long as the 3 lance-oblong petals. Stamens 3, opposite the sepals; filaments long, exserted; anthers linear, bright-yellow. Style thread-like, exserted, declined; stigma minutely 2-lobed. Capsule globular, truncated, 3-celled, many-seeded; seeds few on each fleshy placenta, flat and rounded, fixed by the middle (W.—G.).

History.—This plant is a native of the United States, growing in sandy swamps and along borders of ponds, near the Atlantic coast, from Rhode Island to Florida, flowering in July. The root has been used for dyeing purposes, and, according to Dr. Byron, has been used among the Florida Indians to produce a brilliancy of the eye, a flushed and swollen face, a bold appearance, and eloquent speaking; after these peculiar stimulating effects pass off, the person becomes stupid and very irritable. The method of employing it is to make the whole plant into a saturated tincture.

Action, Medical Uses, and Dosage.—Large doses of lachnanthes produce dilatation of the pupils, impaired vision, dizziness, and other unpleasant symptoms, somewhat similar to those produced by belladonna. Lachnanthes has been more particularly recommended in *pneumonia, nervous* and *typhus fevers*, some *diseases of the brain*, in the *delirium of fever*, in *morbid conditions of the brain and nervous system*, especially when in these several maladies redness of the cheeks and brilliancy of the eyes are accompanying symptoms. It has also been efficient in *rheumatic wry neck, hoarseness, laryngeal cough, tinnitus aurium*, and in *nervous headache*. A fluid drachm of the tincture added to 4 fluid ounces of water, and administered in fluid drachm doses, every 3 or 4 hours, is the proper method of administering it.

LACMUS.—LITMUS.

A peculiar blue coloring matter obtained from *Roccella tinctoria*, Acharius, and other lichens.

Nat. Ord.—Lichenes.

Common Names and Synonyms: *Litmus, Turnesole, Tournesol, Lacca cærulea, Lacca musica.*

Botanical Source.—*Roccella tinctoria*, or *Orchilla weed*, is a small, dry lichen, with a rounded, glaucous, nearly erect thallus, forked and subdivided into numerous branchy, roundish, gray, yellowish, or brownish threads; the apothecia are scattered, red and elevated; the disks are flat, cæsius, pruinose, and as broad as the border.

History, Preparation, and Description.—Roccella tinctoria is found on the maritime rocks of the eastern Atlantic Islands, as the Azores, Canaries, etc., the western coast of South America, south of England, Portland Islands, Scilly Islands, and various other countries. Litmus was formerly obtained from this plant alone, but other lichens have now in a great measure supplanted it, as the *Roccella fuciformis*, or *Angola weed*, from Angola and Madagascar; the *Lecanora tartarea*, or *Tartarean moss*, from Norway and Sweden; the *Variolaria dealbata*, from Auvergne and the Pyrenees, and some others.

LACMUS, or *Litmus*, was formerly prepared only in Holland, but at present is manufactured from various lichens in Italy, France and Britain. It is made "by macerating powdered lichen for several weeks, with occasional agitation, in a mixture of urine, lime, and potashes, in a wooden trough under shelter. A kind of fermentation takes place, and the lichen becomes first reddish, and subsequently blue. When the pulp has acquired a proper blue color, it is placed in brass or steel molds, and the cakes thus obtained are subsequently dried. An addition of aqueous ammonia answers the same purpose as that of urine in the above mixture. "Litmus is imported in the form of small, rectangular, light and friable cakes of an indigo-blue color. Examined by the microscope, we find sporules and portions of the epidermis, and mesothallus of some species of lichen, moss, leaves, sand, etc. Its odor is that of indigo and violets" (P.). Litmus is usually mixed with chalk or gypsum in order to form it into cakes.

Chemical Composition.—The chromogenic bodies in the lichens mentioned are crystallizable phenols and phenol acids. To the latter class belong *lecanoric acid*, discovered in 1842 by Schunck, with which *beta-orsellinic acid* of Stenhouse (1848) is identical; *erythrinic* and *roccellic acids* (Heeren, 1830), *usnic acid*, *evernic acid*, etc. (For details regarding these acids, see Husemann and Hilger, *Pflanzenstoffe*, Vol. I, p. 303.) They are in themselves colorless, but become converted into coloring matters by the joint action of water, air, and ammonia.

Lecanoric acid ($C_{16}H_{14}O_7$, Gerhardt and Hesse), crystallizes in white stellate needles soluble in 2500 parts of boiling water with acid reaction, more soluble in hot acetic acid, also soluble in alcohol and ether. Its melting point is 153° C. (307.7° F.), and it forms crystallizable salts with acids. Heated with water, alcohol or aqueous alkalies, *lecanoric acid* adds one molecule of water and is converted into crystallizable *orsellinic acid* ($C_8H_8O_4$). This when continuously boiled with water, loses carbonic acid and forms *orcin* or *dihydroxy-toluene* ($C_7H_8O_2$ or $C_6H_3.CH_3.[OH]_2$), which is also obtained by dry distillation of lecanoric acid. *Orcin* is the chromogene body proper of this group. It forms colorless needles of sweetish, nauseating taste, is easily soluble in water, alcohol, and ether; ferric chloride produces with it a violet coloration. Exposed to light and air it turns reddish. In alkaline solution it changes to red or brown upon exposure to the air. In contact with moist air containing ammonia, it is converted into *orceïn* ($C_7H_7NO_3$), a brown substance soluble in aqueous alkalies with purple-red color, being precipitated from this solution by acids. *Orceïn* is the coloring principle of *orseille* or *archil* (see below).

Orcin, when exposed to moist and ammoniated air in the presence of alkali carbonates, is converted into *azolitmin*, the blue coloring matter of *litmus*. The coloring bodies in litmus, according to Dr. Kane (*Chem. Centralblatt*, 1841, p. 567; also see Pereira, *Mat. Med.*, edition by J. Carson, 1846), are: (1) A purplish-red semifluid material, *erythrolein*. It is soluble in ether and alcohol, and yields with ammonia a rich purple solution; (2) a crystalline body of a light red color, *erythrolitmin*, nitrogen free, soluble in alcohol, but sparingly so in ether and water, and striking blue with ammonia; (3) a brownish-red, noncrystalline body, the chief coloring principle of litmus, named *azolitmin* ($C_7H_7NO_4$); it turns blue with alkalies, is insoluble in alcohol and ether, and sparingly soluble in cold water; (4) a small amount of a bright-red body, *spaniolitmin*, which is colored blue by alkalies; water dissolves it sparingly; insoluble in alcohol and ether.

Action and Uses.—*Orcin* resembles resorcin in its effects upon skin diseases. It is said to be a decided antiseptic, and to cause death in toxic doses by paralyzing the heart-muscle.

Litmus is employed in urinary, chemical, and pharmaceutical analysis, and is a familiar test for free acids and alkalies. The acids impart a red color to blue litmus; the alkalies restore the original blue color to the reddened litmus. Carbonate of calcium dissolved in water by a considerable excess of carbonic acid, will also restore the blue color of reddened litmus. It is used either in infusion, or in the form of *litmus paper.* The infusion, sometimes erroneously called *tincture of litmus,* is made by adding 1 part of litmus to 25 parts of distilled water, to which, for the purpose of preserving it about $\frac{1}{10}$ part of spirit or alcohol may be added.

Litmus Paper.—Blue Litmus Paper (*Charta Exploratoria Cœrulea*) is prepared by dipping strips of paper in a clear and strong infusion of litmus, or by brushing the infusion over the paper. White unsized paper is the best for this purpose; and the infusion may be made by adding 1 part of litmus to 6 parts of boiling water. Good litmus paper should be of uniform color, neither too light nor too dark, and when carefully dried, should be kept in well-stopped vessels in a dark place; when it has a purplish tint, it is a more delicate test for acids than when pure blue. An extremely delicate test-paper may be made by almost neutralizing the alkali contained in the litmus; thus: Divide the filtered infusion of litmus into two parts; stir one portion with a glass rod which has been previously dipped into very dilute sulphuric acid, and repeat this until the liquid begins to look reddish; then add the other portion of liquid, and immerse the paper in it (P.).

Red Litmus Paper (*Charta Exploratoria Rubefacta*) is best prepared by dipping the blue paper in a very dilute acetic or hydrochloric acid, merely acid enough to redden it.

Related Products.—The following pigments are produced from the same plant which yields lacmus. They are similarly prepared, excepting that alkalies, caustic soda, or potash, are not added to the ammoniacal mixture (see *Chemical Composition* above).

Orchil, or Archil, is used for dyeing, coloring, and staining. There are two kinds, called *blue orchil* and *red orchil,* which differ merely in the degree of their red tint. They are deep-reddish purple liquids, or pasty masses, with an ammoniacal odor. Orchil is prepared by steeping the lichens in an ammoniacal liquor, in a covered wooden vessel.

Cudbear, or *Persio,* is obtained by the same process as orchil, and when the proper purplish-red color has been developed, the mixture is dried in the air and reduced to fine powder. It is used as a dye, and sometimes as a test for acids and alkalies. (An interesting article on the manufacture and chemistry of orchil, cudbear, and litmus, by Dr. Crace-Calvert is to be found in *Pharm. Jour. Trans.,* Vol. II, 1871, pp. 514 and 535.)

LACTUCA.—LETTUCE.

The flowering herb of *Lactuca virosa,* Linné, and other species of *Lactuca.*

Nat. Ord.—Compositæ.

Common Name: *Strong-scented lettuce.*

Illustration: Bentley and Trimen, *Med. Plants,* 160 and 161.

Botanical Source.—*Lactuca virosa* has a tap-shaped root, with a solitary stem, 2 or 3 feet high, erect, round, smooth, sparingly leafy, scarcely branched, panicled at the top, and a little prickly below. The leaves are horizontal, nearly smooth, and finely toothed; the radical ones numerous, obovate, undivided, depressed; those of the stem smaller, often lobed; arrow-shaped, clasping at their base; the midrib of all more or less beset underneath with prominent prickles, such as often occur on the margin also. The flower-heads are numerous and panicled, with an abundance of small, heart-shaped, pointed bracteas. Involucral scales downy at the tip, destitute of any keels or ribs. Corolla small and light-yellow. Pappus rough (L.). There are many varieties of lettuce; they all have large leaves, often corrugated, and containing more or less of a whitish juice, the lactucarium. Their stems are round and corymbose at the summit; the leaves suborbicular and runcinate; cauline ones cordate or obovate; flowers yellow.

Lactuca sativa has an annual, tap-shaped root, with a corymbose stem, 2 or 3 feet in height, and suborbicular leaves; cauline ones cordate. Heads numerous and small, with yellowish corolla (W.). It is not so rank in odor as the *L. virosa*, has not blood-red spots on its stems, and no prickles on the keel of its leaves. Previous to the appearance of the flowering stems, the garden lettuce contains a pleasant, sweet, watery juice, and in this condition the plant is employed as a salad; but in both species, no sooner does the flowering stem rise above the early leaves than the juice grows milky, very bitter, and of a strong, peculiar, rank odor, not unlike that of opium (see *Chemical Composition*).

Lactuca Scariola, Linne, differs from *L. virosa* in having vertical, spinescent, toothed, deeply-cut, or pinnatifid leaves.

History.—The *Lactuca virosa*, Linné, is the only species recognized by the *Br. Pharm.*, 1885, and is directed by the *U. S. P.* as the source of *Lactucarium* (see *Lactucarium*). Several other species, however, yield this product. *Lactuca sativa*, or common lettuce of the gardens, is supposed to be a native of the East Indies; it is extensively cultivated in Europe and this country. According to Prof. J. M. Maisch, the *L. canadensis*, var. *elongata* (wild lettuce), of our country possesses narcotic principles similar to the others. Mr. H. Flowers (*Amer. Jour. Pharm.*, 1879, p. 343) observed in a growing specimen of this plant a strong, narcotic odor of the milky juice, but a remarkable change in the taste, from sweetish to bitter, took place later in the season. *Lactucarium*, or *lettuce-opium*, so-called, is obtained from the plants "by cutting the stem of the lettuce at the time of flowering, imbibing the milky juice that flows out by a sponge or by cotton, and squeezing it out into a vessel containing a little water. It is then left in a dry place until it concretes into a solid mass" (Thompson's *Org. Chem.*). The juice, in drying, loses about half its weight of water. By making another cut a short distance below the first, and so proceeding several times daily, the whole of the juice contained in the plant may be collected. There are several other modes recommended for procuring the lactucarium, but no one of them obtains an article equal to that collected by the above plan. After the middle period of inflorescence, the juice becomes thicker, but deteriorates in its medicinal principles. A single plant of *L. sativa* is said to yield 17 grains of lactucarium, while a plant of *L. virosa* gives 56 grains. *L. Scariola*, or prickly lettuce, yields 25 grains. As found in commerce, lactucarium is in roundish, compact, rather hard masses, weighing several ounces, of a reddish-brown color externally, of a bitter, narcotic, and somewhat acid taste, and an odor approximating that of opium. It is asserted that two species—*L. Scariola*, Linné, and *L. altissima*, Bieberstein—furnish a superior article of lettuce-opium. Fairgrieve, of Scotland, cultivated the *L. virosa*, var. *montana*, and Aubergier, of France, the *L. altissima*.

Chemical Composition.—The chief constituent of lactuca is *lactucarium* (see *Lactucarium*). Potassium nitrate is an additional constituent. Mr. T. S. Dymond (*Pharm. Jour. Trans.*, 1891, Vol. XXII, p. 449), having observed mydriatic action with extracts of *Lactuca sativa* (common garden lettuce) and *L. virosa*, the former being collected while flowering, succeeded in isolating therefrom an alkaloid (not exceeding 0.02 per cent), which he identified as *hyoscyamine*. Specimens of English and German *lactucarium*, on the other hand, did not contain a trace of the alkaloid. The occurrence of an alkaloid in so widely-used a vegetable need not, however, cause alarm. It is probably in insignificant quantity in the early stages of growth of the vegetable.

Medical Uses.—(See *Lactucarium.*)

LACTUCARIUM (U. S. P.)—LACTUCARIUM.

"The concrete milk-juice of *Lactuca virosa*, Linné"—(*U. S. P.*).

Nat. Ord.—Compositæ.

Common Name: *Lettuce-opium*.

Description.—(For source, history, and collection of Lactucarium [in part], see *Lactuca*. Lactucarium comes to us chiefly from Germany and Scotland, and is also produced in France, although little of the latter product reaches American markets. The *Scotch*, or *English*, variety is said to be of better quality than the *German*. It occurs in angular pieces of various sizes, is brown in color, and earthy in appearance. The *German* product occurs in brown quarter-sections of plano-convex, circular, or saucer-shaped cakes. French lactucarium comes in small, circular cakes, otherwise resembling the German drug.

The official product is thus described: "In sections of plano-convex, circular cakes, or in irregular, angular pieces, externally grayish-brown, or dull reddish-brown, internally whitish or yellowish, of a waxy luster; odor heavy, somewhat narcotic; taste bitter. It is partly soluble in alcohol and in ether. When triturated with water, it yields a turbid mixture, and, when boiled with water, it softens and yields a brownish-colored liquid which, after cooling, is not colored blue by iodine T.S."—(*U. S. P.*). Lactucarium does not absorb moisture from the atmosphere; is softened by heat, and at a high temperature burns with a large, white flame. Cold water takes up about a sixth of it, forming a deep-brown infusion; boiling water, proof-spirit, alcohol, and ether a much larger proportion. The addition of acetic acid to water or alcohol improves their solvent powers upon this article. It pulverizes with difficulty. It does not readily emulsionize with water, unless gum Arabic be present. By previous trituration with a small quantity of nitrous ether, it may be readily incorporated with water (Vogeler).

Chemical Composition.—Lactucarium contains neither morphine nor hyoscyamine, nor any other alkaloid (see *Lactuca*), but is found to consist of the bitter substances *lactucin*, *lactuco-picrin*, and *lactucic acid*, large amounts of *caoutchouc* and *lactucerin* (*lactucon*), a camphoraceous volatile oil (Thieme), sugar, gum, pectic acid, albumen, oxalic acid, mannit, potassium nitrate, etc.

Lactucin ($C_{11}H_{14}O_4$, Kromayer, 1861), one of the bitter principles of lactucarium, may be obtained by extracting lactucarium with cold alcohol of specific gravity 0.85. It is a colorless, odorless, fusible, neutral substance, crystallizing in rhombic plates, or in pearly-white scales. It dissolves in from 60 to 80 parts of water, is slightly soluble in ether, readily so in alcohol, and in acids. It reduces Fehling's solution, but yields no sugar upon hydrolysis. *Lactucic acid* (Ludwig, *Archiv der Pharm.*, 1847) is light yellow, very bitter, soluble in water and alcohol, and does not readily crystallize. Alkalies turn its aqueous solution red. By some this acid is considered a prominent active constituent. The mother liquor of lactucin yielded (Kromayer, 1861) *lactuco picrin* ($C_{44}H_{32}O_{21}$). It is a brown, amorphous, bitter body, faintly acid in reaction, soluble in water and alcohol. It is probably an oxidation product of lactucin. Kromayer regards lactucic acid as the product of the oxidation of lactuco-picrin.

By far the most abundant substance in lactucarium is *lactucerin* (*lactucon* of Lenoir, 1846) ($C_{19}H_{30}O$, Flückiger and O. Schmidt, 1875), constituting half or more of its weight. It is obtained by extracting lactucarium with cold, then with boiling alcohol, which leaves caoutchouc undissolved; or by extracting lactucarium with a mixture of 1 part of chloroform and 3 parts of alcohol. It forms odorless, tasteless, colorless needles, soluble in alcohol, ether, benzin, benzol, chloroform, and volatile and fixed oils, but not soluble in water. Its exact chemical nature remains yet to be established (see O. Hesse and G. Kassner. *Jahresb. der Pharm.*, 1886, p. 37; and 1887, p. 65; also *Lieb. Annal.*, 1886 and 1888). Flückiger (*Pharmacographia*) calls attention to the fact that it is remarkably analogous to *euphorbon* (from euphorbium), *cynanchol* ($C_{15}H_{24}O$) (from *Cynanchum acutum*, Linne), *echicerin* (from Alstonia), and *taraxacerin* (from *Taraxacum*). Lactucarium is liable to be adulterated with bread crumbs, hence the pharmacopœial test for starch above given.

THRIDACE is the inspissated, expressed juice obtained, in France, from *Lactucarium gallicum s. parisiense*, by collecting the stalks near the flowering period, depriving them of their leaves, and then subjecting them to pressure. It is not identical with lactucarium as was at one time supposed.

Action, Medical Uses, and Dosage.—Lactucarium has never been thoroughly and satisfactorily investigated in relation to its therapeutical influences; indeed, various experimenters differ in their views on this point, some asserting it to be a stimulant and others a sedative. It is, when employed at all, usually given as a calmative and hypnotic, and as a substitute for opium, to which it is to be preferred in many instances, on account of its freedom from unpleasant after-effects, as constipation, excitement of the brain, etc. However, it is not considered equal in power to opium. The most energetic lactucarium is said to be obtained from *L. virosa* and *L. altissima*. Moderate doses of it act as a narcotic poison on the lower animals, and 10 or 20 grains swallowed by a dog will cause sleep, or the watery solution injected into a vein occasions sleep, coma, and death. It appears to be of use in *insomnia*, due to mental overwork. A syrup of lactucarium is of value in the *cough of phthisis*, and even garden lettuce appears to exert a good influence in this disease, tending to allay the broncho-pulmonary irritation. Dose of lactucarium in pill or powder, which is the most efficient mode of administration, from 5 to 20 grains; of the tincture, 30 to 60 drops; of the alcoholic extract, 1 to 5 grains.

LAMELLÆ.—DISCS.

Synonyms: *Gelatin discs, Medicated gelatin.*

Preparation and History.—Under this head the *British Pharmacopœia* (1885), without giving processes for making them, introduces discs of gelatin, medicated with powerful alkaloids, for insertion under the eyelids for ocular effects. They weigh about $\frac{1}{50}$ grain and are about $\frac{1}{25}$ of an inch thick. They are prepared by pouring upon glass or porcelain, slightly greased to prevent their adhering, hot solutions of the desired alkaloids in gelatin, allowing them to cool, and finally cutting them into the form of discs. To keep them pliable glycerin is added. The following are official in the *British Pharmacopœia*, 1885:

Lamellæ Atropinæ, *Discs of atropine.*—"Discs of gelatine, with some glycerine, each weighing about $\frac{1}{50}$ grain, and containing $\frac{1}{5000}$ grain of sulphate of atropine"—(*Br. Pharm.*, 1885).

Lamellæ Cocainæ, *Discs of cocaine.*—"Discs of gelatine, with some glycerine, each weighing about $\frac{1}{50}$ grain, and containing $\frac{1}{200}$ grain of hydrochlorate of cocaine"—(*Br. Pharm.*, 1885).

Lamellæ Physostigminæ, *Discs of physostigmine.*—"Discs of gelatine, with some glycerine, each weighing about $\frac{1}{50}$ grain, and containing $\frac{1}{1000}$ grain of physostigmine"—(*Br. Pharm.*, 1885).

The *British Pharmacopœia*, of 1898, has added the following.

Lamellæ Homatropinæ, *Discs of homatropine.*—"Discs of gelatine, with some glycerine, each weighing about $\frac{1}{50}$ grain (1.3 milligrammes), and containing $\frac{1}{100}$ grain (0.65 milligramme) of homatropine hydrobromide"—(*Br. Pharm.*, 1898).

LAMINARIA.—LAMINARIA.

The sea weed *Laminaria Cloustoni*, Edmonston (*L. digitata*, Lamouroux).

Nat. Ord.—Algæ.

Common Names: *Sea tangles, Sea girdles.*

Botanical Source and History.—This marine plant, together with another, the *Laminaria flexicaulis*, Le Jolis (*Laminaria stenophylla*, Harvey), were included by Linnæus under the name *Fucus digitatus*. The last has a deep-brown, flexible, shining stem, and, when dry, becomes thin and fibre-like. The *Laminaria Cloustoni* is not flexible, but rigid and erect, its stem being cylindrical and from 3 to 6 feet long and 2 inches thick at the base. In color it is light-brown. Below the stem it divides into root-like branches, which spread and attach the plant to the submarine rocks. The frond is flat, coriaceous, of an olive-green color, and divided into finger-like divisions. The cylindrical part of the stem only is used. The plants grow upon the rocks in the Atlantic, Pacific, and Arctic Oceans.

Description and Chemical Composition.—Laminaria, in commerce, consists of dried, cylindrical portions of the stem, somewhat irregular, deeply corrugated, a half inch or less in thickness, horny in consistence, of great strength and elasticity, and breaking with a smooth, corneous fracture. The color is brown, the internal portion being paler than the outer. Its value depends upon its property of softening and swelling to several times its diameter when immersed in water, and when in contact with the secretions of the body. A whiter, inner layer is composed of large cells, while smaller cells occupy the outer, brownish portion. Large, elongated, mucilage cells are also present. When formed into conical and cylindrical sticks they are ready for use. Mannit was found in the plant by Stenhouse. Dextrose is likewise present. It contains an abundance of mucilage, from which Schmiedeberg (1885) isolated *laminaric acid*, a substance having the property of swelling up with water to an unusual degree, and *laminarin*, an indifferent mucilage; and the mineral constituents common to marine plants (see *Chondrus*). The ash of this class of algæ (*Laminaria*) amounts to about 14 per cent. and the species, *L. digitata*, is the chief source of the production of iodine on the Norwegian coast, containing about 1 per cent of this element (Jensen, *Jahresb. der Pharm.*, 1888, p. 155). Laminaria, when distilled with sulphuric acid and water, yields a liquid (*fucusol*) containing *furfurol* (*furfuraldehyde*, $C_4H_3.CHO$) and derivatives (Flückiger, *Pharmacognosie*, 1891, p. 279).

Action and Uses.—Laminaria was brought forward as a substitute for sponge tents for the dilatation of such parts as the uterine os, urethra, etc. Being of smaller size, and of greater rigidity, they are more easily introduced into small apertures and tortuous canals than sponge tents, while, on the other hand, their very rigidity renders them more liable to produce hemorrhage when organic changes occur in the uterus, or when such growths as polypi occlude the os. They readily swell to four times their diameter by the ease with which they absorb fluids, and do not so retain the discharges as to induce putrefactive changes. If greater dilatation is desired than is produced by a single tent, several may be fastened together. Sea tangle tents are considered less eligible than the rubber bag, or the sponge tents, for inducing premature births.

Related Plants and Preparations.—*Laminaria esculenta*, Lamouroux, as well as the *Laminaria saccharina*, Lamouroux, which has entire fronds and a flattish stem, and when washed with water becomes sweet, are edible. They likewise yield iodine.

Several pharmaceutical preparations from various species of *laminaria* and related algæ, were suggested by Mr. James Wheeler (see *Amer. Jour. Pharm.*, 1882, p. 124).

Tupelo.—On account of the greater ease with which absorption of fluids and consequent swelling of tissues take place, the root-wood of two species of *Nyssa* has been used for tents and bougies instead of laminaria. The tissue is light, spongy, and white, and, when in contact with fluid, doubles in thickness. This root-wood is known as *Tupelo*, from the trees (of *Nat. Ord.*—Cornaceæ) which yield it, the species being the *Nyssa grandidentata*, Michaux filius. the *Cotton-gum*, or *Large tupelo;* and the *Nyssa capitata*, Walter, the *Sour-gum*, *Tupelo-gum*, or *Ogechee lime*. They grow near the coast in the southern states.

LAPPA (U. S. P.)—BURDOCK.

The root and seeds of the *Arctium Lappa*, Linné (*Lappa officinalis*, Allioni). The *U. S. P.* directs: "The root of *Arctium Lappa*, Linné, and of some other species of *Arctium*."

Nat. Ord.—Compositæ.

Common Name: *Burdock*.

Botanical Source.—Burdock is a well-known biennial weed, with a tapering, fleshy, brown-colored root, from 8 to 15 inches in length, throwing off slender fibers. It has a round, solid, fleshy, juicy stem, 3 feet or more in height, furrowed, hairy, and having many wide-spreading branches. The leaves are large, alternate, on very long petioles, and are nearly entire, or slightly dentated, heart-shaped, undulated, veiny, 3-ribbed at the base, and somewhat hoary and downy beneath. The flower-heads are axillary and globose; the florets, anthers, and stigmas of which are purple, and occasionally white. The involucre is composed of imbricated scales, terminating in recurved or hooked extremities, and, when in fruit easily breaks from the stalk, and is well-known as the "burdock bur," sticking to the hair or clothing of persons who come in contact with it. The fruit is a smooth, oblong, laterally compressed achenia, transversely wrinkled, with a short, rough, prickly pappus. The seeds are quadrangular.

Fig. 156.

Arctium Lappa.

History.—By De Candolle this plant is named *Lappa minor;* by Gaertner, *Lappa major;* and by Lamarck, *Lappa tomentosa*. The plants named by these botanists are now considered as varieties only, and are all, at the present time, included under the one term *Arctium Lappa*, Linné. Burdock is indigenous to Asia and Europe, and grows freely in uncultivated soils, in waste places, and around dwellings in this country, flowering in July and August. The root and seeds are the medicinal parts; the root is to be collected in the spring, or the autumn of its first year, and loses four-fifths of its weight by drying. The root only is official in the *U. S. P.* A tincture of the seeds (*Tinctura Lappæ Fructus*) is prepared by percolating with diluted alcohol (3 of alcohol to 1 of water) 4 ounces of the ground fruit, to obtain 1 pint.

Description.—Radix Lappæ. The root is long, tapering, subcylindrical, or fusiform, externally black-brown or grayish-brown, internally of a light color. It is fleshy when recent; scaly, and longitudinally corrugated when dried, and breaks with a horn-like fracture. At the top of the root the white, silky bases of the leaf-stalks may remain as a small, tuft-like crown. It has a weak, unpleasant smell. The bark has a subsaline, and the internal, spongy parenchyma a sweetish, afterward bitter, mucilaginous taste.

Fructus Lappæ, *Burdock seeds.*—Small, curved, compressed, angular seeds, of a dark-brown color, or spotted with black, having an oily, spicy, bitter, subacrid taste, but no odor.

Chemical Composition.—The *root* was quantitatively analyzed by G. A. Weckler (*Amer. Jour. Pharm.*, 1887, p. 393), who found fixed oil (0.4 per cent), mucilage, sugar, altered tannin (*phlobaphene*, 0.075 per cent), *inulin*, resin, ash (3.67 per cent), etc. The aqueous solution of the alcoholic extract gave indications of a *glucosid.* The *seeds* were analyzed by Prof. Trimble and Mr. F. D. McFarland (*Amer. Jour. Pharm.*, 1885, p. 127, and 1888, p. 79). Moisture was 7.3 per cent, and ash 5.34 per cent. Petroleum spirit abstracted 15.4 per cent of a bland, fixed oil, drying upon exposure in thin layers to the air. It has a specific gravity of 0.930, and is soluble in ether, chloroform, benzol, and hot, absolute alcohol. A crystalline, bitter substance was also obtained by extracting the drug first with petroleum spirit, then with alcohol, pouring the concentrated alcoholic solution into water, whereby resin is separated. The aqueous solution contains the bitter principle, which proved to be a glucosid devoid of alkaloidal reaction. The name *lappin* is applied to it. Upon hydrolysis with very dilute acid, it is decomposed into sugar and alcohol-soluble resin.

Action, Medical Uses, and Dosage.—The root is alterative, aperient, diuretic, and sudorific. A decoction of it has been used in *rheumatic, gouty, venereal, leprous*, and *other disorders*, and is preferred by some to that of sarsaparilla. It is also useful in *scurvy, scrofula*, etc. The seeds are recommended as very efficient diuretics, given either in the form of emulsion, or in powder to the quantity of a drachm, or, preferably, in alcoholic form, as in specific lappa officinalis. They form a good diuretic alterative, and are used in *diseases of the kidneys*, and to remove *boils* and *styes* on the eyelids. The action of the seeds upon the urinary tract is direct, relieving irritation and increasing renal activity, assisting at the same time in eliminating morbid products. In chronic disorders lappa may be used to remove worn-out tissues, where the saline diuretics are inadmissible. *Dropsy* and *painful urination*, due to *renal obstruction*, have been relieved by it. A tincture of the fresh fruit or specific lappa should be employed. It is of marked value in *catarrhal* and *aphthous ulcerations of the digestive tract.* A favorable action is obtained from it in *dyspepsia.* When a cachectic condition of the blood is manifest, and where an alterative is demanded, it relieves *broncho-pulmonic irritation and cough. Rheumatism*, both muscular and articular, when previous inflammations have left no structural alteration, are said to be benefited by the seeds. *Skin diseases*, depending upon a depraved state of the cutaneous tissues and less upon the state of the blood itself, are conditions in which lappa has gained a reputation. It has been particularly praised in *psoriasis*, its use being long-continued to produce good results. *Chronic erysipelas, milk crust*, and various forms of *eczema* have been cured with it. The cutaneous circulation is feeble in cases requiring burdock seeds. A tincture of the recent seeds may be given in doses of from 1 to 60 drops; of specific lappa officinalis, 1 to 25 drops. An ointment of the leaves, or their juice, has been used advantageously in certain *diseases of the skin* and *obstinate ulcers.* The dose of a decoction, or syrup, of the root is from 4 to 6 fluid ounces, 3 or 4 times a day.

Specific Indications and Uses.—Feeble cutaneous circulation; scaly, dry eruptions; impaired nutrition of skin; urinary irritation; psoriasis.

LARICIS CORTEX.—LARCH-BARK.

The bark, denuded of its outer corky layer, of *Larix europœa*, De Candolle (*Pinus Larix*, Linné; *Abies Larix*, Lamarck; *Larix decidua*, Miller).

Nat. Ord.—Coniferæ.

Common Names: *European larch-bark, Larch-bark.*

Illustration: Bentley and Trimen, *Med. Plants*, 260.

Botanical Source.—The larch is a tree of straight and lofty growth, with wide-spreading branches, whose extremities droop in the most graceful manner. The buds are alternate, perennial, cup-shaped, scaly, producing annually a pencil-like tuft of very numerous, spreading, linear, bluntish, entire, smooth, tender, bright-green, deciduous leaves, about an inch long. The male flowers are drooping, about ½ inch long, and yellow; the female catkins, erect, larger than the male flowers, variegated with green and pink; the cones are erect, ovate, about an inch long, purple when young, reddish-brown when ripe, their scales spreading, orbicular, slightly reflexed, and cracked at the margin (L.).

History.—The larch inhabits the mountainous regions of central and south Europe, and is cultivated in Europe and America for ornamentation. *Venice Turpentine* (see *Terebinthina Canadensis*), is obtained from the trunk. The bark contains a large amount of tannic acid. "A saccharine matter called *Manna of Briançon* exudes from the branches, and when the larch forests in Russia take fire, a gum issues from the trees during their combustion, which is termed *Gummi Orenbergense*, and which is wholly soluble in water like gum arabic" (Lindley, *Flor. Med.*, p. 555). The manna referred to contains a peculiar sugar called by Berthelot *melezitose.*

Description and Chemical Composition.—The bark is the part employed and was official in the *British Pharmacopœia* of 1885, as *Laricis Cortex*, or larch-bark. It is collected from the branches and trunk in the spring of the year. It is of a rose or deep-red color externally (after the corky layer is removed), the internal surface being yellowish or pinkish. The pieces are flat or quilled, and break with a fibrous fracture. It is astringent to the taste, and its odor is somewhat balsamic and terebinthinate. The bark contains gum, sugar, resinous matter, and a peculiar tannin, which strikes olive-green with iron salts. A syrupy preparation, obtained by evaporating an aqueous infusion of larch-bark, yielded to Stenhouse, by cautious distillation, a peculiar volatile body, *larixinic acid* or *larixine* ($C_{10}H_{10}O_5$), which exists ready-formed in the bark of larix. It sublimes at 93° C. (199.4° F.), and forms beautiful long, colorless, lustrous crystals, freely soluble in hot water, alcohol, diluted alkalies, or acids, and sparingly so in ether. It has a faintly bitter, aromatic taste, and a feebly empyreumatic or somewhat camphoraceous odor. It is inflammable and is allied to pyrocatechin and pyrogallol, yielding in solution a purple color with ferric chloride. With an excess of concentrated solution of baryta it forms a thick, gelatinous, and transparent precipitate. It occurs most abundantly in the bark of young trees (*Amer. Jour. Pharm.*, 1862, p. 555).

Action, Medical Uses, and Dosage.—(For uses of *Venice Turpentine*, see *Terebinthina Canadensis.*) Larch-bark resembles the other terebinthinous barks, and in strong tincture has been used in *chronic genito-urinary inflammations, chronic bronchitis* to check secretions, and to control the bleeding of *purpura hemorrhagica*, and in *passive hemorrhage.* Dose of tincture, 5 to 30 drops.

LARIX AMERICANA.—TAMARAC.

The bark of *Larix americana*, Michaux.

Nat. Ord.—Coniferæ.

Common Names: *American larch, Tamarac, Hackmetack, Black larch.*

Botanical Source.—This is the *Pinus pendula, Pinus microcarpa*, and *Abies americana* of various botanists, and is known by the several names of Black larch, American larch, Hackmetack, etc. The tree has a straight and slender trunk, with slender horizontal branches, and attains the height of 80 or 100 feet. The leaves are short, 1 or 2 inches long, very slender, almost thread-form, soft, deciduous, without sheaths, in fascicles of from 20 to 40, being developed early in the spring from lateral, scaly, and globular buds, which produce (the same or the second year) growing shoots on which the leaves are scattered. The cones are oblong, of few rounded scales, inclining upward, from ½ to 1 inch in length, and of a deep-purple color. The scales are thin and inflexed on the margin. The bracts are elliptical, often hollowed at the sides, abruptly acuminate, with a slender point, and, together with the scales, persistent (W.—G.).

History.—This is a beautiful tree, more common throughout New England; it is found in swamps and moist places, and flowers in April and May. It may be distinguished from the pines, by the branches being without leaves for nearly half the year. Its wood is very heavy, strong, and durable, and is the most valuable of all the pines or spruces. The bark is the part used as medicine.

Action, Medical Uses, and Dosage.—A decoction of the bark of this tree is said to be laxative, tonic, diuretic, and alterative, and is recommended in *obstructions of the liver*, *rheumatism*, *jaundice*, and some *cutaneous diseases;* a decoction of the leaves has been employed in *piles*, *hemoptysis*, *menorrhagia*, *diarrhœa*, and *dysentery*, and externally in *cutaneous diseases*, *ulcers*, *burns*, etc. In *dropsy*, combined with spearmint, juniper berries, and horseradish, it has proved valuable. Dose of the decoction, from 2 to 4 fluid ounces, 2 to 4 times a day.

LAUROCERASI FOLIA.—CHERRY-LAUREL LEAVES.

The leaves of *Prunus Laurocerasus*, Linné (*Cerasus Laurocerasus*, Lois).

Nat. Ord.—Rosaceæ.

COMMON NAME: *Cherry-laurel.*

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, Plate 98; Woodville's *Med. Bot.*, Plate 185; Artus' *Hand Atlas*, Vol. I, p. 205.

Botanical Source and Description.—Cherry-laurel is a small evergreen tree, native of Asia Minor, and often cultivated as an ornamental shrub in the southern part of Europe. The flowers are small, white, and disposed in axillary racemes, which are shorter than the leaves. The fruit is an ovate, acute, purple drupe, with a globular stone. The leaves are very thick and leathery, about 6 inches in length, and one-third as broad, tapering at the apex to a sharp point, and at the base to a short leaf-stalk. The margin is denticulated with sharp, appressed, rather distant, serrate teeth. The upper surface of the leaf is of a bright-shining green color; the lower pale and dull. The tree belongs to the section *Cerasus* (Jussieu), which, by many botanists, is considered distinct from Prunus, chiefly on account of the globular fruit-stone.

History.—The leaves are employed in medicine. When fresh and bruised, they evolve hydrocyanic acid, but the unbroken fresh leaf is odorless. If the perfect leaves are dried and then powdered, they do not give rise to hydrocyanic acid, but the addition of a little water at once develops the acid (Hanbury). At a meeting of the *Pharmaceutical Society of Paris*, December 6, 1871, Mr. Marais stated that a temperature of —22° C. (—7.6° F.), applied to the leaves and twigs prevented subsequent formation of hydrocyanic acid, although other volatile products were formed.

Chemical Composition.—The leaves of the cherry-laurel, as well as the bark and the seeds of the tree, when distilled with water, yield a distillate of *hydrocyanic acid*, and *benzoic aldehyde* (*benzaldehyde*, *bitter almond oil*, $C_6H_5.CHO$). W. A. Tilden (*Pharm. Jour. Trans.*, Vol. V, 1875, p. 761), finds that the essential oil of cherry-laurel is not absolutely identical with that of the bitter almond; it consists mainly of benzoic aldehyde, and is accompanied by hydrocyanic acid, possibly some *benzoic alcohol* ($C_6H_5.CH_2OH$), and minute quantities of a resin having the peculiar odor of the cherry-laurel leaf. Both substances constitute the medicinal principles of *Aqua Laurocerasi* (*Br.*) or cherry laurel water (see *Aqua Laurocerasi*).

The formation of these substances suggests the presence of *amygdalin* in these parts of the plant (see *Amygdalus*). Lehmann (1874), testing the leaves for amygdalin, obtained 1.3 per cent of crystallizable but deliquescent bitter *laurocerasin*, which behaved toward the ferment *emulsin* exactly like amygdalin, yielding hydrocyanic acid, benzaldehyde, and dextrose. The similarity also holds good in the products obtained from both when boiled with baryta water; ammonia is split off in both cases, and the barium salt of *amygdalic acid* ($C_{20}H_{28}O_{13}$) is formed, which must not be confused with *mandelic acid* ($C_8H_8O_2$). With *laurocerasin*, however, 2 molecules of amygdalic acid were formed for each molecule of ammonia, while *amygdalin* yielded but one. Hence, Lehmann accepts that 1 molecule of *laurocerasin* ($C_{40}H_{67}NO_{30}$) is composed of equal molecules of *amygdalin* (anhydrous, $C_{20}H_{27}NO_{11}$), *amygdalic acid* ($C_{20}H_{28}O_{13}$), and 6 molecules of water. Laurocerasin is believed also to exist in the unripe bitter almonds, and to evolve amygdalin during the process of maturing. It is also contained in the bark of *Prunus padus*, the bird-cherry tree, while in its seeds, as well as those of cherry-laurel, amygdalin is present. The theoretical yield of *hydrocyanic acid* from laurocerasin ($C_{40}H_{67}NO_{30}$) is only about one-half of that from crystallized amygdalin ($C_{20}H_{27}NO_{11}+3H_2O$). Flückiger (*Pharmacognosie*, 3d ed., 1891, p. 766), obtained on an average 0.12 per cent of hydrocyanic acid in the distillate of bruised fresh leaves. The yield also varies with the season, being highest in the spring and lowest late in the fall, being then reduced to about one-half. The leaves also contain reducing sugar, an iron-greening tannin, and a fatty or waxy matter. Bougarel (1877) isolated from the leaves crystallizable *phyllic acid*, soluble in alcohol and ether, insoluble in water, and melting at 170° C. (338° F.). It also occurs in the leaves of the apple tree, maple, peach, almond, etc. Young leaves incinerated, yielded to Flückiger about 7 per cent of ash.

Action, Medical Uses, and Dosage.—(See *Aqua Laurocerasi.*) The bruised leaves are anodyne.

LAURUS.—LAUREL.

The leaves, fruit, and oil of *Laurus nobilis*, Linné.

Nat. Ord.—Laurineæ.

Common Names: *Laurel*, *Bay*, *Sweet bay*, *Sweet bay tree.*

Illustration: Bentley and Trimen, *Med. Plants*, 221.

Botanical Source.—The bay tree is either a shrub or small tree, usually growing to a height of from 20 to 30 feet. The leaves are short-petioled, oblong-lanceolate or oblong, veined, entire, or occasionally repand, somewhat acute at each end, and alternately affixed. They are smooth, leathery, glossy-green above, and paler beneath. The veins meet the midrib at an acute angle, and by means of small lateral veinlets, form a network which does not anastomose prominently near the leaf-margin. The flowers are diœcious, yellow, or yellowish-white, axillary, and borne in umbellate clusters. The fruit is an oval, deep-purple, almost black drupe.

History, Decription, and Chemical Composition.—This plant, the well-known bay tree, is cultivated in Mexico, but is indigenous to the countries round about the Mediterranean. The leaves, expressed oil, and berries are employed.

I. Folia Lauri, *Laurel leaves.*—These, as well as the fruit, have been described above. When dried they are of a yellow-green or brown-green color, and possess an aromatic, bitter taste, and an aromatic agreeable odor. Their virtues are due to the presence of a volatile oil ($\frac{1}{3}$ per cent, Flückiger, *Pharmacognosie*, 1891; from 0.8 to 2.5 per cent, referred to dried leaves, Schimmel & Co.'s *Report*, October, 1893). It is probably identical with that from the fruit (which yields 0.8 per cent), but has a finer aroma. Its specific gravity is 0.924. According to Prof. Wallach (1889), the oil both from the leaves and the berries, contains for the most part *cineol* (*eucalyptol*), a terpene derivative, and small quantities of the terpene *pinene.* (For list of 22 essential oils in which *cineol* has been found to occur, see Schimmel & Co.'s *Report*, 1891, p. 68.)

II. Fructus (or Baccæ) Lauri, *Laurel* or *Bay-berries.*—The dry berries are fragile, wrinkled, green-black, or black-brown, having a thin, friable integument enclosing an aromatic, oily, bitter, dicotyledonous kernel. Bonastre (1824) found the fruits to contain 0.8 per cent of volatile oil, 12.8 per cent of a green fatty oil. and 5.1 per cent of solid fat. According to analysis by Staub (1879) a variety of fatty matters are present, viz., the glycerides of acetic, oleic, linoleic, stearic, palmitic, myristic, and lauric acids, with small amounts of free acetic acid.

III. Oleum Lauri, *Oil of Laurel.*—This is the expressed oil of the fruit, and is known also as *Oleum Lauri Expressum*, *Oleum Laurinum*, and *Oleum Lauri Unguinosum*. This oil is a green, granular, lard-like mixture, melting at 40° C. (104° F.), to a dark-green aromatic fluid, and consisting of a semi-solid fat (chiefly *laurostearine*, the glyceryl-ester of *lauric acid* $C_{12}H_{24}O_2$), fragrant ethereal oil of bitter, balsamic taste, and green chlorophyll, which is permanent toward ammonia. An adulteration with indigo and curcuma can therefore be recognized by the formation of a red color upon the addition of ammonia water to an alcoholic extract of the oil. These coloring matters are also insoluble in ether, while oil of laurel is completely soluble with green color. Cold alcohol dissolves out essential oil and chlorophyll, leaving the fatty matter undissolved.

Action, Medical Uses, and Dosage.—The ancients valued bay leaves and laurel berries, using them as astringents, stimulants, and stomachics. In Europe pastry is at the present day flavored with the leaves, the belief prevailing that they render the food more easily digested. Active emmenagogue properties were formerly ascribed to laurel, and a decoction of the root-bark was in vogue as a remedy in *dropsies* and *disorders of the urinary tract.* Locally, in powder or decoction, the leaves and fruit were applied to *insect bites* and *stings*, *scalp eruptions*, and in *leucorrhœa* when accompanied by lax vaginal walls. All that now remains of this ancient medication is the use of the oil (both volatile and fixed) as a stimulant topical agent for *rheumatic* and other *painful parts.*

Related Species.—*Persea gratissima*, Gærtner (*Laurus Persea*, Linné), *Alligator pear.* The fruit, from its long, pear shape, is also known as the *Avacado pear*, and from its butyraceous, rich pulp, *Midshipman's butter*, or *Vegetable marrow.* The tree closely resembles our sassafras tree, and the fruit is either green, purple, or red, the first variety being preferred by the natives who consume the fruit. If eaten before maturity the fruit is liable to induce dysenteric and febrile disorders. The seeds, which are the medicinal parts, are hard and globose, contain a milky juice which leaves a red ineffaceable mark upon a white surface when exposed to the atmosphere. The seeds contain *amygdalin*, and a ferment capable of producing therefrom *hydrocyanic acid;* fat, starch, mannit, and sugar; the fruit, gum, sugar, fixed oils, and salts of malic acid (Betancourt). The seeds are reputed anthelmintic, and are applied locally and given internally, in fluid extract, for *rheumatism* and *intercostal neuralgia.*

LAVANDULA.—LAVANDULA.

The flowers of *Lavandula vera*, De Candolle (*Lavandula spica*, var. *a.* Linne; *Lavandula officinalis*, Chaix; *Lavandula angustifolia*, Ehrhart).

Nat. Ord.—Labiatæ.

Common Names: *Lavender*, *Lavender flowers.*

Illustration: Bentley and Trimen, *Med. Plants*, 199.

Botanical Source.—*Lavandula vera*, of De Candolle, is a small shrub, generally 1 or 2 feet high, but sometimes growing to even 6 feet. The leaves are oblong-linear or lanceolate, entire, opposite, sessile, and, when young, hoary and revolute at the edges. The flowers are of a lilac color, small, in terminal, cylindrical spikes, formed of interrupted whorls of 6 to 10 flowers, each whorl with 2 minute bracts. The corolla is tubular, 2-lipped, upper lip large and 2-lobed, lower lip 3-lobed. The floral ~~leaves are~~ rhomboid-ovate, acuminate, membraneous, all fertile, the uppermost shorter than the calyx. Stamens 4, declinate; anthers reniform, 1-celled; style slender; stigma bilobate (L.).

History and Chemical Composition.—*Lavandula vera* inhabits southern Europe and north Africa, growing in dry, sterile soils in mountainous and other sunny elevations. It is largely cultivated in the United States, flowering in July and August. It is subject to a disease, which can only be avoided by not allowing the plants to grow too closely together. The whole plant is aromatic. The flowers are the parts used; they are gathered shortly after their appearance, or before fully expanded, usually in June and July, and carefully dried. They have a rich, peculiar fragrance, which is retained long after drying, and a strong, bitter, aromatic, somewhat camphoraceous taste. Their properties are yielded to alcohol or ether. They contain volatile oil (see *Oleum Lavandulæ*), resinous matter, tannic acid, a bitter principle, and woody fiber. The recent flowers yield from about 1.2 to 1.6 per cent of the volatile oil.

Action and Medical Uses.—Lavender is a tonic, stimulant, and carminative. It is seldom given in the crude state, but in its official preparations, which see. Colic is said to be occasioned by the infusion if immoderately used. Lavender fomentations are occasionally employed in *painful local affections*. The infusion is prepared with 1 drachm of the flowers and 1 pint of water. Prof. Scudder considered lavender the child's stimulant, preferring the tincture of the oil (℥ii) to alcohol (Oj).

Fig. 157.

Lavandula vera.

Related Species.—*Lavandula spica*, of De Candolle, is more dwarfish and more hoary than the *Lavandula vera*. Leaves oblong-lanceolate, somewhat spatulate, entire, much narrowed at the base, hoary on both sides. Spikes somewhat interrupted. Bracts linear-subulate, shorter than the calyx. This plant is not used in medicine, but yields what is called *oil of spike*, much used in the preparation of artistical varnishes and by porcelain painters. The chief constituent of this oil is *cineol*.

Lavandula stœchas, Linné.—This small shrub, the flowering spikes of which are known as *French* or *Arabian lavender*, is found in the countries bordering on the Mediterranean. They bear small-stalked, deep-purple, small flowers, having a camphoraceous, pronounced aroma.

Ocimum basilicum, Linné, *Basil*, *Sweet basil*.—This herb is an annual, belonging to the Labiatæ, and indigenous to Africa and Asia, in the tropical portions, and often cultivated in gardens. It has a cooling, balsamic taste, and a strongly aromatic, agreeable odor. It contains a small amount of tannin and a volatile oil. This plant is employed in some sections as a flavoring herb in cooking, and in southern South America, the fresh juice is employed to expel *worms*. It has been used in *mild nervous disorders*. The oil is nervine and carminative.

LEDUM.—LABRADOR TEA.

The leaves of *Ledum latifolium*, Aiton.

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Labrador tea*, *James' tea*.

Botanical Source.—*Ledum latifolium* is an evergreen shrub, with an irregularly branched stem, from 2 to 5 feet in height. The branches are woolly. The leaves are alternate, subsessile, entire, 1 or 2 inches in length, nearly one-third as wide, obtuse, elliptical or oblong, smooth above, clothed with a dense, rusty wool beneath, and have revolute or replicate margins. The flowers are large, white, in dense, terminal corymbs of about a dozen flowers; the pedicels nearly as long as the leaves, filiform and pubescent. The calyx is very minute. Corolla white, consists of 5 spreading, obovate, obtuse petals. Stamens 5 or 10, as long as the petals; filaments slender and smooth; anthers small, opening by 2 simple, terminal pores. Ovary roundish; style straight, about as long as the stamens; stigma small and obtuse. Capsule ovate-oblong, subpubescent, 5-celled and 5-valved; valves splitting from the base upward, with the margins inflexed and connivent; and receptacles linear, extending into the cells of the capsule. The seeds are minute, terminating in a membrane at each extremity (L.—Torrey).

History and Chemical Composition.—This plant is a native of North America, and is found in the northern part of the United States and in Canada, growing in cold bogs and damp mountain woods, flowering in June and July. It is also found further south, growing on the mountains. The leaves are the parts used. They have a pleasant flavor, and yield their virtues to hot water in infusion, or to alcohol. It contains the glucosid *ericolin* (R. Thal, 1883). They were much employed instead of tea leaves during the Revolutionary War. Their medicinal virtues were well-known to the Cree Indians in the territory of the Hudson Bay, and to other Indian tribes.

Action, Medical Uses, and Dosage.—Ledum latifolium is pectoral and tonic, and, in small doses, is useful in *coughs, irritations of the pulmonary membranes*, and in *dyspepsia*. It increases the urinary flow. Reputed also to possess similar, but less energetic, properties than the *Ledum palustre* (see below), which is supposed to possess narcotic powers. An infusion of the leaves has been successfully employed in decoction in *pertussis*, *dysentery*, and to allay *pruritic irritation in exanthematous diseases*. In *leprosy*, *itch*, and *several diseases of the skin*, the decoction internally and externally has been beneficially used. Clothes, among which it is strewed, are said to be preserved from the ravages of moths. A strong decoction, used externally, will kill *lice* and other insects. Dose of the infusion of either of the above plants, from 2 to 4 fluid ounces, 3 or 4 times a day. A tincture may be prepared from the fresh leaves (℥viii to alcohol, 98 per cent, Oj). Dose, 1 to 10 minims.

Related Species.—*Ledum palustre*, Linné, or *Marsh tea*, also known as *Marsh cistus*, *Wild rosemary*, and *Rosmarinus sylvestris*, inhabits sphagnous swamps in the cold regions of the two continents, and may be distinguished by its linear leaves, having uniformly 10 stamens, and especially by its oval pods. The leaves have a pleasant, resinous odor, and a not unpleasant, amarous, and somewhat spicy taste, with slight astringency. They were formerly used in place of hops in the making of beer in some parts of Germany and Sweden. Water, by infusion, or alcohol, extracts the properties of ledum. Its chief proximate principles are: (1) *Ericolin* ($C_{26}H_{30}O_3$, R. Thal, 1883), a resinous, bitter glucosid without odor, decomposing with water, or more rapidly with diluted mineral acids, into sugar and *ericinol* ($C_{20}H_{26}O$), which readily absorbs water and forms *hydroericinol* ($C_{10}H_{20}O_4$), a thick fluid of a peculiar odor; (2) *leditannic acid* ($C_{25}H_{20}O_4$); (3) volatile oil containing crystallizable *ledum camphor* ($C_{15}H_{26}O$, Rizza, *Jahresb. der Pharm.*, 1887, p. 363, and Hjelt, *Chemiker Ztg.*, 1895, p. 2126), melting at 105° C. (221° F.). 0.7 per cent of the oil was obtained by Hjelt and Collan (1882) from the herb grown in wet localities. The flowering tops yielded (Schimmel & Co., Oct., 1894) 1.2 per cent of the oil, while the non-flowering shrub yields only about 0.35 per cent. The poisonous *andromedotoxin* was established, by Prof. Plugge and De Zaayer, to be absent from Ledum palustre (*Amer. Jour. Pharm.*, 1889, p. 360).

LEONURUS.—MOTHERWORT.

The tops and leaves of *Leonurus Cardiaca*, Linné.
Nat. Ord.—Labiatæ.
Common Name: *Motherwort.*

Botanical Source.—*Leonurus Cardiaca* is a perennial plant, with stems from 2 to 5 feet in height, wand-like, minutely downy, acutely quadrangular, with intermediate channels, purplish, beset with numerous pairs of opposite, long-stalked, rough, dark-green, somewhat downy leaves in 4 vertical rows. The lower stem-leaves are palmate-lobed and broadest; the upper ones acutely 3-lobed; those about the summit lanceolate and undivided; and all toothed and cuneiform at the base. The flowers are purplish or whitish-red, in numerous axillary whorls. The calyx is rigid and bristly. Corolla purplish, upper lip clothed with dense, white, shaggy, upright hairs; lower deeply colored, variegated, smooth, in 3 nearly equal entire lobes; middle lobe obcordate. Stamens didynamous; anthers approximated in pairs, with parallel transverse cells and naked valves, sprinkled with shining dots. Achenia oblong, or linear-obovate, blunt and squamosely muricated at the summit, and longitudinally striated, with a long beak; pappus white, hair-like, very soft, simple, and radiated in many rows (L.—W.—G.).

Fig. 158.

Leonurus Cardiaca.

History and Chemical Composition. Motherwort is an exotic plant, but extensively introduced into this country, growing in fields and pastures, and flowering from May to September. It is supposed to be a native of Tartary, and may probably be indigenous to the northern sections of this country. In some sections of continental Europe, and particulary in Russia *Leonurus Cardiaca* has been highly endorsed as a remedy for hydrophobia. It has not, however, been as extensively used as a medicinal agent in this country, as its virtues warrant. The root sends forth a number of small, long fibers of a dark-yellowish color. The whole plant is medicinal. It has a peculiar, aromatic, not disagreeable odor, and a slightly aromatic, very bitter taste, and yields its properties to water or alcohol. Mr. W. A. H. Naylor (*Pharm. Jour. Trans.*, Vol. XXV, 1894, p. 181) found the following constituents of *Leonurus Cardiaca:* A bitter principle soluble in alcohol, chloroform, and ether, insoluble in water, benzol, and petroleum ether; an *alkaloidal* substance, not reacting, however, with Mayer's Solution;

a hard resin, a soft resin, fixed oil, wax, and potassium chloride, calcium phosphate, and citric, malic, and tartaric acids. Some interesting notes on the early literature of Leonurus, by E. M. Holmes, precede Mr. Naylor's article.

Action, Medical Uses, and Dosage.—Motherwort is emmenagogue, nervine, antispasmodic, and laxative. It is usually given in warm infusion in *amenorrhœa from colds;* and in *suppressed lochia* we have found it superior to any other remedy. Also useful in *hysteria* and *chorea* (King). The extract is recommended in *nervous complaints, pains peculiar to females,* in *irritable habits, delirium tremens, typhoid stages,* with morbid nervous excitability, all chronic diseases attended with restlessness, wakefulness, disturbed sleep, *spinal irritation,* and *neuralgic pains* in the stomach and head, and in *liver affections.* It is adapted to cases of *nervous debility* with irritation, nervous unrest, tendency to choreic or spasmodic movements, pelvic and lumbar uneasiness or pain, bearing down pains, and the irritability due to *female disorders.* Combined with ictodes and resin of black cohosh, it forms a superior antispasmodic, nervine, and emmenagogue. Externally, it may be used as a fomentation to the bowels in *suppressed and painful menstruation,* etc. Dose of decoction, from 2 to 4 fluid ounces, every 1, 2, or 3 hours; of the extract, from 3 to 6 grains, every 2 to 4 hours. The root in infusion is diuretic, and is stated to be efficient in *obstinate intermittents.* The seeds have been given in half-teaspoonful doses in water, in *bilious colic,* and, it is said, will pass through the bowels when quicksilver will not; they must not be pulverized. This, however, requires more satisfactory evidence (King).

Related Species.—*Stachys palustris,* Linné, *Hedge nettle.* Europe and North America, in wet situations. This, with other species of *Stachys,* has been employed as a topical and general stimulant.

Ballota nigra, Linné, *Black horehound.*—New England, naturalized. Has been used as a stimulant, antispasmodic, and vermifuge.

Galeopsis Tetrahit, Linné, *Hemp nettle.*—Formerly used in *bronchitis* and *intermittent fever.*

LEPTANDRA (U. S. P.)—LEPTANDRA.

"The rhizome and rootlets of *Veronica virginica,* Linné" (*Leptandra virginica,* Nuttall).

Nat. Ord.—Scrophularineæ.

Common Names: *Black root, Culver's root,* etc. (see *History*).

Illustration: Bentley and Trimen, *Med. Plants,* 196.

Botanical Source.—This is the *Veronica virginica,* of Linnæus, and *Leptandra virginica,* of Nuttall. It is an indigenous, perennial plant, with a simple, straight, smooth, herbaceous stem, from 2 to 5 feet in height. The leaves are whorled in fours to sevens, short-petioled, lanceolate, acuminate, finely serrate, and glaucous beneath. The flowers are white, numerous, nearly sessile, in long, terminal, and verticillate, sub-terminal spikes. Spikes panicled and crowded; bracts very small. Calyx 4-parted. The corolla is small, nearly white, with a deeply 4-cleft, spreading border, the lateral or lower segments narrower than the others, tubular and pubescent inside; the tube of the corolla is longer than its limb, and much longer than the calyx. Stamens 2, very much exserted. Capsule oblong-ovate, not notched, opening by 4 teeth at the apex, and many-seeded (G.—W.).

History.—Leptandra is one of the very old Eclectic drugs. Like most medicinal plants it is known by several popular names, as Black root, Culver's root, Culver's physic, Bowman root, Tall speedwell, Veronica, Tall veronica, Physic root, and Whorlywort. Its name Veronica is probably derived from St. Veronica. Black root is found more or less plentifully throughout the United States, from Vermont to Wisconsin, and southward, growing in wet, or moist, rich ground near streams, in woods, thickets, glades, and open plains. It is particularly plentiful in limestone districts. It is a perennial herb, growing from 1 to 5 feet high, with an upright stalk, having whorls of leaves, and surmounted by spikes of crowded white flowers. It blooms in July and August. The rhizome is perennial, and should be gathered in the fall of its second year. When fresh, it has a faint, almond-like odor, and a bitter, nauseous taste, which is somewhat lessened by drying, and yields its properties to water at 100° C. (212° F.), or still better to alcohol. Age does not impair its virtues.

This drug was well-known to the Indian Herb Doctor Peter Smith, and to Dr. Hough. To the former it was known as Culver's, or Brinton's root, and he states that his father "used to cure the pleurisy with amazing speed" with it. Hough said of it that it was "a most mild and efficacious purge in fevers, in disorders of the stomach, or the bowels, to destroy vicious humors in the blood, to remove costiveness, or to cool fevers." The Wyandots were acquainted with its virtues, and regarded it as "a very good healing purge." The early Eclectic physicians considered it one of their most valuable therapeutic agents.

Specific Leptandra, the most extensively used preparation, has a dark-brown color, the peculiar, and markedly so, odor of the drug, and a bitter taste that is accompanied by the aroma of the root from which it is prepared. When dropped into water it produces a turbidity or milkiness. If specific leptandra be allowed to evaporate by rubbing a few drops in the palm of the hand the skin is impregnated with the strong odor of leptandra in an intensified degree.

Description.—Leptandra is officially described as "of horizontal growth, from 10 to 15 Cm. (4 to 6 inches) long, and about 5 Mm. ($\frac{1}{5}$ inch) thick, somewhat flattened, bent, and branched, deep blackish-brown, with cup-shaped scars on the upper side, hard, of a woody fracture, with a thin, blackish bark, a hard, yellowish wood, and a large, purplish-brown, about 6-rayed pith; roots thin, wrinkled, very fragile; inodorous; taste bitter and feebly acrid"—(*U. S. P.*). (See also illustration of the microscopic structure of leptandra, by A. P. Breithaupt, *Amer. Jour. Pharm.*, 1897, p. 235.)

Chemical Composition.—The root of leptandra, as well as its preparations, possesses a peculiar, strong odor, and yields, with diluted sulphuric acid, an acid distillate of an unpleasant odor, and containing traces of *formic acid* (F. F. Mayer, *Amer. Jour. Pharm.*, 1863, p. 298). Prof. E. S. Wayne procured a bitter principle by the following process: The root, in coarse powder, was treated with water in a percolator until the infusion was no longer bitter; subacetate of lead was added to this, and the precipitate removed by filtration; carbonate of sodium was then added to remove excess of lead, and the liquid again filtered. The pale-yellow liquid was then allowed to filter through a column of purified animal charcoal. The liquid that passed through was totally devoid of taste and color. The coal was then washed with water until this commenced to have a bitter taste; it was then dried and treated with boiling alcohol, and the alcoholic solution allowed to evaporate spontaneously. It dried to a dark-green mass, no signs of crystallization being observed during the time. It was again dissolved in water, treated with ether, and allowed to evaporate, when a number of bitter, pale-green, needle-shaped crystals were obtained (*Amer. Jour. Pharm.*, Vol. CXXV, p. 510).

G. Steinmann (*Amer. Jour. Pharm.*, 1887, p. 229) obtained a bitter principle by pouring a concentrated tincture of the root into water, which precipitates the resin. The filtrate was acidulated and shaken out with benzol. Upon evaporation of this solvent, 0.1 per cent of a crystalline and very bitter residue was left, which was again crystallized from ether. The pale, lemon-yellow crystals are insoluble in petroleum benzin, soluble in alcohol, ether, benzol, hot water, and yield no precipitate with Mayer's solution, nor with tannic acid; neither does it reduce Fehling's solution after being boiled with diluted sulphuric acid. The resinous matter, precipitated by water and purified by repeated precipitation is absolutely inert (see *Leptandrin*). The filtrate from the first precipitation of the resin contains *mannit* (E. S. Wayne, *Amer. Jour. Pharm.*, 1859, p. 557). J. U. Lloyd (*Amer. Jour. Pharm.*, 1880, p. 491) calls attention to the fact that the bitterness of the tincture of leptandra disappears when in prolonged contact with diluted sulphuric acid, or more rapidly upon boiling. An inert resin is formed in both cases, and the solution contains a great amount of reducing substance.

LEPTANDRIN.—Leptandrin was discovered and introduced about the year 1850, by Mr. William Stanley Merrell. It was one of the class of Eclectic concentrations or resinoids and followed podophyllin, macrotin and irisin, which were previously discovered by Prof. John King. As found in commerce it is prepared by pouring an evaporated alcoholic tincture of leptandra, of a thick, syrupy consistence, into cold water. A black, tarry substance is thrown down. This precipitate is then washed with pure cold water and becomes tasteless. This product has a deep-black color, resembling asphaltum, and breaks with a shiny fracture. By this process the bitter principle of leptandra remains dissolved in the water used as a precipitant. The *leptandrin* made by the foregoing process (Greve) is inferior as a medicine. Prof. Lloyd agrees with Dr. Greve, that a dried alcoholic extract (not precipitated in water) possesses more nearly the medicinal qualities of the drug. He further states that the dried precipitated resin differs so markedly from the dried alcoholic extract as to forbid their substitution for each other. If the resin be rubbed with distilled water and filtered the filtrate will be colorless, nearly tasteless, and without bitterness, while the filtrate from the dried alcoholic extract, similarly treated, is dark-colored and extremely bitter. The resin of leptandra, or *leptandrin*, will not run together nor lump in any temperature or in any atmosphere. Under like conditions, or if not well dried, the alcoholic extract will run together and form a hard mass. The root, which should be well dried and at least one year old after collecting, yields about 6 per cent of resin. Of the alcoholic extract the yield is about 10 per cent. The yield of resin increases with age and exposure after collection, consequently the roots of two or more years of age are preferable for the production of *leptandrin*. Prof. John King, to whom may be ascribed the popularity of leptandra as a medicinal agent, did not employ the so-called "*leptandrin*," but found the therapeutic value of the drug to depend upon a mixture of the aqueous and alcoholic extracts (see *Amer. Pharm. Assoc. Proc.*, Vol. XXVIII, p. 421). In this connection the following remarks from former editions of this work may be used to indicate the opinion of Prof. King concerning the preparation sold under the name *leptandrin*.

"Dr. T. L. A. Greve states that 'under the name of *leptandrin* various preparations have been sold. Originally, the soft resin was simply dried and powdered but it was found to be nearly inert. The alcoholic extract, dried and powdered, makes a good preparation, and would, probably, be better if deprived of its resin. It is very difficult, however, to dry it without the addition of magnesia or some other absorbent. Most of the so-called leptandrin made at present for medicinal purposes, is merely a dried aqueous extract, so that our practitioners may observe how much they have been imposed upon heretofore by the representations of some manufacturers of the concentrated principles as to their modes of preparation, etc. (N. B.—The powder known heretofore by the name 'leptandrin,' being at this day prepared so as to be nearly worthless, I have substituted the extract for it in nearly all the formulæ in this work where its use occurs)" (King.)

At present, neither leptandrin nor other "resinoids" are used to any great extent by Eclectic physicians.

Action, Medical Uses, and Dosage.—Physiologically, leptandra acts upon the gastric, hepatic, and intestinal apparatus. The fresh root is actively and dangerously cathartic, and has produced violent emesis and bloody purging, accompanied by vertigo, and administered to the pregnant female has produced miscarriage. In this state, it is totally unfit for a cathartic, but upon drying the root loses its drastic qualities, and becomes a safe cholagogue, laxative, and cathartic. In ordinary doses it does not produce copious alvine discharges, but gently stimulates the functions of the liver. It does not debilitate nor lower the tone of the bowels or the general system, but gently stimulates and strengthens the functional activity of the whole intestinal appendages. It favors normal intestinal excretion and improves digestion. Prof. Scudder regarded it as a gastro-intestinal tonic, and thought it indicated where there is enfeebled circulation with tendency to stasis. The only condition in which the green root has been used was for *intermittent fever*, but as we possess better remedies for this state, its use as a cathartic is at least injudicious.

No better laxative can be used in atonic states of the system than leptandra. No matter how great the intestinal atony, it will be found to operate gently and without systemic disturbance. It is an exceedingly useful drug for conditions depending upon hepatic torpor. Small doses restore the liver to its normal condition. The cathartic action of leptandra is beneficial in the forming stages of *fevers* and in the early stages of *dysentery*. It relieves the constipated upper bowel, increases the biliary secretions, and acts as an unirritating intestinal tonic, and the dysenteric discharges are speedily checked. In *acute dysentery* it should be used early. It is an admirable remedy for *chronic dysentery*, with *chronic enteritis*, accompanied by dizziness, cold extremities, headache, abdominal and hepatic pain, with mental depression. It is a good agent for *atonicity of the stomach and liver.* The indications pointing to its use are drowsiness, coldness of the extremities, hot, dry skin, sluggish circulation, abdominal plethora, dull aching pain in hepatic region and in left shoulder, and dull heavy frontal headache, sallow or yellow skin, with a pale, white-coated, broad, thick tongue, and a bitter, disagreeable taste.

Leptandra stimulates the glandular system to activity, and is valuable in *chronic diseases of the mucous membranes.* For *indigestion*, with deficient secretion and constipation, it may be combined with podophyllin triturate (1 in 100). When the stools are clay-colored, with a deficiency of the biliary secretion, it may be used to bring about bilious discharges, even though diarrhœa be already present. In *dyspepsia*, with an unpleasant frontal headache, yellow, furred tongue, with nausea and yellowness of the skin and conjunctiva, specific leptandra will be found an excellent drug. In gastric atony, if necessary, it may be combined with hydrastis, xanthoxylum, chelone, and the milder bitter tonics in general. Black root is a good remedy in *diarrhœa* when indicated. There is a passage of undigested aliment, the liver is inactive, there is dull abdominal pain, and the stools may be of a light clay color. Here leptandra will be found to act kindly. Another condition in which it will prove serviceable, is in the diarrhœa of children passing through the period of *dentition.* Chamomilla or rhubarb may be exhibited with it, when specifically indicated. When the skin shows a jaundiced condition, and there is hepatic tenderness, ℞ Compound syrup of rhubarb and potassa fl℥iij, specific leptandra fl℥i. Mix. Sig. Ten to 20 drops every hour until the diarrhœa ceases.

Leptandra is a useful remedy in disorders of the liver. It is a valuable agent in that state known as "*biliousness.*" In *acute hepatitis* combine the dried alcoholic extract with a small portion of diaphoretic powder to relieve the congested viscus. An occasional dose is not without good effect in *chronic inflammation of the liver.* Specific leptandra may be employed after the passage of *biliary calculi.* Combined with hydrastis, it will materially alter the condition upon which the formation of the concretions depends. In *jaundice* it may be combined with dioscorea, chionanthus, or chelidonium, as indicated. It has been successfully employed in *acute muco-enteritis* and *chronic enteritis.* In the formative stage of *fevers*, particularly *bilious fever*, its cathartic action will be appreciated. Many times it checks the morbid process, and puts the patient on the road to recovery. It has been used with advantage in *typhoid fever* in malarious districts, though it is questionable whether, as a rule, any agent should be employed which has a tendency to increase the intestinal secretions and alvine evacuations. It is better suited to those cases showing typhoid characteristics, but not evidencing lesions of Peyer's patches.

Leptandra has been found useful in *malaria.* The chill should first be broken with quinine and followed by a cathartic dose of leptandra. Many contend that by its exhibition in this manner, the abnormal condition producing the chill is rectified and a return of the unpleasantness is wholly averted, while under the influence of quinine alone, though the chill be broken, there is likely to be a return of the malady. *Dropsy* has been quite successfully treated with leptandra. In *hydrocephalus* its cathartic action is desirable. It should be combined with cream of tartar and mentha viridis for this purpose. In *ascites*, with hepatic congestion and great mental depression, it will be administered both with a view to removing the excess of fluid and to prevent its further accumulation. Dose of the powdered root as a cathartic, from 20 to 60 grains, which may be given in sweetened water; of the infusion, in typhoid conditions, ½ fluid ounce every hour until it operates, and to be repeated daily. Dose of the alcoholic extract, which is one of its best forms of administration, from 1 to 5 grains in form of pills, Specific leptandra, 2 drops to 1 fluid drachm.

Specific Indications and Uses.—Drowsiness, dizziness, and mental depression, with tenderness and heavy pain in the hepatic region; the tongue is coated markedly white, the skin is yellow, there is a bitter taste cold extremities, nausea, and dull frontal headache; thirst, with inability to drink; restlessness, with insomnia; diarrhœa, with half-digested passages, or clay-colored evacuations; enfeebled portal circulation, with lassitude and gloomy and depressed mental state.

LEUCANTHEMUM.—OX-EYE DAISY.

The whole plant of *Chrysanthemum Leucanthemum*, Linné (*Leucanthemum vulgare*, Lamarck).

Nat. Ord.—Compositæ.

Common Names: *Ox-eye daisy, White weed, Great ox-eye, Field daisy, Moon daisy, Maudlin daisy, White daisy, Horse gowan, Grande Marguerite, Goldens.*

Botanical Source.—*Chrysanthemum Leucanthemum*, of Linnæus (*Leucanthemum vulgare*, of Lamarck), generally known as Ox-eye daisy, is a perennial herb, with an erect, branching, furrowed stem, growing from 1 to 2 feet high. The leaves are comparatively few, small, alternate, amplexicaul, lanceolate, serrate, and cut-pinnatifid at the base; the lower ones petiolate, with deep, irregular teeth; the upper ones small, subulate, and those of the middle sessile, deeply cut at base, with remote teeth above. The heads are large, terminal, and solitary. Disk yellow. Rays numerous and white (W.).

Fig. 159.

Chrysanthemum Leucanthemum.

History.—This plant was introduced into this country from Europe, and is a very troublesome weed to farmers in nearly every section. It generally grows from 1 to 2 feet high, and bears white flowers in June and July. In the eastern states it is now used for fodder. The leaves are odorous and somewhat acid; the flowers are bitterish; they impart their virtues to water.

Action, Medical Uses, and Dosage.—Tonic, diuretic, and antispasmodic. Large doses emetic. Used as a tonic instead of chamomile flowers, and has been found serviceable in *whooping-cough*, *asthma*, and *nervous excitability*. Very beneficial externally and internally in *leucorrhœa;* and its internal use has been highly recommended in *colliquative perspiration*. When used locally for the latter purpose, as it sometimes is, it stains the skin. Externally, it has been used as a local application to *wounds*, *ulcers*, *scald-head*, and some other *cutaneous diseases*. Dose of the decoction, from 2 to 4 ounces, 2 or 3 times a day. Said to destroy or drive away fleas.

LIATRIS.—LIATRIS.

The rhizomes of several species of *Liatris*.

Nat. Ord.—Compositæ.

Botanical Source and History.—Liatris spicata, Willdenow, *Button snakeroot*. This plant, also known by the names of *Gay-feather*, *Devil's bit*, etc., has a perennial, tuberous root, an erect, annual stem, 2 to 5 feet in height, mostly stout, and very leafy. The leaves are linear, glabrous, alternate, punctate, ciliate at base, lower ones 3 to 5-nerved, and narrowed at base. The flowers are sessile, of a bright-purple color; the heads many, densely crowded in a long, terminal spike, and from 8 to 12-flowered. The scales of the cylindrical, bell-shaped involucre are oblong or oval, and appressed, with slight scarious margins. Achenia pubescent, obconic. Pappus permanent, colored, barbellate, not evidently plumose to the naked eye. Receptacle naked. This plant is found in moist places in the middle and southern states, and in abundance in the prairies (G.—W.).

Liatris squarrosa, Willdenow, or *Blazing-star*, has a perennial, tuberous root, with a stem 2 to 3 feet high, thickly beset with long-linear, nerved leaves; the lower ones attenuated at the base. The heads are few, sessile or nearly so, with brilliant purple flowers; the racemes flexuous and leafy; the involucre ovate-cylindric, and the scales of the involucre large, numerous, squarrose-spreading; outer ones larger and leafy, inner ones mucronate-acuminate, and scarcely colored. Pappus plumose. This plant is found in the middle and southern states, in dry soil, and is known in the South by the name of *Rattlesnake's master* (G.—W.).

Liatris scariosa, Willdenow, or *Gay-feather*, has a perennial, tuberous root, with a stout, scabrous-pubescent stem, 4 to 5 feet in height, whitish above. The leaves are numerous, lanceolate, tapering at both ends, glabrous, with rough margins, entire, lower ones on long petioles, 3 to 9 inches long, upper ones 1 to 3 inches in length by 1 to 3 lines in width. The heads number from 5 to 20, an inch in diameter, and are disposed in a long raceme, with 20 to 40 purple flowers. The involucre is globose-hemispherical; the scales of the involucre obovate or spatulate, very obtuse, with dry and scarious margins, often colored. Pappus scabrous. This plant is found in dry woods and sandy fields from New England to Wisconsin, and extending southward (G.—W.).

Liatris odoratissima, Willdenow.—This plant, known as *Deer's tongue* or *Vanilla plant*, has radical and stem leaves; the former are obovate-spatulate, tapering below, generally 7-veined, and sometimes slightly obtusely toothed. The stem leaves are oblong and clasping. The leaves are more or less glaucous and fleshy. The flower-heads are arranged in a panicle or corymb, and are from 4 to 10-flowered, the blossoms being of a vivid purple hue. The involucre has but few scales, and these are spatulate-oblong, and imbricated. Pappus not plumose, but finely barbellate. The rhizome of this species is not tuberous. Deer's tongue is found from Virginia south, and flowers in September and October. The leaves, when dry, have a pleasant odor.

History and Chemical Composition.—All the above plants are splendid natives, and flowering through August, September, and October. There are several other species of this genus which appear to possess medicinal properties analogous to each other, and which deserve further investigation—*e. g.*, *L. cylindracea*, *L. graminifolia*, etc. The roots are the medicinal parts; they are all tuberous, except *L. odoratissima*, with fibers, and have a hot, somewhat bitter taste, with considerable acrimony, and an agreeable, turpentine odor. They appear to contain a resinous substance, volatile oil, and a bitter principle. Their virtues are extracted by alcohol, and partially by hot water in infusion. The leaves of *L. odoratissima* are often covered with glistening crystals of *coumarin* ($C_9H_6O_2$) (Procter, *Amer. Jour. Pharm.*, 1859, p. 556). On account of this constituent, it is used in North Carolina for keeping moths out of clothes. Deer's tongue is also of interest as a reputed adulterant of tobacco, it being said to be especially employed in the making of cigarettes, the deleterious effects of which have been attributed, by some, to the coumarin present in them. *Liatris spicata* was analyzed by W. F. Henry (*Amer. Jour. Pharm.*, 1892, p. 603). It contained 0.09 per cent of volatile oil, about 4.5 per cent of resin, 2.3 per cent of a caoutchouc like body, 16 per cent of inulin, also mucilage, glucose, etc., but no glucosid nor alkaloid.

Action, Medical Uses, and Dosage.—These plants are diuretic, with tonic, stimulant, and emmenagogue properties. A decoction of them is very efficient in *gonorrhœa*, *gleet*, and *nephritic diseases*, in doses of from 2 to 4 fluid ounces, 3 or 4 times a day. It is also reputed beneficial in *scrofula*, *dysmenorrhœa*, *amenorrhœa*, *after-pains*, etc. It is likewise of advantage used as a gargle, in *sore throat*, and *chronic irritation of the throat*, with relaxed tissues, and in injection has proved useful in *leucorrhœa*. It acts kindly on the stomach, and is of some value in *dyspepsia* associated with renal torpor. While it relieves *colic* and other *spasmodic bowel affections of children*, it has some reputation as a remedy for *pain and weakness in the lumbar region*. Said to be beneficial in Bright's disease (?) in connection with Lycopus virginicus and Aletris farinosa; equal parts of each in decoction. These plants are celebrated for their alexipharmic powers in *bites of venomous snakes*. Pursh states that, when bitten, the inhabitants of the southern states bruise the bulbous roots, and apply them to the wound, at the same time drinking freely of a decoction of them in milk. This requires corroboration. The eliminative action of liatris may be taken advantage of in removing morbific products left in the system after serious forms of illness. The decoction is prepared from an ounce of the root to 1 pint of water. Dose, 1 fluid drachm to 4 fluid ounces.

LIGUSTRUM.—PRIVET.

The leaves of *Ligustrum vulgare*, Linné.

Nat. Ord.—Oleaceæ.

Common Names: *Privet*, *Privy*, *Prim*.

Botanical Source.—This plant is a smooth shrub, growing 5 or 6 feet high, with wand-like branches. The leaves are dark-green, 1 or 2 inches in length, about half as wide; opposite, entire, smooth, lanceolate, and obovate, obtuse, or acute, and borne on short petioles. The flowers are small, numerous, white, in tetramerous, thyrsoid, terminal panicles. The calyx is minutely 4-toothed, deciduous, and short-tubular; the corolla funnel-form, tube short, limb with 4 spreading, ovate, obtuse lobes. The stamens are 2, on the tube of the corolla; the anthers large and exserted. Style very short; stigma 2-cleft. Berries spherical, black, in conical bunches, 2-celled, from 2 to 4-seeded; seeds convex on one side, angular on the other (W.—G.).

Fig. 160.

Ligustrum vulgare.

History, Description, and Chemical Composition.—Privet is found growing wild in woods and thickets, and along the roadsides from New England to Virginia, and west to Missouri, flowering in May and June. It is used in England for hedges, from which place it is supposed to be introduced; but it is indigenous in Missouri. It is often cultivated in gardens. The leaves are the medicinal parts; they have but little odor, and an agreeable, bitterish, and astringent taste; they yield their virtues to water or alcohol. The flowers have been employed for similar purposes with the leaves. The berries have a sweetish-bitter taste, are reputed cathartic, and to render the urine brown; they have been used for dyeing. Probably the bark will be found equal if not superior in efficacy to the leaves. M. G. Polex (1841) found the bark to contain sugar, mannit, starch, bitter resin, and a peculiar substance which he called *ligustrin*, which has since been shown by Kromayer (*Archiv der Pharm.*, 1863, Vol. CLXIII, p. 19), to be identical with *syringin* ($C_{19}H_{28}O_{10}.H_2O$), a crystallizable glucosid occurring in our common lilac (see *Related Species*). It is odorless and tasteless, soluble in hot water and alcohol, insoluble in ether. Kromayer found, in addition, a bitter crystalline body named by him *ligustron*, soluble in water, alcohol, and ether. A third principle, amorphous and of bitter taste, *syringopikrin*, probably also occurs in the bark of ligustrum. (For details regarding the chemistry of these substances, see Husemann and Hilger, *Pflanzenstoffe*, 1884, p. 1273.)

Action, Medical Uses, and Dosage.—Privet leaves are astringent; a decoction of them is very valuable in *chronic bowel complaints*, *ulceration of stomach and bowels*, as a gargle for *ulcers of mouth and throat*, for which it is peculiarly effective, and as an injection for *ulcerated ears*, with offensive discharges, *leucorrhœa*, *gleet*, and *ulceration of the bladder*, likewise in *diabetes*. They may be employed either in decoction or powder. Dose of the powdered leaves, from 30 to 60 grains. 3 times a day; of the decoction, from 2 to 4 fluid ounces.

Specific Indications and Uses.—Aphthous sore mouth; sore throat.

Related Species.—*Syringa vulgaris*, *Common lilac*. A well-known shrub, the fruit and leaves of which are bitterish and sub-acrid. Besides a sweet principle Petroz and Robinet found a bitter glucosid ($C_{19}H_{28}O_{10}.H_2O$, Kromayer, 1863), the *lilacin* of Meillet, and *syringin* of Bernays, and identical with the *ligustrin* of Polex. This body, when pure, is not bitter, but tasteless (see *Ligustrum* above). Dilute acids split it into sugar and *syringenin* ($C_{13}H_{18}O_5$), an amorphous, pale, rose-colored mass soluble in alcohol, but not in ether and water. The fruit and leaves are antiperiodic and tonic.

LILIUM CANDIDUM.—MEADOW LILY.

The bulb of *Lilium candidum*.

Nat. Ord.—Liliaceæ.

COMMON NAMES: *White lily*, *Meadow lily*.

Botanical Source.—This plant has a perennial root or bulb, composed of imbricated fleshy scales, from which arises a thick stem 3 to 4 feet in height. The leaves are scattered, lanceolate, and narrowed at the base. The flowers are large, snow-white, campanulate, smooth inside, and borne in a terminal raceme (W.).

History.—This is an exotic, a native of Syria and Asia Minor, and is much cultivated in this country on account of its beautiful white flowers, which have long been regarded as the emblems of purity, and which appear in June and

July. The bulb is the part used; it is inodorous, but has a mucilaginous, amarous, rather unpleasant taste. Mucilage enters largely into its constitution, together with a small quantity of an acrid substance, which disappears by heat. Water extracts its virtues.

Action, Medical Uses, and Dosage.—Meadow lily, or white lily, as it is sometimes called, is mucilaginous, demulcent, tonic, and astringent. Useful in *leucorrhœa* and *prolapsus uteri*, the decoction taken internally and employed in injection; it is more decided in its effects when combined with senecio. Boiled in milk, it forms an excellent poultice for *ulcers*, *external inflammations*, *tumors*, etc. The recent root is stated to have been useful in *dropsy*. The flowers are very fragrant, which property they communicate to oily or fatty bodies, forming liniments or ointments useful to relieve the heat and pain attending *local inflammations;* the oil obtained from the petals is reputed efficient in *pains of the womb*, and in *otitis*.

Related Species.—*Lilium tigrinum* or *Tiger lily*. The tiger lily, so-called from the fact that the flowers are spotted after the manner of the skin of the tiger, is a native of Japan and China, but has been widely cultivated as a garden plant. The flowers, which appear in July and August, are large and borne in a pyramidal cluster at the top of the stem. They are of a dark-orange hue and marked with somewhat elevated black or deep crimson spots. A tincture of the plant, in flower, is used quite largely by homœopathic physicians, to whom it was introduced by Dr. W. E. Payne.

Tincture of tiger lily has acquired considerable of a reputation as a remedy for *uterine irritation and congestion*, its effects being slowly produced. It has relieved the *nausea of uterine irritation*, and the *nausea of pregnancy*, and excellent results are reported of its efficacy in *congestive dysmenorrhœa*. It is reputed a leading remedy for *chronic ovarian neuralgia*, being indicated by darting, burning pains in the ovaries. When pelvic weight and prolonged lochia accompany a tardy recovery from parturition, this remedy promises relief, and much testimony points to its value in relieving the bearing-down sensations incident to *uterine prolapse*. The dose is from ½ drop to 5 drops of a strong tincture of the fresh plant. The remedy deserves a careful study. Vomiting, purging, and drowsiness were the symptoms produced in a little girl poisoned by the pollen of tiger lily (Wyman, 1863).

Phormium tenax, Forster. *New Zealand flax*, *New Zealand hemp*. *Nat. Ord.* Liliaceæ. A tall flowering plant, indigenous to some of the South Pacific Islands and introduced into other countries, and frequently found in hot-houses. The leaf-fibers constitute the silky appearing and cream-colored, tough *New Zealand flax*, used for cordage. The roots and leaf-bases, in concentrated decoction, with the addition of carbolic acid, have been employed as a surgical dressing in *amputations* and other fresh *wounds*. It is said to reduce or prevent excessive suppuration (Monckton). It needs further investigation.

LIMON.—LEMON.

The rind and juice of *Citrus* (*Limon*) *Limonum*, Risso (*Citrus medica*, var. *B.*, Linne).

Nat. Ord.—Rutaceæ.

Common Name: *Lemon*.

Illustration: Bentley and Trimen, *Med. Plants*, 54.

Official Parts.—I. Limonis Cortex (*U. S. P.*), *Lemon peel*. "The rind of the recent fruit of *Citrus Limonum*, Risso (*Nat. Ord.*—Rutaceæ)"—(*U. S. P.*).

II. Limonis Succus (*U. S. P.*), *Lemon juice*.—"The freshly expressed juice of the ripe fruit of *Citrus Limonum*, Risso (*Nat. Ord.*—Rutaceæ)."

Botanical Source.—The lemon tree is an evergreen, about 15 or 20 feet in height, with branches easily bent. The leaves are alternate, ovate-oblong, usually serrulated, smooth, glossy, and dark-green, with a winged petiole. The flowers are middle-sized, white, purple externally, and odoriferous. The calyx and petals are similar to those of the orange. The fruit is an oblong-spheroid, sometimes almost globular, with a thin, pale-yellow rind, and a juicy, very acid pulp (L.).

History, Description, and Chemical Composition. This plant, as well as those varieties of it producing the *citron* and the *lime*, is of Asiatic origin, and cultivated in the West Indies, and some other tropical countries. The exterior rind of the lemon and the juice of its pulp are official. The finest lemons are those which are smoothest and thinnest in the skin.

Limonis Cortex (*U. S. P.*).—The rind, or *lemon peel*, as officially used, is described by the *U. S. P.* as occurring "in narrow, thin bands or in elliptical segments, with very little of a spongy, white, inner layer adhering to them; outer surface deep lemon yellow, and ruggedly glandular; odor fragrant; taste aromatic and bitterish. The spongy, inner layer usually present in the segments should be removed before the lemon peel is used"—(*U. S. P.*).

Lemon peel imparts its properties to alcohol, wine, or water. These depend upon a volatile oil contained in the minute vesicles with which it is filled, and, when obtained by distillation with water, or by expression, it forms the oil of lemon of commerce (see *Oleum Limonis*). The white portion of the rind contains *hesperidin* ($C_{22}H_{26}O_{12}$), a bitter, crystalline glucosid, splitting, when heated with diluted acids, into glucose and *hesperetin* ($C_{16}H_{14}O_6$) (see *Aurantii Amari Cortex*). The seeds of the fruit contain bitter *limonin*, soluble in cold alcohol, almost insoluble in water.

LIMONIS SUCCUS (*U. S. P.*).—*Lemon juice*, according to the official description, is "a slightly turbid, yellowish liquid, usually having an odor of lemon, due to the accidental presence of some of the volatile oil of the rind. Taste acid, and often slightly bitter. Specific gravity not less than 1.030 at 15° C. (59° F.). It has an acid reaction upon litmus paper, due to the presence of about 7 per cent of citric acid. On evaporating 100 Gm. of the juice to dryness, and igniting the residue, not more than 0.5 Gm. of ash should remain"—(*U. S. P.*).

One part of brandy or alcohol added to 10 parts of lemon juice, and then filtered to separate the mucilage, will preserve the acid for a long time; it will become slightly bitterish, but retains its strong acidity undiminished. The juice is frequently preserved in sugar, forming lemon syrup, which, however, is apt to spoil by age. Hence, citric acid in solution may be substituted for it, about 4 drachms of the acid being dissolved in 8 fluid ounces of water, which may be flavored with a few drops of oil or essence of lemon. The strained juice has been preserved for some time by putting it into a bottle, and pouring upon it a layer of sweet, or almond oil. The juice may be concentrated by gentle evaporation or by freezing. All methods, however, are rather unsatisfactory, the juice either spoiling or becoming altered in flavor. Lemon juice, as stated above, contains about 7 per cent of citric acid; furthermore mucilage, malic acid, and salts of potassium and calcium are present. However, its proportion of acid is rather variable. As high as 44 grains of citric acid to the ounce of juice were obtained by Stoddard.

Action, Medical Uses, and Dosage.—Lemon peel is used in cookery and confectionery, and also in medicine to correct the taste and augment the power of bitter infusions and tinctures, its virtues being similar to that of the orange peel. The juice of lemon is tonic, refrigerant, and antiscorbutic, forming a refreshing and agreeable drink, called *lemonade*, possessing some medicinal influence, and which, as with orange juice, may be used freely and advantageously in the *febrile* and *inflammatory diseases*, with reddened mucous membranes, for which this last has been recommended. It may also be added to the nutritive drinks of the sick, as gum-water, gruel, barley-water, etc. Its power in preventing and arresting *scurvy* is unequaled by any other remedy, except a liberal supply of fresh vegetables of the cruciform family. In scurvy, an ounce or an ounce and a half of the juice per day, is a preventive dose, and when the disease manifests itself, 4 or 6 ounces per day will arrest it. Occasionally, but rarely, it fails to effect any benefit in this disease. Ships about to make long voyages, should be furnished with a bountiful supply of citric acid and oil of lemon, or lemon syrup, with a small portion of brandy added. *Scrotal pruritis* and *uterine hemorrhage* have been benefited by a local application of the juice. Prof. A. J. Howe, M. D., states that although chloroform will arrest a paroxysm of *hiccough* temporarily, yet, if a permanent subsidence of the spasmodic action of the stomach and diaphragm be required, lemon juice is superior to all other known remedies; in several instances he has cured obstinate and dangerous hiccough with it. Both citric acid and lemon juice appear to exert considerable influence in preventing or modifying *Asiatic cholera*. When the mucous membranes and tongue are very red and the urine alkaline, *rheumatism* is benefited by lemon juice. One or two daily applications of lemon juice with a camel's-hair pencil will reduce *enlarged uvula* and *tonsils*. It also gives temporary relief in *hoarseness*, and has benefited some cases of *malaria*.

Specific Indications and Uses.—Fevers and inflammations, with very red membranes; rheumatic pain, with very red tongue and mucous tissues and alkaline urine; obstinate hiccough; scurvy; and should be given a trial in Asiatic cholera.

Related Varieties.—*Citrus acida*, Roxburgh. The lime is a tree about 8 feet in height, with a crooked trunk and diffuse branches with prickles. Leaves ovate, obovate, oblong, and serrate, being placed upon petioles not winged as in the orange and lemon. Flowers small, white. Stamens 30. Fruit ovate or roundish, pale-yellow, with a boss at the point, and about 1½ inches in diameter. Cysts in the rind concave. Pulp very acid, flat, slightly bitter.

The lime is of considerably less size than the lemon, globular or oval, of a similar color, but frequently with a green or greenish tinge. Its outer coat is not so thick and rough as that of the lemon, and its internal pulp contains a large amount of juice of an excessively acid taste. This juice is chiefly used in the manufacture of citric acid. A variety of the lime tree, *C. Limetta*, furnishes a fruit from the rind of which is obtained the *Oil of Bergamot*. (For *varieties of Lime*, see below.)

De Candolle (*Origin of Cultivated Plants*) gives *Citrus medica*, Linné, as the name of the tree giving rise to the varieties, *lemon*, *lime*, *citron*, etc., and gives as such varieties those four enumerated by Brandis and Sir Joseph Hooker, viz.:

I. *Citrus medica proper*, or the CITRON of the English (*cedro* of the Italian, and *cédratier* of the French). The fruit of this variety is oblong and large, not spherical, has an aromatic, lumpy rind, and a juice neither very acid nor very plenty. This is the *Citrus medica* of Risso.

II. *Citrus medica Limonum*, the LEMON.

III. *Citrus medica acida*, *Citrus acida*, Roxburgh.—Juice very acid, fruit small and of variable shape, and flowers small. The LIME, SOUR LIME. *Citrus acris*, Miller, and other varieties, probably furnish a part of the sour limes.

IV. *Citrus medica Limetta* (*C. Limetta* and *C. Lumia* of Risso), SWEET LIME.—Fruit spherical, with non-aromatic, sweet juice.

LINARIA.—TOAD FLAX.

The plant *Linaria vulgaris*, Miller (*Antirrhinum Linaria*, Linné).

Nat. Ord.—Scrophulariaceæ.

COMMON NAMES: *Snap-dragon*, *Butter and eggs*, *Toad flax*, *Ramsted.*

Botanical Source.—This plant is a perennial whose stem reaches a height of from 1 to 2 feet, and has pale-green, smooth, lance-linear, crowded, sessile, alternate leaves. The flowers, yellow and orange in color, are dense and imbricate, and borne in a showy terminal spike or raceme. . The corolla is personate and its base extended into a spur. The calyx is smooth and not so long as the curved spur.

History.—Linaria is a native of Europe, but is naturalized in this country, where it is common in waste places, and sometimes becomes so plentiful in fields as to become a nuisance. When fresh the plant has a nauseously unpleasant odor, which it loses for the most part upon drying. Its taste is subacrid, bitter, and slightly saline. It should be gathered when in bloom, which is in July and August, quickly and carefully dried, and placed in close containers protected from light and air. A yellow coloring substance (*anthokirrin*) was obtained by Rigel, in 1843, from the blossoms. Walz, in 1854, isolated *antirrhinic acid* (a peculiar volatile substance); *linarosmin* (an oily residue from the distillation with water); bitter crystalline *linariin*, an acrid resin *linaracrin*, and tannic and citric acids, gum, sugar, mineral matters, etc.

Action, Medical Uses, and Dosage.—This plant is recommended for "*bad blood*," *splenic* and *hepatic hypertrophies*, *jaundice*, *skin diseases*, and *scrofula*. An ointment prepared by covering 1 part of the bruised fresh plant with 10 parts of hot lard or mutton tallow, forms a soothing application for *hemorrhoids* and similar conditions. A strong tincture (℥viii to alcohol 98 per cent Oj), may be given in doses of a fraction of a drop to 10 drops. A decoction is prepared from 1 ounce of the plant to 1 pint of water.

LINDERA.—SPICE-BUSH.

The bark and berries of *Lindera Benzoin*, Meissner (*Benzoin odoriferum*, Nees; *Laurus Benzoin*, Linné).

Nat. Ord.—Lauraceæ.

COMMON NAMES: *Spice-bush*, *Fever-bush*, *Wild allspice*, *Spicewood*, *Feverwood*, *Benjamin bush.*

Botanical Source.—Spice-bush is an indigenous shrub growing from 5 to 12 feet in height, with obovate-lanceolate, veinless, entire deciduous leaves, green on each side, and slightly pubescent beneath. The flowers, which are yellow, in little naked umbels on the naked branches, often diœcious; the buds and pedicels are smooth; the fruit is the size of an olive, bright-red, borne in clusters, and contains an ovate, pointed nut. The calyx is 6-cleft, with oblong segments (W.).

History.—This shrub grows in damp woods, along streams and shaded places, in the United States and Canada, bearing greenish-yellow flowers in March and April, before the leaves are unfolded, and maturing its fruit, which consists of bright, crimson-colored, ovoid berries, growing in small bunches, in the middle of autumn. The whole plant has a pleasant, aromatic taste, owing chiefly to a volatile oil, and yields its virtues to boiling water or alcohol. The dried berries were used during the American Revolution, and in the South during the late Rebellion, as a substitute for allspice.

Description.—BARK. Benzoin bark occurs in quills or thin, curved fragments, externally black-brown, somewhat shining and smooth, except where covered with small cork-like warts. In older specimens the corky warts are more conspicuous and the bark is more of an ashen color. Internally it is smooth, and yellow or light brown in color. Its fracture is abrupt and granular. It has a faint aromatic odor, and to the taste is sharp and astringent.

FRUIT.—The fruit is a long, red, ovate drupe, with a circular depression indicating the point of attachment of the pedicel. It contains 1 white seed, quite large, possessing an oleaginous taste. The integuments of the fruit become very dark—almost black—on drying, appearing granular, and have an agreeable odor and spice-like flavor.

Chemical Composition.—J. Morris Jones (*Amer. Jour. Pharm.*, 1873, p. 301), found in the bark a volatile oil, probably of the cinnamyl series, developing, on treatment with oxidizing substances, a bitter-almond odor. He also found sugar, resin, starch, and tannin. From the berries Dr. A.W. Miller (*Proc. Amer. Pharm. Assoc.*, 1878, p. 772), obtained by warm expression and extraction with gasoline, 50 per cent of fatty and volatile oil of a greenish-brown color. By distilling this oil with steam, about 1 per cent of a pale-green, volatile oil was obtained, of a specific gravity of 0.850, and possessing a warm aromatic taste resembling that of allspice. Mr. P. M. Gleim (*Amer. Jour. Pharm.*, 1875, p. 246), obtained by the distillation of fresh berries the unusual yield of 5 per cent of a colorless, fragrant, volatile oil, having a density of 0.87.

Action, Medical Uses, and Dosage.—Aromatic, tonic, and stimulant. An infusion or decoction has been successfully used in the treatment of *ague* and *typhoid forms of fever;* also as an anthelmintic. The berries afford a stimulant oil much esteemed as an application to *bruises, chronic rheumatism, itch*, etc., and has some reputation as a carminative in *flatulence, flatulent colic*, etc. The bark, in decoction, is said to be refrigerant and exhilarating, and exceedingly useful in all kinds of *fever*, for allaying excessive heat and uneasiness; a warm decoction is employed to produce diaphoresis. The decoction may be drank freely.

Related Species.—*Lindera sericea*, Blume. Japan. Tonic and stimulant. Source of the Japanese *kuromoji oil*, an essential oil distilled from the leaves and young twigs, and having considerable fragrance (see Schimmel & Co.'s *Report*, April, 1897; also see analysis by W. Kwasnik, *Archiv der Pharm.*, 1892, p. 265).

Lindera triloba, Blume. Japan. Tonic and stimulant.

LINIMENTA.—LINIMENTS.

SYNONYMS: *Embrocations.*

These preparations are designed for external application, and should always be of a consistence which will enable them to be applied to the skin by gently rubbing with the naked hand, or flannel. They are usually composed of oily, spirituous, gummy, or saponaceous substances, are more fluid than the ointments, denser than water, and at the temperature of the body are always liquid. Water is seldom employed as a vehicle. The benefit derived from them depends either upon their counter-irritating influences, or from absorption of their active constituents. Liniments are usually prescribed extemporaneously by physicians, each having a preference; yet it is absolutely necessary that there be some established rule in relation to them, and that the official preparations be generally known. A solution of ammonium chloride formed the basis of many liniments employed by Prof. King, who was not an admirer of greasy embrocations.

LINIMENTUM ACONITI.—ACONITE LINIMENT.

SYNONYM: *Linimentum aconiti radicis.*

Preparation.—Take of aconite root, in powder, 4 ounces; glycerin, 2 fluid drachms; alcohol, a sufficient quantity. Macerate the aconite with ½ pint of alcohol for 24 hours, then pack it in a small percolator, and add alcohol gradually until a pint of tincture has passed. Distill off 12 fluid ounces, and evaporate the residue until it measures 12 fluid drachms. To this add alcohol, 2 fluid drachms, and the glycerin, and mix them. This preparation was offered by W. Procter, Jr., as a substitute for aconitine as an external anæsthetic application. It is twice the strength of the root, and is exceedingly active. The glycerin is added for the purpose of retarding evaporation after application of the liniment to the skin, and which may be further secured by using oiled silk.

Aconite liniment, based on Procter's formula, was official in the *U. S. P.*, 1870. A similar liniment may be prepared by mixing together ½ fluid ounce of glycerine with 4 fluid ounces of fluid extract of aconite root. Evaporate to 4 fluid ounces.

Action and Medical Uses.—This liniment may be used in all cases in which aconitine would prove useful, as in *gout*, *neuralgia*, and *rheumatism*. It is to be used as follows: Cut a piece of lint or muslin of the size and form of the part to be treated, lay it on a plate or waiter, and by means of a camel's-hair brush, saturate it with the liniment. Thus prepared, it should be applied to the surface, a piece of oiled silk laid over and kept in place by an adhesive edge, or by a bandage. Care should be taken not to apply it to an abraded surface, and in its use the patient should be informed of its character, and avoid bringing it in contact with the eyes, nostrils, or lips.

LINIMENTUM ACONITI ET CHLOROFORMI.—LINIMENT OF ACONITE AND CHLOROFORM.

Preparation.—Take of castor oil, 2 fluid drachms; chloroform, water of ammonia, tincture of aconite root, each, 2 fluid drachms; camphorated tincture of soap, 1 fluid ounce. Mix them well together.

The *National Formulary* prepares this liniment as follows: "Tincture of aconite (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; chloroform, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; soap liniment (*U. S. P.*), seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏]. Mix them"—(*Nat. Form.*).

Action and Medical Uses.—This forms a liniment useful in *rheumatic* and *neuralgic pains*, and wherever such a combination is desired. If the solution above does not readily form a perfectly homogeneous mixture, a few moments' heating in a water-bath will effect it (W. Procter, Jr.).

The following form excellent liniments, which have been found very efficient in *rheumatic and neuralgic pains:* (1) Take of fluid extract of aconite, 2 fluid ounces; American petroleum, 6 fluid ounces. Mix. (2) Take of fluid extract of aconite, chloroform, each, 2 fluid ounces; benzol, 4 fluid ounces. Mix (J. King).

LINIMENTUM ACONITINÆ COMPOSITUM.—COMPOUND LINIMENT OF ACONITINE.

SYNONYM: *Anodyne pomade.*

Preparation.—Take of glycerin, diluted hydrocyanic acid, each, 1 fluid drachm; aconitine, 1 grain. Rub the glycerin and aconitine thoroughly together, and then add the hydrocyanic acid; when thoroughly mixed, put in a well-stoppered vial.

In preparing this, care should be employed not to inhale any of the mixture, and after the addition of the hydrocyanic acid, the mixture should be bottled as quickly as possible.

Action and Medical Uses.—Anodyne; to be applied locally by means of a camel's-hair pencil, over parts affected with *neuralgia;* when painted on the regions about the eye it will allay the pains incident to several affections of the internal coats of the eye (Prof. A. J. Howe, M. D.).

LINIMENTUM AMMONIÆ (U. S. P.)—AMMONIA LINIMENT.

SYNONYMS: *Volatile liniment*, *Common liniment.*

Preparation.—"Ammonia water, three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]; alcohol, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; cotton seed oil, six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏]. To make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them by agitation in a bottle, which should be well stoppered. This liniment should be freshly prepared when wanted"—(*U. S. P.*).

Or, take of solution of ammonia, 1 fluid ounce; olive oil, 2 fluid ounces. Mix and agitate them well together (*Ed.—Lond.*). The *British Pharmacopœia* (1898) formula differs from the latter in adding 1 fluid ounce of almond oil. In this liniment a soap is formed by the union of the oil and ammonia, which is but imperfectly dissolved, and a white oleo-compound of ammonium is formed with some glycerin.

The *U. S. P.* formula gives a liniment fluid at ordinary temperature, and differs from that of 1870 in the substitution of cotton seed oil for olive oil. This liniment is liable to separate into two parts. The alcohol is designed to retard this separation. It has been suggested by Prof. Maisch that if ⅙ portion of olive oil be substituted for a like amount of cotton seed oil, a better liniment would result. Lard oil is said to form quite a uniform mixture. By substituting camphor liniment for the olive oil *Camphorated volatile liniment* (*Linimentum Ammoniæ Camphoratum*) may be formed.

Action and Medical Uses.—This preparation is used as a rubefacient in *rheumatic and neuralgic pains*, *sore throat*, *pleurisy*, *sprains*, *bruises*, etc. It may be applied over the part on flannel, or the skin may be gently rubbed with it. If it becomes too active, it must be weakened with a sufficient quantity of oil. It will vesicate if evaporation be prevented. Care should be exercised in applying it to children and to old people lest blistering occurs.

LINIMENTUM BELLADONNÆ (U. S. P.)—BELLADONNA LINIMENT.

Preparation.—"Camphor, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; fluid extract of belladonna root, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the camphor in about two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of the fluid extract, and then add enough of the latter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—This preparation may be applied locally to *rheumatic and neuralgic parts*, *sprains*, and other *painful conditions*, particularly when there is also spasmodic muscular action.

LINIMENTUM CAJUPUTI COMPOSITUM.—COMPOUND CAJEPUT LINIMENT.

Preparation.—Take of oils of sassafras, cajeput, and hemlock, each, 1 ounce; soap, a sufficient quantity. Mix them together and form a liniment.

Action and Medical Uses.—This forms a valuable stimulating and discutient application. It is principally used in *indolent scrofulous tumors*, and in the *mammary inflammations* of nursing women (J. King).

LINIMENTUM CALCIS (U. S. P.)—LIME LINIMENT.

SYNONYM: *Carron oil.*

Preparation.—"Solution of lime, linseed oil, of each, 1 volume. Mix them by agitation"—(*U. S. P.*).

Or, take of olive oil, or linseed oil, and lime-water, equal parts. Mix and agitate them together (*Ed.—Lond.*).

The lime and oil unite and form a calcareous soap, the oleate of calcium, with some glycerin. It is called *Carron oil.* Turpentine may be sometimes advantageously added to it.

Action and Medical Uses.—This is a very useful and probably the best application to recent *burns* and *scalds;* it is best applied on carded cotton. It is recommended to prevent the pitting of *variola.* The following is also reputed beneficial in *burns:* Take of lime-water, 2 fluid ounces; oil of turpentine, olive oil, each, 1 fluid ounce. Mix. If it be used immediately after the accident, add oil of pennyroyal, 1 fluid ounce.

LINIMENTUM CAMPHORÆ (U. S. P.)—CAMPHOR LINIMENT.

SYNONYMS: *Linimentum camphoratum, Camphorated oil.*

Preparation.—"Camphor, in coarse powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; cotton seed oil, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Introduce the camphor and the cotton seed oil into a suitable flask, and apply a gentle heat, by means of a water-bath, loosely stoppering the flask during the operation. Agitate from time to time, until the camphor is dissolved"—(*U. S. P.*).

Action and Medical Uses.—This forms a stimulant and anodyne application in *contusions, sprains, bedsores, rheumatic, neuralgic,* and other *pains.* In *glandular enlargements* it is used as a resolvent, being particularly employed in the forming stage of *mastitis,* both as a resolvent and to assist in checking the secretion of milk. For the latter purpose, it should be applied as warm as can be borne.

LINIMENTUM CAMPHORÆ COMPOSITA.—COMPOUND LINIMENT OF CAMPHOR.

SYNONYMS: *Rheumatic liniment,* or *drops, Tinctura camphoræ composita, Compound tincture of camphor, Rheumatic tincture.*

Preparation.—Take of camphor, 1 pound; oil of origanum, oil of hemlock, each, ½ pound; oil of sassafras, oil of cajeput, each, 2 ounces; oil of turpentine, 1 ounce; capsicum, 4 ounces; alcohol, 1 gallon. Macerate for 14 days and filter.

Action and Medical Uses.—This is exceedingly efficient as an external application in almost every painful affection, and is of advantage in *chronic rheumatism, pains* in various parts of the system, *bruises, sprains, chilblains, contusions, lameness, numbness, white swellings,* and other *swellings,* etc. In ordinary cases apply 2 to 4 teaspoonfuls to the affected part, and rub it well by the fire, and apply warm flannel over the region of the affected part several times a day. Internally, take 20 drops on sugar, but in severe and obstinate cases, after bathing as above directed, apply an additional piece of flannel, which must be kept constantly wet with the drops, until relieved. When applied to the teeth, wet a small quantity of cotton, and introduce it into the *decaying teeth.* If the face is swollen, bathe with it likewise (J. King). That of the *British Pharmacopœia* (1885) is stimulant and rubefacient on account of the stronger ammonia employed. It may be employed in *local painful conditions.*

LINIMENTUM CAPSICI COMPOSITUM.—COMPOUND CAPSICUM LINIMENT.

Preparation.—Take of tincture of capsicum, 2 fluid ounces; tincture of opium and aqua ammoniæ, each, 3 fluid drachms; oil of origanum, 2 fluid drachms; oil of cinnamon and tincture of camphor, each, 1 fluid drachm. Mix.

Action and Medical Uses.—This is a very efficient application in *rheumatic*, *pleuritic*, *neuralgic*, and other *pains*.

LINIMENTUM CANTHARIDIS (N. F.)—CANTHARIDES LINIMENT.

Preparation.—"Cantharides, in No. 60 powder, one hundred and fifty grammes (150 Gm.) [5 oz. av., 127 grs.]; oil of turpentine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Digest the cantharides with one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of oil of turpentine, in a closed vessel, by means of a water-bath, for 3 hours; then strain, and add enough oil of turpentine through the strainer to make the liniment measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Uses.—(See *Cantharis.*)

LINIMENTUM CHLOROFORMI (U. S. P.)—CHLOROFORM LINIMENT.

Preparation.—"Chloroform, three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏]; soap liniment, seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏]; to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them by agitation"—(*U. S. P.*).

The *Linimentum Chloroformi* of the *British Pharmacopœia* (1885) is prepared by combining equal parts of camphor liniment and chloroform.

Action and Medical Uses.—Employed as a local anæsthetic for *neuralgias* and other *superficial pains.*

LINIMENTUM CROTONIS.—CROTON-OIL LINIMENT.

Preparation.—"Take of croton oil, 1 fluid ounce; oil of turpentine, 7 fluid ounces. Mix together with agitation"—(*Dub.*).

Action and Medical Uses.—This acts as a prompt rubefacient, and when used for some time, produces pustulation. From 10 to 30 minims may be placed upon a limited surface, and rubbed in; and when pustulation is required, this should be repeated two or more times every day.

Related Preparation.—The *National Formulary* directs besides Croton-oil liniment, the following:

Linimentum Tiglii Compositum (N. F.), *Compound croton-oil liniment:* "Croton oil, twenty cubic centimeters (20 Cc.) [325 ♏]; oil of sassafras, twenty cubic centimeters (20 Cc.) [325 ♏]; oil of turpentine, twenty cubic centimeters (20 Cc.) [325 ♏]; oil of olive, forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏]. Mix them"—(*Nat. Form.*).

LINIMENTUM IODI.—LINIMENT OF IODINE.

Preparation.—The *National Formulary* directs: "Iodine, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; potassium iodide, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; glycerin, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; water, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix eight hundred cubic centimeters (800 Cc.) [27 fl℥.

25 ♏] of alcohol with the other ingredients, and dissolve the solids by agitation. Then add enough alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—The proportion of the ingredients above given yields a product practically identical with that prescribed by the *British Pharmacopœia*, 1885"—(*Nat. Form.*).

Action and Medical Uses.—The uses of this liniment are those of iodine (see *Iodinum*).

Related Preparation.—Linimentum Ammonii Iodidi (N. F.), *Liniment of ammonium iodide.* "Iodine, four grammes (4 Gm.) [62 grs.]; oil of rosemary, fifteen cubic centimeters (15 Cc.) [243 ♏]; oil of lavender, fifteen cubic centimeters (15 Cc.) [243 ♏]; camphor, thirty grammes (30 Gm.) [463 grs.]; water of ammonia (U. S. P.), one hundred and ten cubic centimeters (110 Cc.) [3 fl℥, 345 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the iodine, the oils, and the camphor, in seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of alcohol, and then add the water of ammonia, and lastly, enough alcohol to make one thousand cubic centimeters [33 fl℥, 391 ♏]. *Note.*—On standing, the liquid will become colorless, and there will, usually, be a slight precipitate, which may be separated by filtration"—(*Nat. Form.*). This liniment is designed for the purpose of using iodine locally in a form that will not stain.

LINIMENTUM NIGRUM.—BLACK LINIMENT.

Preparation.—Take of olive oil, 1½ fluid ounces; sulphuric acid, 1 fluid drachm; mix well together, and then add oil of turpentine, ½ fluid ounce.

Action and Medical Uses.—An active counter-irritant, but does not vesicate. To be rubbed on the part with a piece of lint twice a day until the skin becomes tender and inflamed. It may be used in *indolent swellings of the joints*, *rheumatic pains*, and wherever active counter-irritation is indicated (Brodie).

LINIMENTUM OLEORUM.—LINIMENT OF OILS.

Synonym: *Linimentum olei.*

Preparation.—Take of oils of cedar, cajeput, cloves, and sassafras, of each, 1 fluid ounce. Mix.

Action and Medical Uses.—This forms an efficient application to *rheumatic* and other *painful affections;* it should also be rubbed on affected part, 3 or 4 times daily.

Related Preparation.—Linimentum Olei Compositum, *Compound liniment of oils, Concentrated liniment.* Take of oils of origanum, hemlock, cajeput, and camphor, each, 4 ounces, by weight; capsicum, 2 ounces. Mix the oils and dissolve the camphor in the mixture; then add the capsicum and let it macerate for 14 days, frequently agitating. Then filter. This is a powerful counter-irritant, and may be employed with advantage in *indolent tumors, indurated mammæ, rheumatic and other pains*, and to the spine, in *epilepsy, nervous debility*, etc. (J. King).

LINIMENTUM OPII.—LINIMENT OF OPIUM.

Synonym: *Anodyne liniment.*

Preparation.—Tincture of opium, liniment of soap, each, 2 fluid ounces. Mix—(*Br. Pharm.*, 1885).

Action and Medical Uses.—This is an anodyne and mild rubefacient application in *contusions, sprains, neuralgic and rheumatic pains*, etc.

Related Liniment.—Linimentum Opii Compositum (N. F.), *Compound liniment of opium, Canada liniment.* "Tincture of opium (U. S. P.), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; camphor, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; oil of peppermint, twenty-five cubic centimeters (25 Cc.) [406 ♏]; water of ammonia (U. S. P.), three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl℥, 327 ♏]; oil of turpentine, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the camphor and the oil of peppermint in the alcohol, then add the tincture of opium, water of ammonia, and enough oil of turpentine to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Shake the mixture whenever any of it is to be dispensed. *Note.*—This liniment will separate a short time after it has been mixed. It may be made somewhat more permanent by adding twenty-five cubic centimeters (25 Cc.) [406 ♏] of tincture of quillaja (*U. S. P.*), to the water of ammonia, before adding it to the mixture"—(*Nat. Form.*).

LINIMENTUM PETROLEI COMPOSITUM.—COMPOUND LINIMENT OF PETROLEUM.

Preparation.—Take of American petroleum (sp. gr. 40° to 42° Baumé), 6 fluid ounces; aqua ammoniæ, tincture of opium, each, 1 fluid ounce; camphor 60 grains. Mix.

Action and Medical Uses.—This forms a very useful application in *rheumatism*, *sprains*, *bruises*, *sore throat*, and *painful affections*. A *Camphorated petroleum* for similar purposes may be prepared by dissolving 1 ounce of camphor in 1 pint of American petroleum (40° to 45° Baumé).

LINIMENTUM PLUMBI SUBACETATIS (N. F.)—LINIMENT OF LEAD SUBACETATE.

Preparation.—"Solution of lead subacetate (*U. S. P.*), three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]; cotton seed oil, six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏]. Mix them."

Action and Medical Uses.—This agent was used chiefly as a discutient, and is applicable to *chilblains*, *chapped hands*, *contusions*, *sprains*, and *glandular inflammations*. It is no longer official.

LINIMENTUM POTASSII IODIDI CUM SAPONE.—LINIMENT OF POTASSIUM IODIDE AND SOAP.

Preparation.—Powder 1½ ounces (av.) of potassium iodide in a mortar. Then mix with 10 fluid ounces (Imp.) of distilled water, 1 fluid ounce (Imp.) of glycerin, and into the mixture, contained in a porcelain dish, introduce 2 ounces (av.) of curd soap, cut small, and dissolve over a water-bath. Next pour the liquefied soap upon the potassium iodide in the mortar, and triturate briskly until the mixture becomes cold. After setting it aside for 1 hour, rub well into the creamy mixture 1 fluid drachm of oil of lemon. This accords with the *British Pharmacopœia*, 1885.

Action and Medical Uses.—This liniment is designed to give a topical preparation of iodide of potassium. Probably a concentrated solution of the potassium salt in water alone will be more effectual, being more readily absorbed.

LINIMENTUM SAPONIS (U. S. P.)—SOAP LINIMENT.

SYNONYMS: *Tinctura saponis camphorata* (*U. S. P.*, 1850), *Camphorated tincture of soap; Liquid opodeldoc, Spiritus nervinus camphoratus.*

Preparation.—"Soap, in fine powder, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; camphor, in small pieces, forty-five grammes (45 Gm.) [1 oz. av., 257 grs.]; oil of rosemary, ten cubic centimeters (10 Cc.) [162 ♏]; alcohol, seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Introduce the camphor and the alcohol into a suitable bottle, and shake until the camphor is dissolved. Then add the soap and oil of rosemary, and shake the bottle well for a few minutes. Lastly, add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], and again shake until the liquid becomes clear. Set it aside, in a cool place, for 24 hours, then filter"—(*U. S. P.*).

On account of its greater solubility in alcohol, soap made from soda and olive oil, and not that made from animal fats, should be employed. Castor oil

(Sayre) has been recommended, as has a potassa-soap prepared with rape-seed oil (Barckhausen).

Action and Medical Uses.—This forms a very useful stimulating and anodyne application in *contusions, sprains, rheumatic and other painful affections.*

LINIMENTUM SAPONIS CAMPHORATUM.—CAMPHORATED SOAP LINIMENT.

SYNONYM: *Opodeldoc.*

Preparation.—Take of common white soap, 2 ounces; camphor, 1 ounce; oil of rosemary, 3 drachms; oil of origanum, 2 drachms; aqua ammoniæ (*U. S. P.*), 1 ounce; alcohol, 1½ pints. Place the soap in the alcohol and digest on a sand-bath; when the soap is dissolved, add the ammonia, oils, and camphor; agitate until they are dissolved, and immediately pour into wide-mouthed vials. When cold, this liniment becomes of a semi-solid consistence.

This liniment assumes an appearance of solidity, which is owing to its formation with a soap made with animal oil, instead of one with vegetable or olive oil. It is yellowish-white, translucent, and becomes fluid at the temperature of the body. Before cooling it is usually placed in 2 or 4-ounce vials with wide mouths, and is known by the name of *Opodeldoc*. The *Opodeldoc* of the *U. S. P.* (1850) was prepared by digesting, on a sand-bath, common soap (sliced), 3 ounces, in alcohol, 1 pint. When dissolved, add camphor, 1 ounce; oils of rosemary and origanum, each, 1 fluid drachm. Pour into wide-mouthed bottles. There are other formulas for opodeldoc. The *National Formulary* directs:

LINIMENTUM SAPONATO-CAMPHORATUM (N. F.), *Camphorated soap liniment, Opodeldoc, Solid opodeldoc:* "White castile soap, dried and powdered, seventy-five grammes (75 Gm.) [2 ozs. av., 284 grs.]; camphor, twenty-five grammes (25 Gm. [386 grs.]; alcohol, nine hundred and fifty cubic centimeters (950 Cc.) [32 fl℥, 59 ♏]; oil of thyme, three cubic centimeters (3 Cc.) [49 ♏]; oil of rosemary, six cubic centimeters (6 Cc.) [97 ♏]; stronger water of ammonia (*U. S. P.*), fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]. Introduce the castile soap, camphor, and alcohol, into a flask or suitable bottle, and apply a gentle heat until solution is effected, taking care that no loss of alcohol be incurred by evaporation. Filter the liquid, while hot, into another flask or bottle; warm again, if necessary, to render the contents liquid, add the oils and stronger water of ammonia, and when the whole has been thoroughly mixed, pour it into small dry vials, which should have been previously warmed, and should immediately be corked and cooled. *Note.*—The quantity above given is usually divided into from 18 to 20 vials. Solid opodeldoc is directed by the *German Pharmacopœia* to be prepared with soap made from animal fats; but pure, white castile soap may be used, provided it has been previously deprived of water. The stronger water of ammonia should be of the full strength prescribed by the *U. S. P.*"—(*Nat. Form.*).

Action and Medical Uses.—Camphorated soap liniment is an excellent anodyne embrocation in all *local pains, rheumatism, contusions, sprains, sore throat*, etc.

LINIMENTUM SAPONIS MOLLIS (U. S. P.)—LINIMENT OF SOFT SOAP.

SYNONYM: *Tinctura saponis viridis* (*Pharm.*, 1880).

Preparation.—"Soft soap, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; oil of lavender flowers, twenty cubic centimeters (20 Cc.) [325 ♏]; alcohol, three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the oil of lavender with the alcohol, dissolve in this the soft soap by stirring or agitation, and set the solution aside for 24 hours. Then filter it through paper, and pass enough water through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—This is *Hebra's tincture of green soap*, so-called. It is used in *cutaneous disorders*, especially in *eczema, prurigo, lichen*, and *psoriasis*.

LINIMENTUM SINAPIS COMPOSITUM (U. S. P.)—COMPOUND LINIMENT OF MUSTARD.

Preparation.—"Volatile oil of mustard, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; fluid extract of mezereum, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; camphor, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; castor oil, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; alcohol, a sufficient quantity to made one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the camphor in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol, and add the fluid extract of mezereum; then add the oil of mustard and the castor oil, and finally, enough alcohol to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Action and Medical Uses.—This is powerfully counter-irritant, and may be employed as a revulsive. Care should be exercised in its use, however, as the sores produced by both mustard and mezereum are sometimes productive of great harm, and are difficult to heal.

LINIMENTUM STILLINGIÆ COMPOSITUM.—COMPOUND LINIMENT OF STILLINGIA.

SYNONYMS: *Stillingia liniment, Compound tincture of stillingia.*

Preparation.—Take of oil of stillingia, 1 fluid ounce; oil of lobelia, oil of cajeput, of each, ½ fluid ounce; alcohol and glycerin, of each, 2 fluid ounces. Mix in the order named. This formula is that revised by Prof. W. E. Bloyer, and is far preferable to the formula given below. Prepared in this manner, the component parts of the liniment do not separate as readily as in the old preparation, the formula for which is as follows: Take of oil of stillingia, 1 fluid ounce; oil of cajeput, ½ fluid ounce; oil of lobelia, 2 fluid drachms; alcohol, 2 fluid ounces. Mix together.

Stillingia liniment is prone to precipitate, and often thickens to a magma or jelly. It should be well shaken before being used. If it has solidified, it should be replaced by a fresh supply.

Action and Medical Uses.—This forms a peculiar kind of liniment, possessing stimulant and relaxant properties. It is used in *chronic asthma, croup, epilepsy, chorea*, etc. In *asthma* and *croup*, the throat, chest, and neck are to be bathed with it 3 or 4 times a day. With Prof. Scudder it was regarded as of great value externally in *croup*, and given internally it forms a good remedy for *irritative* and *chronic coughs*. It may be given on sugar, discs, or in syrup. In *chorea, epilepsy*, and *spasmodic diseases*, the whole vertebral column is to be bathed with it. In *rheumatism, sprains*, and *painful affections*, the diseased parts are to be bathed with it. In asthma its action is very prompt and effectual, relieving and ultimately curing some very obstinate cases. In the majority of instances, when applied to the chest, neck, etc., the patient experiences a peculiar taste in the mouth, somewhat resembling that of the lobelia and stillingia combined. It is often used of less strength, as—Take of oil of stillingia, ½ fluid ounce; oil of cajeput, ½ fluid ounce; oil of lobelia, 1 fluid drachm; alcohol, 3 fluid ounces. Mix. It is an agent peculiar to Eclectic practice, and is very active and efficient (R. S. Newton). The dose of stillingia liniment is from 1 to 5 drops.

LINIMENTUM SUCCINI COMPOSITUM.—COMPOUND LINIMENT OF OIL OF AMBER.

Preparation.—Take of oil of stillingia, rectified oil of amber, each, 1 fluid ounce; oil of lobelia, 3 fluid drachms; olive oil, 2 fluid ounces. Mix.

Action and Medical Uses.—I have found this preparation very efficient in *chronic asthma, croup, pertussis, chorea, epilepsy, rheumatism, sciatica*, and various other *spasmodic and painful affections;* in many instances being much superior to the compound liniment of stillingia. Its manner of application is the same as recommended for the preceding liniment. In very severe cases, it may be applied every hour, or half-hour, and continued until vomiting ensues. It acts as a stimulant, relaxant, and antispasmodic. In many of the above diseases it will effect a cure without the exhibition of any internal medicine, and is especially useful among children to whom it is difficult to administer remedies by mouth, or in cases where the stomach rejects all medicines. Care must be taken not to use too much of this liniment at any one application. Owing to the presence of stillingia in this preparation, the liniment is prone to precipitation (see remarks concerning *Compound Stillingia Liniment*) (J. King).

LINIMENTUM TEREBINTHINÆ (U. S. P.)—TURPENTINE LINIMENT.

Preparation.—"Resin cerate, six hundred and fifty grammes (650 Gm.) [1 lb. av., 6 ozs., 406 grs.]; oil of turpentine, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the resin cerate in a capsule, on a water-bath, then add the oil of turpentine, and mix them thoroughly"—(*U. S. P*).

This is *Kentish liniment.* In its preparation a low heat should be employed to melt the cerate, after which the oil may be added gradually with constant stirring.

Action and Medical Uses.—This was at one time highly praised as an application to *burns* and *scalds.* It should be applied as soon as possible after the accident, and be allowed to remain on for at least a day. It should be applied on lint, care being taken to keep it from contact with the sound tissues. After healthy granulations set in, it should be discontinued. It may be employed in *erythematous* and *erysipelatous conditions*, when superficial or arising from injury, and in *frost-bites.*

LINIMENTUM TEREBINTHINÆ COMPOSITUM.—COMPOUND LINIMENT OF TURPENTINE.

SYNONYM: *White liniment.*

Preparation.—Take of rose-water, 2½ fluid ounces; yolk of egg, 1; oil of turpentine, 3 fluid ounces; oil of lemon, ½ fluid drachm; pyroligneous acid (or in its absence acetic acid), 1 fluid ounce. To the yolk slowly add the rose-water, and rub together in a mortar, then add the turpentine and oil of lemon. Pour the mixture into a pint bottle, and agitate to mix thoroughly; then add the acid, and agitate quickly and briskly. It must be kept well corked.

Action and Medical Uses.—Used in *asthma* and *inflammation of the lungs*, rubbing it on the throat and chest with a sponge or cloth, from the epiglottic region to the epigastric; also useful whenever a counter-irritant is required.

Related Preparation.—The *National Formulary* gives the following formula and name: LINIMENTUM TEREBINTHINÆ ACETICUM (N. F.), *Acetic turpentine liniment, Linimentum album, Stokes' liniment, St. John Long's liniment.*—"Oil of turpentine, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; fresh egg, albumen and yolk, one (1); oil of lemon, four cubic centimeters (4 Cc.) [65 ♏]; acetic acid (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; rose-water (*U. S. P.*), eighty-five cubic centimeters (85 Cc.) [2 fl℥, 420 ♏]. Triturate or beat the contents of the fresh egg with the oil of turpentine and the oil of lemon in a mortar until they are thoroughly mixed. Then incorporate the acetic acid and rose-water. Shake the mixture, whenever any of it is to be dispensed"—(*Nat. Form.*).

As this last preparation bears the same name as the *Br. Pharm. Linimentum Terebinthinæ Aceticum* (glacial acetic acid, 1 fluid part; liniment of camphor and oil of turpentine, each, 4 fluid parts; mix), the two should not be confounded with each other. Acetic turpentine liniment is rubefacient and vesicatory. It may be applied to relieve *localized pains* or *inflammatory swellings*, and has been found useful in *neuralgia* and *muscular rheumatism*, and is a counter-irritant in *gastric inflammations* to allay irritation and vomiting.

LINTEUM.—LINT.

SYNONYMS: *Linteum carptum, Charpie* (of the French).

Source, Preparation, and Description.—Originally, lint was prepared by scraping with a knife bleached linen, such as towels, shirts, table cloths, sheets, etc., until soft and fleecy. As thus prepared, it was designated hand-made lint, to distinguish it from that afterward made by mechanical appliances, and known as machine-made lint. It is now, however, made almost wholly by machinery from a cloth especially prepared, and is known as *patent lint.* When prepared from cotton, as is often the case, it is called cotton lint. The latter, however, is not so useful as linen lint, for, upon becoming wet, it quickly loses its elasticity, and, unless the oil has been well removed, it fails to properly absorb fluids. Besides, the fibers of the linen are much softer and do not irritate like cotton. Good lint should be soft, flocculent, and unirritating, yet firm enough to be torn in any one direction, and also be capable of taking upon its surfaces, cerates, etc., should be sufficiently loose to absorb discharges, and should be compact enough to leave no detached portions in the wound to which it is applied. Patent lint comes in soft, fleecy sheets of considerable thickness. Microscopically, the linen lint presents its fibers as long, almost straight, cylindrical tubes, with a small, central cavity; cotton fibers are flattened, often twisted, and have a wide, central canal (see also article on *Lint*, in *Amer. Jour. Pharm.*, 1861, p. 359).

Tests.—Aside from microscopical differences exhibited by cotton and linen fibers, they also present some differences in their behavior toward chemical reagents. Linen fiber, dipped first in *rosolic acid* (*aurin*, *yellow corallin*) solution, and afterward in strong sodium carbonate solution, becomes rose-red; while cotton, under like treatment, remains colorless. Tincture of madder colors linen orange-red. cotton pale-yellow. Linen fiber becomes translucent when rubbed with a fixed oil, while cotton remains an opaque white. Cotton fiber is destroyed and dissolved in less than two minutes by cold sulphuric acid (concentrated), while linen is not appreciably altered in the same time. Linen is turned bright-yellow by boiling caustic potash solution, while cotton is either not altered or becomes but faintly yellow. This test must be quickly applied, as the color fades rapidly.

Surgical Uses.—Lint is used as a surgical dressing to protect *injured parts*, absorb discharges, to prevent too great pressure from surgical appliances and bandages, etc. It should be soft and unirritating. Cotton lint quickly loses its elasticity when wet, and is, therefore, not so useful as charpie and linen lint.

Related Substances.—SPANISH MOSS, PEAT MOSS, and WOOL WOOD, or WOOL CLOTH, a spongy tissue composed of wood fibre, have been applied like lint.

OAKUM is a substance introduced, in 1862, by Dr. L. A. Sayre, of the United States Navy. It is composed of the hempen fibers of old rope impregnated with tar. It is often preferred for wounds discharging pus. Tow has been similarly used. (See Dr. Ruschenberger, in *Amer. Jour. Pharm.*, 1863, p. 161, for comparative tests of the absorbing power of equal weights of cotton, oakum, tow, coarse-scraped and patent lint. Oakum absorbed only one-fourth, but patent lint seven and a half times its weight of water.)

CHARPIE.—Strictly speaking, *charpie*, as used by the French surgeons, consisted of bundles (4 or 5 inches in length) of straight, unravelled threads of linen, but the name has also become synonymous with scraped lint.

LINUM (U. S. P.)—LINSEED.

"The seed of *Linum usitatissimum*, Linné"—(*U. S. P.*).

Nat. Ord.—Lineæ.

COMMON NAMES: *Flaxseed*, *Linseed* (*Lini semina*, *Br. Pharm.*, 1885).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 39.

Botanical Source.—Flax is an annual plant, very smooth, with a slender fibrous root, and 1 or more straight, round, leafy corymbose stems, 1 or 2 feet in height. The leaves are small, alternate, sessile, acute, 3-veined, and rather glaucous; the lowermost short and blunt. The flowers are several, large, blue, erect, borne in a terminal, corymbose panicle, on long footstalks. The calyx is persistent, consists of 5 ovate, acute sepals, which are 3-veined at base, and membranaceous on the margin, The corolla is composed of 5 thin, delicate, roundish, wedge-shaped, crenate petals, which are glossy, have numerous veins, and readily drop off. Stamens 5, straight, and awl-shaped. Anthers 2-celled, and arrow-shaped. Ovary ovate, superior; styles 5; stigmas obtuse. The fruit is a round capsule, 5-celled, the cells nearly divided by a false dissepiment; seeds 2 in each cell, ovate, compressed, brown, smooth, and glossy (L.—W.—Torrey and Gray).

History.—The native country of flax is unknown, though supposed to be derived from Egypt, or from Central Asia. It has been known from remote antiquity (see *Gen.* xli, 42, and *Exod.* ix, 31). It is now naturalized in nearly all civilized countries. It blossoms from May to August, and matures its seeds early in autumn. The seeds and their expressed oil are used in medicine. The seeds are described by the *U. S. P.* as follows:

"About 4 or 5 Mm. ($\frac{1}{6}$ to $\frac{1}{5}$ inch) long, oblong-ovate, flattened, obliquely pointed at one end, brown, glossy, covered with a transparent, mucilaginous epithelium, which swells considerably in water; the embryo whitish or pale greenish, with 2 large, oily, plano-convex cotyledons, and a thin perisperm; inodorous; taste mucilaginous, oily, and bitter. *Ground linseed* (linseed meal, or flaxseed meal), for medicinal purposes, should be recently prepared, free from unpleasant or rancid odor. When extracted with carbon disulphide, it should yield not less than 25 per cent of fixed oil. The filtered infusion of ground linseed, prepared with boiling water and allowed to cool, has an insipid, mucilaginous taste, and should not be colored blue by iodine T.S. (absence of starch)"—(*U. S. P.*). In this connection see paper by J. U. Lloyd, on the testing of flaxseed for starch, in the *Pharm. Rundschau*, 1895, p. 210.

Oil-cake (*cake-meal*, when ground) is the compressed refuse portion remaining after the oil has been pressed out; it contains the mucilage of the husk and all of the nitrogenous matter of the seed in condensed form (about 5 per cent nitrogen), and is therefore used to feed cattle. Starch should be absent from the cake, and the ash should not exceed 5 per cent. The seeds finely ground, furnish a dark, ash-colored powder, *flaxseed meal*, which forms with hot water a tenacious substance, used for luting in chemical operations. For poultices, the official (*Ground linseed*, *Farina lini*, or *Linseed meal*) is the best.

Chemical Composition.—The chief constituents of flax seeds are *mucilage* (about 6 per cent), residing in the epithelial cells of the epidermis, and *fixed oil* (see *Oleum Lini*, linseed oil), contained in the cotyledons (from 25 to 33 per cent; as high as 38 per cent, W. A. Puckner, *Amer. Jour. Pharm.*, 1889, p. 442). Starch is absent in ripe seeds. (An adulteration of linseed meal with 40 per cent of corn meal is on record; see G. M. Beringer, *Amer. Jour. Pharm.*, 1889, p. 167.) The mucilage probably has its origin in the starch occurring in the unripe seeds. When the unbruised seeds are covered with water, a viscid, odorless, and almost tasteless mucilage is obtained, precipitable by alcohol. When deprived of its ash (amounting to 10 per cent), the composition of the mucilage corresponds to the formula $C_{12}H_{20}O_{10}$ (Tollens & Kirchner, 1874). It is precipitated also by basic acetate of lead, but not by tannic acid. It is not colored blue by the addition of iodine and sulphuric acid, nor does it redden litmus when in fresh condition. Boiling with diluted sulphuric acid produces mostly a dextro-rotatory sugar, and about 5 per cent of insoluble cellulose. Nitric acid converts it partly into *mucic acid*, oxalic acid being likewise formed.

Flax seeds contain about 4 per cent of nitrogen, corresponding to about 25 per cent of *protein bodies*. Part of the nitrogen is due, however, to the presence of a crystallizable, bitter substance formerly believed to be *amygdalin*, but differentiated from it as *linamarin* (Jorissen and Hairs, see *Jahresb. der Pharm.*, 1891, p. 114). The presence of this substance gives rise to the frequently observed formation of *hydrocyanic acid* in ground flaxseed meal by spontaneous fermentation (see A. Jorissen, *Jahresb. der Pharm.*, 1883 and 1894; and W. O. Senior, *Pharm. Jour. Trans.*, 1885, Vol. XVI, p. 514). The seeds contain on an average 3.6 per cent of ash, which is rich in phosphoric acid (*Amer. Jour. Pharm.*, 1881, p. 552). (As regards the manufacture and composition of linseed cake and meal, as well as enumeration of the possible impurities by weeds, etc., consult interesting article in *Amer. Jour. Pharm.*, 1893, p. 195.)

Action, Medical Uses, and Dosage.—Flaxseed is used as a demulcent and emollient. An infusion of the entire seeds, an ounce to a quart of water at 100° C. (212° F.), forms a mucilaginous draught which is much employed in *ardor urinæ* and *urinary diseases*, *nephritic pains*, *coughs*, *colds*, *colo-rectitis*, *pulmonary*, *gastro-enteric*, and *urinary inflammations*. When not contraindicated, the addition of lemon juice improves the flavor, or it may be sweetened with loaf sugar or honey. An infusion of flaxseed, or of flaxseed meal, forms an excellent laxative injection;

and the meal added to boiling water, and made of the proper consistence, makes an excellent cataplasm (see *Cataplasma Lini*). Dose of the infusion, 1 or 2 pints daily. Linseed oil in doses of 2 fluid ounces twice a day, is said to have cured severe cases of *piles* within 2 or 3 weeks; while using it liquors and stimulating diet are to be avoided. It is likewise reputed beneficial when internally administered in *dysentery*, *colic*, and *lumbricus*. Used as an enema it is advantageous in *dysentery*, *hemorrhoids*, and *ascarides;* and combined with lime-water, it forms Carron oil, an excellent application to *burns*. One pint of linseed oil, combined with ½ ounce each, of oils of origanum and wintergreen, forms a pleasant cathartic; to be given in the same doses as castor oil.

Related Species.—*Linum catharticum, Purging flax.* This is a European annual bearing very small white flowers, and having a very bitter subacrid taste. Water extracts its virtues, the infusion being yellow. The active cathartic principle is *linin*, which occurs in neutral, white, silky, and lustrous crystals. It is most abundant in the plant just after the flowers have fallen. Its alcoholic solution is persistently and strongly bitter. For further details, see Husemann and Hilger, *Pflanzenstoffe*, 1884, p. 829.) Purging flax has the reputation on the continent of being mildly purgative, and has been employed in *hepatic, catarrhal,* and *rheumatic disorders.* The dose of the powdered plant is 1 drachm; of the extract, 4 to 8 grains. Diuretic properties are also ascribed to it.

LIQUIDAMBAR.—SWEET-GUM.

The balsamic exudate, or concrete juice of *Liquidambar styraciflua*, Linne.
Nat. Ord.—Hamamelaceæ.

Common Names: (Tree) *Sweet-gum tree, Bilsted, Copalm;* (Gum) *Sweet-gum, Gum wax.*

Botanical Source.—The sweet-gum tree attains the height of 50 to 60 feet, with a diameter of 3 to 5 feet. It is covered with a gray, deeply furrowed bark, with corky ridges on the branchlets. The leaves are palmate, deeply 5 to 7-lobed, rounded, smooth, shining, of a rich green color; the lobes finely glandular, serrate, and acuminate; the veins villous at their bases. When bruised the leaves, which are fragrant, turn crimson or deep-red in autumn. The sterile flowers are in a conical cluster of several globular heads, naked or achlamydeous; the aments monœcious, roundish, and surrounded with a 4-leaved involucre; the stamens numerous and intermixed with minute scales; the filaments short, and the anthers numerous, oblong, and subsessile. The fertile flowers consist of 2-celled ovaries, subtended by minute scales, all more or less cohering and hardening in fruit, forming a spherical catkin or head. The catkins are racemed, nodding, inclosed in the bud by a 4-leaved, deciduous involucre. Styles 2, long. Fruit a kind of strobile, composed of the indurated scales and capsules. Capsules or pods 2-beaked, 2-celled, opening between the two awl-shaped, or prickly diverging styles. Seeds small, several, amphitropous, with sparing albumen, and a straight embryo; cotyledons foliaceous (G.—W.).

Fig. 161.

Liquidambar styraciflua.

History and Description.—This is a large and beautiful tree, with fine-grained wood, growing throughout the United States in moist woods from Connecticut and New Jersey, southward; but found in greater abundance in the southern and middle states, as well as in Guatemala and Mexico. In warm climates, a whitish-yellow, somewhat limpid juice exudes from the incisions made into the tree, especially during the warm seasons; it has the density of thick syrup, but by standing it forms a soft, resinous-like, adhesive mass, somewhat like white turpentine, but opaque and almost black. Or, it may become hard, breaking with a resinous fracture. It is known as *Sweet-gum, Gum wax*, or *Liquidambar* (*Liquidum Liquidambar Styraciflua*); it has a pleasant, benzoinic odor, and a benzoinic, somewhat bitter, and pungent taste. It is soluble in alcohol, chloroform, ether, oil, lard, or fats, softens in warm weather, and becomes harder in cold. Its tincture slightly reddens litmus paper.

Chemical Composition.—Liquidambar is closely allied in its composition to *storax*, an exudation of the bark of *Liquidambar orientalis*. Miller (see *Styrax*).

William L. Harrison (*Amer. Jour. Pharm.*, 1874, p. 161), from a semiliquid specimen collected in Virginia, obtained by distillation with an aqueous solution of sodium carbonate 1.5 per cent of volatile *styrol*, a hydrocarbon of a peculiar aromatic odor. The yield is stated to have been as high as 7 per cent (Bonastre). When extracting sweet-gum with petroleum benzin, a mixture of *cinnamic acid* ($C_6H_5CH{:}CH.COOH$) and *styracin* (*cinnamyl-cinnamate*, [$C_6H_5CH{:}CH.COO.C_9H_9$], discovered by Bonastre, 1827), results, from which diluted ammonia extracts all of the cinnamic acid which may be precipitated by means of diluted acids (see Prof. Maisch, *Amer. Jour. Pharm.*, 1874, p. 166). The total yield of cinnamic acid was 5½ per cent. No benzoic acid could be detected.

W. von Miller (*Archiv der Pharm.*, 1882, p. 648), obtained by the distillation with steam of a rather firm specimen of the resin *styrol* contaminated with an oxygenated oil; in the residue was found *cinnamic acid*, melting at 133° C. (271.4° F.), but no benzoic acid; *styracin*, in beautiful crystals, melting at 44° C. (112° F.) and a thick, yellow oil, consisting chiefly of *phenyl-propyl-cinnamate* ($C_6H_5.CH{:}CH.COO.CH_2CH_2CH_2C_6H_5$). The ethyl- and benzyl-esters of cinnamic acid were found to be absent. *Storesin*, a peculiar, complex alcohol occurring in storax free and as cinnamate, in large quantity (von Miller, 1877), is also present in liquidambar. The *leaves* of Liquidambar styraciflua contain tannin and small quantities of a volatile oil. Sweet-gum contains nearly 10 per cent of impurities, such as portions of the bark, etc.

Action, Medical Uses, and Dosage.—Sweet-gum probably has virtues similar to the concrete juice of *Styrax officinale*, which see. It makes an excellent and agreeable ointment when melted with equal parts of lard or tallow, which I have found decidedly useful in *hemorrhoids*, *psora*, *ringworm of the scalp*, *porrigo scutulata*, and many other *cutaneous affections;* also in that *indolent species of ulcer*, known as "*fever sores on the legs*." In *anal fistula*, it maintains an increased discharge, softens the callosity of the walls of the sinus, and produces a normal result, and effects this without pain to the patient. If necessary, in *fistula*, a little creosote, or other stimulant may be added to it. This employment of sweet-gum is not generally known, and physicians would do well to avail themselves of its use in the above diseases. It is also used in *chronic catarrh*, *coughs*, and *pulmonary affections*. The dose internally is from 10 to 20 grains (J. King).

LIQUORES.—SOLUTIONS.

Under the term *liquor*, or *solution*, the *U. S. P.* includes all aqueous solutions of substances wholly soluble in that menstruum, and not containing sugar, volatile oils, or gases. This excludes such aqueous preparations as infusions, decoctions, medicated waters and syrups.

LIQUOR ACIDI ARSENOSI (U. S. P.)—SOLUTION OF ARSENOUS ACID.

SYNONYMS: *Liquor arsenici chloridi* (*U. S. P.*, 1870), *Liquor arsenici hydrochloricus* (*Br. Pharm.*, 1885), *Solution of arsenic chloride*, *Hydrochloric solution of arsenic*.

Preparation.—"Arsenous acid, ten grammes (10 Gm.) [154 grs.]; diluted hydrochloric acid, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the diluted hydrochloric acid with two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of distilled water, add the arsenous acid, and boil the mixture until all the arsenous acid is dissolved. Filter the solution and pass enough distilled water through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

This contains the two acids (arsenous and hydrochloric) uncombined, the latter acid simply aiding in dissolving the former. The name, solution of arsenic chloride is, therefore, erroneous and misleading. The strength of the *U. S. P.* solution is 1 per cent (4.56 grains to fluid ounce; density, 1.009).

Description and Tests.—"A clear, colorless liquid, odorless, having an acidulous taste and an acid reaction. If 24.7 Cc. of solution of arsenous acid be boiled for a few minutes with 2 Gm. of sodium bicarbonate, the liquid cooled, diluted with water to 100 Cc., and mixed with a little starch T.S., it should require from 49.4 to 50 Cc. of decinormal iodine V.S. to produce the blue tint of iodide of starch (corresponding to 1 Gm. of arsenous acid in 100 Cc. of the solution "—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This agent is used for the same purposes as Fowler's solution of arsenic. The dose is from ⅛ to 3 minims, well diluted, after food.

Related Preparations.—De Valangin's Solution. "*Liquor arsenici chloridi*," *Solution of chloride of arsenic*, or *De Valangin's solutio solventis mineralis*. To distilled water, 1 fluid ounce, add hydrochloric acid, 1½ fluid drachms, and arsenous acid, in small pieces, ½ drachm. Boil until the arsenic is dissolved, then add distilled water, a sufficient quantity to make the whole measure 1 pint. The dose is from ⅛ to 3 drops, 3 times a day, beginning with the smallest dose and gradually increasing.

Liquor Potassii Arsenatis et Bromidi (N. F.), *Solution of potassium arsenate and bromide, Liquor arsenii bromidi, Solution of bromide of arsenic, Clemens' solution.*—"Arsenous acid, ten grammes (10 Gm.) [154 grs.]; potassium bicarbonate, ten grammes (10 Gm.) [154 grs.]; bromine, fifteen and one-half grammes (15½ Gm.) [239 grs.]: water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Boil the arsenous acid with the potassium bicarbonate and one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏] of water, until solution is effected. Allow this to cool, add six hundred and twenty-five cubic centimeters (625 Cc.) [21 fl℥, 64 ♏] of water, then the bromine, and afterward enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Let the mixture stand a few hours, agitating it occasionally, then filter. This solution contains an amount of arsenic in combination, corresponding to 1 per cent of arsenous acid. *Note.*—The title, "Solution of Bromide of Arsenic" (*Liquor Arsenii Bromidi*), which is often applied to Clemens' solution or similar preparations, is a misnomer, since arsenic bromide can not exist, as such, in presence of water, but is split up into hydrobromic and arsenous acids. The proportions of the ingredients, in the formula above given, have been adjusted, as closely as practicable, so as to yield definite compounds, viz.: arsenate and bromide of potassium. In order to prevent injury to the balances by weighing a definite amount of bromine, the plan suggested in the note to No. 213 may be applied to this preparation, viz.: To prepare such a quantity of the latter at one time as will be commensurate to the actual contents of an original vial of bromine"—(*Nat. Form.*).

A somewhat similar, but modified, Clemens' solution is the following:

Liquor Arsenici Bromidi.—Mix powdered arsenous acid (1 part) with potassium carbonate (1 part) and dissolve them in boiling water (10 parts). Add water (80 parts) and bromine (2 parts). Set aside in moderate atmosphere until the liquid is decolorized, and, lastly, add enough water to bring the solution to 100 parts by weight. This solution is probably one of potassium bromide and potassium arsenate. It improves on keeping. Pure ingredients must be used in making it.

Liquor Auri et Arsenii Bromidi (N. F.), *Solution of bromide of gold and arsenic.*—"Arsenous acid, two and one-half grammes (2½ Gm.) [39 grs.]; tribromide of gold, three and one-fourth grammes (3¼ Gm.) [50 grs.]; bromine water, distilled water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Introduce the arsenous acid and about one hundred and thirty-five cubic centimeters (135 Cc.) [4 fl℥, 271 ♏] of bromine water into a flask and heat gently until all free bromine has disappeared. Then add bromine water, twenty (20) to thirty (30) drops at a time, until it will be present in slight excess, or until the solution does not become colorless after some time. Transfer the solution to a porcelain capsule, expel the excess of bromine with the aid of gentle heat, dilute it with water to about nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏], and dissolve in this the tribromide of gold, adding enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Ten (10) minims of this solution contains $\frac{1}{32}$ grain of tribromide of gold and the equivalent of $\frac{1}{16}$ grain of tribromide of arsenic. *Note.*—Bromine water is made by shaking bromine with about 30 times its weight of water, occasionally during several hours, and decanting the water from the undissolved bromine"—(*Nat. Form.*).

LIQUOR ACIDI CARBOLICI.—SOLUTION OF CARBOLIC ACID.

Preparation.—Take of carbolic acid (commercial), 1 part; oil of lemon, 3 parts; alcohol, 100 parts. Mix.

Action and Medical Uses.—This forms an intimate and permanent solution, which is deprived of the unpleasant odor of the carbolic acid without impairing its properties, by the presence of the lemon oil. It may be used wherever carbolic acid is indicated, and may be more or less diluted as required.

LIQUOR ACIDI CHROMICI.—SOLUTION OF CHROMIC ACID

Preparation.—Dissolve chromic acid, 1 ounce (av.) in distilled water, 3 fluid ounces (Imp.).

Description.—This accords with the *British Pharmacopœia*, and, according to that authority, contains the equivalent of 25 per cent of chromic anhydride (CrO_3); or 29.5 per cent of real chromic acid (H_2CrO_4). It is a caustic and strongly acid, odorless, orange-red liquid.

Action and Medical Uses.—May be used as a caustic, as it is simply an aqueous solution of chromic acid (see *Acidum Chromicum*).

LIQUOR ACIDI PHOSPHORICI COMPOSITUS (N. F.)—COMPOUND SOLUTION OF PHOSPHORIC ACID.

Synonym: *Solution of acid phosphates.*

Preparation.—"Bone ash, in fine powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; sulphuric acid (sp. gr. 1.830), seven hundred and eighty grammes (780 Gm.) [1 lb. av., 11 ozs., 225 grs.]; water, four thousand cubic centimeters (4000 Cc.) [135 fl℥, 122 ♏]. Mix the bone ash with one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏] of water, add the sulphuric acid, diluted with two thousand cubic centimeters (2000 Cc.) [67 fl℥, 362 ♏] of water, and mix thoroughly with a porcelain or glass stirrer. Now add the remainder of the water and set the mixture aside for 24 hours, stirring occasionally. Then transfer the mixture to a strong muslin strainer, and subject this to a gradual pressure (avoiding contact with metals), so as to express as much of the liquid as possible. Lastly, filter this through paper. The specific gravity of this solution is about 1.113 at 15° C. (59° F.). *Note.*—The quantity of the product obtained depends on the degree of force used in pressing. By strong pressure about 3500 parts may be obtained. If desired, the magma may also be poured into a glass percolator, the neck of which contains a layer of fine quartz sand or asbestos, previously deprived of matters soluble in sulphuric or phosphoric acids. On cautiously pouring water on top, so as not to mix it with the magma, the acid solution will be displaced. But the percolation must be interrupted as soon as the specific gravity of the percolate begins to fall below 1.113. The sulphuric acid used in this preparation may be the commercial variety, provided it is free from arsenic, and of a specific gravity not less than 1.830"—(*Nat. Form.*).

Medical Uses.—(See *Acidum Phosphoricum.*)

LIQUOR ALUMINI ACETATIS (N. F.)—SOLUTION OF ALUMINUM ACETATE.

Preparation.—"Aluminum sulphate, crystallized, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; acetic acid (*U. S. P.*), three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; calcium carbonate, one hundred and thirty grammes (130 Gm.) [4 ozs. av., 256 grs.]; water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the calcium carbonate in the acetic acid mixed with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, and the aluminum sulphate in eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]. Mix the two solutions, and allow the mixture to stand for 24 hours, agitating occasionally. Then pour off the clear solution and filter. The solution contains from 7.5 to 8 per cent of basic aluminum acetate. *Note.*—Practically identical with the *Liquor Aluminii Acetici* of the *German Pharm.*"—(*Nat. Form.*).

Uses.—(See *Aluminum Acetate.*)

Related Preparation.—Liquor Alumini Acetico-tartratis (N. F.), *Solution of aluminum acetico-tartrate*: "Alum (*U. S. P.*), seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; sodium carbonate, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; glacial acetic acid (*U. S. P.*), one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; tartaric acid, one hundred and thirty-five grammes (135 Gm.) [4 ozs. av., 333 grs.];

water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the alum and the sodium carbonate each in ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏] of water; mix the solutions and wash the precipitate with water, first by decantation, and afterward on a strainer, until the washings run off tasteless. Allow the precipitate to drain and to shrink in volume by exposure on the strainer. Then transfer it to a tared capsule, add the glacial acetic and the tartaric acids, and apply heat until solution has been effected. Finally, evaporate the liquid to one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. The product contains about 50 per cent of dry, so-called aluminum acetico-tartrate. *Note.*—The dry salt may be obtained by evaporating the solution"—(*Nat. Form.*). This agent is a disinfectant and caustic. Diluted one-half, it has been employed in *affections of the naso-pharynx and fauces.*

LIQUOR AMMONII ACETATIS (U. S. P.)—SOLUTION OF AMMONIUM ACETATE.

"An aqueous solution of ammonium acetate ($NH_4C_2H_3O_2=76.87$), containing about 7 per cent of the salt, together with small amounts of acetic and carbonic acids"—(*U. S. P.*).

SYNONYMS: *Spiritus Mindereri, Spirit of Mindererus, Acetas ammonicus liquidus.*

Preparation.—"Ammonium carbonate, five grammes (5 Gm.) [77 grs.]; diluted acetic acid, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Add the ammonium carbonate (which should be in translucent pieces, free from white, pulverulent bicarbonate), gradually to the cold diluted acetic acid, and stir until it is dissolved. This preparation should be freshly made when wanted"—(*U. S. P.*).

If the above directions be exactly followed a uniform product of definite strength will be obtained, provided a good ammonium carbonate has been employed. Ammonium carbonate which has been kept loose in the drawers of pharmacies will not answer for this purpose, for as a rule, a large share of the active portion (*ammonium carbamate*), has become dissipated, and the bulk of the material left is but ammonium bicarbonate, of no worth so far as the value of the above solution is concerned. The solution should be prepared *only* when needed for immediate use. The *Br. Pharm.* (1885) directs: Strong solution of acetate of ammonium, 4 fluid ounces (Imp.); distilled water, enough to make 20 fluid ounces (Imp.). Keep in bottles free from lead. Density, 1.022.

LIQUOR AMMONII ACETATIS FORTIOR (*Br.*, 1885) is made by gradually adding to acetic acid (45 ounces), crushed ammonium carbonate (17½ ounces). Then add more acetic acid (usually about 5 ounces), until the liquid is neutralized. Lastly, by means of water, bring the product to measure 60 fluid ounces (Imp.). Keep in vessels free from lead (see also *Related Preparations*).

Description.—"A clear, colorless liquid, free from empyreuma, of a mildly saline acidulous taste, and an acid reaction. It is wholly volatilized by heat. When solution of acetate of ammonium is heated with potassium or sodium hydrate, vapor of ammonia is evolved. When heated with sulphuric acid, the solution gives off vapor of acetic acid"—(*U. S. P.*).

Liquor ammonii acetatis is colorless, has a faint smell of acetic acid and ammonia, a feeble saline and somewhat bitter taste, in which that of ammonia is perceptible. This taste of ammonia, which is also perceptible in other salts of this base having a neutral reaction, is caused by the free or feebly combined soda in the saliva combining with the acid and evolving the ammonia. It should not be kept any considerable time, as it undergoes decomposition, and should be made only in small quantities at a time. It is subject to all the impurities named under the heads of acetic acid and carbonate of ammonium. If the solution be colored, this may generally be removed by filtering it through animal charcoal. If quite neutral, neither litmus nor turmeric papers will be affected by it. The tests of its impurities are the same as named in aqua ammoniæ, and carbonate of ammonium. Good liquor ammonii acetatis yields soluble crystals of acetate of silver with nitrate of silver; evolves ammoniacal gas if lime or potassa be added Liquor ammonii acetatis is incompatible with the alkalies, strong acids, corrosive sublimate, nitrate of silver, metallic sulphates, lime-water, alum, chloride of calcium, magnesia, and some of its salts, etc.

Action, Medical Uses, and Dosage.—In small doses this solution is regarded as a refrigerant; in large doses diaphoretic and diuretic. The diuretic influence is more obvious when the patient is kept cool; the diaphoretic, when he is kept warm. It is principally used in *fevers* and *inflammatory affections* when not of a high grade, and is frequently associated with opium, tincture of camphor, nitrate of potassium, etc. Its diuretic influence is more marked when combined with sweet spirit of nitre. It is useful in the *exanthemata* when the circulation is feeble and eruption tardy, overcoming both of these conditions, while in the declining stages, with depression of the nervous system, dry skin, and renal inactivity, it may be given in ½-drachm doses to reestablish the secretions. Spirit of Mindererus may be given where alcohol can not be administered, being a stimulant of a different character, and it is frequently used as a sobering agent for *drunkenness*. This use of it to overcome the effects of alcohol is quite popular in some localities. When a stimulant that will not disturb the brain is required in low forms of *typhoid fever*, this agent may be selected, and often the *sick headache of depression* may be relieved by ½-drachm doses of the solution. *Uterine colic* and *dysmenorrhœa* are sometimes relieved by it, tincture of opium (20 drops), being used with it in the first-named trouble. *Gout*, *rheumatism*, and some forms of *dropsy* and *heart disease* have been benefited by its use. It is an excellent agent in *influenza* and the initial stages of *acute catarrh*. Applied on cloths, moistened with it, it has been found useful in *hydrocele* and *mumps*, and resolves *glandular enlargements* and early stage of *mammitis*. Four parts of the solution added to 28 parts of rose-water and 1 part of tincture of opium, form a very excellent collyrium in some *chronic inflammations of the eye*. Its dose is from ½ fluid drachm to 1 fluid ounce, in some sweetened water, which may be repeated every 3, 4, or 6 hours.

Specific Indications and Uses.—Impaired capillary circulation, with tardy eruption in the exanthemata; alcoholic intoxication; sick headache with depression.

Related Preparations.—The following preparation has been recommended as an elegant and pleasant anodyne, and diaphoretic in *fevers*, worthy the notice of the profession:

LIQUOR AMMONII ACETATIS ET MORPHINÆ: Take of solution of acetate of ammonium, 1 fluid drachm; acetate of morphine, 1 grain; syrup of lemon, enough to make 1 fluid ounce; mix together. The dose is from ½ to 1 fluid drachm, to be taken in water. Each fluid drachm contains ⅛ grain of acetate of morphine (W. S. Merrell).

LIQUOR AMMONII ACETATIS CONCENTRATUS (N. F.), *Concentrated solution of ammonium acetate:* "Acetic acid (*U. S. P.*), five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; ammonium carbonate, water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Neutralize the acetic acid with a sufficient quantity of ammonium carbonate, carefully avoiding an excess. Then add enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—The product is about 3 times the strength of the official *Liquor Ammonii Acetatis*. *Note.*—It is not recommended to keep this solution on hand for the preparation of the official *Liquor Ammonii Acetatis*, as this is preferably made fresh when wanted for use. When it is, however, required or deemed of advantage, to dispense the concentrated solution, it is suggested that it be diluted with carbonic acid water, or be directed to be diluted with this at the time of administration"—(*Nat. Form.*).

LIQUOR AMMONII CITRATIS.—SOLUTION OF CITRATE OF AMMONIUM.

Preparation.—Dilute 5 fluid ounces (Imp.) of strong solution of citrate of ammonium with enough distilled water to make 20 fluid ounces (Imp.). Density, 1.062.

Description.—A clear, colorless fluid, saline to the taste, and should be unaffected by either litmus or turmeric papers. Keep in bottles free from lead.

Action, Medical Uses, and Dosage.—(Same as for *Liquor Ammonii Acetatis*, which see.) Dose, 2 to 6 fluid drachms.

Related Preparation.—LIQUOR AMMONII CITRATIS FORTIOR, *Strong solution of citrate of ammonium:* Neutralize citric acid, 12 ounces (av.) with strong solution of ammonia, 11 fluid ounces (Imp.), or a sufficient amount, and by means of distilled water bring the product to measure 20 fluid ounces (Imp.). Density, 1.209. Dose, 25 to 75 minims. This is used in preparing the solution of citrate of ammonium. Both solutions were official in the *British Pharmacopœia* 1885. (See also *Liquor Ammonii Citratis Fortior*.)

LIQUOR AMMONII CITRATIS FORTIOR (N. F.)—STRONGER SOLUTION OF AMMONIUM CITRATE.

Preparation.—"Citric acid, five hundred and sixty grammes (560 Gm.) [1 lb. av., 3 ozs., 329 grs.]; stronger water of ammonia (*U. S. P.*), water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Neutralize the citric acid with the stronger water of ammonia, and add enough water to make one thousand cubic centimeters (1000 Cc. [33 fl℥. 391 ♏]. The solution should be kept in bottles free from lead. Each fluid drachm contains about 40 grains of ammonium citrate. *Note.*—This solution is apt to take up notable quantities of lead if kept in bottles made of flint glass. *Liquor Ammonii Citratis* (*Br. Pharm.*) may be prepared from this solution by mixing 1 volume of it with 4 volumes of water"—(*Nat. Form.*).

Uses.—This preparation is employed in making mixtures of liquids from tannin-yielding drugs and tincture of chloride of iron. It blends them together so as to prevent the inkiness otherwise a factor in such mixtures.

LIQUOR ANTIMONII CHLORIDI.—SOLUTION OF CHLORIDE OF ANTIMONY.

SYNONYMS: *Liquor antimonii terchloridi, Solution of terchloride of antimony, Liquid butter of antimony, Antimony trichloride, Butter of antimony, Butyrum antimonii, Butyrum stibii, Liquor stibii chlorati, Chloridum stibicum, Chloruretum stibicum, Antimonium muriaticum liquidum.*

Preparation.—"Take of purified black antimony, 1 pound; hydrochloric acid, 4 pints. Place the purified black antimony in a porcelain vessel, pour upon it the hydrochloric acid, and, constantly stirring, apply to the mixture, beneath a flue with a good draught, a little heat, which must be gradually augmented as the evolution of gas begins to slacken, until the liquid boils. Maintain it at this temperature for 15 minutes, then remove the vessel from the fire, and filter the liquid through calico into another vessel, returning what passes through first, that a perfectly clear solution may be obtained. Boil this down to the bulk of 2 pints and preserve it in a stoppered bottle"—(*Br. Pharm.*, 1885). Weights, avoidupois; measures, Imperial.

History.—In earlier days butter of antimony was prepared by distilling the evaporated solution of antimony trisulphide in hydrochloric acid. A white, semi-transparent, crystalline mass resulted. The red color of the solution, as prepared by the above official process, is due to the impurities present, chiefly of iron and other metals. If this be distilled a colorless solution of antimony trichloride ($SbCl_3$) will be obtained. In the process above given double decomposition ensues, antimony trichloride is formed, and hydrogen sulphide escapes with effervescence. The operation should be conducted under a hood.

Description.—Butter of antimony is a heavy, yellow-red fluid of about the specific gravity 1.47. When a little of it is dropped into water a white precipitate falls, which is colored orange upon treatment with hydrogen sulphide. After filtering out the white deposit the filtrate gives an abundant precipitate with silver nitrate. "One fluid drachm of it mixed with a solution of ¼ ounce of tartaric acid in 4 fluid ounces of water, forms a clear solution, which, if treated with sulphuretted hydrogen, gives an orange precipitate, weighing, when washed and dried at 212° F. (100° C.) about 22 grains"—(*Br. Pharm.*, 1885). The white powder which falls upon the addition of water is the *powder of Algaroth*, or antimonous oxychloride ($2SbCl_3.5Sb_2O_3$). The antimonium chloride of the *French Codex* is the soft, crystalline mass above referred to. It fumes in the air and is very deliquescent. It is a powerful caustic. The impurities are likely to be iron, lead, copper, and arsenic. Copper will strike blue with an excess of ammonia; lead crystallizes out from the cold liquid; that remaining may be detected with sulphuric acid.

Action, Medical Uses, and Dosage.—This article is used only as a caustic to *fungous growths, poisonous bites of reptiles or animals, malignant pustules, chancres,* etc. Having first carefully removed the blood, which decomposes it, apply the caustic liquid to the *wound* or *tumor* by means of a camel's-hair pencil, or on a dossil of lint. This agent is a poison, a charred surface and symptoms of collapse resulting from its use. The antidotes are tannin solutions, magnesia, and magnesium and calcium carbonates. These should be followed by demulcent drinks. The agent is not used in Eclectic medicine.

LIQUOR ARSENI ET HYDRARGYRI IODIDI (U. S. P.)—SOLUTION OF ARSENIC AND MERCURIC IODIDE.

SYNONYMS: *Donovan's solution, Solutio Donovani, Solution of hydriodate of arsenic and mercury.*

Preparation.—"Arsenic iodide, ten grammes (10 Gm.) [154 grs.]; red mercuric iodide, ten grammes (10 Gm.) [154 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Powder the arsenic iodide, and mix it with the red mercuric iodide by trituration. Add one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of distilled water, and continue the trituration until solution is effected. Filter the solution, and pass enough distilled water through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix thoroughly"—(*U. S. P.*).

Description.—A clear, pale-yellowish liquid, without odor, but having a disagreeable, metallic taste. It is a 1 per cent solution each of arsenic iodide and red mercuric iodide (4.56 grains each to the ounce). It should be kept in the dark, and should free iodine be apparent, as evinced by its odor, or should it become orange or yellow-red, it should not be dispensed. It is not compatible with the soluble compounds of morphine, nor with tincture of opium. Alkalies and silver, and alkaloidal salts produce precipitates with it.

Action, Medical Uses, and Dosage.—Donovan's solution is one of the few preparations containing mercury that have been endorsed by Eclectic teachers. Its use in our school, however, is limited, the indications being those mentioned below. Our use of it is chiefly in *secondary syphilis*. It is said to be useful, in doses of from 10 to 30 drops, 2 or 3 times a day, in *lupus, lepra, diseases of the scalp, psoriasis, impetigo, venereal eruptions*, and other *obstinate cutaneous affections*. This dose, however, is too large, and the quantities employed for its specific uses are small, the usual proportion being from 1 to 10 drops in 4 fluid ounces of water, the dose of which solution is a teaspoonful.

Specific Indications and Uses.—Small, contracted, elongated, and pointed tongue, with prominent papillæ and increased redness.

Related Preparation.—LIQUOR HYDRARGYRI ET POTASSII IODIDI (N. F.), *Solution of iodide of mercury and potassium, Solution of potassium iodohydrargyrate, Channing's solution.* "Red iodide of mercury, ten grammes (10 Gm.) [154 grs.]; potassium iodide, eight grammes (8 Gm.) [123 grs.]; distilled water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the salts in the distilled water"—(*Nat. Form.*).

LIQUOR ATROPINÆ SULPHATIS.—SOLUTION OF SULPHATE OF ATROPINE.

Preparation.—Dissolve 9 grains of sulphate of atropine (1 part) in 16½ fluid drachms of camphor water (99 fluid parts). Contains 1 per cent of atropine sulphate. This accords with the *British Pharmacopœa*, 1885. This solution decomposes after a time, and should be prepared in small amounts only, or as needed. The *British Pharmacopœia* (1898) employs distilled water and salicylic acid, one-ninth the quantity of atropine sulphate.

Action, Medical Uses, and Dosage.—(See *Atropina*.) A drop may be instilled upon the eye for effecting dilatation of the pupil whenever this is desired for ophthalmoscopic examinations, or for operations on this organ. Dose, 1 to 4 minims.

Related Liquor.—LIQUOR ATROPINÆ SALICYLATIS, *Solution of atropine salicylate.* Atropine, 2.7 grains; salicylic acid, 1.3 grains; distilled water, 1 ounce. This solution is said to keep for any length of time (Tichborne).

LIQUOR BISMUTHI ET AMMONII CITRATIS.—SOLUTION OF BISMUTH AND AMMONIUM CITRATE.

SYNONYMS: *Liquor bismuthi, Liquor bismuth, Solution of ammonio-citrate of bismuth.*

Preparation.—Take bismuth oxynitrate and potassium citrate, of each, 613 grains (Imp.) or 70 grammes (metric); potassium carbonate, 175 grains (Imp.) or 20 grammes; nitric acid, 1 fluid ounce (Imp.) or 50 cubic centimeters; solution of ammonia, distilled water, of each a sufficient quantity. "Dissolve the bismuth oxynitrate in the nitric acid, diluted with an equal volume of distilled water; add distilled water with constant stirring until the liquid is very faintly opalescent; add the potassium citrate and carbonate dissolved in a little distilled water; heat the liquid to the boiling point; cool; separate the precipitate; wash it with distilled water until free from nitrates. Gradually add solution of ammonia to the moist precipitate until it is just dissolved; dilute with distilled water to 1 pint (or one thousand cubic centimeters). Filter"—(*Br. Pharm.*, 1898).

This compound originated in a secret preparation termed *Liquor Bismuthi*, prepared by Mr. Schacht, of England. Various formulæ have from time to time been given for the preparation of an identical liquid, one of these being that of Mr. C. H. Wood, in the *Lond. Pharm. Jour.*, March, 1868.

Description.—As prepared by the British process, *Liquor Bismuthi* is a colorless solution having a slightly metallic taste and a density of 1.07. It mixes freely with water, and has a neutral or but feebly alkaline reaction. Heated in the presence of the alkalies ammonia is expelled and a white precipitate falls. If the solution be evaporated and the dry residue be ignited a "charred mass" with a yellow edge is left behind. The bismuth contained in a fluid drachm of the solution is about equivalent to 3 grains or 5 per cent of bismuth oxide. "A mixture of 10 cubic centimeters of the solution with 40 cubic centimeters of water, treated with hydrogen sulphide in excess, yields a black precipitate, which, when washed and dried, should weigh at least 0.55 gramme"—(*Br. Pharm.*, 1898). In case the solution precipitates by reason of the escape of ammonia, a small amount of ammonia added thereto will redissolve it.

Action, Medical Uses, and Dosage.—The salts of bismuth are extensively employed to allay gastro-intestinal irritation. For gastric irritation alone small doses of the subnitrate are efficient, but larger doses are required where the intestinal tract is also involved. Preferable to the impalpable powder—the subnitrate—for *chronic gastro-intestinal irritation* with diarrhœa, Eclectic physicians have used the liquor bismuth or solution of bismuth and ammonium citrate. It is equally valuable in the *diarrhœa of typhoid fever*, and in *dysenteric diarrhœa*. It is especially serviceable in many forms of *diarrhœa* accompanied with pain, and due to irritation of the stomach and bowels from undigested aliment. Watery diarrhœa coming in sudden gushes is frequently best controlled with liquor bismuth. The indications for its selection are given below. Dose, ½ to 1 fluid drachm, 4 times a day.

Specific Indications and Uses.—Long, pointed, red tongue, irritation, uneasy or painful sensations in the stomach, with heat; eructations of acrid or acid material; irritative diarrhœa.

Related Preparation.—LIQUOR BISMUTHI (N. F.), *Solution of bismuth, Liquid bismuth:* "Glycerite of bismuth (F. 185), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; alcohol, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; distilled water, seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏]. Mix the glycerite of bismuth with the distilled water, then add the alcohol.

Solution of bismuth may also be prepared in the following manner: "Bismuth and ammonium citrate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; alcohol, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; water of ammonia (*U. S. P.*), distilled water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the bismuth and ammonium citrate in seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of distilled water and allow the solution to stand a short time. Should any insoluble matter have deposited, pour off the clear liquid and add just enough water of ammonia to the residue to dissolve it, or to cause it to retain a faint odor of ammonia. Then filter the united liquids, add the alcohol, the glycerin, and enough distilled water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This preparation should be freshly made when wanted for use. Each fluid drachm represents 1 grain of bismuth and ammonium citrate" (*Nat. Form.*).

LIQUOR BROMI (N. F.)—SOLUTION OF BROMINE.

SYNONYM: *Smith's solution of bromine.*

Preparation.—"Bromine, twenty-five grammes (25 Gm.) [386 grs.]; potassium bromide, twelve and one-half grammes (12.5 Gm.) [193 grs.]; water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Dissolve the potassium bromide in the water contained in a bottle, add the bromine, and shake the mixture until this is dissolved. Keep the solution in glass-stoppered vials in a dark place. *Note.*—As bromine vapor is very injurious to the respiratory passages and destructive to balances, it is often preferable to take the contents of an original bottle of bromine—weighing the bottle, both before opening it and after emptying it, in order to ascertain the exact weight of the bromine contained therein—and then to use a quantity of potassium bromide and of water proportionate to the quantities above given"—(*Nat. Form.*).

Uses.—(See *Bromine.*)

LIQUOR CALCIS (U. S. P.)—SOLUTION OF LIME.

"A saturated, aqueous solution of calcium hydrate ($Ca[OH]_2=73.83$). The percentage of calcium hydrate varies with the temperature, being somewhat over 0.17 per cent at 15° C. (59° F.), and diminishing as the temperature rises"—(*U. S. P.*).

SYNONYMS: *Aqua calcis, Solution of calcium hydrate, Lime-water, Aqua calcariæ ustæ, Calcaria soluta, Oxydum calcicum aqua solutum.*

Preparation.—"Lime, twelve grammes (12 Gm.) [185 grs.]; distilled water, a sufficient quantity. Slake the lime by the gradual addition of seventy cubic centimeters (70 Cc.) [2 fl℥, 176 ♏] of distilled water, then add three hundred and sixty cubic centimeters (360 Cc.) [12 fl℥, 83 ♏] more of distilled water, and agitate occasionally during ½ hour. Allow the mixture to settle, decant the liquid, and throw it away. Then add to the residue thirty-six hundred cubic centimeters (3600 Cc.) [121 fl℥, 351 ♏] of distilled water, agitate thoroughly, wait a short time for the coarser particles to subside, and pour the liquid, holding the undissolved lime in suspension, into a glass-stoppered bottle. From time to time shake the bottle, so as to keep the solution saturated. Pour off the clear liquid when it is wanted for use"—(*U. S. P.*).

Description and Tests.—Lime from marble should be preferred if it can be obtained. By the action of the water the calcium oxide is converted into calcium hydroxide ($Ca[OH]_2$), and this is dissolved in the water. As lime is more soluble in cold than in hot water, the former should be used in making this preparation. The purpose of throwing away the first washings in the above-given official process, is to get rid of the water-soluble alkali salts frequently contained in ordinary lime. If marble is employed in the preparation of the latter, this precaution is superfluous. The *U. S. P.* describes *Liquor Calcis* as "a clear, colorless liquid, without odor, and having a saline and feebly caustic taste. It absorbs carbon dioxide from the air, so that a pellicle of calcium carbonate forms on the surface of the liquid. On being heated, it becomes turbid from separation of calcium hydrate, which redissolves again when the liquid is cooled. It gives a strongly alkaline reaction with litmus paper"—(*U. S. P.*). Bottles containing it should always have an excess of lime, and be kept well stopped.

It is not a good plan to keep adding water to the excess of lime in the container as the liquor is poured off, as is done by some pharmacists. "The alkaline reaction of the solution should entirely disappear after it has been saturated with carbon dioxide, and subsequently boiled (absence of alkalies and their carbonates). In other respects it should conform to the reactions and tests given under lime (see *Calx*). Fifty cubic centimeters of solution of lime should require, for complete neutralization, about 20 Cc. of decinormal oxalic acid V.S. (corresponding to about 0.14 [0.148] per cent of calcium hydrate), phenolphtalein being used as an indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Lime-water is astringent (topical and internal), and styptic, but not caustic. Taken internally it counteracts acidity, but is probably not all neutralized by the gastric acids, for after passing the stomach it still acts as an astringent in *diarrhœa*. It has been found useful in *pyrosis*, *gastrodynia*, and other *painful gastric symptoms* due to deranged digestion, likewise in *epilepsy*, and other *spasmodic and chronic diseases*, which are accompanied with *acidity of the stomach*. It is specifically indicated in *indigestion* and *dyspepsia* caused by the development of lactic acid from the decomposition of the food. In *scrofula* and *scrofulous skin affections* with deposits in all parts but the lymphatic glands, it is peculiarly effective. In *dyspepsia*, *phthisis*, and other forms of disease. where, from acidity or irritability of the stomach, the usual food is rejected, or if retained gives rise to uneasiness and many unpleasant symptoms, 1 part of lime-water added to 1, 2, or 3 parts of good sweet milk, will be found useful as an antacid, calmative and diet. It frequently cures *thrush*. A tablespoonful of lime-water will often allay troublesome *vomiting*. When in *infantile dyspepsia* with passages of green stools, and the child vomits curdled milk, it is specifically indicated. Lime-water has proved beneficial as an astringent in *chronic diarrhœa* and *dysentery*, and *diabetes*, especially when given in combination with a decoction of white-oak bark. It acts specially upon the subcutaneous cellular tissues, subduing inflammation, is a specific in cases of obstinate and repeated formation of *boils*, and is advantageous in cases where there is an *excess of uric acid*. It relieves irritation of the cellular tissues, checks determination of blood, and promotes absorption of the exudation products of the inflammatory process. It is sometimes used in combination with wormseed oil, or other fluid anthelmintics, for the removal of *worms;* and will be found more especially efficient in cases attended with great acidity. It has been advantageously used as an injection in *gleet*, *gonorrhœa*, *leucorrhœa*, *ulceration*, and increased discharges from the bladder, etc., and in fact is a very simple and useful wash for mucous or purulent profluvia from any of the mucous surfaces.

Externally, it has been employed as a wash in various affections of the skin, as *scabies*, *prurigo*, *lepra*, *psoriasis*, *ringworm of the scalp*, *eczema capitis*, and also in *scrofulous and indolent ulcers*. Mixed with linseed oil, it forms a calcareous soap or liniment, now official and well known as *Carron Oil*, which is very valuable in *scalds* and *burns*, being probably the best immediate application for these accidents. Oil of turpentine is sometimes advantageously added to it. Lime-water has been asserted to dissolve false membranes. Whether this be true or not, the use of a dilution of 1 part of lime-water to 10 or 15 parts of water, used as a spray or gargle, or better still, this proceedure alternated with exposure to the vapor of slaking lime, has contributed as much as any method to what little success has been attained in the treatment of *diphtheria*, *pseudo-membranous croup*, and allied disorders. Lime-water should not be given during the presence of active inflammation; nor should its use be too long continued, as it weakens the stomach and digestive powers. Its dose is from ½ fluid ounce to 4 fluid ounces, and may be taken alone, in milk, or in some aromatic water. An overdose occasions unpleasant symptoms, which are best combated by bland and mucilaginous fluids.

Specific Indications and Uses.—Infantile dyspepsia with green stools and vomiting of curdled milk; successive formation of boils, and other cellular inflammations resulting in suppuration; indigestion from the formation of lactic acid from food decomposition. Locally (*Carron Oil*) in burns and scalds.

LIQUOR CALCIS CHLORINATÆ.—SOLUTION OF CHLORINATED LIME.

Preparation.—"Take of chlorinated lime, 1 pound (av.); distilled water, 1 gallon (Imp.). Mix well the water and the chlorinated lime by trituration in a mortar, and, having poured the mixture into a stoppered bottle, let it be well shaken several times for the space of 3 hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle"—(*Br. Pharm.*, 1885).

Description.—This liquor has the general properties of chlorinated lime. "Specific gravity about 1.055. Eighty grains, by weight, mixed with 20 grains of iodide of potassium, dissolved in 4 fluid ounces of water, when acidulated with 2 fluid drachms of hydrochloric acid, gives a red solution, which requires for the discharge of its color not less than 450 grain-measures of the volumetric solution of hyposulphite of sodium, corresponding to about 2 per cent of available chlorine" (*Br. Pharm.*, 1885).

Action, Medical Uses, and Dosage.—Solution of chlorinated lime is an excellent deodorizer. It has the general uses of chlorinated lime, being particularly employed as a stimulant to the skin in *low febrile states* and *chronic skin eruptions*. The dose is from 20 to 60 minims; for external use, from half to full strength. It antidotes hydrogen and potassium sulphides, hydrocyanic acid, and ammonium sulphydrate.

Related Preparation.—Liquor Calcii Chloridi, *Solution of chloride of calcium*. The *British Pharmacopœia* (1885) directs 88 grains (1 part) of chloride of calcium to be dissolved in 1 fluid ounce (5 fluid parts, Imp.) of distilled water, and filtered, if necessary. Density, 1.145. (For uses, see *Calcii Chloridum*.) Dose, 15 to 50 minims.

LIQUOR CALCIS SULPHURATÆ (N. F.)—SOLUTION OF SULPHURATED LIME.

Synonyms: *Solution of oxysulphuret of calcium*, *Vleminck's solution* (or *lotion*).

Preparation.—"Lime, freshly slaked, one hundred and sixty-five grammes (165 Gm. [5 ozs. av., 359 grs.]; sublimed sulphur, two hundred and fifty grammes (250 Gm. [8 ozs. av., 358 grs.]; water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the slaked lime with the sulphur, and add the mixture gradually to sixteen hundred and fifty grammes (1650 Gm.) [3 lbs. av., 10 ozs., 88 grs.] of boiling water. Then boil the whole, under constant stirring, until it is reduced to one thousand grammes (1000 Gm. [2 lbs. av., 3 ozs., 120 grs.]; strain, and, having allowed the solution to become clear by standing in a well-stoppered bottle, decant the clear, brown liquid, and keep it in completely filled and well-stoppered bottles"—(*Nat. Form.*).

Action and Medical Uses.—This solution is very efficient as a local application in *itch*, *tinea capitis*, *pityriasis*, and other *parasitic cutaneous affections*. In itch, the patient should be thoroughly washed with warm soap suds, and then well dried; following this, the solution is to be applied, which must not be rubbed off. Upon drying, the sulphide is left upon the skin in the form of a thin coating, which may be removed in 20 or 30 minutes. Two or 3 applications at most effect the cure. It is probably the promptest and surest agent for this purpose.

LIQUOR CARMINI (N. F.)—SOLUTION OF CARMINE.

Preparation.—"Carmine, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; water of ammonia (*U. S. P.*), three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]; glycerin, three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the carmine to a fine powder in a wedgewood mortar, gradually add the water of ammonia, and afterward the glycerin, under constant trituration. Transfer the mixture to a porcelain capsule, and heat it upon a water-bath, constantly stirring, until the liquid is entirely free from ammoniacal odor. Then cool and add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—The best quality of carmine, known in commerce as 'No. 40,' should be used for this preparation"—(*Nat. Form.*).

Uses.—Solution of carmine is employed as a coloring agent for medicines and for syrups.

Related Preparation.—Liquor Coccineus (N. F.), *Cochineal color*. "Cochineal, in No. 50 powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; potassium carbonate, thirty grammes (30 Gm. [oz. av., 25 grs.]; alum, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; potassium bitartrate, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; glycerin, five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]; alcohol, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏], water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the cochineal intimately with the potassium carbonate and five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water. Then add the alum and potassium bitartrate successively, heat the mixture to boiling in a capacious vessel, then set it aside to cool, add to it the glycerin and alcohol, filter, and pass enough water through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.* . This agent is used in pharmacy as a coloring substance.

LIQUOR COCAINÆ HYDROCHLORATIS.—SOLUTION OF COCAINE HYDROCHLORATE.

Preparation.—"Cocaine hydrochlorate, 33 grains; salicylic acid, $\frac{1}{2}$ grain; distilled water, sufficient to produce 6 fluid drachms. Boil the water, add the salicylic acid, and then the cocaine hydrochlorate; cool, and add water, if necessary, to produce the required volume"—(*Br. Pharm. Add.*, 1885).

Each minim contains about $\frac{1}{11}$ grain of cocaine, or 5.5 grains to the fluid drachm.

Action, Medical Uses, and Dosage.—(See *Cocainæ Hydrochloras.*) Dose, 1 to 5 minims. The custom in America is to make a 4 per cent solution of cocaine hydrochlorate by dissolving 4 grains of the salt in 96 grains of distilled water. The preparation looses its energy by keeping, and must be frequently replaced.

LIQUOR CUPRI ALKALINUS (N. F.)—ALKALINE SOLUTION OF COPPER.

SYNONYM: *Fehling's solution.*

Preparation.—I. THE COPPER SOLUTION. "Sulphate of copper, pure, thirty-four and six hundred and thirty-nine one thousandths grammes (34.639 Gm.) [1 oz. av., 97 grs.]; distilled water, enough to make five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]. Dissolve the sulphate of copper which, before being weighed, should have been reduced to powder and pressed between blotting paper, in a sufficient quantity of distilled water to produce the volume required by the corresponding formula above given.

II. THE ALKALINE SOLUTION.—"Tartrate of potassium and sodium, one hundred and seventy-three grammes (173 Gm.) [6 ozs. av., 45 grs.]; soda (*U. S. P.*, 1880), sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; distilled water, enough to make five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏]. Dissolve the tartrate of potassium and sodium and the soda in a sufficient quantity of distilled water to produce the volume required by the corresponding formula above given. Set the mixture aside until the suspended impurities have been deposited; then remove the clear solution with a siphon.

"Keep both solutions, separately, in small, well-stoppered vials, in a cool and dark place. For use, mix exactly equal volumes of the two solutions by pouring the copper solution into the alkaline solution. *Note.*—The two solutions should be prepared with cold distilled water, and should be made up to their respective volumes at one and the same temperature. They should also be at the same temperature at the time of mixing. On diluting a small quantity of the mixed reagent with about 3 volumes of distilled water, and heating the liquid in a test-tube to boiling, it should remain entirely clear, without any trace of discoloration or precipitate. After the solutions have been mixed for use, and assuming that they have been prepared and mixed at the average indoor temperature, 10 Cc. of the mixture, prepared by metric weight and measure, correspond to 0.05 Gm. of glucose. Of the mixture, prepared by apothecaries' weight and measure, 210 minims correspond to 1 grain of glucose"—(*Nat. Form.*).

Uses.—This is the well-known Fehling's test solution for the detection of glucose in urine.

LIQUOR ELECTROPOEICUS (N. F.)—BATTERY FLUID.

A.—For the Carbon and Zinc Battery.

Preparation.—I. FOR ORDINARY USE. "Sodium bichromate, in coarse powder, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sulphuric acid, commercial, one hundred and twenty-five cubic centimeters (125 Cc.)

[4 fl℥, 109 ♏]; water, cold, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour the sulphuric acid upon the powdered bichromate, and stir the mixture occasionally during 1 hour. Then slowly add the water"—(*Nat. Form.*).

II. For Use with the Galvano-Cautery.—"Sodium bichromate, in coarse powder, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; sulphuric acid, commercial, three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏]; water, cold, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Proceed in the same manner as directed under No. 1. *Note.* Sodium bichromate is more soluble than the potassium salt, and its products of decomposition, in the battery, are also more soluble. As it is also much cheaper, it is now preferred in all large electric laboratories. When it can not be obtained, potassium bichromate may be used in place of it, as heretofore. The two salts may be substituted for each other, weight for weight."

B.—For the Leclanché Battery.

"Ammonium chloride, three hundred and twenty-five grammes (325 Gm.) [11 ozs. av., 203 grs.]; water, enough to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the salt in the water"—(*Nat. Form.*).

Uses.—These fluids are used for charging electric batteries.

LIQUOR EPISPASTICUS.—BLISTERING LIQUID.

Synonym: *Linimentum cantharidis.*

Preparation.—"Take of cantharides, in powder, 5 ounces (av.); acetic ether, a sufficiency. Mix the cantharides with 3 fluid ounces of acetic ether; pack in a percolator, and, at the expiration of 24 hours, pour acetic ether over the contents of the percolator, and allow the solution to pass slowly through until 20 fluid ounces are obtained. Keep the liquid in a stoppered bottle"—(*Br. Pharm.*, 1885). The preparation of the *British Pharmacopœia* (1898) has twice the strength of the above.

Action and Medical Uses.—This is designed for rapid vesication of the parts to which it is applied. It should be used only upon limited areas, and rubbed upon the skin by means of a sponge, or like body, having a handle attached. When the parts become red, enough has been used to raise a blister.

LIQUOR ERGOTINÆ.—LIQUOR OF ERGOTIN.

Synonym: *M. Yvon's solution of ergotin.*

Preparation and Description.—Coarsely powder ergot and deprive it of its fixed oil by washing it with rectified disulphide of carbon, then dry it in the open air and protected from the light until the odor of the solvent has entirely disappeared. Introduce this powder into a cylindrical percolator, and exhaust it in the cold by distilled water, to every one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of which two grammes (2 Gm.) [31 grs.] of tartaric acid have been added. Heat the liquid obtained, so as to coagulate any albuminous matters that may be present in it, then filter, and by means of a water-bath, evaporate it to about one-third of its volume. When cool, filter, digest the filtered liquid with a slight excess of recently precipitated carbonate of calcium so as to saturate the excess of tartaric acid. Filter, evaporate to the consistence of thick syrup, and precipitate with alcohol of sp. gr. 0.822, added in such quantity as to furnish with the aqueous liquid an alcohol of sp. gr. 0.871. Again filter, and then evaporate to drive off the alcohol. Exhaust the residuum by the addition of distilled water in quantity slightly less than that of the weight of the ergot employed, a little animal charcoal being used. Again filter, and to the filtered liquid add, for each one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of ergot employed, fifteen centigrammes (15 Cgm.) [2⅓ grs.] of salicylic acid. Complete the process by adding distilled water, in such quantity as to obtain a weight of liquid equal to that of the ergot employed in the preparation of the solution. Allow this to rest for several days in a cool place, and then pour it into small vials having well-fitted, ground stoppers.

Hypodermatic injections of ergotin have rapidly come into favor with the profession, being employed in various forms of disease. One great objection formerly to their employment has been the irritating quality of the solutions used, occasioning abscesses and indurations. M. Yvon succeeded in forming a solution wholly free from irritating principles, the process for preparing which, as described by himself, we have deemed proper to present. The liquid obtained by this process is of a fine amber color, clear, non-fermentable, and keeps well; all the reagents of the alkaloids form abundant precipitates with it. One Gm. of this solution represents 1 Gm. of ergot, and it contains the obstetrical and hemostatic principles of this drug.

Action, Medical Uses, and Dosage.—(See *Ergota.*)

LIQUOR EXTRACTI GLYCYRRHIZÆ (N. F.)—SOLUTION OF EXTRACT OF GLYCYRRHIZA.

SYNONYM: *Solution of extract of liquorice.*

Preparation.—"Purified extract of glycyrrhiza (F. 158), a sufficient quantity; alcohol, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. In a small portion of purified extract of glycyrrhiza, weighed into a tared capsule, determine the amount of water, by drying it to a constant weight. Then take of the purified extract a quantity equivalent to two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.] of dry extract, dissolve this on a water-bath, in two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water, add the glycerin, and allow the liquid to cool. Lastly, add the alcohol and enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 15 grains of dry extract of glycyrrhiza"—(*Nat. Form.*).

Action and Medical Uses.—(See *Glycyrrhiza.*)

LIQUOR FERRI ACETATIS (U. S. P.)—SOLUTION OF FERRIC ACETATE.

"An aqueous solution of ferric acetate ($Fe_2[C_2H_3O_2]_6$=464.92), containing about 31 per cent of the anhydrous salt, and corresponding to about 7.5 per cent of metallic iron"—(*U. S. P.*).

Preparation.—"Solution of ferric sulphate, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glacial acetic acid, two hundred and sixty grammes (260 Gm.) [9 ozs. av., 75 grs.]; ammonia water, eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏]; water, distilled water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the ammonia water with three thousand cubic centimeters (3000 Cc.) [101 fl℥, 212 ♏] of cold water, and the solution of ferric sulphate with ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏] of cold water. Add the latter solution slowly to the diluted ammonia water, stirring constantly. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate six thousand cubic centimeters (6000 Cc.) [202 fl℥, 424 ♏] of boiling water, mix well, and again set the mixture aside, as before. Repeat the washing with successive portions of boiling water, in the same manner, until the washings are no longer affected by sodium cobaltic nitrite test solution (showing the removal of ammonia and its salts). Transfer the mixture to a wet muslin strainer, allow the precipitate to drain completely, and press it folded in the strainer, until its weight is reduced to seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.], or less. Now add the precipitate gradually to the glacial acetic acid contained in a tared jar provided with a glass stopper, stirring the mixture after each addition until each portion added is nearly dissolved before adding another portion. Finally, add enough distilled water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]: mix thoroughly, allow it to become clear by subsidence, and decant the clear solution. Keep the product in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Description and Tests.—"A dark reddish-brown, clear liquid, of an acetous odor, a sweetish, acidulous, somewhat styptic taste, and a slightly acid reaction. Specific gravity, about 1.160 at 15° C. (59° F.). The diluted solution yields a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide T.S. When heated to boiling the solution yields a brownish-red precipitate, and when heated with sulphuric acid, it emits acetous vapors. If the iron be completely precipitated from a portion of the solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or dark-colored precipitate with hydrogen sulphide T.S. (absence of zinc or copper), nor should it leave a residue on evaporation and gentle ignition (absence of salts of the fixed alkalies). If to a small portion of the solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 15 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P.*).

The LIQUOR FERRI ACETATIS of the *British Pharmacopœia* (1898) has a specific gravity of 1.031, and contains only 1.57 per cent of metallic iron.

Action, Medical Uses, and Dosage.—(See *Tinctura Ferri Acetatis.*) Dose, 1 to 15 minims.

LIQUOR FERRI CHLORIDI (U. S. P.)—SOLUTION OF FERRIC CHLORIDE.

"An aqueous solution of ferric chloride (Fe_2Cl_6=323.98), containing about 37.8 per cent of the anhydrous salt, corresponding to 62.9 per cent of the crystallized salt ($Fe_2Cl_6+12H_2O$=539.5), or to about 13 per cent of metallic iron"—(*U. S. P.*).

SYNONYMS: *Solution of chloride of iron, Strong solution of perchloride of iron, Ferrum sesquichloratum solutum, Liquor ferri muriatici oxydati.*

Preparation.—"Iron, in the form of fine, bright wire, and cut into small pieces, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; hydrochloric acid, eight hundred and seventy grammes (870 Gm.) [1 lb. av., 14 ozs., 301 grs.]; nitric acid, distilled water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Introduce the iron wire into a flask having a capacity of about two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏], pour upon it a mixture of five hundred and forty grammes (540 Gm.) [1 lb. av., 3 ozs., 21 grs.] of hydrochloric acid and two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of distilled water, and let the mixture stand in a moderately warm place until effervescence ceases; then heat it to the boiling point, filter it through paper, and, having rinsed the flask and iron wire with a little hot distilled water, pass the rinsings through the filter. To the filtered liquid add two hundred and eighty grammes (280 Gm.) [9 ozs. av., 384 grs.] of hydrochloric acid, add the mixture slowly and gradually, in a stream, to eighty grammes (80 Gm.) [2 ozs. av., 360 grs.] of nitric acid contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, until the liquid is free from nitrous odor. Then test a few drops of the liquid, diluted with water, with freshly prepared potassium ferricyanide test-solution. Should this reagent produce a blue color, add a little more nitric acid, drop by drop, as long as effervescence is observed, and evaporate off the excess. Finally, add the remaining fifty grammes (50 Gm.) [1 oz. av., 334 grs.] of hydrochloric acid and enough distilled water to make the solution weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*U. S. P.*).

Description and Tests.—"A reddish-brown liquid, having a faint odor of hydrochloric acid, an acid, strongly styptic taste, and an acid reaction. Specific gravity about 1.387 at 15° C. (59° F.). The diluted solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S. If the iron be completely precipitated from a portion of the solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or a dark-colored precipitate with hydrogen sulphide T.S. (absence of zinc or copper); nor should it leave a fixed residue on evaporation and gentle ignition (absence of salts of the fixed alkalies). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute portion of the solution, the crystal should not become colored brown, nor should there be a brownish-black color developed around it (absence of nitric acid). If to a diluted portion of the solution a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). On diluting 1 Cc. of the solution with water, to 40 Cc., and boiling, the liquid should remain clear (absence of oxychloride). If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for ½ an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 26 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron) "—(*U. S. P.*).

This preparation is also known as Liquor Ferri Perchloridi and Solution of Perchloride of Iron. It is used mainly for making tincture of chloride of iron, which see. The solution of this name in the latest *British Pharmacopœia* (Liquor Ferri Perchloridi) has the strength of the tincture in the same work; both are prepared from a strong solution of ferric chloride (Liquor Ferri Perchloridi Fortis), containing 22.5 Gm. of iron in 100 Cc. of the preparation.

Action and Medical Uses.—(See *Ferri Chloridum.*) Solution of ferric chloride may be kept on hand for the preparation of freshly precipitated hydroxide of iron, the antidote for arsenic and its compounds. A solution of Liquor Ferri Chloridi in alcohol forms the well-known muriated tincture of iron (tincture of **iron**, or tincture of chloride of iron) (see *Tinctura Ferri Chloridi*).

Related Solution.—Liquor Ferri Protochloridi (N. F.), *Solution of protochloride of iron, Solution of ferrous chloride.* "Iron, in the form of fine, bright, and finely cut wire, one hundred and sixty grammes (160 Gm.) [5 ozs. av., 282 grs.]; hydrochloric acid (*U. S. P.*), six hundred and twenty-five grammes (625 Gm.) [1 lb. av., 6 ozs., 20 grs.]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; diluted hypophosphorous acid (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; distilled water a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. To the iron, contained in a flask, add three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of distilled water, and the hydrochloric acid, and apply a gentle heat until effervescence ceases. Then raise the liquid to boiling, keep it at this temperature for a short time so that the iron may be brought into solution as far as possible, filter the solution through a pellet of absorbent cotton placed in the neck of a funnel, and wash the cotton with a little distilled water. Evaporate the filtrate, over a boiling water-bath, until crystals begin to form, and the escaping vapors cease to redden, or only slightly affect, moistened blue litmus paper. Now add the glycerin and the diluted hypophosphorous acid, continue the heat, if necessary, until a perfect solution is obtained; then transfer the liquid to a graduated bottle, allow it to cool, and add enough distilled water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 20 grains of protochloride of iron (ferrous chloride)"—(*Nat. Form.*).

Other Solutions of Iron Salts.—Liquor Ferri Oxysulphatis (N. F.), *Solution of oxysulphate of iron.* "Sulphate of iron, one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 grs.]; nitric acid (*U. S. P.*), one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sulphate of iron in eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏] of boiling distilled water, in a flask, gradually add the nitric acid, and continue the heat until the escaping vapors cease to have a nitrous odor. When the reaction is completed, allow the liquid to cool, and add enough distilled water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Howe's Acid Solution of Iron.—This solution is prepared by triturating ferrous sulphate (2 parts) in a mortar, and adding 10 parts of water and 1 part of nitric acid. No heat is to be employed. When the liquid assumes a clear, amber color it is to be bottled. This preparation contains excess of nitric acid, and, probably, also part of the unexpelled nitrous acid. Its medicinal value probably consists in the associated actions of these substances as well as the iron salt. Howe's acid solution of iron is a favorite preparation with Eclectic physicians to fulfil the indications for iron and an acid. It is less apt than any other fluid preparation of iron to provoke febrile phenomena. It is an excellent agent in *chronic catarrhal affections*, *anæmia*, *chlorosis*, and *general debility*. We have found it best adapted to cases exhibiting a pallid, waxy skin and cherry-red mucous membranes. The dose should be about 2 drops, 3 or 4 times a day. A very pleasant preparation is the following: ℞ Acid solution of iron, fl℥i; syrup of orange, fl℥iv. Mix. Sig. Dose, 1 teaspoonful, given preferably before meals and at bedtime. This is the best preparation of iron for use in *phthisis* and other wasting diseases.

Loeffler's Solution.—Various solutions, to be used for the disinfection of the throats of *diphtheria* patients, have been devised by Prof. Loeffler, of Greifswald. Chief among these is that prepared after the following formula: ℞ Menthol, ten grammes (10 Gm.) [154 grs.]; toluene, a sufficient quantity to make thirty-six cubic centimeters (36 Cc.) [1 fl℥, 104 ♏]; then add creolin, two cubic centimeters (2 Cc.) [33 ♏]; solution of chloride of iron, four cubic centimeters (4 Cc.) [65 ♏]; alcohol, sufficient to make one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Of all the solutions recommended by Loeffler the preceding is preferred for children and sensitive individuals, being applied as follows: After first cleansing the throat of mucus by means of a piece of dry cotton, carried by means of forceps or wire applicator, neatly wrap a piece of cotton upon the wire applicator and saturate it with the solution. Pass the application to the throat and gently, but firmly, press against the diphtheritic exudate for 10 seconds, immediately repeating the application. Continue the application every 3 or 4 hours for several days, or until the local manifestations have disappeared. This should be followed in the course of 20 minutes with an irrigation of the nose and throat with antiseptic cleansing solutions, such as of hydrogen peroxide, listerine, lime-water, Dobell's solution, etc. Other solutions recommended by Loeffler are as follows: (1) Carbolic acid, 1 part; alcohol, 25 parts; turpentine, 25 parts. (2) Alcohol, 16 parts; toluene, 9 parts. (3) Alcohol, 16 parts; benzene, 9 parts.

Liquor Ferri Iodidi (N. F.), *Solution of iodide of iron.*—"Iron, in the form of fine, bright, and finely cut wire, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; iodine, six hundred and sixty-four grammes (664 Gm.) [1 lb. av., 7 ozs., 185 grs.]; diluted hypophosphorous acid (*U. S. P.*), twenty-five cubic centimeters (25 Cc.) [406 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the iron with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of distilled water in a flask, add about one-half of the iodine, and agitate continuously until the liquid becomes hot. Then moderate the reaction by placing the flask in cold water, or by allowing cold water to flow over it, meanwhile keeping up the agitation. When the reaction has moderated, add one-half of the remaining iodine at a time, and carefully moderate the reaction each time, in the manner above directed. Finally, raise the contents of the flask to boiling, and filter immediately through moistened pure filtering paper (the point of the filter being supported by a pellet of absorbent cotton) into a bottle containing the diluted hypophosphorous acid. When all the liquid has passed, rinse the flask with thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏] of boiling distilled water, and pass this through the filter. Cork the bottle and set it aside to cool. Finally, add enough distilled water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—This solution contains about 85 per cent of iodide of iron (ferrous). On mixing 1 volume with 7 volumes of syrup (*U. S. P.*), the product will be practically identical with syrup of iodide of iron (*U. S. P.*)"—(*Nat. Form.*).

Liquor Ferri Hypophosphitis (N. F.), *Solution of hypophosphite of iron*, *Solution of ferric hypophosphite.*—"Iron and ammonium sulphate (*U. S. P.*), in perfect crystals, three hundred and thirty grammes (330 Gm.) [11 ozs. av., 280 grs.]; sodium hypophosphite, two hundred and twenty grammes (220 Gm.) [7 ozs. av., 333 grs.]; potassium citrate, two hundred and fifteen grammes (215 Gm.) [7 ozs. av., 255 grs.]; glycerin, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the iron and ammonium sulphate, and the sodium hypophosphite, each, in fifteen hundred cubic centimeters (1500 Cc.) [50 fl℥, 364 ♏] of water, and, if necessary, filter each solution. Then mix them, and stir thoroughly; after a few minutes transfer the resulting magma to a close linen or muslin strainer, and wash the precipitate with about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water. Allow it to drain, and then press it forcibly in the strainer, so as to remove as much of the liquid as possible. Transfer the precipitate from the strainer to a mortar, add to it the potassium citrate, and triturate until a perfectly smooth paste results. Then add the glycerin, and gradually, while stirring, enough water to make the solution measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Place it for several days in a cold place, if convenient; then pour off the clear solution from any precipitate or crystals that may have formed, and keep the solution in small, completely filled and well-corked bottles"—(*Nat. Form.*).

Solution of hypophosphite of iron (ferric) may also be prepared in the following manner: "Hypophosphite of iron (F. 183), one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 grs.]; potassium citrate, two hundred and fifteen grammes (215 Gm.) [7 ozs. av., 255 grs.]; glycerin, one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the hypophosphite of iron with three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏] of water to a perfectly smooth mixture, then add the potassium citrate and glycerin, and apply a gentle heat, until solution has been effected. Allow the liquid to cool, and add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Place the solution for several days in a cold place, if convenient; then pour off the clear solution from any precipitate or crystals that may have formed, and keep the solution in small, completely-filled and well-corked bottles. About 6 minims of this solution represent 1 grain of hypophosphite of iron (ferric)"—(*Nat. Form.*).

LIQUOR FERRI CITRATIS (U. S. P.)—SOLUTION OF FERRIC CITRATE.

"An aqueous solution of ferric citrate, corresponding to about 7.5 per cent of metallic iron"—(*U. S. P.*).

Synonyms: *Liquor ferri citrici, Citras ferricus liquidus.*

Preparation.—"Solution of ferric sulphate, one thousand and fifty grammes (1050 Gm.) [2 lbs. av., 5 ozs., 17 grs.]; citric acid, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; ammonia water, eight hundred and eighty cubic centimeters (880 Cc.) [29 fl℥, 363 ♏]; water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the ammonia water with three thousand cubic centimeters (3000 Cc.) [101 fl℥, 212 ♏] of cold water and the solution of ferric sulphate with ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏] of cold water. Add the latter solution slowly to the diluted ammonia water with constant stirring. Pour the mixture on a wet muslin strainer, and allow the liquid to run off and the precipitate to drain. Then remove the moist mass from the strainer, mix it well with six thousand cubic centimeters (6000 Cc.) [676 fl℥, 132 ♏] of cold water, again pour it on the strainer, and let it drain. Repeat this washing with several successive portions of cold water in the same manner, until the washings cease to produce more than a slight cloudiness with barium chloride test-solution. Then allow the precipitate to drain completely, transfer it to a porcelain capsule, add the citric acid, and heat the mixture on a water-bath, to 60° C. (140° F.), stirring constantly until the precipitate is dissolved. Lastly, filter the liquid, and evaporate it, at the above-mentioned temperature, until it weighs one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*U. S. P.*).

In this process ferric hydroxide is first produced, and as this holds a large amount of water, the preparation becomes liquid as the citric acid is added, and citrate of iron is produced. The heat should be maintained at about 60° C. (140° F.), never more than a few degrees higher, until the ferric hydroxide is dissolved.

Description and Tests.—According to the *U. S. P.*, this solution is "a dark-brown liquid, odorless, and possessing a slightly ferruginous taste. Specific gravity, about 1.250 at 15° (59° F.). Upon evaporating 100 Gm. of the solution in a thin layer, on plates of glass, about 42.5 to 43 Gm. of garnet-red scales will be obtained. The solution has an acid reaction upon litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S., it affords a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid. On heating the solution with potassium or sodium hydrate T.S., it will yield a brown precipitate, without evolving vapor of ammonia. If a portion of the solution, diluted with 4 volumes of water, be deprived of its iron by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate slightly acidulated with acetic acid, a portion of this liquid, when allowed to stand for some time, should not give a white, crystalline precipitate (absence of tartrate). If to another portion of the acidulated and cooled filtrate a little calcium chloride T.S. be added, and the liquid heated to boiling, it should gradually deposit a white, crystalline precipitate. If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 15 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Ferri Citras*, or *Ferri et Ammonii Citras.*) Dose, 1 to 10 minims.

LIQUOR FERRI ET AMMONII ACETATIS (U. S. P.)—SOLUTION OF IRON AND AMMONIUM ACETATE.

SYNONYMS: *Mistura ferri et ammonii acetatis* (*Pharm.*, 1880), *Basham's mixture.*

Preparation.—"Tincture of ferric chloride, twenty cubic centimeters (20 Cc.) [325 ♏]; diluted acetic acid, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; solution of ammonium acetate, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; aromatic elixir, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; glycerin, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. To the solution of ammonium acetate (which should not be alkaline) add, successively, the diluted acetic acid, the tincture of ferric chloride, the aromatic elixir, and the glycerin, and, lastly, enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This preparation should be freshly made when wanted"—(*U. S. P.*).

The reaction here, by double decomposition, produces ferric acetate and ammonium chloride. A large proportion, however, of the ammonium acetate remains uncombined. While this solution may keep for quite a length of time, it should, to insure a good and fresh preparation, be made only as needed for use. It is a bright-red, transparent fluid.

Action, Medical Uses, and Dosage.—This agent is diuretic and acts kindly upon the stomach. In doses of ¼ to 1 fluid ounce, it has been administered in *albuminuria*. Said to be most valuable when *tubular nephritis* is present.

LIQUOR FERRI NITRATIS (U. S. P.)—SOLUTION OF FERRIC NITRATE.

"An aqueous solution of ferric nitrate ($Fe_2[NO_3]_6=483.1$), containing about 6.2 per cent of the anhydrous salt, and corresponding to about 1.4 per cent of metallic iron"—(*U. S. P.*).

SYNONYMS: *Liquor ferri pernitratis, Solution of pernitrate of iron.*

Preparation.—"Solution of ferric sulphate, one hundred and eighty grammes (180 Gm.) [6 oz. av., 153 grs.]; ammonia water, one hundred and sixty cubic centimeters (160 Cc.) [5 fl℥, 197 ♏]; nitric acid, seventy-one grammes (71 Gm.) [2 ozs. av., 221 grs.]; distilled water, water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the ammonia water with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of cold water, and the solution of ferric sulphate with fifteen hundred cubic centimeters (1500 Cc.) [50 fl℥, 346 ♏] of cold water. Add the latter solution slowly to the diluted ammonia water, with constant stirring. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of cold water, mix well, and again set the mixture aside, as before. Repeat the washing with successive portions of cold water, in the same manner, until the washings produce but a slight cloudiness with barium chloride test-solution. Pour the washed ferric hydrate on a wet muslin strainer, and let it drain thoroughly. Then transfer it to a porcelain capsule, add the nitric acid, and stir with a glass rod until a clear solution is obtained. Finally, add enough distilled water to make the finished product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Filter, if necessary"—(*U. S. P.*).

History.—Mr. William Kerr introduced this preparation to the profession in 1832 (*Ed. Med. and Surg. Jour.*, XXXVII, p. 99). When correctly made it is of a deep-red color (amber-colored if an excess of acid be present), clear, and powerfully astringent. On standing, sesquioxide of iron forms, which at first destroys the transparency of the liquid, but is finally deposited, and which may be prevented by the addition of a drachm of hydrochloric acid. On account of the great liability to change in this preparation, various suggestions have been made for the purpose of procuring a permanent solution; among them a process offered by

W. Procter, Jr., of Philadelphia, which forms the basis for the *U. S. P.* process (*Amer. Jour. Pharm.*, Vol. XXIX, p. 306).

Description.—"A clear, amber-colored, or reddish liquid, odorless, having an acid, styptic taste, and an acid reaction. Specific gravity about 1.050 at 15° C. (59° F.). The solution gives a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide T.S. If a clear crystal of ferrous sulphate be added to a cooled mixture of equal parts of the solution and of concentrated sulphuric acid, the crystal will become brown and be surrounded by a brownish-black zone. If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for ½ an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 2.8 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P*).

Action, Medical Uses, and Dosage.—Solution of nitrate of iron is astringent, and possesses the property of diminishing tenderness and irritability of the mucous membranes with which it comes in contact. It has been found useful in *chronic diarrhœa*, where intestinal ulceration is absent, and in the *diarrhœa* of weak and nervous persons. It is contraindicated if inflammatory symptoms are present. It has also been used in *hæmatemesis*, *hemorrhage from the bowels*, *uterine hemorrhage*, and *menorrhagia*, especially in pale, feeble, and languid constitutions. It has also been found advantageous as an injection, and by mouth, in *leucorrhœa*. In the *colliquative diarrhœa of tuberculous phthisis*, it has afforded much benefit, as well as in *chronic diarrhœa* and *cholera infantum* of anemic or scrofulous patients. The dose is from 5 drops, gradually increased to 15 or 20 drops, or more, sufficiently diluted with water, and repeated 3 or 4 times a day; the ordinary dose to commence with is 10 or 12 drops. Injected into the vagina, it will cause considerable irritation, unless previously weakened with water.

LIQUOR FERRI SUBSULPHATIS (U. S. P.)—SOLUTION OF FERRIC SUBSULPHATE.

An aqueous solution of basic ferric sulphate (of variable chemical composition), corresponding to about 13.6 per cent of metallic iron.

Synonyms: *Solution of basic ferric sulphate*, *Monsel's solution*, *Solution of persulphate of iron* (erroneously).

Preparation.—"Ferrous sulphate, in clear crystals, six hundred and seventy-five grammes (675 Gm.) [1 lb. av., 7 ozs., 354 grs.]; sulphuric acid, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; nitric acid, distilled water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Add the sulphuric acid to five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of distilled water in a capacious porcelain capsule, heat the mixture to nearly 100° C. (212° F.), then add sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.] of nitric acid, and mix well. Divide the ferrous sulphate, coarsely powdered, into 4 equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the ferrous sulphate is dissolved, add a few drops of nitric acid, and, if this causes a further evolution of red fumes, continue to add nitric acid, a few drops at a time, until it no longer causes red fumes to be evolved; then boil the solution until it assumes a ruby-red color, and is free from nitrous odor. Lastly, add enough distilled water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Keep the product in well-stoppered bottles, in a moderately warm place (not under 22° C. or 71.6° F.), protected from light. This solution will sometimes crystallize, forming a semi-solid, whitish mass. When this occurs the application of a gentle heat to the bottle will restore the liquid condition. *Note.*—Solution of ferric subsulphate is to be dispensed when solution of persulphate of iron has been prescribed by the physician"—(*U. S. P.*).

History.—This process is practically that of Dr. E. R. Squibb (186[illegible]). The ferrous sulphate is changed into ferric sulphate, but as there is not a sufficient quantity of the sulphuric acid present to produce the normal ferric sulphate, an oxysulphate, basic or subsulphate is formed, of the approximate composition $Fe_4(SO_4)_5(OH)_2$.

Description and Tests.—"A dark reddish-brown liquid, odorless or nearly so, of an acid, strongly styptic taste, and an acid reaction. Specific gravity, about 1.550 at 15° C. (59° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S. On slowly mixing 2 volumes of the solution with 1 volume of concentrated sulphuric acid, in a beaker, a semisolid, white mass will separate on standing (difference from tersulphate). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the solution, the crystal should not become brown, nor should there be a brownish-black color developed around it (absence of nitric acid). If to a small portion of the solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for ½ hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 27.2 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This agent is an almost unirritating styptic. Its action on blood and albumen is powerful; with the former it produces a voluminous clot, absolutely insoluble, which continues to enlarge for several hours after its application, and becomes quite hard and firm. If applied to a *superficial wound* as soon as made, not a drop of blood escapes, and no pain results from the application. It acts by producing instantaneous coagulation of the blood, and will be found invaluable in *hemorrhages from the mouth, nose,* and *throat*, when it is impossible to ligate the vessels, and may be equally efficient in alarming *uterine hemorrhage*. The solution is readily applied by a glass or wooden brush, or by saturating cotton or sponge, or may be used diluted with water as an injection. The dry salt (*Monsel's salt*), is very deliquescent, and speedily dissolves in water. A solution of from 1 to 10 drops of Monsel's solution in a fluid ounce of water, has been successfully used by atomization in *hemoptysis*. From 1 to 5 minims in water, is useful in *hematemesis*. Instances have occurred in which the coagulating power of this solution upon blood has produced mischief, followed by gangrene of the parts to which it was applied.

LIQUOR FERRI TERSULPHATIS (U. S. P.)—SOLUTION OF FERRIC SULPHATE.

"An aqueous solution of normal ferric sulphate ($Fe_2[SO_4]_3$=399.22), containing about 28.7 per cent of the salt, and corresponding to about 8 per cent of metallic iron"—(*U. S. P.*).

SYNONYMS: *Liquor ferri persulphatis, Solution of persulphate of iron, Solution of normal ferric sulphate.*

Preparation.—"Ferrous sulphate, in clear crystals, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; sulphuric acid, seventy-eight grammes (78 Gm.) [2 ozs. av., 329 grs.]; nitric acid, distilled water, each, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Add the sulphuric acid to two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of distilled water in a capacious porcelain capsule, heat the mixture to nearly 100° C. (212° F.), then add fifty-five grammes (55 Gm.) [1 oz. av., 411 grs.] of nitric acid, and mix well. Divide the ferrous sulphate, coarsely powdered, into 4 equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the ferrous sulphate is dissolved, add a few drops of nitric acid, and, if this causes a further evolution of red fumes, continue to add nitric acid, a few drops at a time, until it no longer causes red fumes to be evolved; then boil the solution until it assumes a reddish-brown color and is free from nitrous odor. Lastly, add enough distilled water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Filter, if necessary"—(*U. S. P.*).

By clear crystals, as directed, is meant the uneffloresced salt. The reaction here taking place is precisely the same as when *Liquor Ferri Subsulphatis* is formed, excepting that sufficient sulphuric acid is employed to produce the non-basic or normal ferric sulphate ($Fe_2[SO_4]_3$). The equation $6FeSO_4+3H_2SO_4+2NO_3H=4H_2O+3Fe_2(SO_4)_3+N_2O_2$ illustrates the reaction.

Description and Tests.—"A dark reddish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction. Specific gravity, about 1.320 at 15° C. (59° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S. On slowly mixing 2 volumes of the solution with 1 volume of concentrated sulphuric acid, in a beaker, no solid, white mass will separate on standing (difference from subsulphate). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately diluted portion of the solution, the crystal should not become brown, nor should there be a brownish-black color developed around it (absence of nitric acid). If to a small portion of the solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). If 1.12 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for ½ hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 16 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 0.5 per cent of metallic iron)"—(*U. S. P.*).

Action and Medical Uses.—May be used like Monsel's solution, but is less desirable because not so astringent, and is more strongly irritant. It should be kept on hand for the preparation of freshly precipitated hydroxide of iron, the antidote for arsenic.

LIQUOR GUTTA-PERCHÆ (N. F.)—SOLUTION OF GUTTA-PERCHA.

Preparation.—"Gutta-percha, in thin slices, fifteen grammes (15 Gm.) [231 grs.]; commercial chloroform, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; lead carbonate, in fine powder, seventeen grammes (17 Gm.) [262 grs.]. Add the gutta-percha to seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏] of the chloroform contained in a bottle, cork it well, and shake it occasionally until the gutta-percha is dissolved. Then add the lead carbonate, previously mixed with the remainder of the chloroform, and, having several times shaken the whole together, at intervals of ½ hour, set the mixture aside until the insoluble matters have subsided and the solution has become perfectly clear. Lastly, decant the liquid and preserve it in small, cork-stoppered vials"—(*Nat. Form.*).

As chloroform does not make a clear solution of gutta-percha, Maschke proposed agitation of the solution with water (1 to 1½ per cent), to hasten the collection of the impurities at the top of the solution. Others have proposed heavy, insoluble substances to carry with them in precipitation the insoluble matter. Chief among these was lead carbonate, proposed by Wm. Hodgson, Jr., in 1861, which, by causing the impurities to subside with it, renders the solution clear and colorless, or nearly so. The liquid may then be decanted. On account of its character it can not be filtered. Should it by evaporation become too dense, a little chloroform may be added. Under the name TRAUMATICINE, Auspitz, of Vienna, introduced a solution of gutta-percha (1 part) in chloroform (10 parts).

Action and Medical Uses.—An adhesive protective. (For uses, see *Gutta-percha.*)

LIQUOR HYDRARGYRI NITRATIS (U. S. P.)—SOLUTION OF MERCURIC NITRATE.

"A liquid containing about 60 per cent of mercuric nitrate ($Hg[NO_3]_2$ 323.58), together with about 11 per cent of free nitric acid"—(*U. S. P.*).

SYNONYMS: *Liquor hydrargyri nitratis acidus, Liquor hydrargyri nitrici oxydati, Acid solution of nitrate of mercury, Solution of nitrate of mercury, Solution of pernitrate of mercury, Hydrargyrum oxydatum nitricum solutum.*

Preparation.—"Red mercuric oxide, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; nitric acid, forty-five grammes (45 Gm.) [1 oz. av., 257 grs.]; distilled water, fifteen grammes (15 Gm.) [231 grs.]; to make one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]. Mix the nitric acid with the distilled water, and dissolve red mercuric oxide in the mixture. Keep the product in glass-stoppered bottles"—(*U. S. P.*).

Description and Tests.—In the foregoing process the mercuric oxide combines with the nitric acid as follows: $HgO+2HNO_3 = Hg(NO_3)_2+H_2O$. It is "a clear, nearly colorless, heavy liquid, having a faint odor of nitric acid, and a strongly acid reaction. Specific gravity, about 2.100 at 15° C. (59° F.). On evaporating a few drops of the solution in a porcelain capsule, a white residue is left, which, on being heated, becomes successively yellow, red, and brown, and is finally completely volatilized. On a bright surface of copper, the solution deposits a coating of metallic mercury. The solution, diluted with water, yields with potassium or sodium hydrate T.S. a yellow precipitate; and with potassium iodide T.S. a bright red one, soluble in an excess of the reagent. A clear crystal of the ferrous sulphate dropped into the solution rapidly acquires a brown color, and becomes surrounded by a brownish-black zone. No precipitation or cloudiness should occur in the solution on the addition of water, or of diluted hydrochloric acid (absence of mercurous salt)"—(*U. S. P.*). When strong nitric acid is added to this solution a deliquescent, crystalline mass of mercuric nitrate may be obtained, and this salt may be obtained in large crystals, having the composition $2Hg(NO_3)_2.H_2O$, by slowly evaporating the solution over sulphuric acid. If alcohol be mixed with this solution and heated, the dangerous explosive, *fulminating mercury*, is produced, and great care must be used to avoid such a compound.

Action and Medical Uses.—This forms a thick, heavy, very caustic solution, which has been employed with some success in *lupus, ulcerated cervix uteri, obstinate lepra, psoriasis, porrigo, herpes exedens,* etc., *syphilitic and scrofulous ulcers.* It is applied by means of a camel's-hair pencil to a surface not exceeding an inch in diameter at any one time, and over this a pledget of lint is applied, which has been previously dampened with some of the solution. It whitens the part at once, a kind of erysipelatous inflammation is induced in the neighboring parts, and a scab of yellow color forms and falls off in 3, 4, or 5 days. In *ulcerated cervix uteri*, one application is said to have materially improved the character of the sore. As salivation has been caused by a single application, Mialhe proposed to prevent absorption of the mercury by washing the cauterized part immediately after the caustic has been applied (P.). It is seldom, if ever, employed by the Eclectic physicians.

Related Preparations.—MILLON'S TEST SOLUTION. Dissolve by means of a gentle heat an equal weight of mercury in concentrated nitric acid, add twice its bulk of water, and decant from the precipitate which forms. This reagent, which must contain some uncombined nitric and nitrous acid, is employed as a test for proteids, the latter imparting to it a red coloration upon warming.

LIQUOR HYDRARGYRI NITRICI OXYDULATI (*Liquor Bellostii*, or *Hydrargyrum oxydulatum solutum*).—Take mercurous nitrate, 100 parts; nitric acid, 15 parts; enough water to make 1000 parts. Dissolve without heat. If exposed to the air this solution changes to mercuric nitrate through oxidation.

LIQUOR HYDRARGYRI PERCHLORIDI.—SOLUTION OF PERCHLORIDE OF MERCURY.

SYNONYMS: *Liquor hydrargyri bichloridi, Solution of mercuric chloride, Solution of corrosive sublimate.*

Preparation.—"Take of perchloride of mercury, chloride of ammonium, of each, 10 grains; distilled water, 1 pint. Dissolve"—(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) omits chloride of ammonium.

Description.—A colorless liquid having a saline, metallic taste, and containing $\frac{1}{2}$ grain of mercuric chloride in the Imperial fluid ounce. It is decomposed by the alkalies and alkaline carbonates, medicinal extracts, and the juices of vegetables. It is a solution of the alchemist's *Sal Alembroth.* By substituting for the water bitter almond emulsion, *Gowland's Cosmetic Lotion* is formed. *Van Swieten's Liquor* (*Liqueur de Van Swieten*, of the *French Codex*), contains mercuric chloride. 1 part; alcohol, 100 parts; water, 900 parts.

Action, Medical Uses, and Dosage.—(See *Hydrargyrum Chloridum Corrosivum.*) Dose, $\frac{1}{4}$ to 1 fluid drachm (equal to $\frac{1}{48}$ to $\frac{1}{16}$ grain of corrosive sublimate).

LIQUOR HYPOPHOSPHITUM (N. F.)—SOLUTION OF HYPOPHOSPHITES.

Preparation.—"Calcium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.] sodium hypophosphite, twenty grammes (20 Gm.) [309 grs.]; potassium hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; citric acid, sixteen grammes (16 Gm.) [247 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the salts and citric acid in water so as to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]; filter, if necessary, and pass enough water through the filter to restore the original volume. Each fluid drachm contains 2 grains of calcium hypophosphite, $1\frac{1}{4}$ grains of sodium hypophosphite, and 1 grain of potassium hypophosphite"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See the respective hypophosphites. Dose, 1 drachm.

LIQUOR IODI COMPOSITUS (U. S. P.)—COMPOUND SOLUTION OF IODINE.

SYNONYMS: *Solution of iodine, Lugol's solution.*

Preparation.—"Iodine, five grammes (5 Gm.) [77 grs.]; potassium iodide, ten grammes (10 Gm.) [154 grs.]; distilled water, a sufficient quantity to make one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]. Dissolve the iodine and potassium iodide in a sufficient quantity of distilled water to make the product weigh one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]. Keep the solution in glass-stoppered bottles"—(*U. S. P.*).

Metallic iodine is very slightly dissolved by water, but is extremely soluble in a solution of iodide of potassium. In preparing this solution, 2 parts of the iodide are generally added with 1 of iodine, forming a concentrated solution of iodine, which is the active medicinal agent in the solution. The solution loses its strength by exposure to the air, in consequence of the evaporation of the iodine; light also appears to exert a deleterious influence upon it. It should, therefore, be kept in well-stoppered bottles, and in a dark place.

Description.—Lugol's solution is a deep brownish-red fluid having the characteristic, caustic, iodine taste. Starch paste is colored blue by it. A portion of the iodine is driven off on boiling it. It may be decolorized by shaking it with ether, chloroform, or carbon disulphide. "If 12.66 Gm. of the solution be mixe with a few drops of starch T.S., it should require, for complete decoloration, from 49.3 to 50 Cc. of decinormal sodium hyposulphite V.S. (each cubic centimeter of the volumetric solution corresponding to 0.1 per cent of iodine)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Compound solution of iodine possesses all the virtues of iodine, and may be used advantageously in *scrofulous*, *syphilitic*, and all *tuberculous diseases*, or wherever iodine is indicated. The dose is 5 drops in a tablespoonful of water, sweetened if desired, and gradually increased to 20 or 30 drops; the dose to be repeated 3 times a day. Twelve drops are equal to about ½ grain of iodine.

Related Preparations.—LUGOL'S CAUSTIC, *Causticum iodi*. One part each of iodine and potassium iodide, dissolved in 2 parts of water.

HEBRA'S IODINE CAUSTIC.—One part each of iodine and iodide of potassium, dissolved in 2 parts of glycerin.

LIQUOR IODI CAUSTICUS (N. F.), *Caustic solution of iodine, Iodine caustic, Churchill's iodine caustic*.—"Iodine, twenty-five grammes (25 Gm. [386 grs.]; potassium iodide, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; water, one hundred cubic centimeters (100 Cc. [3 fl℥, 183 ♏]. Dissolve the potassium iodide and the iodine in the water"—(*Nat. Form.*).

LIQUOR IODI CARBOLATUS (N. F.), *Carbolized solution of iodine, Boulton's solution, French mixture*.—"Compound tincture of iodine (*U. S. P.*), fifteen cubic centimeters (15 Cc. [243 ♏]; carbolic acid, liquefied by a gentle heat, five and one-half cubic centimeters (5.5 Cc.) [89 ♏]; glycerin, one hundred and sixty-five cubic centimeters (165 Cc. [5 fl℥, 278 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the glycerin with the carbolic acid and compound tincture of iodine, add enough water to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏], and expose the mixture to sunlight until it has become colorless"—(*Nat. Form.*).

LIQUOR MAGNESII CITRATIS (U. S. P.)—SOLUTION OF MAGNESIUM CITRATE.

SYNONYMS: *Solution of citrate of magnesium, Liquor magnesii citrici.*

Preparation.—"Magnesium carbonate, fifteen grammes (15 Gm.) [231 grs.]; citric acid, thirty grammes (30 Gm.) [463 grs.]; syrup of citric acid, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]; potassium bicarbonate, two and one-half grammes (2.5 Gm.) [39 grs.]; water, a sufficient quantity. Dissolve the citric acid in one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏] of water, and, having added the magnesium carbonate, stir, until it is dissolved. Filter the solution into a strong bottle of the capacity of about three hundred and sixty cubic centimeters (360 Cc.) [12 fl℥, 83 ♏], containing the syrup of citric acid. Then add enough water to nearly fill the bottle, drop in the potassium bicarbonate, immediately close the bottle with a cork, and secure it with twine. Lastly, shake the mixture occasionally, until the potassium bicarbonate is dissolved"—(*U. S. P.*).

This solution is more effervescent than that formerly official. It is colorless, pleasantly acidulous, not bitter, and should deposit no sediment at first, although it does so in time, under which conditions its medicinal properties are impaired. It should preferably be prepared for immediate use. Liquid citrate of magnesia is preferred to magnesium citrate in powder, because the latter is only slowly soluble in water, and does not readily make a clear solution. This preparation, about 1863-65, was very popular. It was made on a large scale by dissolving freshly precipitated magnesium carbonate in water under pressure of carbon dioxide. This solution was then poured into a citrate of magnesia bottle, and at the bottom, through a funnel tube, enough syrup of citric acid was carefully added to produce magnesium citrate. The bottles were then corked, tied over with strong twine, and finally agitated. This carbonated liquid was a great favorite with physicians The writer's early experience in pharmacy consisted largely in making and filling "Effervescing Solutions of Citrate of Magnesia." The following is the formula employed:

Solution No. 1.—Take of carbonate of sodium, 8½ ounces; dissolve this in tepid water, 2 pints; likewise dissolve in another vessel sulphate of magnesium, 8 ounces, in tepid water, 2 pints. After the two solutions are perfected and clear, mix them in a convenient vessel, when a precipitate will take place. The precipitate, when completed, must be washed frequently until the excess of sulphate of sodium is removed. The hydrate of magnesium thus formed, is to be mixed with clear water, 4 pints, and the mixture charged with carbonic acid gas until all the hydrate is dissolved, which will require a pressure of 100 or 110 pounds.

Solution No. 2.—Take of citric acid, 8 ounces; calcined magnesia, 10 drachms; simple syrup, 2½ pounds; tepid water, 2 pints. Dissolve the citric acid in the tepid water, then add the magnesia gradually until it is taken up and forms a clear solution, and then add the syrup.

To place in bottles.—Take bottles of 12 fluid ounces each, fill them at first two-thirds with Solution No. 1, and then one-third with Solution No. 2, pouring the second solution through a long-stemmed funnel to the bottom of the bottle, corking immediately. This forms a pleasant, cooling purgative, operating without pain or griping. The dose is the contents of one bottle, one-half of which, or 6 fluid ounces, will prove gently laxative. (See M. E. Robiquet's process for a soluble citrate of magnesium, in *Amer. Jour. Pharm.*, Vol. XXVII, p. 317.)

Action, Medical Uses, and Dosage.—Solution of citrate of magnesium is a pleasant, cooling purgative, acting mildly upon the bowels, operating without pain or griping. It is best administered in broken doses of 4 to 6 fluid ounces. The dose, as a cathartic, is about 12 fluid ounces; as a laxative, 6 fluid ounces.

Other Magnesia Solutions.—LIQUOR MAGNESII BISULPHITIS. Archibald prepared this solution by acting upon magnesium carbonate with sulphurous acid, forming thereby a sulphite, 16 grains of which he added to an ounce of water, and passed through the mixture enough sulphur dioxide to render the solution transparent. This solution he proposed as a remedy for *pyrosis*, as butyric acid fermentation is checked by this sulphite.

SOLUTION OF CHLORINATED MAGNESIA.—This preparation may be prepared after R. E. Fairthorne's process (*Amer. Jour. Pharm.*, 1868). In 2 pints of water dissolve ½ pound (av.), of magnesium sulphate; to this add a solution made by triturating in a mortar a like quantity of water and 33 drachms of chlorinated lime. Agitate the mixture occasionally, and after allowing it to stand ½ day, pour off the overlying fluid. Nearly 9 grains of magnesia are contained in each fluid ounce. It was proposed by its author as an internal medicament, being less irritant than its corresponding sodium and potassium solutions.

LIQUOR MAGNESII SULPHATIS EFFERVESCENS (N. F.), *Liquor magnesiæ effervescens, Effervescent solution of magnesium sulphate.*—"Magnesium sulphate, twenty-five grammes (25 Gm.) [386 grs.]; citric acid, four grammes (4 Gm.) [62 grs.]; syrup of citric acid (*U. S. P.*), sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; potassium bicarbonate, crystals, two and one-half grammes (2.5 Gm.) [39 grs.]; water, a sufficient quantity to make three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]. Dissolve the magnesium sulphate and the citric acid in two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏] of water, add the syrup of citric acid, and filter the solution into a strong bottle of about three hundred and sixty cubic centimeters (360 Cc.) [12 fl℥, 83 ♏) capacity. Then add enough water to nearly fill the bottle, drop in the crystals of potassium bicarbonate, immediately close the bottle with a cork, and secure it with twine. Lastly, shake the bottle occasionally, until the crystals are dissolved"—(*Nat. Form.*).

LIQUOR MAGNESII BROMIDI (N. F.), *Solution of magnesium bromide.*—"Diluted hydrobromic acid (*U. S. P.*), one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]; magnesium carbonate, a sufficient quantity. Saturate the diluted hydrobromic acid with a sufficient quantity, about sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.] of magnesium carbonate. When effervescence has ceased, filter. Each fluid drachm contains about 7 grains of magnesium bromide"—(*Nat. Form.*).

LIQUOR MAGNESII CARBONATIS, *Solution of carbonate of magnesium, Fluid magnesia, Aqua magnesio-efferrescens.*—"Take of sulphate of magnesium, 2 ounces; carbonate of sodium, 2½ ounces; distilled water, a sufficiency. Dissolve the two salts separately, each in ½ pint of water. Heat the solution of sulphate of magnesium to the boiling point, then add to it the solution of carbonate of sodium, and boil them together until carbonic acid gas ceases to be evolved. Collect the precipitated carbonate of magnesium on a calico filter, and wash it with distilled water until what passes ceases to give a precipitate with chloride of barium. Mix the washed precipitate with a pint of distilled water, and putting them into a suitable apparatus, force into it pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk. Let the mixture remain in contact with excess of carbonic acid, retained there under pressure of about 3 atmospheres for 24 hours or longer, then filter the liquid to remove any undissolved carbonate of magnesium, and again pass carbonic acid gas into the filtered solution. Finally keep the solution in a bottle securely closed, to prevent the escape of carbonic acid. This solution contains nearly 10 grains of the official carbonate of magnesium in a fluid ounce, or about 2 per cent"—(*Br. Pharm.*, 1885). (Weights, avoirdupois; measures, Imperial.) Magnesium carbonate is insoluble in water, but soluble in carbonic acid water, the freshly prepared hydrated carbonate being more readily dissolved than the normal carbonate which has been prepared for some time. Hence, the directions leading to the production of the oxycarbonate of magnesium, $4(MgCO_3).Mg(OH)_2$.

This solution is clear, slightly acidulous, and free from bitterness. Upon opening the container for the first time, it may slightly effervesce, due to the escape of carbon dioxide. The white residue left upon evaporating a fluid ounce of the solution to dryness, should, upon being calcined, weigh about 4 grains, and answer to the tests for magnesia. This is an agreeable form in which to administer magnesia in cases of excessive *acidity of the system* and where *acid deposits* occur in the urine. It is used in England in *constitutional gout.* Dose, 1 to 2 fluid ounces.

LIQUOR MORPHINÆ ACETATIS.—SOLUTION OF ACETATE OF MORPHINE.

Preparation.—"Take of acetate of morphine, 9 grains; diluted acetic acid, 18 minims; rectified spirit, ½ fluid ounce; distilled water, 1½ fluid ounces. Mix the acid, the spirit, and the water, and dissolve the acetate of morphine in the mixture" (*Br. Pharm.*, 1885).

Freshly prepared acetate of morphine should be used. The strength is about 1 in 100. Each fluid drachm contains ½ grain of morphine acetate. The spirit is present as a preservative.

Action, Medical Uses, and Dosage.—(See *Morphina.*) Dose, 10 to 60 minims.

LIQUOR MORPHINÆ BIMECONATIS.—SOLUTION OF BIMECONATE OF MORPHINE.

Preparation.—"Take of hydrochlorate of morphine, 9 grains; solution of ammonia, a sufficiency; meconic acid, 6 grains; rectified spirit, ½ fluid ounce; distilled water, a sufficiency. Dissolve the hydrochlorate of morphine in 2 or 3 drachms of distilled water, aiding the solution by warmth; then add solution of ammonia until morphine ceases to be precipitated; cool; filter; wash the precipitate with distilled water, until the washings cease to give a precipitate with nitrate of silver; drain; mix the precipitate with sufficient water to produce 1½ ounces; add the rectified spirit and the meconic acid; dissolve"—(*Br. Pharm.*, 1885). See also *Morphinæ Bimeconas*, under *Morphina.*)

Description.—A colorless or nearly colorless solution, each fluid ounce containing about 5½ grains of morphine bimeconate. Solutions of morphine bimeconate are sometimes colored with burnt sugar. Dose, 5 to 40 minims. The solution mentioned under *Morphinæ Bimeconas* is an excellent preparation. These preparations are free from many of the disagreeable features of morphine sulphate.

LIQUOR MORPHINÆ HYDROCHLORATIS.—SOLUTION OF HYDROCHLORATE OF MORPHINE.

Preparation.—"Take of hydrochlorate of morphine, 9 grains; diluted hydrochloric acid, 18 minims; rectified spirit, ½ fluid ounce; distilled water, 1½ fluid ounces. Mix the hydrochloric acid, the spirit, and the water, and dissolve the hydrochlorate of morphine in the mixture"—(*Br. Pharm.*, 1885).

This solution contains 1 per cent of morphine hydrochlorate, or 1 part in 100. Each fluid drachm contains ½ grain of the morphine salt.

Action, Medical Uses, and Dosage.—(See *Morphina.*) Dose, 10 to 60 minims.

LIQUOR MORPHINÆ HYPODERMICUS (N. F.)—HYPODERMIC SOLUTION OF MORPHINE.

SYNONYM: *Magendie's solution of morphine.*

Preparation.—"Morphine sulphate, three and one-half grammes (3.5 Gm.) [54 grs.]; distilled water, warm, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Dissolve the morphine sulphate in the warm distilled water, and filter the solution through a small pellet of absorbent cotton. When the solution is cold, pass a little distilled water through the cotton, if necessary, to make the filtrate measure one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Keep the solution in well-stoppered vials in a dark place. *Note.*—Particular care should be taken in dispensing and labelling this solution, so that it may not be mistaken for the so-called United States Solution of Morphine (*Liquor Morphiæ Sulphatis, U. S. P.*, 1870), containing only 1 grain of morphine sulphate in each fluid ounce, which is still used in some parts of this country. The development of fungoid growths or micro-organisms in this and similar solutions used hypodermatically, may be prevented, or at least greatly retarded, by using chloroform water instead of plain distilled water as a solvent. This should, however, be done only with the knowledge, or by the direction, of the physician. Another efficient method to preserve such solutions, is to sprinkle a little benzoic acid on the surface of the absorbent cotton, through which the solutions are filtered. Or, about 5 grains of boric acid may be added to each fluid ounce"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Morphina.*) Each fluid drachm contains about 3 grains of morphine sulphate; 1623 minims contain 54 grains.

Related Morphine Solutions.—Liquor Morphinæ Sulphatis of the *British Addenda*, is composed of 35 grains of morphine sulphate dissolved in sufficient distilled water and rectified spirit (2 fluid ounces), to make 8 fluid ounces of finished product. About ½ grain of morphine sulphate is contained in each fluid drachm. Dose, 10 to 60 minims.

Liquor Morphinæ Citratis (N. F.), *Solution of morphine citrate.*—"Morphine (alkaloid), three and one-half grammes (3.5 Gm.) [54 grs.]; citric acid, three grammes (3 Gm.) [46 grs.]; cochineal, one-tenth of a gramme (0.1 Gm.) [1.5 grs.]; alcohol, twelve and one-half cubic centimeters (12.5 Cc.) [203 ♏]; distilled water, a sufficient quantity to make one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Triturate the solids with the alcohol and eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏] of water: filter, and pass enough distilled water through the filter to make one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. This solution should not be kept on hand, but prepared only when required. Each fluid drachm contains 2 grains of morphine in the form of citrate"—(*Nat. Form.*).

LIQUOR PHOSPHORI (N. F.)—SOLUTION OF PHOSPHORUS.

Synonym: *Thompson's solution of phosphorus.*

Preparation.—"Phosphorus, seven centigrammes (0.07 Gm.) [1 gr.]; absolute alcohol, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; spirit of peppermint (*U. S. P.*), one-half cubic centimeter (0.5 Cc.) [8 ♏]; glycerin, sixty-four and one-half cubic centimeters (64.5 Cc.) [2 fl℥, 87 ♏]. Dissolve the phosphorus in thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of absolute alcohol, in a stoppered vial or test-tube, by immersion in a water-bath and frequent agitation, taking care that any loss of alcohol by evaporation, be made up from time to time. Allow the solution to become nearly cold, and then add to it the remainder of the absolute alcohol and the glycerin, previously mixed and slightly warmed. Finally, add the spirit of peppermint. Keep the solution in a well-stoppered bottle, in the dark. Each fluid drachm contains about $\frac{1}{24}$ grain of phosphorus. *Note.*—This solution must not be confounded with the Spiritus Phosphori (*U. S. P.*), which is not intended to be administered as such, but is only to be used in compounding the elixir or other preparations of phosphorus. The phosphorus should be perfectly translucent, cut and weighed under water, and quickly dried with filtering paper before being dropped into the alcohol"—(*Nat. Form.*).

Uses.—(See *Phosphorus.*)

LIQUOR PICIS ALKALINUS (N. F.)—ALKALINE SOLUTION OF TAR.

Preparation.—"Tar, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; potassa, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; water, six hundred and twenty-five cubic centimeters (625 Cc.) [21 fl℥, 64 ♏]. Dissolve the potassa in the water. Shake the solution with the tar so that the latter may be dissolved, and strain the solution through muslin"—(*Nat. Form.*).

Medical Uses.—(See *Pix Liquida.*)

LIQUOR PLUMBI SUBACETATIS (U. S. P.)—SOLUTION OF LEAD SUBACETATE.

"An aqueous liquid, containing in solution about 25 per cent of lead subacetate (approximately $Pb_2O[C_2H_3O_2]_2 = 546.48$)"—*U. S. P.*

Synonyms: *Goulard's extract, Acetum plumbicum, Acetum saturni, Subacetas plumbicus liquidus, Plumbum hydrico-aceticum solutum.*

Preparation.—"Lead acetate, one hundred and seventy grammes (170 Gm.) [5 ozs. av., 436 grs.]; lead oxide, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the lead acetate in eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.] of boiling distilled water, in a glass or porcelain vessel. Then add the lead oxide, previously passed through a fine sieve, and boil for ½ hour, occasionally adding hot distilled water to make up the loss by evaporation. Remove the heat, allow the liquid to cool, and add enough distilled water, previously boiled and cooled, to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Finally, filter the liquid in a closely-covered funnel. Keep the product in well-stoppered bottles"—(*U. S. P.*).

This solution contains basic acetates, the character of it depending upon the relative proportions of the two lead compounds employed. If molecular proportions be used (and this is aimed at in the official process), a basic salt of the composition $Pb(C_2H_3O)_2.Pb(OH)_2$ is chiefly formed. This preparation changes on keeping, and in reality, like many similar compounds, has the exact pharmacopœial composition but once in its existence, and that is immediately after it is finished.

Description and Tests.—"A clear colorless liquid, odorless, having a sweetish astringent taste, and an alkaline reaction. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate. Specific gravity, about 1.195 at 15° C. (59° F.). When solution of lead subacetate is added to a solution of acacia, it produces a dense, white precipitate (distinction from an aqueous solution of normal lead acetate). In other respects the solution conforms to the reactions and tests given under lead acetate (see *Plumbi Acetas*). If 13.67 Gm. of the solution be diluted with 50 Cc. of water, there will be required, for complete precipitation of the lead about 25 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 1 per cent of lead subacetate), methyl-orange being used as indicator"—(*U. S. P.*).

Action and Medical Uses.—This agent has not been used to any extent in Eclectic practice. By some practitioners it is applied as a topical sedative and astringent to allay *inflammation*, and to lessen *discharges from relaxed tissues. Sprains, bruises, burns, abscesses, inflammatory skin eruptions*, etc., are asserted to have been benefited by its employment. It should never be given internally, nor should it be applied to denuded surfaces, as excoriations, in which it is occasionally recommended, lest lead poisoning should result from its absorption. The diluted form (see *Liquor Plumbi Subacetatis Dilutus*), is more generally preferred.

LIQUOR PLUMBI SUBACETATIS DILUTUS (U. S. P.)—DILUTED SOLUTION OF LEAD SUBACETATE.

SYNONYMS: *Lead water, Aqua plumbica, Aqua saturnina.*

Preparation.—"Solution of lead subacetate, thirty cubic centimeters (30 Cc.) [487 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏). Mix the solution of lead subacetate with enough distilled water, previously boiled and cooled, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Keep the solution in well-stoppered bottles"—(*U. S. P.*).

Lest this solution become cloudy in preparation, great care should be exercised that a previously boiled, pure distilled water be employed, and that the finished product be excluded from the air. As usually dispensed, however, it is somewhat opalescent. It is best prepared in small amount.

Action and Medical Uses.—(Same as *Liquor Plumbi Subacetatis.*)

LIQUOR POTASSÆ (U. S. P.)—SOLUTION OF POTASSA.

"An aqueous solution of potassium hydrate (KOH=55.99), containing about 5 per cent of the hydrate"—(*U. S. P.*).

SYNONYMS: *Solution of potassium hydrate, Solution of potash, Kali hydricum solutum, Lixivium causticum.*

Preparation.—"Potassium bicarbonate, eighty-five grammes (85 Gm.) [3 ozs. av.]; lime, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; distilled water, a sufficient quantity. Dissolve the potassium bicarbonate in four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of distilled water, heat the solution until effervescence ceases, and then increase the heat to the boiling point of the liquid. Slake the lime with about twenty cubic centimeters (20 Cc.) [325 ♏] of distilled water, then mix it well with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of distilled water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of potassium bicarbonate, and boil during 10 minutes. Then add enough distilled water to the flask to make the contents weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and set the flask aside, well-stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation or by means of a siphon"—(*U. S. P.*). The directions of the Pharmacopœia aim at the separation of the carbonic acid radical from the carbonates employed, which is accomplished by the slaked lime. The *U. S. P.* prefers the use of potassium bicarbonate to the carbonates, on account of its greater purity.

Solution of Potassa may also be prepared in the following manner: "Potassa, fifty-six grammes (56 Gm.) [1 oz. av., 427 grs.]; distilled water, nine hundred and forty-four grammes (944 Gm.) [2 lbs. av., 1 oz., 131 grs.]. To make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the potassa in the distilled water. The potassa used in this process should be of the full strength directed by the Pharmacopœia (90 per cent). Potassa of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute potassa (potassium hydrate) contained therein. Solution of potassa should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum"—(*U. S. P.*).

Description and Tests.—"Official Liquor Potassæ is a clear, colorless liquid, odorless, having a very acrid and caustic taste, and a strongly alkaline reaction. Specific gravity, about 1.036 at 15° C. (59° F.). It should conform to the same reactions and tests as an aqueous solution of potassa (see *Potassa*). To neutralize 28 Gm. of solution of potassa should require about 25 Cc. of normal sulphuric acid (each cubic centimeter of the volumetric solution indicating 0.2 per cent of absolute potassium hydrate, phenolphtalein being used as an indicator)"—(*U. S. P.*). A brownish color in liquor potassæ indicates organic matter. It causes a soap-like sensation when rubbed between the fingers, and reddens yellow turmeric paper. It strongly attracts carbon dioxide from the atmosphere, and should, therefore, be kept in closed vessels. It corrodes flint glass, and should be preserved in green glass bottles.

According to Dr. A. B. Garrod, liquor potassæ destroys or renders inert the active principle of hyoscyamus, stramonium, belladonna, etc.; and other caustic alkalies produce similar results. The carbonates or bicarbonates of these alkalies have not the property of destroying the activity of the plants named.

Liquor potassæ decomposes all the alkaloidal salts, and tannin and compounds derived from it. Wool, skins, animal tissue, and some vegetable structures are destroyed by it. Fats are decomposed by it, a soluble soap resulting. The *British Pharmacopœia* (1898) requires liquor potassæ to be of the specific gravity of 1.058, and to contain 5.85 per cent by weight, of hydroxide of potassium, KOH.

Action, Medical Uses, and Dosage.—Solution of potassa, when rubbed between the fingers imparts to them a soapy sensation, which is due to the union of the caustic potash with the oily matter of the skin, producing a soft soap. When the stomach is active, as it is after a meal, solution of potassa in ordinary doses unites with the free gastric acids; but if the stomach be empty and inactive, the solution is absorbed, enters the circulation, neutralizing acidity, and particularly overcoming the acidity of the urine, for it is chiefly eliminated by the kidneys. Hence, if its action on the urine be desired, it should be given between meals, when the stomach is at rest. Symptoms closely resembling those of scurvy are the effect of its continued use. (For acute poisoning with Liquor Potassæ and treatment therefor, see *Potassa*.)

Liquor potassæ is used as an antacid in conjunction with a bitter tonic infusion in *acidity of the stomach.* The solutions of the carbonates are, however, preferable as an antacid. It has also been recommended to remove the tendency to formation of *uric acid in the urine*, but is inferior to the carbonates, which may be used for a longer time, and without debilitating the stomach so soon as the liquor potassæ. This fluid has been found useful as a resolvent in *induration* and *enlargement of the lymphatic glands*, and especially in excessive *enlargement of the glandulæ papillæ* at the end of the tongue. In *scalding of the urethra* accompanying *gonorrhœa*, combined with 10 or 12 drops of laudanum, liquor potassæ will be found to afford prompt relief. It has also been used in *gout* and *rheumatism*, attended with uric acid in the urine, to diminish the viscidity of the mucus in *chronic bronchitis* (injurious in consumption), and in some *chronic skin diseases;* externally it has been used as an application to *ulcers*, and in weak solution in some *skin diseases.* It softens *corns, bunions, warts*, and is employed to destroy *ingrown nails.* The dose is from 5 minims to ½ drachm; it should be taken in some mucilage, or sweetened water, and be repeated 2, 3, or 4 times a day. When taken in quantities to injure the stomach, or in an undiluted state, the proper antidotes are acids which neutralize the alkali, as vinegar, or solutions of acetic or citric acid, or oil may be given to convert it into a harmless soap. If a concentrated solution has been swallowed, and in large quantities, the stomach pump should be preferred to emetics.

Specific Indications and Uses.—Frequent desire to urinate, with a sense of perineal constriction, difficult urination, or strangury; leaden pallor of the tongue and mucous tissues; feeble, tremulous muscles; fullness of muscles; debility all out of proportion to the diseased condition.

LIQUOR POTASSÆ EFFERVESCENS.—EFFERVESCING SOLUTION OF POTASH.

SYNONYMS. *Aqua potassæ effervescens, Potash-water.*

Preparation.—Dissolve potassium bicarbonate, 30 grains, in water, 1 pint (Imp.). Filter. Into the solution pass as much pure washed carbon dioxide (that has been prepared by acting upon chalk with sulphuric acid) as can be forced into it with a pressure of 4 atmospheres. Keep in securely-stoppered bottles to prevent the escape of the imprisoned gas. This accords with the *British Pharmacopœia*, 1885.

Description.—A clear, colorless, sparkling solution, strongly effervescing from the liberation of carbonic acid gas, when the stopper is removed from the container. It has a pleasant acidulous taste.

Medical Uses.—(Same as *Liquor Magnesii Carbonatis.*)

Related Solutions.—LIQUOR SODÆ EFFERVESCENS, *Effervescing solution of soda, Soda water, Aqua sodæ effervescens, Aqua alcalmia effervescens.* This is prepared precisely like the above solution, employing the same quantities, excepting that sodium bicarbonate is used instead of potassium bicarbonate. Its properties and uses are likewise the same as for *Effervescing Solution of Potash.*

LIQUOR LITHIÆ EFFERVESCENS, *Effervescing solution of lithia, Lithia water, Aqua lithiæ effervescens.*—Lithium carbonate, 10 grains; water, 1 pint (Imp.). Prepare precisely like *Effervescing Solution of Potash.* This is a sparkling, clear liquid of a pleasantly acidulous taste. Upon evaporation, each fluid ounce (Imp.) should yield ½ grain of lithium carbonate. For uses, see *Lithii Carbonas.* Dose, 4 to 12 fluid ounces.

LIQUOR SODII CITRO-TARTRATIS EFFERVESCENS (N. F.), *Effervescent solution of sodium citro-tartrate, Tartro-citric lemonade.*—"Sodium bicarbonate, twenty-six grammes (26 Gm.) [401 grs.]; tartaric acid, twenty-four grammes (24 Gm.) [370 grs.]; citric acid, two grammes (2 Gm.) [31 grs.]; syrup of citric acid (*U. S. P.*), fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏︎]; water, a sufficient quantity to make three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏︎]. Dissolve twenty-four grammes (24 Gm.) [370 grs.] of the sodium bicarbonate in two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏︎] of water, add the tartaric and citric acids, and when they are dissolved, the syrup of citric acid. Filter the solution into a strong bottle of about three hundred and sixty cubic centimeters (360 Cc.) [12 fl℥, 83 ♏︎] capacity, and pass enough water through the filter to make the filtrate measure three hundred and twenty cubic centimeters (320 Cc.) [10 fl℥, 394 ♏︎]. Dissolve the remainder of the sodium bicarbonate (2 Gm.) [31 grs.] in thirty cubic centimeters (30 Cc.) [487 ♏︎] of water, filter the solution, pour it on top of the solution in the bottle, which close immediately with a cork, and secure it with twine. Then shake the bottle"—(*Nat. Form.*).

LIQUOR POTASSII ARSENITIS (U. S. P.)—SOLUTION OF POTASSIUM ARSENITE.

Synonyms: *Fowler's solution, Solutio arsenicalis Fowleri, Arsenical solution, Kali arsenicosum solutum.*

Preparation.—"Arsenous acid, in fine powder, ten grammes (10 Gm.) [154 grs.]; potassium bicarbonate, twenty grammes (20 Gm.) [309 grs.]; compound tincture of lavender, thirty cubic centimeters (30 Cc.) [487 ♏]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Boil the arsenous acid and potassium bicarbonate with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of distilled water until solution has been effected. Then add enough distilled water to make the solution, when cold, measure nine hundred and seventy cubic centimeters (970 Cc.) [32 fl℥, 384 ♏], and, lastly, add then the compound tincture of lavender. Filter through paper"—(*U. S. P.*).

Fowler's solution should be prepared every 4 or 5 months instead of being made in large batches to be kept for a longer period, for by oxidation the arsenous acid is gradually changed to arsenic acid, thus rendering the preparation weaker. A fungous vegetation is likewise liable to form in it when long kept. Care should be exercised in the selection of the arsenous acid.

Description.—Fowler's solution is at first an opalescent, afterward pinkish or reddish fluid, having an agreeable slight odor of lavender. It is alkaline in reaction. "If 24.7 Cc. of the solution be boiled for a few minutes with 2 Gm. of sodium bicarbonate, and the liquor, when cold, diluted with water to 100 Cc., and mixed with a little starch T.S., it should require from 46.4 to 50 Cc. of decinormal iodine V.S. to produce the blue tint of iodide of starch (corresponding to 1 Gm. of arsenous acid in 100 Cc. of the solution)"—(*U. S. P.*).

Fowler's solution was introduced into medicine by Dr. Fowler, of Stafford, England, to take the place of a remedy then known as "*tasteless ague drop.*" It is still a question as to whether it be a solution of potassium arsenite, as many believe, or whether it is simply an alkaline solution of arsenous acid.

Action, Medical Uses, and Dosage.—(See *Acidum Arsenosum.*) Dose, ¼ to 5 minims, well diluted, after meals.

LIQUOR POTASSII CITRATIS (U. S. P.)—SOLUTION OF POTASSIUM CITRATE.

"An aqueous liquid, containing in solution about 9 per cent of anhydrous potassium citrate ($K_3C_6H_5O_7$=305.63), together with small amounts of citric and carbonic acids"—(*U. S. P.*).

Synonyms: *Mistura potassii citratis, Liquor kali citrici.*

Preparation.—"Potassium bicarbonate, eight grammes (8 Gm.) [123 grs.]; citric acid, six grammes (6 Gm.) [93 grs.]; water, a sufficient quantity. Dissolve the potassium bicarbonate and the citric acid, each, in forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏] of water. Filter the solutions separately, and wash the filters with enough water to obtain, in each case, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]. Finally, mix the two solutions, and, when effervescence has nearly ceased, transfer the liquid to a bottle. This preparation should be freshly made, when wanted"—(*U. S. P.*).

Description.—"A clear, colorless liquid, odorless, having a mildly saline taste, and a slightly acid reaction. It should conform to the reactions and tests of potassium citrate (see *Potassii Citras*)"—(*U. S. P.*). This preparation is designed to take the place of the less stable, but more agreeable *Mistura Potassii Citratis* (*U. S. P.*, 1880), or *Neutral Mixture*, the formula for which was as follows: "Fresh lemon-juice, strained, 100 parts; bicarbonate of potassium, about 10 parts, or a sufficient quantity. Add the bicarbonate of potassium gradually to the lemon juice until it is neutralized. This preparation should be freshly made when wanted for use"—(*U. S. P.*, 1880). This differs from the official solution in possessing the agreeable flavor of lemons, and in having a yellowish hue. It has been suggested that the two solutions be prepared as above directed and kept separately in proper containers, to be mixed when called for. This, in our opinion, is unwise, inasmuch as solutions of citric acid are prone to decomposition, becoming moldy, and developing, among other substances, free acetic acid, when kept on hand for any great length of time. The old formula of this Dispensatory is as follows:

Triturate citric acid, 2 drachms, with oil of lemons, 2 minims, and then with water, 4 fluid ounces; when the solution is perfected, gradually add crystallized bicarbonate of potassium until effervescence no longer takes place, and filter. In this formula the alkaline salt is decomposed by the citric acid; carbonic acid is given off with effervescence, and citrate of potassium is formed by the combination of the citric acid and the alkali, which is held in solution with some free carbonic acid. When the acid is saturated by the alkali, the solution, after the carbonic acid has been allowed to pass off, will exert no action on blue or red litmus paper. This preparation is similar in medicinal virtue, to the official solution, the citric acid and lemon oil being intended to supply the absence of the lemon juice. It is proper to filter, in order to remove foreign or undissolved substances.

This preparation, like solution of ammonium citrate and solution of sodium citrate, has the power of preventing the inkiness that follows the mixing of ferric salts, such as tincture of chloride of iron, and vegetable astringents. The dry citrates have the same property. The preparation known as *Tasteless Tincture of Iron* is a mixture of tincture of chloride of iron and one of the above salts or solutions. It has a greenish color, an insipid, ferruginous taste, and mixes clear with liquids containing vegetable astringents.

Action, Medical Uses, and Dosage.—This solution is a refrigerant preparation, acting mildly on the skin, bowels, and kidneys. It is very useful in allaying *gastric irritability*. Its sedative and diaphoretic properties may be augmented by the addition of aconite or of digitalis; its diuretic influence is rendered more certain by combining it with sweet spirit of niter; and in *diarrhœa* or *irritable bowels*, some opium or morphine may be added to it. It forms a very grateful draught for fever patients, and may be sweetened with sugar if needed. The dose is a tablespoonful, diluted with about an equal measure of water, and repeated 5 or 6 times, or oftener, in the course of the day. A similar preparation may be given as an effervescent drink, by forming one solution of lemon juice and water, each, ½ fluid ounce; and another, by dissolving bicarbonate of potassium, 1½ drachms in 4 fluid ounces of water. The two solutions are to be mixed, and the whole taken at a draught during the effervescence.

Related Preparation.—Liquor Sodii Citratis (N. F.), *Solution of sodium citrate, Mistura sodii citratis, Saturatio, Potio riveri* (*Ger. Pharm.*). "Citric acid, twenty grammes (20 Gm.) [309 grs.]; sodium bicarbonate, twenty-five grammes (25 Gm.) [386 grs.]; water, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the citric acid in water contained in a bottle, add the sodium bicarbonate, dissolve it by agitation, and immediately stopper the bottle securely. This preparation should be fresbly prepared when wanted for use. *Note.*—The *German Pharmacopœia* directs that when *Saturatio* is prescribed, without any specification of the ingredients or strength, *Potio Riveri*, represented here by *Liquor Sodii Citratis*, be dispensed"—*Nat. Form.*).

LIQUOR POTASSII PERMANGANATIS.—SOLUTION OF PERMANGANATE OF POTASSIUM.

Preparation.—We prefer the old formula of this work, as follows: "Take of permanganate of potassium, 1 part; distilled water, 9 parts; mix and dissolve." This is prepared by the *British Pharmacopœia* (1885), by dissolving permanganate of potassium, 88 grains (1 part), in distilled water, 1 pint (Imp.) (99 fluid parts). This contains, therefore, 1 per cent of the potassium salt. It has the characteristic purple color, but is not a permanent preparation, as upon exposure it decomposes with the deposition of oxides of manganese. It is too weak for some uses and too strong for others. The dose, according to the *British Pharmacopœia* (1885 and 1898), is from 2 to 4 fluid drachms (equal to 1.2 to 2.4 grains of the permanganate).

Description and Medical Uses.—The first-named solution contains 10 per cent of the permanganate, but may be diluted to whatever extent is deemed necessary. It may be used in all cases where the potassium salt is indicated. One part of the solution added to 200 or more parts of distilled water may be used as a local application in *ozæna, putrid sore throat, leucorrhœa, gonorrhœa, offensive otorrhœa*, and to remove the unpleasant odor from the hands after making dissections.

LIQUOR SACCHARINI (N. F.)—SOLUTION OF SACCHARIN.

Preparation.—"Saccharin, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; sodium bicarbonate, thirty-three grammes (33 Gm.) [1 oz. av., 72 grs.]; alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Dissolve the saccharin and the sodium bicarbonate in six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of water, filter the solution, add the alcohol to the filtrate, and pass enough water through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents 4 grains of saccharin. *Note.*—The saccharin directed in the above formula is, properly speaking, 'anhydro-ortho-sulphamine-benzoic acid,' an artificially prepared member of the so-called aromatic series of organic chemicals. It is a body having feebly acid properties, soluble in about 333 parts of water and in 33 parts of alcohol at 15° C. (59° F.). When neutralized by an alkali, it is quite soluble in water. The solution of saccharin is intended to be used for sweetening liquids or solids, when the use of sugar is objectionable, or when a sweet taste is to be imparted to a liquid without increasing its density"—(*Nat. Form.*).

Uses.—(See *Saccharinum.*)

LIQUOR SODÆ (U. S. P.)—SOLUTION OF SODA.

"An aqueous solution of sodium hydrate ($NaOH = 39.96$), containing about 5 per cent of the hydrate"—(*U. S. P.*).

SYNONYMS: *Solution of sodium hydrate, Solution of caustic soda.*

Preparation.—"Sodium carbonate, one hundred and seventy grammes (170 Gm.) [5 ozs. av., 436 grs.]; lime, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; distilled water, a sufficient quantity. Dissolve the sodium carbonate in four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of boiling distilled water. Slake the lime with about thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏] of distilled water, then mix it well with four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of distilled water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of sodium carbonate, and boil during 10 minutes. Then add enough distilled water to the flask to make the contents weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and set the flask aside, well stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation, or by means of a siphon."

Solution of soda may also be prepared in the following manner: "Soda, fifty-six grammes (56 Gm.) [1 oz. av., 427 grs.]; distilled water, nine hundred and forty-four grammes (944 Gm.) [2 lbs. av., 1 oz., 131 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Dissolve the soda in the distilled water. The soda used in this process should be of the full strength directed by the Pharmacopœia (90 per cent). Soda of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5000 by the percentage of absolute soda (sodium hydrate) contained therein. Solution of soda should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum"—(*U. S. P.*).

Description.—"A clear, colorless liquid, odorless, having a very acrid and caustic taste, and a strongly alkaline reaction. Specific gravity, about 1.059 at 15° C. (59° F.). It should conform to the same reactions and tests as an aqueous solution of soda (see *Soda*). To neutralize 20 Gm. of solution of soda should require about 25 Cc. of normal sulphuric acid (each cubic centimeter of the volumetric solution indicating 0.2 per cent of absolute sodium hydrate), phenolphtalein being used as an indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Formerly used in hepatic torpor, in doses of 5 to 40 drops, well diluted. Seldom now employed internally, but used in the preparation of sodium hydroxide, and other sodium compounds.

LIQUOR SODÆ CHLORATÆ (U. S. P.)—SOLUTION OF CHLORINATED SODA.

"An aqueous solution of several chlorine compounds of sodium, containing at least 2.6 per cent, by weight, of available chlorine"—(*U. S. P.*).

SYNONYMS: *Labarraque's solution, Liquor natri chlorati, Liquor natri hypochlorosi, Liquor sodæ chlorinatæ (Br.), Labarraque's disinfecting liquid.*

Preparation.—"Sodium carbonate, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; chlorinated lime, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Triturate the chlorinated lime with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, gradually added, until a uniform mixture results. Allow the heavier particles to subside, and transfer the thinner, supernatant portion to a filter. Then triturate the residue again with two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, transfer the whole to the filter, and when the liquid has drained off, wash the filter and contents with one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏] of water. Dissolve the sodium carbonate in three hundred cubic centimeters (300 Cc.) [10 fl℥, 69 ♏] of hot water, and add this solution to the previously obtained filtrate contained in a suitable vessel. Stir or shake the mixture thoroughly, and, if it should become gelatinous, warm the vessel until the contents liquefy. Then transfer the mixture to a new filter, and, when no more liquid drains from it, wash the filter and contents with enough water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Keep the solution in well-stoppered bottles, protected from light"—(*U. S. P.*).

Mr. Chas. H. La Wall (*Amer. Jour. Pharm.*, 1895, p. 203) pointed out that the process of the *U. S. P.* (1880) is preferable to that given above. This conclusion is fully confirmed by our own experience. The process is as follows: Take of "carbonate of sodium, 100 parts; chlorinated lime, 80 parts; water, a sufficient quantity to make 1000 parts. Mix the chlorinated lime intimately with 400 parts of water in a tared vessel provided with a tightly fitting cover. Dissolve the carbonate of sodium in 400 parts of boiling water, and immediately pour the latter solution into the former. Cover the vessel tightly, and, when the contents are cold, add enough water to make them weigh 1000 parts. Lastly, strain the mixture through muslin, allow the precipitate to subside, and remove the clear solution by means of a siphon"—(*U. S. P.*, 1880). We prefer, however, to stir the sodium carbonate solution, cold, into the lime magma. The mass gradually thickens, forming a stiff dough, but soon, and rather suddenly, breaks up into a thin liquid from which the calcium carbonate readily separates. The clear solution may then be siphoned off and after being assayed, is diluted to its proper strength by the addition of water.

The disinfecting power of this preparation was discovered by Labarraque about 1820. By the above processes double decomposition occurs; hypochlorite of sodium and chloride of sodium are formed in solution, while carbonate of calcium is precipitated according to the equation $Ca(ClO)_2+Na_2CO_3=2NaClO+CaCO_3$.

Description and Tests.—"A clear, pale-greenish liquid, having a faint odor of chlorine, and a disagreeable, alkaline taste. Specific gravity, about 1.052 at 15° C. (59° F.). The solution at first colors red litmus paper blue, and then bleaches it. The addition of hydrochloric acid to the solution causes an effervescence of chlorine and carbonic acid gas. If 6.7 (6.74) Gm. of the solution be mixed with 50 Cc. of water, then 2 Gm. of potassium iodide and 10 Cc. of hydrochloric acid added, together with a few drops of starch T.S., it should require not less than 50 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish tint of the liquid (each cubic centimeter of the volumetric solution corresponding to 0.052 per cent of available chlorine)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This solution, in large doses, is an irritant poison. In small doses it has been used as an antiseptic in all conditions of the system attended with great prostration, dry, brown-coated tongue, and offensive excretions, as in *malignant fevers*, *exanthematous diseases*, *dysentery*, *putrid sore throat*, *anthrax*, *gangrene*, *mercurial salivation*, etc. It has also been used as a local application to remove *fetor*, check *ulceration* and *sloughing*, in *sore nipples*, *burns*, *ozœna*, and in *foul vaginal discharges*; also in some diseases of the skin, as *eczema*, *scald-head*, *prurigo*, etc. Its dose is 20 drops or more, diluted with some mild aqueous liquid. Under the continued use of it, *glandular enlargements* and *chronic mucous discharges* have disappeared, and the secretion of urine is generally increased. When used externally it must be diluted with from 5 to 30 parts of water, according to the sensibility of the tissues or organs to be acted upon by it. In *contagious* or *malignant diseases*, it may be sprinkled around the rooms of the sick, being one of our most valuable disinfectants. The chlorine emanations given off in the room readily penetrate every crevice and corner, and search out the offending particles, without the liquid coming in direct contact.

Related Preparations.—Liquor Potassæ Chloratæ (Chlorinatæ), *Chlorinated potassa solution*. The *Eau de Javelle* of the French is prepared by substituting for the sodium carbonate (in above process) an equal quantity of potassium carbonate. Its composition and bleaching qualities are analogons to those of Labarraque's Solution. It will remove stains of fruits from linen. The *National Formulary* process is as follows:

Liquor Potassæ Chloratæ (N. F.), *Solution of chlorinated potassa*, *Liquor potassæ chlorinatæ*, *Javelle water*.—"Potassium carbonate, fifty-eight grammes (58 Gm.) [2 ozs. av., 20 grs.]; chlorinated lime (*U. S. P.*), eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the chlorinated lime, contained in a tared flask, with four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.] of water. Dissolve the potassium carbonate in three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.] of boiling water, and pour the hot solution into the mixture first prepared. Shake the flask well, stopper it, set it aside to cool, and then add enough water to make the contents weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Allow the suspended matters to subside, and remove the clear solution by means of a siphon, or by straining through muslin. Keep the product in well-stoppered bottles. *Note*.—The chlorinated lime should not contain less than 25 per cent of available chlorine"—(*Nat. Form.*).

Solution of Chlorinated Magnesia.—Fairthorne (1868) proposed this solution as less irritating for internal use. His method of preparation was to dissolve magnesium sulphate (8 ounces) in water (2 pints). Then in a mortar, triturate chlorinated lime (33 drachms) in water (2 pints). Mix the solutions, occasionally agitate the mixture, and after allowing it to stand a half day, pour off the overlying fluid. A little less than 9 grains of magnesia is contained in each ounce.

LIQUOR SODII ARSENATIS (U. S. P.)—SOLUTION OF SODIUM ARSENATE.

Synonyms: *Solution of arseniate of sodium*, *Liquor sodii arseniatis* (*Br.*, 1885).

Preparation.—"Sodium arsenate, deprived of its water of crystallization by a heat not exceeding 149° C. (300.2° F.), one gramme (1 Gm.) [15.5 grs.]; distilled water, a sufficient quantity to make one hundred cubic centimeters (100 Cc.) [3 fl℥. 183 ♏]. Dissolve the sodium arsenate in a sufficient quantity of distilled water to make one hundred cubic centimeters (100 Cc.) [3 fl℥. 183 ♏]. The solution conforms to the reactions and tests of sodium arsenate (see *Sodii Arsenas*)"—(*U. S. P.*).

Description.—A colorless solution containing 1 per cent of anhydrous sodium arsenate. The British process directs 9 grains of the salt to 2 fluid ounces (Imp.) of distilled water, and is, therefore, a 1 per cent solution. This preparation is practically the same as that directed by the *British Pharmacopœia*, 1898.

Pearson's Arsenical Solution (*Liqueur arsénicale de Pearson*, *French Codex*) is a solution of crystallized sodium arsenate (1 part) in distilled water (600 parts). The *National Formulary* directs as follows:

Liquor Sodii Arsenatis, Pearson (N. F.), *Pearson's solution of sodium arsenate*.—"Sodium arsenate, in perfect crystals, one gramme (1 Gm.) [15.5 grs.]; distilled water, six hundred cubic centimeters (600 Cc.) [20 fl℥. 138 ♏]. Dissolve the sodium arsenate in the distilled water, and filter, if necessary. *Pearson's solu-*

tion of sodium arsenate may also be prepared as follows: Solution of sodium arsenate (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; distilled water, ninety cubic centimeters (90 Cc.) [3 fl℥, 21 ♏]. Mix the solution of sodium arsenate with the distilled water. This solution contains about $\frac{1}{10}$ per cent of anhydrous sodium arsenate. *Note.*—This preparation should not be confounded with the *Liquor Sodii Arsenatis* (*U. S. P.*), which is ten times stronger than the above preparation. Pearson's solution is recognized in the *French Pharmacopœia* under the title *Soluté d'Arséniate de Soude* (or *Solution Arsénicale de Pearson*). It is recommended that Pearson's solution be dispensed only when expressly designated as 'Pearson's' "—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(Uses same as for Fowler's Solution of Arsenic.) Dose $\frac{1}{4}$ to 5 minims.

LIQUOR SODII BORATIS COMPOSITUS (N. F.)—COMPOUND SOLUTION OF SODIUM BORATE.

SYNONYM: *Dobell's solution.*

Preparation.—"Sodium borate, fifteen grammes (15 Gm.) [231 grs.]; sodium bicarbonate, fifteen grammes (15 Gm.) [231 grs.]; carbolic acid, crystallized, three grammes (3 Gm.) [46 grs.]; glycerin, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the salts in about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, then add the glycerin, and the carbolic acid, previously liquefied by warming, and, lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Action and Medical Uses.—Dobell's solution is largely used as a cleansing and antiseptic wash in *catarrhal affections of the nose and throat.*

LIQUOR SODII CARBOLATIS (N. F.)—SOLUTION OF SODIUM CARBOLATE.

SYNONYM: *Phénol sodique.*

Preparation.—"Carbolic acid, crystallized, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; soda (*U. S. P.*), three and one-half grammes (3.5 Gm.) [54 grs.]; water, forty-six and one-half grammes (46.5 Gm.) [1 oz. av., 280 grs.]. Dissolve the soda in the water, add the carbolic acid, and warm gently until it is dissolved. This preparation should be made freshly when wanted for use. *Note.*—The formula is based upon that of the *German Pharmacopœia*, I, 1872"—(*Nat. Form.*).

Action and Medical Uses.—(See *Sodium Carbolate.*)

LIQUOR SODII ETHYLATIS.—SOLUTION OF SODIUM ETHYLATE.

Preparation.—"Take of metallic sodium, free from oxide, 22 grains (1 part); ethylic alcohol (absolute alcohol), 1 fluid ounce (20 fluid parts). Dissolve the sodium in the ethylic alcohol contained in a flask, the latter being kept cool in a stream of cold water. The solution should be recently prepared"—*Br. Pharm.*, 1885. The *British Pharmacopœia* (1898) uses the same proportions.

Description.—A syrupy, colorless liquor of the specific gravity 0.867. Upon keeping, it becomes brown. The solution contains 18 per cent of solid sodium ethylate (NaC_2H_5O). It boils when heated, giving off alcoholic vapors, leaving a white residue, which, upon being heated, strongly chars. Mixed with water and heated, this salt yields alcohol, and, upon evaporation of the solution, a white residue, mostly caustic soda, remains. Water should be kept away from this solution. In warm situations it has been known to explode.

Action and Medical Uses.—This agent has been praised by Richardson and Brunton as a local destructive agent, limited in action to the part to which it is applied and causing far less pain than most similar escharotics. But little effect further than redness is produced by its application to the skin until the agent begins to abstract the moisture from the tissues, thereby causing the formation of caustic soda, which gradually attacks the part. Should bleeding take place, it is in part at least checked by the coagulating effect of the alcohol upon the albuminous constituents of the blood. Besides these effects, it is said to prevent the destroyed tissues from putrefactive decomposition. Its action may be controlled by dropping upon the surface a few drops of chloroform. *Vascular nævi* have been successfully destroyed by this agent, and *mother's marks*, *tattoo*, *warts*, *nasal polypi*, *ringworm*, *pile tumors*, *lupus*, *melanotic growths*, and *hypertrichosis* have yielded to its action. It is said to leave but little scarring. It is recommended that *poisoned wounds* and *cystic tumors* be treated with it. It should be applied with a camel's-hair pencil, and, if it causes too much pain, tincture of opium may be combined with it (Richardson).

Related Preparation.—SODIUM ETHYLATE, *Caustic alcohol* (C_2H_5NaO). The pure salt is prepared by the action of absolute alcohol upon metallic sodium. It is a white powder, occasionally tinted brownish. Water dissolves it with a hissing noise, and even a very small quantity of that fluid causes it to split up into alcohol and sodium hydroxide.

LIQUOR SODII OLEATIS (N. F.)—SOLUTION OF SODIUM OLEATE.

Preparation.—"White castile soap, dry and powdered, six hundred and twenty-five grammes (625 Gm.) [1 lb. av., 6 ozs., 20 grs.]; water, a sufficient quantity to make ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏]. Mix the castile soap with twenty-five hundred cubic centimeters (2500 Cc.) [84 fl℥, 257 ♏] of water, so as to produce a uniform and gelatinous mixture. Then add sixty-five hundred cubic centimeters (6500 Cc.) [219 fl℥, 379 ♏] more of water, apply heat until the soap is dissolved, allow the liquid to cool, and add enough water to make it measure ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏]. *Note.*—This solution is intended to be used in the preparation of *Oleates*"—(*Nat. Form.*).

Uses.—(See above.)

LIQUOR SODII SILICATIS (U. S. P.)—SOLUTION OF SODIUM SILICATE.

"Solution of sodium silicate should be kept in well-stoppered bottles"—(*U. S. P.*).

SYNONYMS: *Vitrium solubile*, *Soluble glass*, *Natrum silicium solutum*, *Liquid glass*.

Preparation.—The ingredients used and the proportions vary with the use to be made of the preparation. As a rule, silicate of sodium is prepared by fusing together fine sand (or flint), 1 part, and dried sodium carbonate, 2 parts. The product so obtained is dissolved in boiling water, filtered, and evaporated. Another method is that of fusing a mixture of charcoal, 1 part; exsiccated sodium carbonate, 8 parts; and fine sand, 15 parts. It is never prepared by the pharmacist.

History.—The base (silicium) of this compound is an important constituent of certain rocks and minerals, always as an oxide, often forming whole mountain chains. *Flint*, *sand*, *quartz*, *agate*, *chalcedony*, *amethyst*, and *tridymite*, or *opal*, all contain silicic oxide (SiO_2). This oxide, also known as silica, is present in a pure state in *rock-crystal*. The element *silicon* (*silicium*) has the symbol Si, and the atomic weight 28.3. In combination it forms a large portion of the crust of the earth, and is found in plants, especially in hickory bark, and constitutes the glossy surface of straw. Glass is a mixture of silicates with an excess of silica, and, when colored, the tints are produced by metallic oxides. Hydrochloric acid will dissolve amorphous silicon, while nitro-hydrochloric acid dissolves the crystalline modification. Van Helmont (1640) was the first to observe that a salt of silicon (SiO_2) and salt of tartar (potassium carbonate) would become fluid in the presence of dampness, and the fluid so produced was called the "*liquor of flints*" (*liquor silicum*). Nearly two centuries thereafter (1818), Fuchs demonstrated that such a solution would render substances incombustible, and soon afterward, soda having been substituted for potassa, the preparation became an article of importance under the name "soluble (or liquid) glass," the potassium preparation also bearing this name. In medicine, solution of sodium silicate is used chiefly as a protective dressing; in the arts it is extensively employed in calico printing, making artificial stone, is added to the cheaper soaps, used in fresco painting, for cements, and various other purposes. It is said to have been used instead of gum Arabic in the production of cheap gum-drops. Substances protected with sodium silicate are not readily inflammable, hence the name "*indestructible varnish*" once applied to it.

Description.—Sodium silicate is a transparent, glassy mass. With variable amounts of water of crystallization it may be obtained in crystals of the formula Na_2SiO_3. Upon exposure it becomes opaque on the surface. Boiling water slowly dissolves it, and a thick, syrup-like fluid may be obtained by evaporating an alkaline solution of it. The solution is officially described as "a semi-transparent, almost colorless, or yellowish, or pale greenish-yellow, viscid liquid, odorless, having a sharp, saline, and alkaline taste, and an alkaline reaction. Specific gravity 1.300 to 1.400 at 15° C. (59° F.). A drop of the solution, when held in a non-luminous flame, imparts to it an intensely yellow color. If a portion of the solution, largely diluted with water, be supersaturated with nitric acid, a gelatinous or pulverulent, white precipitate of silicic hydrate will be produced"—(*U. S. P.*).

Sodium silicate falls as a gelatinous deposit upon adding alcohol to it. It should be preserved in glass or stone containers, stoppered with paraffin-coated glass or stone stoppers, or good cork or rubber stoppers may be used instead. The cheap "office mucilage" of commerce is likely to be solution of sodium silicate. In some instances we have known fine plate-glass windows to be ruined by the corrosive action of the silicate "mucilage" which had been used to stick posters thereon.

Action and Medical Uses.—When pure, this agent is claimed by Löwenhaupt to lack antiseptic properties. The ordinary solution, however, is endorsed by many as an antiseptic, having extraordinary control over putrefactive processes. Solutions of ½ of 1 per cent have been used to check the discharges in *vaginitis*, *ulceration of the womb*, *chronic cystitis*, *gonorrhœa*, and in *ozœna*. This agent has also been recommended as a surgical dressing for *fractures*. Over the roller, next to the skin, a layer of cotton should be applied, and this should be wound with *washed* bandages (lest shrinking should strangulate the parts). The solution should then be painted upon the bandage as applied. The limb should remain at rest until 1 or 2 hours have elapsed, when the bandage will have dried. To remove the bandage, soften it with warm water and cut with scissors.

Related Products.—SODIUM SILICO-FLUORIDE (Na_2SiF_6). *Sodium fluosilicate.* If fluor-spar (calcium fluoride, CaF_2) be acted upon by sulphuric acid in the presence of fragments of glass, and the gaseous product—silicon fluoride (SiF_4)—be passed into water, hydrogen silico-fluoride (H_2SiF_6) is formed. This, when neutralized with sodium hydroxide (or the carbonate), will yield sodium silico-fluoride. It does not readily dissolve in water. A solution of it is known as *salufer*. This agent corrodes steel surgical instruments, and was brought forward as a deodorant and antiseptic, and has been claimed by some to be non-toxic, others claiming to have observed poisonous effects from its use. A solution of ½ part to 2000 of water has been used as a topical antiseptic in *ocular*, *aural*, *obstetrical*, and *surgical disorders*, being preferred by some to corrosive sublimate; later observers, however, deny its equality with the latter as a germicide. Undiluted, it is irritant and caustic.

POTASSII SILICAS (K_2SiO_3), *Potassium silicate*, *Soluble glass.*—This compound resembles the sodium salt, but it is more readily melted. It is prepared by fusing together charcoal, 1 part; potassium carbonate, 10 parts; and fine sand, 15 parts. This agent has been used for the same purposes as sodium silicate.

MAGNESII SILICAS.—This compound is native in several minerals, among them being *asbestos*, *talc*, or *French chalk* (see below), sometimes known as *steatite*; *meerschaum* ($2MgO.3SiO_2$), and *soapstone*, a silicate of magnesium and aluminum. The mineral yields a slippery, soft, tasteless, and insoluble powder. *Talc* was formerly used in the *chronic diarrhœa of tuberculosis*. Large doses, in milk, were administered. The treatment, however, is not admired. Talc is an ingredient of some dusting or infant powders.

TALCUM, or *French chalk*, *Talc* ($4MgO.5SiO_2.H_2O$).—This widely disseminated mineral is found in many countries, notably in Austria, Sweden, Bohemia, Shetland Islands, and in this country in New Jersey. It is often called *steatite* or *soapstone*, though, properly the latter differs in containing some aluminum. It is found in masses which split in only one direction. It is unctuous, compact, and glossy, of a whitish or greenish-gray color, and may be easily scratched. Pure talc is practically insoluble in acids and other fluids. Calcium, aluminum, and ferrous compounds are apt to be present in it. When purified of these it forms a good filtering medium. French chalk is largely used by tailors in marking upon cloth and for removing grease stains.

Talcum Purificatum (N. F.), *Purified talcum*.—"Talcum, in fine powder, 100 parts; hydrochloric acid, 15 parts; water, a sufficient quantity. Mix 500 parts of boiling water with the talcum, gradually add 10 parts of the hydrochloric acid, and boil the mixture during 15 minutes. Then allow the suspended talcum to subside, pour off the supernatant liquid, and boil the residue again with 500 parts of water, mixed with the remainder of the hydrochloric acid. Again allow the mixture to become clear by settling, pour off the supernatant liquid, and wash the residue with water, by repeated decantation, until a portion of the wash-water, filtered and placed in a test-tube, ceases to produce a precipitate with test-solution of silver nitrate acidified with nitric acid. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it by heat. *Note.*—Purified talcum is used as an aid in filtering turbid liquids containing finely-divided matters in suspension, which are apt to pass through the filter, or stop up its pores"—(*Nat. Form.*).

LIQUOR STRYCHNINÆ ACETATIS (N. F.)—SOLUTION OF STRYCHNINE ACETATE.

Synonym: *Hall's solution of strychnine.*

Preparation.—"Strychnine acetate, two and one-tenth grammes (2.1 Gm) [32 grs.]; diluted acetic acid (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; compound tincture of cardamom (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Dissolve the strychnine acetate in about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water mixed with the diluted acetic acid, then add the alcohol, compound tincture of cardamom, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Allow the mixture to stand a few days, if convenient, and filter. Each fluid drachm contains $\frac{1}{8}$ grain of strychnine acetate.

Note.—"The *British Pharmacopœia* (1885) directs a *Liquor Strychninæ Hydrochloratis* (with synonym: *Liquor Strychniæ*) which is much stronger, and should not be confounded with the above preparation. It should never be dispensed unless expressly designated. It may be prepared by dissolving 1 grain of crystallized strychnine (alkaloid) in 80 minims of water with the aid of 2 drops of diluted hydrochloric acid, and then adding 20 minims of alcohol. The product contains $\frac{3}{5}$ grain of strychnine in each fluid drachm"—(*Nat. Form.*).

Action and Medical Uses.—(See *Strychnina.*) One-eighth grain of strychnine acetate is contained in each fluid drachm.

LIQUOR STRYCHNINÆ HYDROCHLORATIS.—SOLUTION OF STRYCHNINE HYDROCHLORATE.

Synonym: *Liquor strychninæ* (see note to *Liquor Strychninæ Acetatis*).

Preparation.—Mix 14 minims of hydrochloric acid with $\frac{1}{2}$ fluid ounce of distilled water, and by the aid of heat dissolve in the mixture 9 grains of strychnine, in crystals. Add rectified spirit, $\frac{1}{2}$ fluid ounce, and distilled water, 1 fluid ounce (Imperial measure). This accords with the *British Pharmacopœia*, 1885. The *British Pharmacopœia* (1898) directs a preparation of the same strength, but starts from the hydrochloride of strychnine, one part of which is dissolved in twenty-five fluid parts of alcohol mixed with sufficient water to make one hundred fluid parts.

Action, Medical Uses, and Dosage.—This is a permanent solution containing 1 per cent of strychnine hydrochlorate. It may be employed where strychnine is indicated. Dose, 5 to 10 minims (equal to $\frac{1}{24}$ and $\frac{1}{12}$ grain of the salt).

LIQUOR STRYCHNINÆ NITRATIS.—SOLUTION OF STRYCHNINE NITRATE.

Preparation.—Take of strychnine, in crystals, 4 grains; nitric acid, 6 minims; distilled water, 1 fluid ounce. Add the strychnine to the water, and then add the acid, and agitate until the strychnine is dissolved. This forms a clear, permanent solution.

Action, Medical Uses, and Dosage. May be employed in cases where strychnine is indicated, whether externally or internally. Ten minims contain $\frac{1}{12}$ grain of strychnine. One part of this solution added to three parts of distilled water forms an excellent local application for *weakness of the eyes* following inflammatory attacks of these organs, for *gleet*, *gonorrhœa*, *leucorrhœa* with enfeebled vaginal walls, and *diarrhœa* with debility of the intestines or walls of the rectum. By hypodermatic injection, strychnine may be used in doses of $\frac{1}{100}$ to $\frac{1}{20}$ of a grain; 1 minim of the above solution contains $\frac{1}{120}$ of a grain of strychnine.

LIQUOR ZINCI CHLORIDI (U. S. P.)—SOLUTION OF ZINC CHLORIDE.

"An aqueous solution of zinc chloride ($ZnCl_2$=135.84), containing about 50 per cent. by weight, of the salt"—(*U. S. P.*).

Preparation.—"Zinc, granulated, two hundred and forty grammes (240 Gm.) [8 ozs. av., 204 grs.]; hydrochloric acid, eight hundred and forty grammes (840 Gm.) [1 lb. av., 13 ozs., 276 grs.]; nitric acid, twelve grammes (12 Gm.) [185 grs.]; precipitated zinc carbonate, twelve grammes (12 Gm.) [185 grs.]; distilled water, a sufficient quantity. To the zinc contained in a glass or porcelain vessel, add one hundred and fifty cubic centimeters (150 Cc.) [5 fl℥, 35 ♏] of distilled water; then gradually add the hydrochloric acid, and digest, until the acid is saturated. Pour off the solution, add the nitric acid, evaporate the solution to dryness, and heat the dry mass to fusion at a temperature not exceeding 115° C. (239° F.). Let it cool, and dissolve it in a sufficient amount of distilled water to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Then add the precipitated zinc carbonate, agitate the mixture occasionally during twenty-four hours, and then set it aside until it has become clear by subsidence. Finally, separate the clear solution by decantation, or by means of a siphon"—(*U. S. P.*).

Description.—"A clear, colorless liquid, odorless, having a very astringent, sweetish taste, and an acid reaction. Specific gravity, about 1.535 at 15° C. (59° F.). It conforms to the reactions and tests of an aqueous solution of zinc chloride (see *Zinci Chloridum*)"—(*U. S. P.*). The *British Pharmacopœia* (1898) solution has a density of 1.530, and contains about 40 grammes of zinc (or about 83 grammes of zinc chloride) in 100 Cc. of the preparation. An aqueous solution of zinc chloride was introduced in 1840, as a disinfectant, by Sir William Burnett, and known as *Burnett's Disinfecting Fluid*. Its density is 2.00; contained 200 grains of zinc to the fluid ounce (Imp.).

Action and Medical Uses.—This agent is destructive to some forms of bacteria, and is used chiefly as a disinfectant and deodorant for sinks, vaults, sewers, hospitals, dissecting rooms, and has been injected into cadavers for their preservation, which it accomplishes, but they are rendered unfit for dissection on account of the corrosive action of the preservative upon the scalpel. Internally taken, it has proved fatal. From 10 to 20 drops in 4 fluid ounces of water, have been used in *leucorrhœa* and *gonorrhœa*, and as a collyrium for *ophthalmia*, the result of the latter disease, and of *diphtheria*. Great care should be exercised in its use.

Related Preparations.—Liquor Zinci et Alumini Compositus (N. F.), *Compound solution of zinc and aluminum.* "Zinc sulphate, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; aluminum sulphate, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; naphthol, three grammes (3 Gm.) [46 grs.]; oil of thyme, ten cubic centimeters (10 Cc.) [162 ♏]; water, a sufficient quantity to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. Dissolve the zinc sulphate and aluminum sulphate in five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏] of water, by the aid of heat, add the naphthol and oil of thyme, and shake the mixture occasionally, in a stoppered bottle, until it cools. Set it aside for a few days, if convenient, and then pass it through a wetted filter, following it with enough water to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. *Note.*—The commercial aluminum sulphate (*not* alum) may be used for this preparation. This generally contains a trace of iron, but by allowing the liquid to stand, this will be gradually precipitated"—(*Nat. Form.*).

Liquor Zinci et Ferri Compositus (N. F.), *Compound solution of zinc and iron, Deodorant solution.*—"Zinc sulphate, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; ferrous sulphate, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; copper sulphate, three hundred and twenty-five grammes (325 Gm.) [11 oz. av., 203 grs.]; naphthol, three grammes (3 Gm.) [46 grs.]; oil of thyme, ten cubic centimeters (10 Cc.) [162 ♏]; diluted hypophosphorous acid (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; water, a sufficient quantity to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. Dissolve the zinc sulphate, ferrous sulphate, and copper sulphate, in five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏] of boiling water, add the naphthol, and oil of thyme, and shake the mixture occasionally, in a stoppered bottle, until it is cold. Then add the diluted hypophosphorous acid, filter the liquid through a wetted filter, and lastly, pass enough water through the filter to make five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]. *Note.*—This solution is used as a simple deodorant and antiseptic for common domestic uses when it is unnecessary or impracticable to employ more powerful agents. When a deodorant solution is required for purposes where iron is objectionable, as for instance where woven fabrics are to be steeped in it, the compound solution of zinc and aluminum (F. 248) may be employed"—(*Nat. Form.*).

LIQUOR ZINGIBERIS (N. F.)—SOLUTION OF GINGER.

Synonym: *Soluble essence of ginger.*

Preparation.—"Fluid extract of ginger (*U. S. P.*), three hundred and thirty-five cubic centimeters (335 Cc.) [11 fl℥, 157 ♏]; pumice, in moderately fine powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.,]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Pour the fluid extract of ginger into a bottle, add to it the pumice, and shake the mixture thoroughly and repeatedly in the course of several hours. Then add the water in portions of about one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏], shaking well and frequently after each addition. When all is added, repeat the agitation occasionally during 24 hours, then filter, returning the first portions of the filtrate until it runs through clear, and, if necessary, pass enough water through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Action and Medical Uses.—(Those of *Zingiber.*)

LIRIODENDRON.—TULIP TREE.

The bark of *Liriodendron Tulipifera*, Linné.

Nat. Ord.—Magnoliaceæ.

Common Names: *Tulip tree*, *Yellow wood*, *White wood*, *Poplar*, *Yellow poplar*, *Canoe wood.*

Illustration: Lloyd's *Drugs and Medicines of North America*, Vol. II. Pl. 26.

Botanical Source.—This tree is ordinarily about 80 feet high, with a diameter of 2 or 3 feet, but in favorable situations it frequently attains a height of 140 feet, with a diameter of 8 or 9 feet. The trunk is perfectly straight, cylindric, covered with a bark of a brown or grayish-brown color, smooth when young, rough and furrowed when old. At the top it divides rather abruptly into coarse, crooked branches, in somewhat regular order, giving a symmetrical aspect to the tree; the bark of the young branches is bluish or of a reddish tinge. The leaves are large, bright-green, alternate, on long petioles, smooth, shining, 3-lobed, lateral lobes ovate, middle one truncated, appearing as if cut off by a broad, shallow notch. Lateral lobes of the large leaves furnished with a tooth or additional lobe on their outside. There is a variety with the lobes of the leaves not pointed, but very obtuse. The flowers are large, solitary, terminal, tulip-shaped, yellowish, and 4 to 6 inches in diameter. The bracts are 2, triangular, falling off as the flower expands. The calyx is double, the inner and proper sepals being 3, large, oval, concave, veined, of a pale-green color, spreading at first, and afterward reflexed. The corolla consists of 6, 7, or more petals, which are obtuse, concave, veined, of a pale, yellowish-green color, marked with an irregular indented crescent of a bright-orange on both sides toward the base. Stamens numerous, with short filaments, and long linear, adnate anthers. Pistil a large, conical, acute body, upper half covered with minute, blackish, recurved stigmas; lower furrowed, being a mass of coalescing styles and ovaries. The fruit is a cone of imbricated seed-vessels, which are woody, and solid, their upper portion formed by the long, lanceolate style; the seeds are 2, blackish, and ovate, and one or both often abortive (L.—B.—W.).

History and Description.—This is one of the most magnificent and remarkable trees in the American forests, on account of its size, its elegant appearance when in flower, its therapeutical virtues, and its serviceable wood. It is found in rich soils from Maine to the Gulf of Mexico, and reaches its greatest size in the middle and southwestern states; its flowers appear in May and June. The wood is compact and light, and is extensively used as a substitute for pine. It is but slightly affected by dampness in the air, and is seldom injured by worms. The medicinal part is the bark of the trunk and root. It is whitish, with a yellow tinge when its epidermis is removed, light, fibrous, easily broken, of an unpleasant, somewhat aromatic odor, and an aromatic, pungent, slightly camphoraceous and amarous taste. The root-bark is colored the darkest. When fresh both kinds of bark are white, that of the root turning orange-colored on the surface next the bark, and finally gives the whole piece a streaked aspect; the tree bark turns yellowish. The fresh root bark is much the stronger, being "intensely acrid and bitter, producing, when chewed, a painful, biting sensation approaching to pepperiness" (Lloyd, in *D. and M. of N. A.*, Vol. II, p. 12). The virtues of this bark are somewhat impaired by time, though it may possess some activity after several years' keeping. Water or alcohol take up its active properties, which are dissipated by a continued heat at 100° C. (212° F.). The bark should be collected during the winter. Squirrels are fond of the mature flower buds, which have an aromatic, terebinthinate, bitter taste, and a turpentine-like odor. The leaves are purely bitter, and not acrid.

Chemical Composition.—Prof. J. P. Emmet (*Amer. Jour. Pharm.*, 1831, p. 5) discovered in the bark a peculiar, putty-like principle which he named *liriodendrin*, and which he considered as a camphor and intermediate between the volatile oils and the resins. Emmet obtained it in colorless scales or in needles, insoluble in cold water, soluble in alcohol, ether, or nitric acid, and having an aromatic, bitter, and somewhat acrid taste.

Prof. J. U. Lloyd, as well as Prof. Coblentz, failed to obtain liriodendrin in crystals. Wallace Procter (1872) was likewise unsuccessful. According to Lloyd, "the characteristic principles, aside from the ordinary constituents of plants, are a bitter extractive, volatile oils, resin, coloring principles, and an alkaloid. The aroma of the fresh bark depends upon the volatile oils; the acridity upon the resin; the bitterness (especially of the green leaves), upon the bitter extractive matter; the coloring matter and the alkaloid are not perceptible to either taste or smell" (*D. and M. of N. A.*, Vol. II, p. 15). The active constituent of the bark, according to the physiological investigations of Prof. Roberts Bartholow, is the alkaloid *tulipiferine* first obtained by Prof. J. U. Lloyd in 1886. According to Lloyd's description, it is colorless, odorless, tasteless, slightly soluble in water, but freely in diluted acids. Ammonia water in small amount precipitates it from aqueous solution, and an excess of ammonia dissolves it. All the alkaloidal reagents afford precipitates with solutions of its salts (*D. and M. of N. A.*, Vol. II, p. 16). (For account of color reactions, by Coblentz and Lloyd, see same authority.) The alkaloid was small in amount. A small quantity of a glucosid, soluble in benzol, was separated by Prof. Coblentz.

Action, Medical Uses, and Dosage.—Tulip-tree bark is an aromatic stimulant tonic, and has proved beneficial in *intermittents*, *chronic rheumatism*, *chronic gastric* and *intestinal diseases*, *worms*, and *hysteria*. In *hysteria*, combined with a small quantity of laudanum, it is said to be speedy, certain, and effectual, and also to abate the *hectic fever*, *night-sweats*, and *colliquative diarrhœa of phthisis*. The warm infusion is diaphoretic, and under certain states of the system has proven diuretic. It is now seldom used. Prof. Bartholow found the alkaloid tulipiferine to act energetically upon the nervous system of frogs and rabbits. Dose of the powdered bark, from 20 grains to 2 drachms; of the saturated tincture, which is the best form of administration, 1 fluid drachm; of the infusion, from 1 to 2 fluid ounces; of liriodendrin, from 5 to 10 grains.

Related Drug.—*Calycanthus floridus*, Linné, *Florida allspice*. *Nat. Ord.*—Calycanthaceæ. A shrub, native of the southern states, and common in cultivation both in this country and Europe. The stem is from 6 to 8 feet high and much branched. The leaves are opposite, entire, coriaceous, oval, and borne on short leaf-stalks. The entire plant is pervaded with an aromatic, camphoraceous odor, which is especially the case with the bark and roots. The flowers are nearly sessile and borne near the ends of the branchlets. They are of a brownish-purple color, and exhale, especially when wilted or crushed, an abundant fragrance compared by some to that of the strawberry.

This shrub, in common with other species of Calycanthus, is known also as *Carolina allspice*, *Sweet-scented shrub*, or "*Bubby.*" The *C. lævigatus*, Willdenow, and *C. glaucus*, are similar plants. The Californian *C. occidentalis*, Arnott and Hooker, is called *Spice bush.* The bark contains resin, volatile oil, tannin, and an acrid principle, and the seeds of *C. glaucus* yield fixed oils, albumen, starch, and 2.25 per cent of an alkaloid *calycanthine*, discovered by R. G. Eccles (*Proc. Amer. Pharm. Assoc.*, 1888, p. 84). It dissolves freely in chloroform and ether, and but slightly in water, and is easily decomposable by caustic alkalies, a new crystallizable alkaloid resulting. A strong sweet odor like that of oil of ylang-ylang is at the same time developed. The seeds of calycanthus contain no essential oil, while the bark, flowers, and leaves do. Dr. H. W. Wiley (*Amer. Chem. Jour.*, 1889; see also *Amer. Jour. Pharm.*, 1890, p. 96), confirms the occurrence of *calycanthine* in the seeds of *Calycanthus glaucus*, as well as the reactions described by Dr. Eccles, and obtained 47 per cent of fatty oil from the seeds. This plant has been suggested for use in medicine as a stimulant, antiperiodic, and aromatic; its virtues in these respects are, very probably, in no way superior to the many agents already named in our materia medicas, possessing similar properties.

LITHII BENZOAS (U. S. P.)—LITHIUM BENZOATE.

SYNONYMS: *Lithium benzoicum, Benzoas lithicus.*

FORMULA: $LiC_7H_5O_2$. MOLECULAR WEIGHT: 127.72.

Preparation.—Add carbonate of lithium to benzoic acid mixed with hot water, until effervescence ceases and the acid is dissolved and saturated; then filter and evaporate the filtrate to dryness upon a water-bath, thus: $Li_2CO_3 + 2HC_7H_5O_2 = 2LiC_7H_5O_2 + H_2O + CO_2$. The salt may be obtained in permanent crystals, by evaporating the solution and setting the capsule or vessel aside. In our own experience, 32 parts of benzoic acid, mixed with 128 parts of water, require 11 parts of carbonate of lithium; and the yield is, practically, about that of the weight of the acid employed. The impurities to be expected are such as accompany carbonate of lithium.

Description and Tests.—The official salt is "a light, white powder, or small, shining, crystalline scales; odorless, or of faint benzoin-like odor, and of a cooling, sweetish taste; permanent in the air. Soluble at 15° C. (59° F.), in 4 parts of water, and in 12 parts of alcohol; in 2.5 parts of boiling water and in 10 parts of boiling alcohol. The presence of sodium benzoate increases the solubility in water and lessens that in alcohol. When heated, the salt fuses; at a higher temperature it chars, emits inflammable vapors having a benzoin-like odor, and finally leaves a residue of lithium carbonate mixed with carbon. This residue imparts a crimson color to a non-luminous flame, and its aqueous solution has an alkaline reaction upon litmus paper. The aqueous solution (1 in 20) of lithium benzoate has a faintly acid reaction upon litmus. If 2 Cc. of ferric chloride T.S. be mixed with a small drop of ammonia water, and added to 2 Cc. of an aqueous solution of the salt, a voluminous brownish-pink precipitate of basic ferric benzoate will result. If 1 Cc. of diluted nitric acid be added to 0.2 Gm. of lithium benzoate dissolved in 2 Cc. of water, and the precipitated benzoic acid be removed by filtration, the clear filtrate should not be rendered turbid on addition of silver nitrate T.S. (absence of chloride), or of barium nitrate T.S. (absence of sulphate). If a concentrated solution of the salt be mixed with hydrochloric acid, a white precipitate of benzoic acid will be formed, which, after being separated from the liquid, and thoroughly washed and dried, should respond to the tests of purity given under *Acidum Benzoicum.* If the filtrate from this precipitate be evaporated to dryness and ignited, 1 part of the residue should be soluble in 5 parts of absolute alcohol. If to this alcoholic solution an equal volume of ether be added, no precipitate or turbidity should appear (limit of other alkalies). The aqueous solution (1 in 20) of the salt should remain unaffected by hydrogen sulphide T.S., or ammonium sulphide T.S. (absence of arsenic, lead, iron, aluminum, etc.), or by ammonium oxalate T.S. (absence of calcium), or by sodium cobaltic nitrite T.S. (limit of potassium); nor should silver nitrate T.S., or barium nitrate T.S., produce in it more than a very slight turbidity (limit of chloride and sulphate). If 1 Gm. of dry lithium benzoate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 Cc. of water, it should require, for complete neutralization, not less than 7.8 Cc.

of normal sulphuric acid (corresponding to not less than 99.6 per cent of the pure salt), methyl-orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage. The employment of lithium compounds in medicine is due to the fact that the urate of lithium is much more soluble than the other alkaline urates. Benzoate of lithium was recommended by E. B. Shuttleworth, as an agent superior to other compounds of lithium in the treatment of *gout*, and certain *disorders of the urinary organs*, more especially when there is an *excess of urates*, or of *uric acid*. It is a stable, non-deliquescent preparation, and consists of a combination of two agents, each of which have been found valuable in the treatment of certain forms of urinary difficulties, as well as in *chronic inflammation of the neck of the bladder*. It acts as a diuretic, and is especially useful to prevent gouty paroxysms, by preventing the formation and subsequent deposition of insoluble urates in the tissues, to remove the tendency to excessive deposition of uric acid or urates in the urine, and to render this fluid neutral or alkaline. It is useful in *chronic rheumatism*, where uric acid deposits are voided with the urine. It corrects *ammoniacal urine*, relieves *cystic irritation* from the presence of *gravel*, and is reputed to retard the formation of *biliary calculi*, and the consequent *hepatic colic*. The dose is from 1 to 30 grains, dissolved in a wineglassful of water, repeating the dose 3 or 4 times daily. Doses of from 1 to 5 grains are preferable to the larger doses.

Specific Indications and Uses.—Bad taste, fetid breath, and imperfect nutrition, associated with continuous urinary irritation; lumbar uneasiness extending to the bladder, urine bearing mucus and earthy phosphates, perineum full and tense with frequent desire to micturate, the urine passing with difficulty.

LITHII BROMIDUM (U. S. P.)—LITHIUM BROMIDE.

FORMULA: LiBr. MOLECULAR WEIGHT: 86.77.

SYNONYMS: *Lithium bromatum, Bromuretum lithicum.*

Preparation.—This salt may readily be prepared as follows: To a given amount of solution of hydrobromic acid, in a glass or porcelain evaporating basin, add gradually, with constant stirring, carbonate of lithium until the acid is saturated and effervescence ceases. Then filter, and evaporate the filtrate to dryness. The reaction is represented as follows: $2HBr+Li_2CO_3=2LiBr+H_2O+CO_2$. Owing to the low atomic weight of lithium, its bromide contains about 92 per cent of bromine, while the potassium bromide contains nearly 66 per cent, and the sodium bromide about 78 per cent. Its taste is not so disagreeable as that of the potassium salt, but more so than that of the sodium or ammonium bromides. It is incompatible with solutions of the carbonates of the other alkali metals, forming, by decomposition, carbonate of lithium (Li_2CO_3). "Lithium bromide should be kept in well-stoppered bottles"—(*U. S. P.*).

Description and Tests.—This salt is officially described as "a white, granular salt, odorless, and having a sharp, slightly bitter taste; very deliquescent. Soluble, at 15° C. (59° F.), in 0.6 part of water, and in 0.3 part of boiling water; very soluble in alcohol, also soluble in ether. At a low, red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame. The aqueous solution is neutral to litmus paper. If a few drops of chloroform be added to 5 Cc. of the solution (1 in 20), then 1 Cc. of chlorine water, and the mixture shaken, the liberated bromine will dissolve in the chloroform, communicating to it a yellow, or yellowish-brown color. If 0.5 Cc. of sodium cobaltic nitrite T.S. be added to 5 Cc. of the aqueous solution, no precipitate or turbidity should occur within 10 minutes (limit of potassium). One part of the salt should dissolve, without residue, in 5 parts of absolute alcohol, and the addition of an equal volume of ether should produce no precipitate in this solution (limit of other alkalies). The aqueous solution (1 in 20) should not be affected by hydrogen sulphide T.S. either before or after acidulation with a drop of hydrochloric acid (absence of arsenic, lead, copper, etc.), nor by ammonium sulphide T.S. (absence of iron, aluminum, etc.). In the aqueous solution no turbidity should be produced by the addition of barium chloride T.S (absence of sulphate). If a few drops of starch T.S. be added to 5 Cc. of the aqueous solution, then 1 or 2 drops of chlorine water, no blue color should appear (absence of iodide). If 0.3 Gm. of dry lithium bromide be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require 35.3 Cc. of decinormal silver nitrate V.S. to produce a permanent red color of silver chromate (corresponding to at least 98 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Roubaud, having investigated the action of this compound, arrived at the following conclusions: That it possesses the lithontriptic properties common to the lithium preparations; that, like other bromides, it affects reflex sensibility, with energy, and without that inconvenient action upon the heart usually following the use of bromide of potassium; and that it is useful as a sedative and antilithic in cases of *uric acid diathesis* accompanied by painful phenomena, or complicating neuroses. E. Levy considers it to have a beneficial effect in *gout*, but less so than some of the other salts of lithium, although its influence in diminishing the quantity of uric acid is very small; being very rich in bromine, it is more active than bromide of potassium, having a marked sedative influence upon the cerebro-spinal axis, without affecting the heart. Dr. S. W. Mitchell has found it to be a rapid and powerful soporific agent, more so than any of the other bromides used in therapeutics, and has employed it advantageously in the milder forms of *epilepsy*, in *headache*, *insomnia*, *wakefulness from mental or physical exertion*, and in *tinnitus aurium*, attended with pain in the temporal region and sleeplessness. It has likewise been found beneficial in certain cases of *spermatorrhœa*, *chronic irritability of the neck of the bladder*, and in *irritable uterus*. It is a remedy for *rheumatism* when dependent on *lithæmia*. The dose is from 3 to 10 grains, in well-diluted solution, which should be repeated 3 or 4 times a day. Owing to its extreme deliquescence, this salt should be kept in aqueous or alcoholic solution.

Specific Indications and Uses.—Flushed countenance; mental depression; insomnia, due to mental and physical exhaustion; severe inter-scapular pain; mild attacks of epilepsy; renal inactivity.

LITHII CARBONAS (U. S. P.)—LITHIUM CARBONATE.

FORMULA: Li_2CO_3. MOLECULAR WEIGHT: 73.87.

SYNONYMS: *Carbonas lithicus*, *Carbonate of lithia*, *Normal carbonate of lithium*.

Preparation.—This salt may be prepared by pouring a concentrated solution of chloride of lithium (LiCl) into a solution of ammonium carbonate, in ammonia water, continuing the process until the precipitate ceases to form upon heating. (For its preparation from the lithium-bearing minerals, *lepidolite*, *petalite*, *spodumene*, etc., see C. Thompson, *Amer. Jour. Pharm.*, 1883, p. 318; also L. F. Kebler, *ibid.*, 1898, p. 600.)

Description and Tests.—"A light, white powder, odorless, and having an alkaline taste; permanent in the air. Soluble in 80 parts of water at 15° C. (59° F.), and in 140 parts of boiling water; much more soluble in water saturated with carbon dioxide; insoluble in alcohol; soluble in diluted acids with active effervescence. At a low, red heat the salt fuses, at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. It imparts a crimson color to a non-luminous flame. The aqueous solution has an alkaline reaction upon litmus paper. If 1 Gm. of lithium carbonate be dissolved in 40 Cc. of diluted acetic acid, no insoluble residue should remain. Separate portions of this solution should not be affected by the following reagents: Hydrogen sulphide T.S. (absence of arsenic, lead, etc.), ammonium sulphide T.S. (absence of iron, aluminum, etc.), ammonium oxalate T.S. (calcium), silver nitrate T.S. (chloride), barium chloride T.S. (sulphate), or sodium cobaltic nitrite T.S. (limit of potassium). If 0.5 Gm. of lithium carbonate be dissolved in 2 Cc. of hydrochloric acid, and the clear solution be evaporated to dryness, the dry residue should completely dissolve in 3 Cc. of absolute alcohol, and an addition of 3 Cc. of ether should not render the solution turbid (limit of other alkalies). If 0.5 Gm. of the dry salt be mixed with 20 Cc. of water, it should require, for complete neutralization, not less than 13.4 Cc. of normal sulphuric acid (corresponding to at least 98.98 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*).

The alcohol-ether test serves to distinguish lithium carbonate from the more probable impurities, carbonates of potassium and of sodium, the chlorides of which elements are not soluble, especially in the latter of the menstrua named. Carbonate of lithium has been fraudulently adulterated with sugar of milk. This may be detected by its reduction of the copper salt in Fehling's solution; also by the adulteration emitting a caramel odor and turning black when exposed to calcination heat.

HYDROGEN LITHIUM CARBONATE, or the *Acid lithium carbonate* ($HLiCO_3$), is formed when freshly precipitated normal carbonate of lithium is suspended in water and exposed to a current of carbon dioxide. This salt is more soluble than the common carbonate, about 5 parts dissolving in 100 parts of water. It readily decomposes by exposure, and by evaporation on the water-bath, forming normal carbonate of lithium, carbon dioxide, and water, thus: $2HLiCO_3 = Li_2CO_3 + H_2O + CO_2$. The acid salt is not obtainable in solid form, except, perhaps, upon exceedingly slow evaporation of the bicarbonate solution (A. Goldammer, *Amer. Jour. Pharm.*, 1886, p. 347). It is, probably, the form in which it exists in mineral waters.

Action, Medical Uses, and Dosage.—Carbonate of lithium is considered a diuretic, and an energetic alkalizing agent of the urine. Administered internally, it causes the insoluble urates of the blood to form soluble urates of lithium, and hence has been advised in *gout*, and in *urinary deposits of uric acid* and *urates*, the same as the benzoate and the citrate of this alkali. The action of these agents may fail under certain conditions of the system, which, after having been ascertained, should be removed by appropriate measures previous to the administration of the lithium salts. Lithium carbonate is reputed a powerful solvent of *false membrane*. The dose of carbonate of lithium is from 1 to 4 grains, in a gill or so of hot water, repeating it 3 or 4 times a day. Garrod and Charcot advise it to be taken as follows: Water, charged with carbonic acid, 1 pint; bicarbonate of sodium, 3 grains; carbonate of lithium, 1½ grains. Mix, and keep well-stoppered. This quantity is to be used daily, in wineglassful doses, continuing to prepare and use it for 2 or 3 consecutive weeks.

Specific Indications and Uses.—Indigestion and acid eructations, with urinary deposits; articular swellings; gout.

Lithium and Its Compounds.—LITHIUM, *Lithium*. Symbol: Li. Atomic Weight: 7.01. Lithium is the metallic base of an alkaline oxide, lithia, and as yet has not been employed in medicine nor in the arts. The name, meaning "stony," is derived from the Greek *lithos*, a stone. The alkali was discovered by Arfvedson, in 1817; the element, by Bunsen and Matthiessen, in 1855. Lithium is very widely distributed, but in small quantities, a fact brought out by the development of spectrum analysis by Kirchhoff and Bunsen. The important minerals which contain it are *triphyline* (a phosphate of iron, manganese, sodium, and lithium), *petalite* and *spodumene* (both silicates of aluminum, sodium, and lithium), and *lepidolite* (a silicate of aluminum, potassium, and lithium). *Lithrophilite* and *amblygonite* are lithium-bearing minerals, also, occurring in North Carolina, and containing from 9 to 10 per cent of lithium oxide. Some mineral springs are likewise found to contain it, notably one in the Wheal Clifford Mine, in Cornwall, England. Our Gettysburg Springs, Penn., and the Buffalo Lithia Springs, Mecklenburg County, Va., likewise contain it. Lithium is much less oxidizable, and harder than either potassium or sodium, but softer than lead. When freshly cut it exhibits a silver-like surface which tarnishes by exposure. It melts at 180° C. (356° F.), is the lightest of all known solids, having a specific gravity of 0.5986, floats on benzin and on water, quickly oxidizing in the latter case, but without fusing. Lithium is of interest to the medical profession from the fact that several compounds of it are employed in medicine. They are chiefly the carbonate, benzoate, bromide, salicylate, and citrate, the first being employed in the production of the others. However, the claims as to the curative properties of lithia and lithia-water springs, in cases of gout, rheumatism, and uric acid diathesis, are liable to be exaggerated. It must be borne in mind, as Mr. L. Siebold, in 1889, has pointed out, that lithia owes its distinction over caustic soda or potassa as a uric acid solvent, only to its small molecular weight. Much less of lithia than of soda or potassa is necessary to dissolve the same quantity of uric acid. Furthermore, lithium in the form of chloride, or sulphate, has not the slightest solvent action upon uric acid (see *Amer. Jour. Pharm.*, 1889, p. 530, and 1894, p. 588).

LITHII BOROCITRAS.—Three borocitrates of lithium have been prepared for medicinal purposes—the mono-, the di-, and the tri-borocitrate of lithium. The first ($C_6H_6Li[BO]O_7 + H_2O$) requires for its production lithium carbonate, 4 parts; boric acid, 6 parts; and citric acid, 20 parts. The second ($C_6H_4Li_2[BO]_2O_7 + 2H_2O$) requires lithium carbonate 7 parts; boric acid, 12 parts; and citric acid, 20 parts. The third ($C_6H_5Li_2O_7 + B_2H_3O_6$) is prepared from lithium carbonate, 11 parts; boric acid, 18 parts; citric acid, 20 parts. The ingredients are dissolved in boiling water, evaporated to dryness, and powdered, or the concentrated, syrupy solution may be painted upon glass and scaled (E. Scheibe, 1880; *Amer. Jour. Pharm.*, 1881, p. 66).

Lithii Chloridum, *Lithium chloride*. Symbol: LiCl. Molecular weight: 42.38. This is prepared from *lepidolite*. This compound forms anhydrous octohedra, soluble in water and alcohol. Its taste is saline, and it fuses at a red heat. Exposed to the air it readily deliquesces. Evaporation of its *aqueous* solution produces slight decomposition, traces of hydrochloric acid being evolved, and a corresponding amount of lithium oxide, of an alkaline reaction, being formed. Lithium chloride combines with water of crystallization in two proportions, forming $LiCl+H_2O$ and $LiCl+2H_2O$.

Lithii Iodidum, *Lithium iodide*. Symbol: LiI. Molecular weight: 133.54. This salt may be prepared by the process for making bromide of lithium, excepting that *hydriodic* is substituted for *hydrobromic acid*. Prof. Zeiset, of Vienna, prepared it by double decomposition of ferrous iodide with lithium carbonate (*Amer. Jour. Pharm.*, 1882, p. 308). This salt is crystalline, and forms with $3H_2O$ deliquescent, prismatic crystals which, when exposed, have a tendency to become yellow, on account of the liberation of iodine. It dissolves readily in water and alcohol, and should be kept in tightly-stoppered vials.

Effervescing Lithium Carbonate may be prepared by heating in a flat vessel, to 100° C. (212° F.), with constant stirring until a granular product results, a mixture (all well powdered) of lithium carbonate (10 parts), sodium bicarbonate (50 parts), and citric acid (40 parts). Pass the product through a coarse sieve, and place the granules in closely-stoppered vials.

LITHII CITRAS (U. S. P.)—LITHIUM CITRATE.

Formula: $Li_3C_6H_5O_7$. Molecular Weight: 209.57.

Synonyms: *Lithiæ citras*, *Lithium citricum*, *Citrate of lithia*.

Preparation.—Take of carbonate of lithium, 1 part; citric acid in crystals, 2 parts, or a sufficient quantity; distilled water, a sufficient quantity. Mix the carbonate of lithium with 2 parts of water heated to the temperature of 82.2° C. (180° F.), in a capacious glass or porcelain vessel. Then dissolve the citric acid in 4 parts of water, at the same temperature, and gradually pour a sufficient amount of the acid solution, with constant stirring, into the mixture of carbonate of lithium and water, to dissolve the carbonate. Then raise the temperature to 93.33° C. (200° F.), and cautiously stir into the solution a few grains of carbonate of lithium; if effervescence ensues, continue adding more of the carbonate until it is in *slight* excess; now filter the solution, evaporate, at a gentle heat, to the consistence of syrup; then dry in a warm-air closet, until the salt will pulverize, and inclose it in a well-stoppered bottle.

As usually made, citrate of lithium is a very unsatisfactory preparation, from its proneness to deliquesce. To a great extent, this property is derived from the *excess* of citric acid usually present. We will call attention to the fact that, by reversing the process of the *U. S. Pharmacopœia* (1870) and adding the solution of citric acid (q. s.) to the carbonate of lithium, better results appear to be obtained than with the process of the Pharmacopœia. Citrate of lithium, prepared as above, may contain a *slight* proportion of carbonate of lithium, an unimportant contamination. It is liable to contain all the impurities present in both the citric acid and the carbonate of lithium employed in its preparation. "Lithium citrate should be kept in well-stoppered bottles"—(*U. S. P.*).

Description and Tests.—The *U. S. P.* describes the salt to be "a white powder, odorless, and having a cooling, faintly alkaline taste; deliquescent on exposure to air. Soluble in 2 parts of water at 15° C. (59° F)., and in 0.5 part of boiling water; almost insoluble in alcohol or ether. At a red heat the salt chars, emits inflammable vapors of a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution is neutral to litmus paper. If the aqueous solution (1 in 20) of lithium citrate be boiled with an equal volume of calcium chloride T.S., a white precipitate will be deposited"—(*U. S. P.*). Crystallizable lithium citrate is not deliquescent. According to Mr. Nunnery it has the composition $Li_3C_6H_5O_7+4H_2O$, corresponding to 74.3 per cent of anhydrous salt. (For a valuable résume of the methods of its preparation and analysis, see C. Thompson, *Amer. Jour. Pharm.*, 1883, p. 314.)

As regards tests, the *U. S. P.* directs as follows: "Separate portions of the solution, slightly acidulated with acetic acid, should not be affected by hydrogen sulphide T.S. (absence of arsenic, lead, etc.); ammonium sulphide T.S. (iron, aluminum, etc.); ammonium oxalate T.S. (calcium); or sodium cobaltic nitrite T.S. (limit of potassium). With barium nitrate T.S., or with silver nitrate T.S., not more than a slight turbidity should appear (limit of sulphate and of chloride). If the residue obtained by calcining the salt at a red heat be dissolved in a slight excess of diluted hydrochloric acid, and the filtrate evaporated to dryness, a portion of the residue, treated with 5 parts of absolute alcohol, should completely dissolve, and the addition of an equal volume of ether should not render the solution turbid (limit of other alkalies). If 1 gramme of dry lithium citrate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 Cc. of water, it should require, for complete neutralization, not less than 14.2 Cc. of normal sulphuric acid (corresponding to at least 99.2 per cent of the pure salt), methyl orange being used as indicator"—(U. S. P.).

Action, Medical Uses, and Dosage.—Citrate of lithium is employed in the same affections as lithium carbonate, and in the same doses; being the more soluble of the two, it has been preferred to that salt. Its dose, as with that of the carbonate, may be carried to from 15 grains to even half a drachm; but these large doses are apt to occasion cardialgic dyspepsia. Lithium citrate is excreted in the urine as a carbonate. The iodide and sulphate of lithium have occasionally been employed therapeutically, but no especial advantage has yet been derived from their use. The specific indications for lithium citrate are those given below.

Specific Indications and Uses.—Indigestion and acid eructations, with urinary deposits; articular swellings; gout.

LITHII CITRAS EFFERVESCENS (U. S. P.)—EFFERVESCENT LITHIUM CITRATE.

Preparation.—"Lithium carbonate, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; sodium bicarbonate, two hundred and eighty grammes (280 Gm.) [9 ozs. av., 384 grs.]; citric acid, three hundred and seventy grammes (370 Gm.) [13 ozs. av., 22 grs.]; sugar, in fine powder, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Triturate the citric acid with about two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.] of sugar, and dry the mixture thoroughly. Then incorporate with it, by trituration, the lithium carbonate and sodium bicarbonate, and enough sugar to make the product weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Keep the powder in well-stoppered bottles"—(U. S. P.).

Action, Medical Uses, and Dosage.—(See *Lithii Citras.*) This furnishes a pleasantly acidulous form for the administration of lithium citrate. Dose, ½ to 2 drachms.

LITHII SALICYLAS (U. S. P.)—LITHIUM SALICYLATE.

FORMULA: $LiC_7H_5O_3$. MOLECULAR WEIGHT: 143.68.

SYNONYM: *Lithium salicylicum.*

Preparation.—Heat together, until effervescence ceases, a mixture of lithium carbonate, 3 parts, salicylic acid, 11 parts, and water, 25 parts. Filter, wash, evaporate, and dry the salt, and place it in a closely-stoppered vial.

Description and Tests.—This salt is official as "a white or grayish-white powder, odorless, and having a sweetish taste; deliquescent on exposure to air. Very soluble in water and in alcohol. When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution slightly reddens blue litmus paper. If copper sulphate T.S. be added to an aqueous solution (1 in 20) of the salt, the mixture should have a bright-green color. If a small quantity of ferric chloride T.S. be added to an excess of a concentrated aqueous solution (1 in 4) of lithium salicylate, a deep-red color will be produced, which, after the liquid is largely diluted and mixed with more ferric chloride T.S., will change to a deep bluish-violet tint. Upon adding to 1 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, then cautiously, in drops, about 1 Cc. of methylic alcohol, and heating the mixture to boiling, the odor of oil of gaultheria will be evolved. Hydrochloric or sulphuric acid produces in the aqueous solution a voluminous precipitate of salicylic acid, which, when separated and washed, should conform to the reactions and tests given under *Acidum Salicylicum*. The aqueous solution should be colorless (absence of iron and organic coloring matters), and should not effervesce on the addition of diluted acids (absence of carbonate). If 1 part of the salt be agitated with 15 parts of sulphuric acid, no color should be imparted to the acid within 15 minutes (absence of readily carbonizable, organic impurities). If a portion of the residue, left after ignition, be dissolved in diluted acetic acid, separate portions of the filtrate should not be rendered turbid on the addition of a few drops of barium chloride T.S. (absence of sulphate), nor be rendered more than slightly turbid by silver nitrate T.S. (limit of chloride). Other portions of the same filtrate should not be affected by hydrogen sulphide T.S. (absence of arsenic, lead, etc.); nor by ammonium sulphide T.S. (aluminum, etc.); nor by ammonium oxalate T.S. (calcium); nor by sodium cobaltic nitrite T.S. (limit of potassium). If another portion of the residue, left after ignition, be dissolved in diluted hydrochloric acid, and the filtrate evaporated to dryness, a portion of the residue, when treated with 5 parts of absolute alcohol, should completely dissolve, and the addition of an equal volume of ether should not render the solution turbid (limit of other alkalies). If 2 Gm. of dry lithium salicylate be thoroughly ignited in a porcelain crucible, so as to burn off most of the carbonaceous matter, and the residue be mixed with 20 Cc. of water, it should require, for complete neutralization, not less than 13.8 Cc. of normal sulphuric acid (corresponding to at least 99.13 per cent of the pure salt), methyl-orange being used as indicator"—(*U. S. P.*). M. Julliard (*Amer. Jour. Pharm.*, 1887, p. 400) records an adulteration of lithium salicylate with from 12 to 15 per cent of sodium salicylate.

Action, Medical Uses, and Dosage.—This agent, like the other lithium compounds, is employed in *gout*, and, like the sodium salicylate, as a remedy for *rheumatic affections of the joints*, claims having been made that it succeeds where the latter fails. It contains more of the salicylic acid radical than the sodium compound, and large doses have been charged with the induction of persistent, painful diarrhœa. Dizziness, tinnitus, impaired hearing and headache, are also effects of immoderate doses, the latter ceasing first. The average dose is from 1 to 8 grains, though as high as 75 grains have been given in a day. Such large doses are unnecessary and unsafe.

LITHOSPERMUM.—LITHOSPERMUM.

The roots and seeds of *Lithospermum officinale*, Linné.

Nat. Ord.—Borraginaceæ.

Common Name: *Common gromwell.*

Illustration: Woodville's *Medical Botany*, Plate 105.

Fig. 162.

Lithospermum canescens.

Botanical Source and Chemical Composition.—This is a large, rough, hairy weed, a native of Europe, and very common in some parts; it is rarely naturalized in the eastern section of the United States, and is found growing in dry and gravelly soils. The stem is from 1 to 2 feet high, erect, much-branched, and covered with small, stiff hairs. The leaves are numerous, veiny, alternate, sessile, ovate, and acute at the apex. They are covered with a close, grayish pubescence, which is rough and stiff on the upper surface, but softer beneath. The flowers appear in June, and are small, in axillary or terminal, revolute, leafy spikes. The calyx has 5 acute lobes. The corolla is salver-form, slightly exceeds the calyx, and is of a pale-yellow color. The fruit consists generally of one or two smooth, hard, shiny, gray, ovate nutlets, which are attached to the persistent calyx by the base. A native species of Lithospermum, *L. latifolium*, Michaux, closely resembling *L. officinale*, especially in the smooth, polished nutlets, and considered a variety of it by Willdenow, is common in the open woods of the middle states. It has green leaves, and is more loosely branched than the introduced species. The ash of the seeds, according to Hornberger (1875), is rich in calcium carbonate (68.2 per cent) and silica (19.39 per cent). The root bark of *Lithospermum arvense*, Linné, contains a red coloring matter, *lithospermum red*, isolated by Ludwig and Kromayer (*Archiv der Pharm.*, 1858, Vol. CXLVI, p. 278).

Action, Medical Uses, and Dosage.—This plant is diuretic, possessing properties analogous to those of the *Onosmodium Virginianum*, and deserves further investigation. It has proved efficient in both *acute* and *chronic cystitis*, and likewise in certain *calculous affections*. A strong infusion of the dried root, 1 ounce to water 1 pint, may be given every 3 hours in tablespoonful doses. The seeds, in powder, are used in half-teaspoonful doses every 4 or 5 hours (King).

Related Species.—*Lithospermum canescens*, Lehm, *Hoary puccoon*, or *alkanet*; also called in some sections *Indian paint root*. Dr. R. C. Ely (*E. M. J.*, 1882 and 1886) claims for this plant wonderful healing properties in *cuts, wounds, old sores, gunshot wounds, eczema*, and *burns*. The ointment is used. It is prepared by simmering the root in lard or fresh butter. The ointment has a pale-purple color, due to a coloring matter identical with alkanet found in the roots of the species of Lithospermum. (See illustration on page 1198.)

LOBELIA (U. S. P.)—LOBELIA.

"The leaves and tops of *Lobelia inflata*, Linné, collected after a portion of the capsules have become inflated"—(*U. S. P.*).

Nat. Ord.—Lobeliaceæ.

Common Names: *Lobelia, Indian tobacco*, etc. (see *History*).

Illustrations: Lloyd's *Drugs and Med. of N. A.*, Plate 34; Bentley and Trimen, *Med. Plants*, 295.

Fig. 163.

Lobelia inflata.

Botanical Source.—This plant, generally known as Wild, or Indian tobacco, is an annual or biennial indigenous plant, more commonly the latter, with a fibrous, yellowish-white root, and an erect, angular, very hairy stem, in the full-sized plant much branched, and from 6 inches to 3 feet in height. The leaves are alternate, scattered, sessile, ovate-lanceolate, serrate, veiny, and hairy. The flowers are small, numerous, pale-blue, on short peduncles, each originating from the axil of a small leaf. The calyx consists of 5, subulate segments. The corolla is tubular, small, slit on the upper side, ventricose at the base; the limb bilabiate; tube prismatic; segments spreading, acute; two upper ones lanceolate, three lower ones oval. The anthers are united into an oblong, curved body, and of a purple color; filaments white. Style filiform; stigma curved, 2-lobed, inclosed by the anthers. The capsule is 2-celled, ovoid, inflated, striated, 10-angled, crowned with the persistent calyx. The seeds are numerous, small, oblong, and brown (L.—B.—W.).

Fig. 164.

Seed of Lobelia inflata.

History.—Lobelia is very plentiful throughout the United States, and is usually found thriving in dry soil along roadsides, in dry fields, and old pastures, as well as in woodland grazing grounds. It flowers from July to September, or until frost checks its blooming. It grows from a few inches to 2 feet in height, and is peculiar in that it will blossom when the flowering time arrives, even if it be but an inch in height. The plant has alternate leaves, and flowers of a light blue color, inconspicuous, yet very pretty when closely examined, having the characteristic split corolla tube (along the upper side) of the *Lobelias*. The fruit is an inflated pod, resembling a small balloon, easily compressible, and contains an innumerable number of minute brown seeds. The plant, when broken or cut, exudes an acrid, milky juice, imparting a taste very much resembling that of tobacco. The whole plant is active, but the leaves and seeds are more usually employed. The root is supposed to be more energetic, medicinally, than any other part of the plant. The proper time for gathering the plant is from the last of July to the middle of October, during which period the seed-vessels are in great abundance. The plant should be dried in the shade, and then be preserved in packages, or covered vessels, more especially if it be reduced to powder. When dried, it has a faint, nauseous, rather disagreeable odor, and a strong, acrid, nauseous taste developed by chewing, somewhat similar to that of tobacco, which powerfully affects the throat and fauces, occasioning ptyalism and sickness at stomach. The leaves form a greenish powder; the seeds a brownish. Hot water, vinegar, ether, or alcohol take up its medicinal principles, but boiling dissipates them.

Few drugs are more favored among Eclectic physicians than lobelia, and certainly none others have so interesting a history. This plant is vulgarly known as Indian tobacco, though why it should have this name is difficult to say, as there is no distinct record as is the case with other plants (unless we accept the statements made that it was known to the Penobscot tribes), that it was ever employed as a medicine by the natives. As the plant resembles somewhat in taste the common tobacco (*Nicotiana Tabacum*), and was for this reason called Wild tobacco, the authors of "*Drugs and Medicines of North America*" advance the opinion that if known as Wild tobacco it was but a step farther to call it Indian tobacco, on the presumption that a tobacco that was wild would be used by the Indians. The earliest botanists did not use a common name for lobelia, and it was not until 1810 that we find the first popular name—Bladder-pod—given it by Aiton. Following this came Inflated lobelia and Bladder-pod lobelia for obvious reasons. So much for names suggested by the plant itself. When it came to be used in medicine a new set of popular names, having reference to its properties, were applied. Thomson and Cutler called it Emetic weed and Emetic herb. These names suggested those to follow—Puke weed, Vomit weed, and Gag root. Although the term gag root was employed, the root was never used in medicine, statements to the contrary notwithstanding. One of its very old names is Eye-bright—a name properly belonging to *Euphrasia officinalis*, and, from its use as an anti-asthmatic, some writers have referred to it as Asthma weed. Its generic name—lobelia—was given it in honor of Matthias de Lobel (de l'Obel), a distinguished botanist of the sixteenth century; its specific name—inflata—on account of its inflated seed pods.

Though lobelia grows nearly all over this country, much of the drug supply of commerce comes from the mountainous districts of North Carolina. Lobelia was known to the Penobscot Indians, and was also extensively used by the people in New England in domestic practice, long before the time of Samuel Thomson, its assumed discoverer. Though used by a few in domestic practice, the credit for the introduction of lobelia into medical practice is due to Drs. Manasseh Cutler and Samuel Thomson. The latter claims to have been the first to employ it and, indeed, it would seem probable that Cutler learned the use of it from Thomson. As before stated, few drugs have been so notoriously historical as the one under consideration. It became widely known to the people during the early part of the present century, through the famous trials of Drs. Thomson and Frost. The name of lobelia became so odious, that to be known as a "lobelia doctor" was sufficient to subject the physician to all manner of ridicule. The prosecution of Thomson was brought at the instigation of a jealous physician—Dr. French—backed by a jealous profession. While under treatment by Dr. Thomson, one Ezra Lovett, of Beverly, Mass., died after a tedious course of medicine applied after the peculiar method of Thomson. The prosecutors charged the latter with killing Lovett with lobelia. Thomson denied it, claiming the drug employed to be marsh rosemary. The prosecutors showed their ignorance by exhibiting to to the court some of the powder alleged to have been employed, which powder actually proved to be marsh rosemary. Judge Parsons instructed the jury to acquit Thomson. The memory of lobelia was again revived, in 1837, by the tria of Dr. R. K. Frost, of New York City, for the alleged killing of T. G. French. Th charge against Frost was that he put French into a "vapor bath" and "administered to him poisonous decoctions of lobelia, and giving deleterious herbs which no reasonable man would administer to a dog." He was tried for manslaughter, the trial lasting ten days, and the jury found him guilty in the fourth degree, but recommended him to the mercy of the court. The court sentenced him to three months' imprisonment.

The first published account of the use of lobelia in regular medicine, is by the Rev. Manasseh Cutler, LL. D., in his "*Account of Indigenous Vegetables*" (1785), stating that the leaves, if chewed, "produce a giddiness and pain in the head, with a trembling agitation of the whole body." Cutler was a great sufferer from asthma and found this drug to give him more relief than any other, and as Thomson had been in the habit of using lobelia for this complaint, and practicing so near to the home of Cutler, in Massachusetts, it is fair to presume that the latter derived his knowledge of the drug from Thomson. As early as 1820, the first edition of the *U. S. P.* recognized lobelia and it has continued official until the present time.

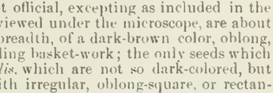
Description.—The *U. S. P.* officially describes lobelia as follows: "Leaves alternate, petiolate, the upper ones sessile, ovate or oblong, about 5 Cm. (2 inches) long, irregularly toothed, pubescent, pale-green; branches hairy, terminating in long racemes of small, pale-blue flowers, having an adherent, 5-toothed calyx, which is inflated in fruit, a bilabiate corolla, and 5 united stamens; odor slight, irritating; taste mild, afterward burning and acrid"—(*U. S. P.*).

LOBELIA SEED.—Lobelia seeds are not official, excepting as included in the inflated pods of the plant. Lobelia seeds, viewed under the microscope, are about $\frac{1}{33}$ of an inch in length, $\frac{1}{35}$ of an inch in breadth, of a dark-brown color, oblong, with ridges and furrows, somewhat resembling basket-work; the only seeds which resemble them are those of the *L. cardinalis*, which are not so dark-colored, but are oval, or almond-shaped, reticulated with irregular, oblong-square, or rectangular reticulations not so well defined, and are of larger size (P.—F. Curtis).

Lobelia in the powdered form enters into the composition of the compound emetic powder, and is a constituent of the compound tincture of lobelia and capsicum (King's Antispasmodic), and the acetous emetic tincture. The oil, as before stated, is contained in the stillingia liniment. Specific lobelia, the preferred preparation of this plant, has a deep wine color and a peculiar fatty odor. When dropped into water it produces a white turbidity, forming a yellowish-white, milky liquid, when viewed by reflected light. It mixes with alcohol without change. The taste is peppery and persistent, leaving a disagreeable acrid impression in the throat and fauces. A few drops only will sicken some persons and even produce emesis. Specific lobelia contains a large amount of oil of lobelia, which preserves the alkaloid in the preparation. Investigations made by Prof. Lloyd demonstrated that solutions devoid of the oil were inferior, being altered by age. Specific lobelia retains its energies indefinitely.

Chemical Composition.—The active principle of lobelia is an acrid, irritating, unstable alkaloid, called *lobeline*, first obtained by Wm. Procter, Jr. (*Amer. Jour. Pharm.*, 1838, p. 98, and 1841, p. 1), as a yellowish liquid of faintly aromatic taste, soluble in water and exhibiting an alkaline reaction. It exists in combination with a vegetable acid—*lobelic acid*—forming precipitates with solutions of metallic salts (Pereira, 1842). Lobeline and its salts are exceedingly active emetics. Though stable when thus combined, it readily decomposes when freed from contact with the other constituents of the plant. Heat applied to either an aqueous preparation or an alcoholic tincture of lobelia, destroys this alkaloid, hence a decoction or hot infusion of this plant is irrational. *Lobeline* was obtained by Prof. Lloyd (see *D. and M. of N. A.*, by J. U. and C. G. Lloyd, Vol. II, pp. 75 and 76), by depriving lobelia seeds of fat by means of benzin, abstracting the seeds with alcohol acidulated with acetic acid in a percolator, and evaporating and extracting the alkaloid with ammoniated ether. As thus obtained, *lobeline*, after further purification, is a colorless, odorless, amorphous, and non-hygroscopic alkaloid, of an alkaline reaction, soluble in alcohol, chloroform, benzol, ether, and carbon bisulphide. It is also somewhat soluble in water and exhibits in solution alkaloidal reactions. No crystallizable salts could be obtained, though Prof. Procter (*loc. cit.*) alludes to a crystallizable muriate, sulphate, nitrate, and oxalate of *lobeline*. Paschkis and Smita obtained from *lobeline* benzoic acid by oxidation with potassium permanganate (*Amer. Jour. Pharm.*, 1890, p. 339).

Fig. 165.



Crystals of Inflatin, typical form.

H. von Rosen (*Amer. Jour. Pharm.*, 1889, p. 393), isolated two alkaloids, one liquid (*lobeline*) and another solid.

According to Prof. Lloyd, the plant also contains a crystallizable, non-basic substance, to which he gave the name *inflatin*. This body exists in the plant, intimately associated with the alkaloid and some *volatile oil* (see below). *Inflatin* is tasteless and odorless, "insoluble in water, or glycerin, but soluble in carbon disulphide, benzol, chloroform, ether, and alcohol, in the order given" (Lloyd, *D. and M. of N. A.*, Vol. II, p. 78). It is not important in a medical sense.

The *lobelacrin* of Enders (1871), which was obtained in warty tufts of a brown color, was regarded by W. H. D. Leurs (*Pharm. Jour. Trans.*, Vol. VIII, 1878, p. 562), as probably *lobeliate of lobeline*. Lobelia contains a non-acrid, *volatile oil* of a pungent odor, possessing but little taste and no acridity. It was named *lobelianin* by Pareira in 1840. In addition, the plant contains about 30 per cent of non-volatile oily matters. The impure oil (so-called) of lobelia, so extensively employed by Eclectic doctors, is simply a syrupy extract of lobelia made with stronger alcohol, preferably acidulated with acetic acid. This so-called oil is the active constituent of that favorite Eclectic preparation, the compound stillingia liniment. The pure or true *fixed oil* of lobelia is non-acrid and bland, but as usually obtained (impure), is acrid and of a green color. The fixed oil of lobelia (impure) may be obtained by bruising the seeds between heated rollers, and pressing while hot in a strong linen cloth, between proper iron plates. Its consistence is nearly like that of linseed oil, and eminently possesses the drying qualities common to many fixed oils. It possesses all the medicinal properties of the seeds.

Action, Medical Uses, and Dosage.—Lobelia, in the ordinary sense of the term, is not a poison. Undoubtedly, its injudicious use has, and might produce death, but the same is true of many other drugs that are not ordinarily considered as poisons. That the alkaloid lobeline will kill animals, has been fully demonstrated. A drop of the alkaloidal solution placed upon the tongue of a strong, healthy man, instantly vomited him. To this property of its alkaloid, is undoubtedly due the failure of lobelia to act as a toxic agent. Its emetic action is so prompt and decided, that the contained alkaloid could not, under ordinary circumstances, produce fatal results. Given in cases *in extremis*, the resulting exhaustion from repeated emesis would very likely hasten death, but death would be more likely due to the act of vomiting exhausting the patient, than to any poisonous effect of the medicine.

If lobelia be chewed, it gives rise to an acrid, prickling, and persistently pungent sensation in the throat and fauces, accompanied by slight nausea and a feeling of warmth and distension along the esophageal tract and in the stomach. The sensation is not very unlike that produced by tobacco. The salivary and buccal glands are impressed, pouring out saliva and mucus in abundance. A sense of epigastric depression succeeds, followed by profound nausea, and if the amount chewed be large enough, severe and thorough emesis results. The gastric mucus is secreted in great abundance and ejected with the contents of the stomach. The emetic action of lobelia is extremely depressing, and is usually accompanied by profuse perspiration. Oppressive prostration, relaxation of the muscular system, and a languid pulse accompany the emetic stage. The depression, however, is of short duration, and is immediately followed by a sense of extreme satisfaction and repose. Under its action the mental powers are unusually acute, and the muscles are powerfully relaxed. The circulation is enfeebled by large and strengthened by small doses, and the bronchial secretions are augmented. When the drug does not prove emetic, it is said that it usually purges. Death, when due to lobeline, is said to result from respiratory paralysis.

Lobelia is nauseant, emetic, expectorant, relaxant, antispasmodic, diaphoretic, sialagogue, sedative, and, secondarily, occasionally cathartic and diuretic and astringent. It is in no sense a narcotic. The earliest use of lobelia, as will be seen from its history, was that of an emetic, and for this purpose it is still employed when we desire the action of a systemic emetic. Though momentarily depressing, its beneficial after-effects cause it to be preferred above other agents, ipecac not excepted, when such an agent is required. Its action is somewhat modified by combination with ipecacuanha, and other vegetable emetics, and rendered safer and more effectual. Such a combination is the emetic powder.

It may be used in forming stages of *febrile affections*, and is especially indicated by a general sluggishness of the whole system with an oppressive feeling, and the tongue is heavily and foully coated at the base. In some chronic diseases its emetic action is salutary in arousing the system from its atonic state. When its emetic action is desired, small doses should be frequently administered until profound nausea is induced, and then the drug should rapidly be pushed to emesis. Copious draughts of warm water will hasten its action and render the act of emesis much easier. Spasmodic movement is incompatible with nervous and muscular relaxation, hence we find prompt relief in many spasmodic conditions by the use of this drug.

The powerfully relaxant properties of lobelia render it a very efficient agent in several conditions, whose chief feature is the *spasmodic element*. For its control over spasmodic movement, nauseant or emetic doses must be given. For this purpose it may be exhibited in *chorea, tetanus*, "*worm fits*" of children, *hysteric* and *infantile convulsions, epileptiform* and other *convulsive disorders*. For *puerperal eclampsia*, chloroform by inhalation, and morphine subcutaneously injected, give better results than lobelia, though the latter drug has been used with success in some cases. Lobelia is of value in obstetrical practice. It powerfully subdues muscular rigidity. It is the remedy to overcome a *rigid os uteri* during parturition, and at the same time it relaxes the perineal tissues. This it does when there is fullness of tissue—a thick, doughy, yet unyielding, os uteri; when, however, the edge of the os is thin and closely drawn, sharp like a knife edge, full doses of gelsemium are indicated. For its antispasmodic action it may be given by mouth and by rectum. *Intestinal obstructions* have been overcome by lobelia when other agents would have been inadmissible, hence it is of value in the reduction of *strangulated hernia*, an enema being employed. *Intussusception* and *fecal impaction* may be treated with this drug when cathartics would result fatally. It is for its antispasmodic effects that it is given in *asthmatic paroxysms, spasmodic croup*, and *whooping-cough*. It has been successfully used to overcome the violent convulsions resulting from *strychnine poisoning*. Chloroform and ether excepted, it is the best antispasmodic drug in the materia medica, and much safer than either of these. In the so-called "*worm fits*" it should be carried to nausea and then followed by santonin, after which a mild purgative may be given.

Lobelia is a stimulant to the sympathetic system. It improves the innervation of the parts supplied by both the pneumogastric and sympathetic nerves. The appetite and digestion are improved by small doses of the drug. It will frequently be found indicated in *indigestion* and *dyspepsia*. We have frequently used it in small doses for *sick headache* due to gastric derangement. It is indicated by the feeling of "qualmishness" and nausea present. Though frequently overlooked when we are looking for a drug to overcome *intestinal atony*, lobelia will be found one of the best drugs at our command for the relief of *habitual constipation*. ℞ Specific lobelia, gtt. i—ij, every 2 hours. Administered with podophyllin it tends to prevent the costiveness so frequently the result after using a "bowel persuader" in cathartic doses. It increases peristalsis. Small doses of it relieve *infantile colic*.

Lobelia is *the* drug for *angina pectoris, neuralgia of the heart*, and *pulmonary apoplexy*. Though evanescent in its action, large doses of specific lobelia (about 20 drops), may be administered with the expectation of relieving the patient. The dose may be repeated if necessary. Lobelia is a cardiac stimulant, thus we class it with the sedatives, for all sedatives in medicinal (small) doses are heart stimulants. When the circulation exhibits a markedly slow pulse-wave it will be better corrected by lobelia than by any other drug we possess. In fact the most prominent indication for the drug is the full, oppressed, sluggish, doughy pulse. Associate this with præcordial oppression, thoracic pain, difficult breathing, soreness or bruised feeling within the chest, nausea with tongue heavily coated at base, fullness of tissue, and we have before us a fair range of the action of lobelia. It is a good remedy in *cardiac congestion*.

Perhaps the most important use for this drug will be in the treatment of respiratory affections. For this class of diseases no remedy is more highly valued by physicians of our school. "Lobelia is an admirable pectoral remedy. As a nauseant expectorant it has no equal. When an emetic is desired in pulmonary complaints it is one of the most efficient that can be employed. It has come to be the first of remedies for *spasmodic asthma*, and is not without utility in *whooping cough*. It improves innervation and the circulation, and is one of the best remedies to employ in congestive conditions. It is frequently indicated in *pleurisy* and *pleuro-pneumonia*. As a sedative it ranks between veratrum and aconite. *Acute pneumonia*, with tendency to congestion, the breathing being oppressed, is quickly relieved by lobelia. All *chronic forms of sore throat*, especially when ulcerated, are benefited by it. *Chronic pneumonia*, *bronchitis*, and *laryngitis* are all conditions in which lobelia will be of great service. In *asthenic laryngitis* of children it is exceedingly useful. It is a remedy of great value in *chronic catarrh*, dry, hard, or barking *coughs*, *colds*, and all forms of *irritation of the respiratory tract*, with oppression. It relaxes the tissues, favors expectoration when a large quantity of mucus is secreted and there is want of power to remove it. The indications for this drug are the full, oppressed, or small, feeble pulse, præcordial oppression, with difficult respiration, oppression anywhere in the chest, with accumulation of the bronchial secretions, cough with loud mucous *rales* within the chest. The "acetous emetic tincture," which contains this agent, may be used to fulfil most of the indications for this drug. Powdered lobelia seeds or leaves, or the "compound powder of lobelia and capsicum," are the best local applications that can be employed in *acute pulmonary complaints*, and give great relief in chronic cases with a sense of suffocation and fullness, accompanied by soreness within the chest" (Felter).

When in the *eruptive diseases* retrocession takes place, lobelia, by promoting determination of blood to the skin, will promptly bring the eruption to the surface. It is also indicated in *scarlatina* and *measles* when the eruption is tardy in making its appearance.

Lobelia was formerly used to a considerable extent in the *eruptive skin diseases*. In the *Western Medical Reformer* for 1838, we find it lauded as a local wash for "*herpes*, *lichen*, *eczema*, *nettlerash*, and *erysipelas*." There is one condition in which its use should not be overlooked, and that is in *poisoning by Rhus Toxicodendron*. An aqueous solution of specific lobelia, or an infusion of the plant should be freely used by wetting the cloths in the lotion and applying frequently to the affected parts. Externally, the infusion has been found useful in *ophthalmic affections;* and the tincture is a valuable local application to *sprains*, *bruises*, *rheumatic pains*, *erysipelas*, and *erysipelatous inflammations*, *tetter*, and other forms of *cutaneous diseases*. A poultice of powdered lobelia and slippery-elm bark, with a weak lye-water, will be found valuable in *erysipelatous diseases*, *bites*, and *stings of poisonous insects*, *spasmodic affections of the limbs*, *pains*, and to produce muscular relaxation. Tincture of lobelia, painted upon the parts before suppuration has begun, is said to abort *felons*.

The oil of lobelia is valuable in *tetanus* and some other extreme cases, as it is easy to introduce enough upon the tongue to relax the whole system immediately. On account of the tendency to produce inflammation of the stomach, it should not be employed alone as a common emetic, but a few drops of it should be triturated with sugar, and diffused in chamomile, boneset, or other emetic infusion. One drop of the oil, triturated with 20 grains of sugar, and divided into from 6 to 12 doses will be found highly useful as an expectorant, nauseant, sedative, and diaphoretic, when given every 1 or 2 hours, as may be required. As a local application, much benefit may be derived from it, where a particular nerve is to be quieted, or a muscle to be relaxed. An excellent liniment may be made of a mixture of ½ ounce, each, of oils of amber and sassafras, 1 drachm of oil of lobelia, and ½ drachm of ethereal oil of capsicum. To be used in *painful neuralgic* and *rheumatic affections*. That lobelia is a valuable remedy will be conceded by all, and that it has been notoriously misrepresented is apparent to all. Carefully used according to its specific indications, it will be better appreciated the more it is used. As an emetic, dose of the powder, from 20 to 60 grains; of the tincture, from 2 to 4 fluid drachms; as a nauseant and expectorant, from 5 to 20 grains. The dose of specific lobelia ranges from 1 to 40 drops, according to use, taken in a little water. When lobelia does not act as an emetic, it is very apt to purge The relaxation caused by lobelia may be counteracted by the stimulating and tonic influence of capsicum.

Specific Indications and Uses.—Lobelia is specifically indicated by the full, labored, doughy pulse; the blood moves with difficulty; pain in chest of a heavy, sore, or oppressive character; angina pectoris; cardiac neuralgia; pulmonary apoplexy; mucus accumulation in bronchiæ; convulsive movements; rigidity of muscular tissues; rigid os uteri, with thick doughy edges; rigid perineum, or vaginal walls; nausea; oppressive sick headache, with nausea. As an emetic when tongue is heavily coated at base.

Related Species.—There are other species of Lobelia, as the *Blue lobelia* (*Lobelia syphilitica*, Linné), and the *Red lobelia* (*L. cardinalis*, Linné). The first is diaphoretic, emetic, and cathartic; also diuretic and antisyphilitic, and a strong infusion of it has cured *gonorrhœa*. It has likewise been used in *dropsy*, *diarrhœa*, and *dysentery*. The root is the part used; dose, from 20 to 60 grains of the powder. The *L. cardinalis* is said to be anthelmintic, nervine, and antispasmodic. These two varieties are seldom, if ever, used in medicine. Wm. Procter, Jr. (1839) obtained a bitter, acrid, aromatic, oily, liquid alkaloidal body from this plant. It was probably a mixture of the alkaloid with impurities (see *D. and M. of N. A.*, Vol. II, p. 106). *Lobelia Kalmii* is the plant shown to Mr. Kalm by Col. Johnson, as the one used by the Indians of some parts of North America to cure *syphilis;* and he was likewise informed that syphilis was known among them previous to their acquaintance with the Europeans, and that they cured it very readily, even when "the patient is half rotten and insupportable to be approached" (*General Practice of Physic*, by R. Brookes, M. D., 7th ed., 1777, Vol. II, pp. 67–71).

LOTIONES.—LOTIONS.

SYNONYM: *Washes.*

These comprise all compounds used as external washes and collyria, in which vegetable or mineral substances are dissolved in water or spirits, but which do not strictly class with infusions, liniments, mixtures, or tinctures. Water is most often used in preparing them.

Glycerin has been proposed as a vehicle for forming lotions with salts of alkaloids, thus: 1. MORPHINE LOTION.—Take of acetate of morphine, 3 grains; glycerin, 5 drachms (troy); dissolve. 2. STRYCHNINE LOTION.—Take of sulphate of strychnine, 6 grains; glycerin, 5 drachms (troy). Dissolve the salt in the glycerin in a porcelain mortar. A teaspoonful of this lotion is applied by friction in *paralysis of the limbs*, on the vertebral column in *chorea*, and on the temple in certain cases of *amaurosis*. 3. VERATRINE LOTION.—Take of veratrine, 15 grains; glycerin, 5 drachms; diluted hydrochloric acid, a sufficient quantity; dissolve. A teaspoonful, applied by friction in *chronic rheumatic pains of the joints*, or in the sacro-lumbar region to relieve *painful menstruation*. 4. ATROPINE LOTION.—Take of atropine, 6 grains; glycerin, 2½ drachms; diluted hydrochloric acid, a sufficient quantity. Dissolve and mix. Forty or 50 drops, 3 times a day, rubbed on the track of the infra- and supra-orbital nerves, on that of the facial nerve, etc.

Liquid preparations in which glycerin forms a large portion of the menstruum, are termed "*Glycerites*," *Glyceroles*, or *Glycerin Solutions* (see *Glycerites*, *Ointments*, and *Plasmæ*).

Other Lotions.—Two mercurial lotions, not employed, however, by Eclectics, are official in the *British Pharmacopœia*. They are also found in the *National Formulary* from which we reproduce them as follows:

LOTIO FLAVA (N. F.), *Yellow lotion, Yellow wash, Aqua phagedænica flava.*—"Corrosive chloride of mercury, three grammes (3 Gm.) [46 grains]; boiling water, solution of lime (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the corrosive chloride of mercury in thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏] of boiling water, and add the solution to a sufficient quantity of solution of lime to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This mixture should be well agitated whenever any of it is to be dispensed"—(*Nat. Form.*).

LOTIO NIGRA (N. F.), *Black lotion, Black wash, Aqua phagedænica nigra.*—"Mild chloride of mercury, seven and one-half grammes (7.5 Gm.) [116 grs.]; water, solution of lime (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the mild chloride of mercury with thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏] of water, and gradually add a sufficient quantity of solution of lime to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This mixture should be well agitated whenever any of it is to be dispensed"—(*Nat. Form.*). Other lotions are:

LOTIO ADSTRINGENS (N. F.), *Astringent lotion, Warren's styptic, Styptic balsam.*—"Sulphuric acid (*U. S. P.*), thirty-eight cubic centimeters (38 Cc.) [1 fl℥, 137 ♏]; oil of turpentine, thirty-one cubic centimeters (31 Cc.) [503 ♏]; alcohol, thirty-one cubic centimeters (31 Cc.) [503 ♏]. To the sulphuric acid, contained in a wedgewood mortar, slowly add the oil of turpentine, in small portions at a time, constantly stirring. Allow the mixture to cool, then add the alcohol cautiously, in the same manner, and continue stirring until no more fumes arise. When the liquid is cold, pour it into a glass-stoppered bottle. *Note.*—In preparing this mixture caution should be used so that the temperature may not rise too high. Particular care is to be observed if a larger quantity of this mixture is to be prepared. In this case it is preferable to prepare it in several portions"—(*Nat. Form.*). This preparation, under the name *Styptic Balsam*, was a favorite with the early Eclectic physicians.

Lotio Plumbi et Opii (N. F.), *Lotion of lead and opium, Lead and opium wash.*—"Lead acetate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; tincture of opium (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the lead acetate in about six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of water, add the tincture of opium and enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This mixture should be well agitated whenever any of it is to be dispensed"—(*Nat. Form.*).

LOTIO ÆTHERIS COMPOSITA.—COMPOUND ETHEREAL LOTION.

Synonym: *Evaporating lotion.*

Preparation.—Take of ether, alcohol, solution of acetate of ammonium, each, 1½ ounces; rose-water, 3½ ounces. Mix together.

Action and Medical Uses.—This lotion may be used to produce a refrigerant or stimulant influence, according to its mode of employment. Applied to the surface and allowed to evaporate by free exposure, it acts as a *refrigerant*, but if the evaporation is prevented by covering the part to which it is applied with the hand or a cloth, it acts as a *stimulant*. The solution of acetate of ammonium, largely diluted (without the addition of ether or alcohol), is a superior cooling lotion in all cases of *fever* where there is a hot and dry state of the surface, often of itself inducing diaphoresis.

LOTIO ALKALINI.—ALKALINE WASH.

Preparation.—Take of carbonate of sodium (sal soda), 2 drachms; warm rain-water, 1 quart. Dissolve; or, make a weak ley, by adding hardwood ashes to hot water.

Action and Medical Uses.—This wash was formerly extensively employed by physicians, as an application to the surface of the body and limbs in all *febrile* and *inflammatory diseases*, and in *chronic affections*. In the former cases it is applied several times a day, especially when the acute symptoms run high; in the latter affections it is commonly used once or twice a week. The surface should be well rubbed and dried immediately after each application. Frequently, when external stimulus is also required, the above proportion of water is lessened ¼ or ½ and the balance of the quantity made up by the addition of whiskey or other spirit.

LOTIO AMMONII CHLORIDI.—LOTION OF AMMONIUM CHLORIDE.

Synonyms: *Lotio ammoniæ hydrochloras, Lotion of hydrochlorate of ammonium.*

Preparation.—Take of chloride of ammonium, 2 drachms; distilled water, 1 fluid ounce; tincture of conium, 1 fluid ounce. Dissolve the ammoniacal salt in the water and add the tincture.

Action and Medical Uses.—This is sedative and resolvent, and is used as a local application to discuss *tumors*, etc. Its external use is sometimes associated with its internal exhibition. Professor King always used a saturated solution of ammonium chloride as a vehicle to carry remedies intended to be used by inunction. His liniments were not fats and oils medicated, but this solution medicated. He claimed for it greater absorptive power, and decidedly greater advantage in cleanliness.

LOTIO BORACIS.—BORAX LOTION.

Synonym: *Cooling wash.*

Preparation.—Take of borax, in powder, 2 drachms; rose water, ½ pint. Dissolve. In this preparation soft river water may be substituted for rose-water, when the latter can not be obtained (Beach's *Amer. Prac.*).

Action and Medical Uses. This forms a cooling application, and may be used in *inflammations of the eyes*, and *inflammation or ulceration of the nipples*, and of the *mouth* and *fauces*, as well as other *irritated or inflamed mucous surfaces.*

LOTIO BORACIS CUM MORPHINÆ.—BORAX LOTION WITH MORPHINE.

Preparation.—Take of borax, in powder, ½ ounce; sulphate of morphine, 6 grains; decoction of golden seal, 8 fluid ounces. Add the borax and morphine to the decoction.

Action and Medical Uses.—This forms a cooling and mild anodyne wash, and may be used in *inflammation of the eyes*, and *sore and inflamed nipples*, *pruritis vulvæ*, *aphthous ulcerations of the mouth and fauces*, and other *irritated or inflamed mucous surfaces.*

LOTIO GLYCERINI. GLYCERIN LOTION.

Preparation.—Take of glycerin, ½ ounce; distilled water, ½ pint. Mix.

Action and Medical Uses.—This lotion has been recommended in *eczema*, *lichen*, and other *cutaneous diseases;* also as an application to the meatus externus in cases of *deafness* owing to want of secretion of cerumen.

LOTIO HYDRASTIS COMPOSITA.—COMPOUND LOTION OF GOLDEN SEAL.

Preparation.—Take of strong infusion of green tea and of golden seal, each, 1 pint; sulphate of zinc, gunpowder, each, 2 drachms. Mix the decoction, then add the remainder of the articles, and agitate briskly. After solution and decomposition have ceased, and the precipitate has subsided, pour off the supernatant liquid.

Action and Medical Uses.—This curious lotion was employed as a collyrium in *chronic ophthalmic diseases*, but it may be advantageously employed in all *chronic affections of mucous surfaces*, as an external application. The affected parts are to be bathed with it several times a day.

LOTIO HYDRASTIS ET ACONITI.—LOTION OF GOLDEN SEAL AND ACONITE.

Preparation.—Take of golden seal, in powder, 4 drachms; boiling water, 4 fluid ounces; tincture of aconite, 1 fluid drachm. Add the golden seal to the water and digest for 3 hours by a gentle heat; then filter and evaporate to 2 fluid ounces, to which add the tincture of aconite.

Action and Medical Uses.—This forms a superior application to the eye in many cases of disease in that organ. It may be applied by means of a camel's-hair pencil, or dropping 1 or 2 minims on the eyeball. I have likewise found immense benefit in these cases by substituting for the tincture of aconite 1 or 2 fluid drachms of the saturated tincture of black cohosh. Some physicians employ the hydrochlorate of berberine in preparing the above formula, but as this is insoluble in water, it can effect but little influence. This preparation, used as a wash or injection, will also be found of service in *chronic mucous difficulties*, as *vaginal leucorrhœa*, etc. (J. King).

LOTIO JUGLANDIS.—WALNUT LOTION.

Preparation.—Take of extract of green walnut shells, 6 grains; distilled water, 50 grains. Mix and dissolve.

Action and Medical Uses.—This is recommended as an efficient agent in *enlargement of the tonsils*, and is stated to be very prompt in its effects. It is applied to the parts by means of a camel's-hair pencil.

LOTIO LOBELIÆ COMPOSITA.—COMPOUND LOBELIA LOTION.

SYNONYM: *Herpetic wash.*

Preparation.—Take of bayberry bark, lobelia leaves and seed, yellow-dock root, each, in powder, 2 drachms; vinegar, 1 pint. Mix all together, and allow them to macerate for 7 days, and filter; or, make the lotion by percolation.

Action and Medical Uses.—This preparation forms an excellent local application to several species of *cutaneous disease*, also to *erysipelas* and *erysipelatous inflammations*. It is frequently prepared with spirits instead of vinegar, especially where more active stimulation is desired. In erysipelas, ½ pint of a saturated solution of chloride of ammonium may be added to the above quantity with advantage.

LOTIO MYRRHÆ COMPOSITA.—COMPOUND MYRRH LOTION.

Preparation.—Take of myrrh, in powder, ½ ounce; acetate of zinc, 1½ drachms; acetate of lead, ½ drachm; water, 2 pints. Add the myrrh to 1½ pints of water, and boil together for 10 or 15 minutes; when cold, add the rest of the water in which the lead and zinc salts have been previously dissolved. Let them stand 24 hours and filter. If necessary, add enough water to pass through the filter to make 2 pints of the lotion (J. King).

Action and Medical Uses.—Compound myrrh lotion was formerly employed in cases of *chronic ophthalmia*. It will, however, be found useful in all *chronic mucous diseases*. It is usually applied 3 or 4 times a day, and must not be used during the presence of inflammation. When too severe, it may be diluted with water.

LOTIO REFRIGERANS.—COOLING LOTION.

SYNONYM: *Saline wash.*

Preparation.—Take of fine salt, ½ ounce; spirits, vinegar, and rain water, each, 4 fluid ounces. Mix the fluids, and then dissolve the salt in them Beach's *Amer. Prac.*).

Action and Medical Uses.—This lotion is extensively employed as a cooling application in cases of pain or determination to the head, during *fevers*, *inflammation of the brain*, *dropsy*, etc. It is used cold or tepid, according to the benefit received from its application at these temperatures.

LOTIO SASSAFRAS.—SASSAFRAS LOTION.

Preparation.—Take of pith of sassafras, 1 drachm; rose water, 1 pint. Mix. Let them stand for 4 hours, and filter (Beach's *Amer. Prac.*). Distilled water may be substituted for the rose water, and the preparation may be made more speedily by boiling the mixture for a few minutes.

Action and Medical Uses.—This is an extemporaneous preparation, and is principally used in *acute ophthalmia*. A similar preparation of marshmallow root, elm bark, or buckhorn brake, will be found equally available.

LOTIO SODII COMPOSITA.—COMPOUND SODA LOTION.

Preparation.—Take of rock salt, 3 ounces; sulphate of zinc, 1 ounce; persulphate of iron, 8 grains; rain water or clear river water, 1 pint. Add the articles together and form a solution.

Action and Medical Uses.—Used as a stimulating collyrium in *chronic ophthalmic diseases.*

LOTIO ZINCI COMPOSITA.—COMPOUND LOTION OF ZINC.

Preparation.—Take of sulphate of zinc, alum, each, 2 grains; distilled water, 2 pints. Mix and, when dissolved, filter.

Action and Medical Uses.—This lotion is used as a stimulating application to the eye in cases of *films*, *specks*, *opacities*, etc.; to abnormal *growths* on mucous surfaces; to *indolent ulcers* with *fungous growths;* and to *gangrene*.

LUPINUS.—LUPIN.

The seeds of *Lupinus albus*, Linné.

Nat. Ord.—Leguminosæ.

COMMON NAMES: *White lupin*, *Lupin*.

Botanical Source.—This is an annual with a stem nearly 2 feet high, having 5 to 7 foliate, palmate leaves, with obovate, oblong leaflets, from 1 to 2 inches in length. They are beset with white hairs beneath, but on their upper surface are smooth. The large, white, short-pedicelled flowers are borne in terminal spikes, or racemes. The fruit is a long, compressed pod, containing from 3 to 6 seeds which are flattish, circular, and of a white color. The seeds have no odor, but a bitterish taste.

History and Chemical Composition.—This plant is indigenous to west Asia and south Europe, besides being met with in our gardens. Various species of Lupinus produce in sheep the so-called lupinose disease. From *Lupinus albus*, a very bitter alkaloid, *lupinine* (or *lupinotoxin* of C. Arnold, *Jahresb. der Pharm.*, 1883, p. 277), was isolated by Campani and Betelli (1882); it was soluble in ether, benzol, chloroform, and alkalized water. H. Weiske (*Jahresb. der Pharm.*, 1883) records the comparative percentage of the toxic principle in various species of Lupinus; *L. Cruikshankii* contained most (1 per cent), *L. hirsutus* least of it (0.02 per cent), while *L. albus* contained 0.5 per cent. A. Soldaini (*Archiv der Pharm.*, 1893, p. 321) found an optically inactive alkaloid ($C_{15}H_{24}N_2O$) melting at 99° C. (230.2° F.), and a deliquescent alkaloid of the same formula. L. Sherman Davis, in Prof. Schmidt's laboratory, ascertained (*Archiv der Pharm.*, 1897, p. 217) that the seeds of *Lupinus albus* contain two alkaloids: 1. *Dextro-lupanin* ($C_{15}H_{24}N_2O$), melting at 44° C. (111.2° F.) and identical with the deliquescent alkaloid of Soldaini, as well as with the *dextro-lupanin* obtained by himself from the seeds of the Blue lupin, *L. angustifolius*, Linne. 2. *Inactive lupanin* ($C_{30}H_{48}N_2O$), composed of equal molecules of *dextro-* and *lævo-lupanin*, which recalls the analogous isomerism existing in the tartaric acid series. The seeds of lupinus also contain the albuminous bodies *conglutin* and *legumin* (Ritthausen, 1883), soluble in diluted alkali, precipitable by acids, and separable by means of salt solution, in which the former is soluble. By distillation of the seeds of *L. albus* with water vapor, Campani and Grimaldi (1888) obtained *vanillin*.

Action and Medical Uses.—The ancients employed lupin medicinally. An enema of 5 ounces of lupin decoction produced, on two occasions, toxic symptoms, as follows: malaise, unpleasant sensations in the head, dimness of vision, palpebral heaviness, dizziness, mental excitation, and laryngeal and pharyngeal constriction (Donnabella [1877], *Practitioner*). Diuretic, anthelmintic, and emmenagogue properties have been ascribed to white lupin seeds, and the same, bruised and soaked in water, were formerly applied to *ulcers*.

Related Species.—*Lupinus hirsutus*, Linné (blue or rose flowers), and *Lupinus luteus*, Linne (yellow flowers), both of south Europe, have similar properties. *L. luteus* is the species that has been most frequently investigated. L. Berend (*Dissert.*, Marburg, 1897) established in the seeds of this species the presence of two alkaloids, viz.: crystallizable *lupinin* [$C_{21}H_{40}N_2O_2$], Baumert, 1881) and liquid *lupinidin* ($C_8H_{15}N$). It is exceedingly probable that the alkaloids of the various species of Lupinus stand in close chemical relationship to one another. E. Schulze and E. Steiger obtained from the germinated seeds of *Lupinus luteus* an alkaloid which they named *arginine*. The young plants likewise contain asparagin, glutanin, leucine, tyrosine, etc., probably as decomposition products from the albuminoids (*Amer. Jour. Pharm.*, 1887, p. 428). E. Steiger (*Amer. Jour. Phar.*, 1886, p. 449) found in the seed of *Lupinus luteus* a peculiar dextrin-like substance, which he named *beta-galactan*. Attempts have also been made to utilize lupinus as food material by depriving it of its bitterness (see Baumert, *Archiv der Pharm.*, 1888, p. 424). Many American species have like properties, among these are *Lupinus perennis*, Linné (blue-flowers), of eastern United States, and *Lupinus densiflorus*, Nuttall, and *Lupinus polyphyllus*, Nuttall, of the western states. The two latter are often found in gardens. (See chemical investigations of *Black lupinus* as well as *L. polyphyllus*, by K. Gerhard, in *Archiv der Pharm.*, 1897, pp. 342–364.

LUPULINUM (U. S. P.)—LUPULIN.

"The glandular powder separated from the strobiles of *Humulus Lupulus*. Linné (*Nat. Ord.*—Urticaceæ)"—(*U. S. P.*).

Preparation.—On beating or rubbing the strobiles of hops, and then sifting them, a glandular powder is separated, and is known in medicine as *Lupulin*. The sifting is necessary to remove the broken bracts and other vegetable parts. About 10 per cent of lupulin is thus obtained from the dried hops.

Description.—"Bright brownish-yellow, becoming yellowish-brown, resinous, consisting of minute granules, which, as seen under the microscope, are subglobular, or rather hood-shaped, and reticulate; aromatic and bitter. When lupulin is agitated with water and the mixture allowed to stand, no considerable sediment (sand, etc.) should be deposited. When ignited, lupulin should not leave more than 10 per cent of ash"—(*U. S. P.*). Lupulin is of a cellular texture and somewhat transparent. The common center around which the cells are arranged, is called the hilum. Lupulin has the odor and taste common to the hop; a gentle heat renders it tenacious; exposed to flame it burns. Owing to the presence of the oil, lupulin, in quantities, is liable to spontaneous combustion (see record of such combustion on board a vessel lying in the Bremen harbor, in *Amer. Jour. Pharm.*, 1893, p. 555). Unless carefully dried it soon loses its properties, which, indeed, under all circumstances are impaired by keeping. It is always preferable to the hop for medicinal purposes. The constituents of lupulin are essentially those described under *Humulus* (hops), which see.

Action, Medical Uses, and Dosage.—(See *Humulus* also.) Lupulin, or its tincture, is used in *delirium tremens*, and wakefulness in connection with nervous irritation, anxiety, or exhaustion; it does not disorder the stomach nor cause constipation, as with opium. Also useful in *after-pains*, to suppress venereal desires, and allay the pain attendant on *gonorrhœa*. Lupulin has been found especially useful in cases of *genito-urinary irritations*, *irritation of the bladder*, as well as in those *irritable conditions of the brain and genital organs*, so often accompanying *nocturnal emissions;* it allays the irritation, promotes sleep, and checks the emissions, in quite a number of cases; it has also been advised as an efficient remedy in *chordee*. In these instances it requires to be given in quite large doses, double or triple the ordinary ones. The ethereal tincture of lupulin forms what was formerly termed the *ethereal oil of lupulin* (see *Oleoresina Lupulini*) by allowing the ether to spontaneously evaporate. It produces at first a stimulant influence, succeded by a very agreeable, calming sensation, and has been used with advantage in some cases of nervous irritability where opium and other narcotics failed. It does not, however, appear to possess any narcotic properties. A mixture of oil of chamomile, 1 fluid drachm, and ethereal oil of lupulin, 1½ fluid drachm, dissolved in sulphuric ether, half a fluid ounce, in doses of from 30 to 60 drops, every 3 or 4 hours, has been found beneficial in *dysmenorrhœa*, and other *painful uterine diseases*. Mr. Duckworth advises as a very remarkable hypnotic, a preparation composed of lupulin, 1 ounce, aromatic spirit of ammonia, half a pint; mix, let them macerate for 7 days, with agitation from time to time, filter, and add more fluid to procure half a pint. The dose is from 15 minims to 1 fluid drachm. The dose of lupulin is from 6 to 10 grains, which may be given in powder, or in pill made by merely rubbing it in a warm mortar till it acquires a pilular consistence. The tincure of lupulin may be given in doses of from 1 to 4 fluid drachms. Tincture of lupulin, as well as tincture of hop, may be used in *dyspepsia*, with marked restlessness, and disposition to brood over trouble. Use it also when fermentation and eructations occur after meals. *Insomnia*, due to worry or neurasthenia, is relieved by lupulin. The odor of lupulin, like that of hop, will cause in susceptible individuals a distressing sick headache, accompanied with extreme and prostrating nausea; on the other hand both lupulin and hop have been employed to relieve various forms of *headache*, chiefly in debilitated subjects, with cerebral hyperemia.

Specific Indications and Uses.—Nervousness, irritability, disposition to brood over trouble, delirium, insomnia, cerebral hyperemia; fermentative dyspepsia, with acid eructations; genital and mental irritability associated with spermatorrhœa.

LYCOPODIUM (U. S. P.)—LYCOPODIUM.

"The spores of *Lycopodium clavatum*, Linné, and of other species of *Lycopodium*"—(*U. S. P.*).

Nat. Ord.—Lycopodiaceæ.

Common Names and Synonym: (Plant) *Club moss;* (Spores) *Lycopodium seed. Pulverized lycopodium, Vegetable sulphur, Sporæ lycopodii.*

Illustration: Bentley and Trimen, *Med. Plants*, 299.

Botanical Source.—Club moss is a creeping perennial with a trailing stem, giving off several ascending leafy branches. The stem is often several feet in length and thickly clothed with lance-linear, awl-shaped, smooth, flat, evergreen leaves, which are imbricated and inflexed. The branches are from 2 to 4 inches high, the fertile ones having a long, terminal peduncle supporting from 1 to 3 erect, long, cylindrical flower spikes, which are clothed with ovate, sharp-pointed bracts, bearing in their axils the yellow reniform sporangia (*thecæ*).

Fig. 166.

Lycopodium clavatum.

History.—Lycopodium, or Common club moss, is found in almost all parts of the earth, especially in northern regions, growing in dry situations, as pastures, mountains, and woods. The spores, the chief medicinal portion, are shaken out of the renal-shaped capsules (*sporangia*) which grow on "the inner side of the bracts covering the fruit spike" (*Pharmacographia*) as a yellowish powder. The drug is gathered in Germany, Russia, and Switzerland, during the months of July and August, by the peasants, who cut the tops from the plants and carry them to their homes, where the powder is obtained by shaking the tops and sifting out the extraneous matter. As the plant fails to be plentiful some years, the annual collection is apt to vary much.

Description.—According to the *U. S. P.*, lycopodium is "a fine powder, pale, yellowish, very mobile, inodorous, tasteless, floating upon water and not wetted by it, but sinking on being boiled with it, and burning quickly when thrown into a flame. Under the microscope the spores are seen to be sphæro-tetrahedral, the surfaces marked with reticulated ridges, and the edges beset with short projections. Lycopodium should be free from pollen, starch, sand, and other impurities, any of which are easily detected by means of the microscope. When ignited with free access of air, lycopodium should not leave more than 5 per cent of ash"—(*U. S. P.*).

If lycopodium be heated slowly it burns with violence, but if brought in contact with a flame, it suddenly catches fire with a vivid flash and a hissing explosiveness. Unlike most bodies, when triturated it becomes darker in color, assuming a somewhat greasy and coherent state. When dried at 100° C. (212° F.), it loses but 4 per cent of moisture (*Pharmacographia*).

Chemical Composition.—Sugar to the extent of 3 per cent (Langer, 1889, 2.1 per cent), was found in lycopodium by Bucholz (1807). *Pollenin* is the name applied to the material composing the walls of the cells. Alfons Langer (*Archiv der Pharm.*, 1889, pp. 241, 289, and 625), obtained from the spores of commercial *Lycopodium clavatum* 49.34 per cent of a greenish-yellow oil having an acid reaction and consisting of about 80 to 86.6 per cent of a peculiar *lycopodium-oleic acid* ($C_{16}H_{30}O_2$ or $[CH_3]_2CH.CH.CH.C[CH_2].(CH_2)_9.COOH$, *decyl-isopropyl acrylic acid*), with varying quantities of glycerin (about 3 to 5 per cent), and solid fatty acids, chiefly *myristic acid*. The spores must be powdered by trituration with quartz-sand if all of the oil is to be extracted (*Pharmacographia*). A Bukowski (*Archiv der Pharm.*, 1889, p. 625), analyzing freshly collected spores, obtained an oil of neutral reaction, and a constant quantity (8.2 per cent) of glycerin. It also differed in chemical composition from that obtained by Langer. The latter found the spores to contain 0.857 per cent of nitrogen, corresponding to 5.3 per cent of protein substance. When heated with solution of caustic potash, the spores yielded *monomethylamine* (CH_3NH_2). Upon being incinerated, they gave 1.16 per cent of ash. The spores have the peculiar property of oxidizing a portion of the alcohol with which they are macerated, to aldehyde.

Adulterations.—Besides the possible adulterants mentioned by the *U. S. P.*, dextrin and spores of other species of *Lycopodium*, gypsum, talc, sulphur, and rosin may be present. According to A. L. Reichert (*Pharm. Review*, 1898, p. 260), most of the specimens of lycopodium examined were practically free from adulteration, containing mostly fragments of the sporangium wall as impurities; one specimen contained 20 per cent of pine pollen, and two other specimens had potato starch, in one amounting to 30 per cent.

Action, Medical Uses, and Dosage.—This agent was for a long time used only as a dusting powder for protective purposes in *erysipelas*, *intertrigo*, *herpes*, *ulcers*, *eczemas*, etc. Druggists used it to prevent pills from adhering to each other in the boxes, and pyrotechnists employed it in the manufacture of their wares. Of recent years it has become quite important as a remedy in our school, the suggestion coming first from the homœopaths, who use it quite extensively. It was introduced to us as a remedy by Prof. Scudder. He prepared a tincture of the fresh plant before it had cast its sporules with 98 per cent alcohol, and also a tincture of the sporules first triturated in a dry mortar until doughy, then placing them in a percolator, covering with alcohol, allowing to macerate 4 days, when the tincture was drawn off. He recommended the tincture of the sporules in "extreme sensitiveness of the surface; sensitiveness of a part, and care to prevent its being touched; slow, painful boils; nodes or swellings; extreme sensitiveness of the organs of special sense, with pale, livid, or dirty complexion" (*Spec. Med.*, 174).

In *fevers* showing an obscure periodicity lycopodium has been found curative. The cases are not distinctly *agues* nor *ordinary intermittents*, and consequently not influenced by quinine. The febrile phenomena are not active, and there may be an irritable stomach, with either *diarrhœa*, *dysentery*, or *constipation*, an obscure *colic* being associated with the latter, and some *sore throat*. The fever, though not active, is intractable, and exceedingly depressing, and the characteristic symptoms guiding the selection of lycopodium are a high-colored red urine staining the clothing, and an afternoon exacerbation, usually occurring in the middle of the afternoon.

Lycopodium is an efficient gastric sedative, and with the high-colored red urine, and the patient suffering more in the afternoon, will be found of value in *dyspepsia*, and especially if constipation and cardiac palpitation are also present. There is tenderness over the stomach and a sense of fullness. *Pyrosis*, with flatulence, is corrected by it, and in *indigestion*, with fermentative changes and borborygmus, it should be remembered when the special indications above alluded to are present. It is reputed useful in *catarrhal gastritis*.

Lycopodium is prominent as a remedy in urinary disorders. *Spasmodic retention of urine* in children, and *catarrhal cystitis* in adults, with deposits of mucus or mucus and blood, with frequent painful micturition, are disorders in which it has rendered good service. It is a remedy for the *lithic acid diathesis*, when there is pain in the kidneys, ureters, and bladder, with unpleasant sensations in micturition, and there are red, sandy deposits in the urine. *Gonorrhœa*, *gleet*, *vesical catarrh*, and *rheumatism* with uric acid diathesis, are said to be benefited by lycopodium. Dr. Scudder recommended the tincture of the plant in *chronic kidney diseases* with blood in the urine; and in cases of "cough with bloody expectoration, congestive headache, dizziness, and tendency to syncope." The usual method of administering lycopodium for its specific effects is as follows: ℞ Specific lycopodium, gtt. x; aqua, fl℥iv. Mix. Sig. Dose, a teaspoonful every 1 or 2 hours.

Specific Indications and Uses.—Intractable forms of fever, not of an active type, showing obscure periodicity, with afternoon exacerbation, and the voiding of a high-colored red urine, staining the clothing; dyspepsia and indigestion with the same urinary symptoms, or with red, sandy deposits in the urine, palpitation, constipation, borborygmus, and water brash; spasmodic retention of urine in children; cystic catarrh in adults, with painful micturition; urine loaded with mucus or blood, or both, or deposits of red sand or phosphates; cough with bloody expectoration, congestive headache, dizziness, and tendency to fainting

Related Species.—There are several varieties of Lycopodium whose spores are sometimes collected with those of *L. clavatum*. Among them may be mentioned the *Lycopodiums—inundatum, complanatum*, and *annotinum*—of Linneus. An alkaloid *lycopodine* ($C_{32}H_{52}N_2O_3$) was obtained from *L. complanatum* by K. Boedeker (1882).

Lycopodium saururus. This plant is the *Piligan* of Brazil. *Piliganine*, a toxic alkaloid not identical with the above lycopodine, was discovered in it by Adrian (*Jahresb. der Pharm.*, 1886 and 1892). A dog succumbed to 2 grains of this alkaloid, which is said to possess emeto-cathartic, and convulsant properties. The plant likewise acts as an emeto-cathartic, doses of 4 grains of the extract producing purgation. As a cathartic, piliganine hydrochlorate may be administered in doses of from ⅙ to ⅓ grain.

LYCOPUS.—BUGLEWEED.

The whole herb of *Lycopus virginicus*, Linné.

Nat. Ord.—Labiatæ.

Common Names: *Bugleweed*, *Sweet bugle*, *Water bugle*, etc. (see below).

Botanical Source.—This plant is an indigenous, perennial herb, with a fibrous root, and a smooth, straight, obtusely four-angled stem, with the sides concave, producing slender runners from the base, and 10 to 20 inches in height. The leaves are opposite, oblong, or ovate lanceolate, toothed, entire toward the base, with glandular dots underneath. The flowers are very small, purplish, in dense, axillary whorls; at the base of each flower are two, small, subulate bracts. The corolla is campanulate, 4-cleft, the tube as long as the calyx, upper segment broadest, and emarginate. The calyx is tubular, 4-cleft, longer than the achenia. Stamens 2, distant, diverging, and simple; anthers erect and bilobed; ovary superior and 4-angled; style straight and slender; stigma bilobate; achenia 4, smooth, obovate, obliquely truncate at apex, compressed, and margins thickened (G.—W.—R.).

History.—Lycopus belongs to a class of perennial herbs somewhat resembling the mints, but lacking their aroma and having but 2 perfect stamens. It is found growing in almost all parts of the United States, being very common, and preferring moist, shady, places, showing particular fondness for wet, boggy soils. It grows from 6 to 18 inches in height, and, like most labiate plants, has a straight, smooth, square stem (obtusely 4-angled), with concave sides, supporting opposite, oblong, ovate or lanceolate, serrately-toothed leaves, having on their under surface small, glandular dots. The entire plant is smooth and often purplish, and the stem occasionally sends off long, slender runners. The flowers, which appear in midsummer (July and August), are very small, and arranged in dense, axillary whorls, or capitate clusters of a purplish color. The whole plant has an agreeable, yet peculiar balsamic, terebinthinate odor, and to most persons, a disagreeable, slightly bitter, balsamic taste. Its virtues are supposed to depend upon a volatile oil and tannin.

Lycopus is popularly known as Bugleweed, Water bugle, Sweet bugle, Water hoarhound, Gypsy-weed, Paul's betony, Green ashangee and Archangel, though the latter name is oftener applied to another plant—the *Archangelica Atropurpurea*. The name lycopus originates from two Greek words—*lukus*, wolf, and *pous*, foot; hence wolf-foot, so called because of a fancied resemblance of the cut leaves to a wolf's foot.

We have evidence that this plant was used early in the present century as a medicine. Schoepf, Ives, and Zollikoffer mention it. In 1828 Rafinesque, whose works were prominently recognized by the early Eclectics, notwithstanding the many liberties he took in his writings on scientific subjects, gave the best account of its introduction into medicine. He wrote of it that it was an excellent sedative, subtonic, subnarcotic, and subastringent. He further states that "it is described as partaking of the properties of digitalis, sanguinaria, cimicifuga, and spigelia; but it is neither diuretic nor anthelmintic, and is rather one of the mildest and best narcotics in existence." The same author claimed "it acts somewhat like digitalis without producing any of its bad effects or accumulating in the system." He complains that volumes have been written on fox-glove, a rank poison, while this excellent substitute has been allowed to pass almost unnoticed.

Among the first to investigate the properties of bugleweed were Drs. Pendleton and Rogers, of New York, who published several cases of hemoptysis and incipient consumption cured by it. In Rafinesque's day it was used to a considerable extent in New York and New Jersey; in the latter state being much employed as a remedy for diarrhœa and dysentery. Rafinesque pointed out that it acted chiefly on the blood vessels, and was especially useful in plethoric and inflammatory states, particularly internal inflammations resulting from inebriety, and for cardiac diseases. While he did not believe that it would cure phthisis, he stated that it was very valuable for hemoptysis, and that it acted on the circulatory system as a sedative, slowing the pulse and thereby allaying irritation and cough.

Until recent years, lycopus has been scarcely mentioned by allopathic writers. It was introduced into homœopathic practice by the late Prof. E. M. Hale, M. D., of Chicago, who first used it on the recommendation of an Eclectic physician in a case of incipient phthisis, for its control over the circulatory apparatus, with marked benefit. At present it is considerably employed by the homœopathic branch of the profession. Since nearly all that has been written on this drug has come from Eclectic pens, we may safely claim the remedy as one of Eclectic development.

Chemical Composition.—The Messrs. Tilden found this plant to contain tannic acid, organic and inorganic matters, bitter principle, and a peculiar principle. Mr. J. L. Weil (*Amer. Jour. Pharm.*, 1890, p. 72) found in it a fat (0.41 per cent) melting at 50° C. (122° F.), a granular, wax-like body (0.68 per cent) fusing at 70° C. (158° F.); a crystalline resin (0.43 per cent) soluble in ether; small amounts of tannic and gallic acids, and a crystallizable glucosid obtainable by extracting an alcoholic extract of the drug with ether. It readily splits into resin and sugar. The herb contains a small quantity (0.075 per cent) of volatile oil (Hennessy, *Amer. Jour. Pharm.*, 1889, p. 70; Schimmel's *Report*, Oct., 1890, p. 62).

Action, Medical Uses, and Dosage.—Lycopus fills an important place in Eclectic therapeutics. Its action is chiefly exhibited on the vascular structures and the sympathetic nervous system. It is a certain sedative, mild narcotic, subastringent, and tonic. Its sedative action is most pronounced and most frequently indicated where the vascular action is tumultuous, the velocity of the pulse rapid, with evident want of cardiac power. It is for this purpose that it is principally employed in advanced stages of acute disease with great debility, and in chronic disease with frequent pulse. It improves the circulation, and its good influence is extended to all the parts under the control of the vegetative system of nerves. As a sedative, Prof. Scudder classes it with aconite and veratrum. It acts somewhat like digitalis in reducing the velocity of the pulse, but is devoid of the dangerous effects resulting from the use of that drug, and hence has proved useful in some *cardiac affections*. It controls excessive vascular excitement, general irritability, and diminishes exalted organic action. Upon the stomach its action is kindly, improving the appetite, and serving as a mild gastric tonic. Normal secretion is established by it, and blood-making and nutrition are improved.

Lycopus is a remedy for *morbid vigilance* and *insomnia* attendant upon either acute or chronic disease. As a remedy for *painful* and *distressing forms of indigestion*, the specific lycopus will be found advantageous as well as a mild tonic in general debility. In the past it has been employed to purify the blood of patients suffering from *old ulcers*, an infusion being employed locally at the same time. Bugleweed, simmered with fresh butter or petrolatum, may be employed as a topical dressing for *burns* and *irritable ulcers*.

Several cases of *diabetes mellitus* have been reported, through the *Eclectic Medical Journal*, as benefited by lycopus. Dr. Gerald (1878) reported an extraordinary case as cured by it, but does not specify which variety of diabetes the patient was afflicted with. Prof. Edwin Freeman, M. D. (1879) used the drug with remarkable results in a case of diabetes, though he did not have the good fortune to see the disease cured, as the patient, who was rapidly improving, moved away and the doctor lost track of the case. Other successful cases were reported by Dr. Ray. Lycopus has proved a good remedy in some cases of *albuminuria* with great irritation and rapid action of the heart. It has given good results in *hemorrhages*, being particularly adapted to those cases in which the bleeding is frequent but small in amount. Under such conditions specific lycopus is valuable in *hemoptysis*, *epistaxis*, *hematemesis*, *hematuria*, and *uterine* and *intestinal hemorrhage*.

Its therapy in *gastro-intestinal affections* is worthy of notice. We have already noticed its use in indigestion. In *dysentery* and *diarrhœa* it may be given with advantage to the patient. It is of special value in the *diarrhœa of phthisis*, and is equally valuable to allay irritation and inflammation in *gastritis* and *enteritis*, especially those acute *gastric disturbances* and *inflammatory diseases* common to the drunkard. Bugleweed has been used both for its sedative effects and for its influence on the gastro-intestinal troubles accompanying *intermittent fevers*.

Cardiac disease, both organic and functional, have been markedly impressed by lycopus. Administered to patients suffering from *endocarditis* and *pericarditis* it quickly subdues the inflammation. It is a good remedy for *cardiac palpitation*, dependent on irritation of the cardiac nerve centers, or when arising from organic lesions. It is best adapted to those forms of heart disease characterized by irritability and irregularity, with dyspnœa and præcordial oppression. Lycopus powerfully increases the contraction of the unstriped muscular fibers, particularly those of the heart and arteries, hence its value in *cardiac dilatation* and *hypertrophy* which have been known to undergo marked improvement under its administration. It quickly relieves the suffering and anxiety nearly always experienced in heart diseases. It has favorably influenced *exophthalmic goitre*.

"Bugleweed is of great value in *acute pulmonary complaints*, and of still greater utility in *chronic lung troubles*. It acts as a gentle sedative and tonic. It reduces the frequency and force of the heart's action, and is indicated in pulmonary lesions with irritation and cough, and with tendency to hemorrhage. It is particularly valuable in chronic cases with copious secretion of mucus or muco-pus. It lessens irritation, allays the distressing cough so frequently encountered in *chronic bronchitis*, *pneumonia*, and *consumption*. By its action as a nervine it gives rest and quiets pain. By its control over the circulatory apparatus it slows the pulse and brings down the temperature. *Tumultuous action of the heart* and consequent increase of the circulation through the lungs are controlled by it. It may be employed in acute cases to control fever and inflammation. Here it gives rest, alleviates the pain, quiets the vascular excitement, besides allaying the irritative cough. It is one of our very best remedies for *hemoptysis*, especially in those cases where the bleeding is small in amount yet frequent, or it may be administered to prevent the tendency to *hemorrhage in phthisis*. In consumption it is a splendid remedy to relieve the distressing symptoms, and may be administered in drop doses every hour. It is valuable in *acute* as well as *chronic pneumonia*. In ordinary *acute catarrh* it may be administered with aconite, eupatorium, and other indicated agents. It is indicated by chronic cough, mucous or muco-purulent expectoration, frequent pulse, high temperature, tubercular deposits, and albuminuria, with vascular excitement" (Felter).

For *pulmonary hemorrhage*, lycopus combined with cinnamon and ipecac, is the best remedy with which we are acquainted. Dose of the powder, from 1 to 2 drachms; of the infusion (℥i to aqua Oj), from 2 drachms to 4 fluid ounces; of a strong tincture (℥viii to alcohol Oj) of the recent plant, from 5 to 60 minims; of specific lycopus, 1 to 30 minims.

Specific Indications and Uses.—Vascular excitement; hemorrhage, in small amounts, resulting from determination of blood to the lungs, kidneys, or gastro-intestinal organs; albuminuria, with frequent pulse; cough, with copious expectoration of mucus or muco-pus, especially debilitating chronic cough; wakefulness and morbid vigilance, with inordinately active circulation; frequent pulse, with high temperature, and in tubercular deposits.

Related Species.—*Lycopus europæus*, Linné; *Water horehound*.—A European plant introduced into this country, is said to possess febrifuge properties, curing severe *intermittents* in doses of 1 or 2 drachms of the powdered plant, every 2 or 4 hours. It has been confounded with the *L. virginicus*, with which it is frequently collected, but may be discriminated by its stem being more *acutely* 4-angled, its leaves not so broad, the lower being somewhat feather-cleft, its flowers more closely grouped, and the calyx divisions presenting short spines. This plant undoubtedly possesses many of the properties of *Lycopus virginicus*.

LYTHRUM.—LOOSESTRIFE.

The *Lythrum Salicaria*, Linné (*Lythrum Salicaria*, var. *pubescens*, Pursh).
Nat. Ord.—Lythraceæ.

Common Names: *Loosestrife*, *Purple willow-herb*, *Milk willow-herb* (*Herba salicariæ*).

Botanical Source.—This plant is a handsome perennial with a woody root branching at the crown, from which arise several erect, acutely quadrangular, either smooth or downy, leafy, generally simple, reddish stems 2 to 5 feet high. The leaves are nearly sessile, lanceolate, acute, entire, 3 to 6 inches long, about one-fourth as wide, the upper ones diminished to sessile bracteas, all mostly opposite, sometimes in whorls of 3 or 4, in which cases the number of angles on the stem is likewise increased. The flowers are large, numerous, showy, nearly sessile, in numerous axillary whorls, six in each, of a variable crimson or purple, composing long, leafy spikes. The calyx is inferior, cylindrical, striated, the limb with 6 broad teeth, and the same number of alternate, smaller, subulate diverging ones; 6 of the teeth long and reddish. Corolla of 6, equal petals. Stamens 12; anthers conspicuous, red, with green or yellow pollen. Capsule small, elliptical, 2-celled, and many-seeded (L.—W.).

History.—This plant grows in several parts of the globe, and is found in wet meadows, ditches, etc., in this country, especially in the northern and eastern states, bearing purple flowers in July and August. It has no odor, but an herb-like, astringent taste, and by chewing, becomes very mucilaginous. The ferruginous salts darken its infusion, and boiling water takes from it a large amount of mucilage, becoming quite viscid. It yields its properties to water. It has not been analyzed, as far as we know, but probably contains tannin and much mucilage.

Action, Medical Uses, and Dosage.—Loosestrife possesses considerable mucilage, rendering it a demulcent, while at the same time its tannic acid gives to it astringent properties. A decoction of it used freely has been serviceable in various affections of the bowels where this class of remedies was indicated, as in *colorectitis*, *summer complaints of children*, *diarrhœa*, etc. Externally, it is very beneficial as a local application in *chronic ophthalmia*, *ulcers*, and some forms of *cutaneous disease;* also in *leucorrhœa*, *gleet*, *chronic gonorrhœa*, etc., being used either as a wash, or in form of poultice. Dose of the decoction, 1, 2, or 3 fluid ounces; of the powder, 30 to 60 grains, repeated every 3 or 4 hours. An infusion is said to be better than a decoction.

Related Species.—*Decodon* (Elliott), or *Lythrum verticillatum*, (*Decodon aquaticum*, Gmelin; *Anonymus aquatica*, Wright), *Swamp willow-herb*, or *Grass-poley*, bearing purple flowers, possesses similar properties to the above; it is said to cause abortion in mares and cows browsing on it in winter, and may, perhaps, exert a medicinal influence on the human uterus. It grows in swamps throughout the United States and Canada, has a stem, woody at the base, often prostrate, and rooting at the summit, 3 to 8 feet long, or when erect 2 to 3 feet in height, and 4 to 6-angled. The leaves are opposite, or in whorls of 3, lanceolate, on short petioles, acute at base, 3 to 5-inches long, gradually acuminate, and acute at apex. The flowers are large, purple, in axillary subsessile umbels of 3 or more, apparently whorled, constituting a long, leafy, terminal, and showy panicle. Calyx short, broadly campanulate, with 5 erect teeth, and 5 elongated, spreading, horn-like processes. Petals 5 or 6. Stamens 10, alternate ones very long; style filiform; capsule globose, included, 3-celled, many-seeded (W.—G.).

Lythrum alatum, Pursh. North America.

Lythrum album, Kunth. Texas.

Lythrum lanceolatum, Elliott. Under the name of *yerba del cancer*, the Mexicans employ these three species in poultices, to be applied to *cancer*.

Cuphea viscosissima, Jacquin. *Nat. Ord.*—Lythraceæ Grows from Massachusetts south and west, flowering in August.

Cuphea lanceolata, Kunth. The *Atlanchana* of the Mexicans. These two plants are reputed useful in *diarrhœa*.

Cuphea microphylla, Kunth. } Branches and leaves employed in South America as an
Cuphea antisyphilitica, Kunth. } antisyphilitic.

MACIS (U. S. P.)—MACE.

"The arillode of the seed of *Myristica fragrans*, Houttuyn (*Nat. Ord.*—Myristicaceæ)"—(*U. S. P.*).

Synonym: *Arillus myristicæ*.

Source and Preparation.—(See *Myristica*.)

After the fruit of the nutmeg-tree is gathered, the outside fleshy pericarp is either thrown away, or made into a preserve, while the arillus, being cautiously removed from the nut, is compressed, exposed to the sun, and when dried, moistened with salt water, in order to aid in its conservation, and is then packed into sacks, forming the mace of commerce.

Description.—"In narrow bands, 25 Mm. (1 inch) or more long, somewhat branched and lobed above, united into broader bands below; brownish-orange; fatty when scratched or pressed; odor fragrant; taste warm and aromatic"—(*U. S. P.*). The best mace (*Banda mace*) is flaky and spread, and of a dingy yellow color. It is seldom used in medicine, being employed chiefly as a flavoring agent. *Bombay mace*, from *Myristica malabarica*, Lamarck, is devoid of aroma, contains much dark, red-brown coloring matter allied to curcuma, and is often used as an adulterant of Banda mace (see description and tests by Tschirch and Hanausek in *Amer. Jour. Pharm.*, 1882, p. 13, and 1890, p. 398; also P. Soltsien, *ibid.*, 1893, p. 457).

Chemical Composition.—By distillation with water, mace yields from 4 to 15 per cent of volatile oil, *oil of mace* (*Oleum Macidis*). It is dextro-rotatory, and contains the hydrocarbons *pinene* and *dipentene* (Wallach, 1889), and the stearopten *myristicin* ($C_{12}H_{14}O_3$) a crystallizable body melting at 30.25° C. (86.5° F.) (F. W. Semmler, *Berichte*, 1890; also see *Amer. Jour. Pharm.*, 1890, p. 442). Prof. Flückiger obtained from mace, by extraction with boiling ether, about 24.5 per cent of a soft, resinous, non-fatty mass, and also found uncrystallizable sugar. Tschirch observed *amylo-dextrin*, a body intermediary between starch and dextrin, yielding a red or violet color with iodine. Starch is not present in mace, hence an adulteration of powdered mace with powdered nutmeg can readily be detected by the starch reaction (P. Soltsien, 1891). The ash of mace should not exceed 2.5 per cent referred to air-dry substance.

Tinctura Macidis, or *Tincture of mace*, is prepared by digesting mace, 1 part, in alcohol, 5 parts. Filter.

Action and Medical Uses.—(See *Myristica*.)

MAGNESIA (U. S. P.)—MAGNESIA.

Formula: MgO. Molecular Weight: 40.26.

Synonyms: *Magnesia usta*, *Magnesia calcinata*, *Calcined magnesia*, *Light magnesia* (*Magnesia levis*), and *Magnesium oxide*.

Preparation.—*Magnesia*, or *Calcined magnesia*, as it is more generally termed, is obtained by placing a convenient quantity of commercial carbonate of magnesium, in small lumps (not finely powdered), in an earthen crucible, which should be firmly packed, nearly filled, loosely covered with a lid, and placed in a good wind furnace. When the crucible is at a dull-red heat, its contents are from time to time carefully stirred with a clean iron spatula; and when the interior portion has also acquired this temperature, a small quantity is withdrawn, and when cool, shaken with sulphuric or hydrochloric acid. If this causes an evolution of gas, the heat must be continued until a small portion, dropped into dilute acid, quietly sinks in the liquid, and after a few minutes dissolves without the slightest evolution of gas. The contents of the crucible are now emptied on a clean copper or iron plate, and before they are quite cool placed in a well-stoppered bottle; the crucible, in the meantime, is filled with a fresh portion, and the heating proceeded with as before. Nine parts of the carbonate yield about four parts of calcined magnesia. The process involved is represented by the following equation: $4MgCO_3.Mg(OH)_2+5H_2O$ (*Magnesium carbonate, U. S. P.*) $=5MgO+6H_2O+4CO_2$. If the heat is continued after the water and carbon dioxide are expelled, the product soon loses it lightness and acquires a compact, lumpy form.

There are two kinds of magnesia known—the *light* and the *heavy*. The former, *Magnesia Levis*, is designated in the *U. S. P.* simply as *Magnesia*. The heavy calcined magnesia, is produced precisely like the light magnesia excepting that *heavy*, instead of *light* magnesium carbonate, is used in its production. The heavy variety is designated by the *U. S. P.* as *Magnesia Ponderosa* or *Heavy magnesia*.

Description.—The official description of light and of heavy magnesia is as follows: Magnesia (*U. S. P.*).—"A white, very light, and very fine powder, without odor, and having an earthy, but not a saline taste. On exposure to the air, it slowly absorbs moisture and carbon dioxide. Almost insoluble in water. and insoluble in alcohol, but soluble in diluted acids. It is not altered by heat, but when very strongly heated its density is increased. When moistened with water, it has a faintly alkaline reaction upon litmus paper. On stirring 1 part of magnesia with 15 parts of water, in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient consistence to prevent it from dropping out when the glass is inverted. A filtered solution of magnesia in diluted sulphuric acid, mixed with ammonium chloride T.S., and an excess of ammonia water, yields, with sodium phosphate T.S., a white, crystalline precipitate"—(*U. S. P.*).

Magnesia Ponderosa (*U. S. P.*), *Heavy magnesia.*—"A white, dense, and very fine powder, which should conform to the reactions and tests given under *Magnesia.* It differs, however, from the latter in not readily uniting with water to form a gelatinous hydrate"—(*U. S. P.*).

Magnesia crackles slightly when thrown into water. Unlike lime, it evolves scarcely any heat when water is added to it, although this fluid in small quantity is absorbed by it. Water, in large quantity, dissolves traces of it; on heating the aqueous solution it becomes turbid, but clears again on cooling. Its specific gravity is variously given as 2.3, 3.07, and 3.2. Continued trituration will considerably increase its density, so that a bottle which would only contain 1 ounce of it when not triturated, will, by this process, readily hold 4 ounces. It is dissolved by the dilute acids without effervescence; if gas-bubbles are given off, carbonic acid is present. Magnesia should be kept in well-closed containers. In the form of light magnesia, or still better, the gelatinous hydrate, separated from the solution of sulphate of magnesium by caustic potash, and dried, magnesia has been recommended as an antidote to arsenic (arsenous acid, As_2O_3) by Bussy, insoluble magnesium arsenite (AsO_3MgH) being formed; and experiments of Christison, as well as Ph. Hoglan (*Amer. Jour. Pharm.*, 1880, p. 487), show that arsenic is as thoroughly removed from a solution as by freshly precipitated ferric hydrate. This treatment must not be employed, however, in the case of *arsenous sulphide* As_2S_3; the latter is comparatively innocuous because it is insoluble in water, but becomes converted into a soluble, and therefore poisonous, compound upon treatment with magnesia (*Amer. Jour. Pharm.*, 1879, p. 153). For solidifying copaiba, magnesia answers best when perfectly anhydrous (Mialhe).

Tests.—"If a mixture of 0.2 Gm. of magnesia with 10 Cc. of water be heated to boiling, and, after cooling, 5 Cc. of the supernatant liquid be filtered off, this filtrate should not give more than a faintly alkaline reaction with litmus paper, and, when evaporated to dryness, should not leave more than a very slight residue (limit of foreign soluble salts). The magnesia mixed with water remaining from the preceding test, when poured into 5 Cc. of acetic acid, should dissolve without the evolution of more than a few isolated gas bubbles (limit of carbonate). This latter solution, when filtered, should not be rendered more than slightly opalescent by ammonium oxalate T.S. (limit of calcium), or by barium chloride T.S. (limit of sulphate), or, after the addition of a few drops of nitric acid, by silver nitrate T.S. (limit of chloride). If 0.4 Gm. of magnesia be dissolved in 10 Cc. of diluted hydrochloric acid, the solution should be colorless, and should not be affected by hydrogen sulphide T.S., nor, after the addition of a slight excess of ammonia water, should it be immediately affected by ammonium sulphide T.S. (absence of metallic impurities). If magnesia be exposed to a low red heat in a porcelain crucible, it should not lose more than 5 per cent of its weight (limit of water of hydration)"—(*U. S. P.*). If iron be present, the addition of tannic acid will occasion a violet or bluish-black turbidness in the neutral solution in sulphuric acid (Wittstein). Messrs. Keasbey and Mattison, in 1889 (*Amer. Jour. Pharm.*, p. 122), called attention to a spurious commercial brand of English heavy calcined magnesia, which consisted of 79 per cent calcium sulphate and 20.7 per cent of water. An admixture with Rochelle salt is likewise on record (*ibid.*, 1873, p. 13).

Action, Medical Uses, and Dosage.—Magnesia is antacid, antilithic, and laxative. The stools produced by it are feculent (unless acid is present in large quantities), and are not strongly odorous. Whenever a laxative is indicated, and *acidity of stomach and bowels* is present, magnesia should be selected. It acts kindly, seldom causing nausea, or griping. It is slow, requiring 5 or 6 hours, but is mild, thorough, and efficient. It is one of the prompt remedies for *heartburn*. It is useful in *dyspepsia with acidity*, and is preferable to the carbonate as it does not give rise to flatus, and the dose is less; its laxative qualities likewise give it some advantage over alkaline remedies. In all cases attended with acidity and *constipation* it will be found useful. It acts as an antilithic, first by correcting *gastric acidity*, and secondly, by forming with free lithic acid, or lithate of ammonium, the more soluble lithate of magnesium. It is on this account beneficial in *gout*, and *rheumatic gout*, frequently giving material relief. When no acid is present in the stomach or intestines, magnesia is liable to lodge in some part of them, hence, in such instances, its administration should be followed by a draught or two of lemonade. From 5 to 10 grains of rhubarb mixed with 20 to 40 grains of magnesia, and a few grains of ginger, form an excellent laxative and antacid. When the stools are green and excoriating in young children, give 5 grains of magnesia with 2 or 3 grains of rhubarb. *Sick headache*, with sour stomach, is often cut short with magnesia, as is occasionally the *vomiting of pregnancy* with gastric acidity. Taken in laxative doses night and morning for a long period it is said to remove warts.

The following is recommended in cases of poisoning, in which the nature of the poison is unknown: After freely evacuating the stomach by emetics, give the following mixture in a sufficient quantity of water—calcined magnesia, pulverized charcoal, and hydroxide of iron, of each, equal parts, mixed together. It is perfectly innocuous, and as its ingredients are antidotes to the most active and commonest poisons, it is very likely to be efficient. Dose of magnesia as a laxative, from half a drachm to a drachm; for children, 5 to 10 grains; as an antacid, or antilithic, from 10 to 30 grains twice a day.

Specific Indications and Uses.—Gastro-intestinal acidity, pyrosis, heartburn; green, excoriating stools; constipation with acidity.

Related Body.—INDIAN YELLOW. A yellow pigment prepared from an Indian substance known as *Purree*. The latter, Stenhouse believes to be the juice of some plant mixed with magnesia, and boiled to a solid state; others regard it as a body deposited in the urine of camels which have been fed upon the fruit of the mango tree, *Mangifera Indica* (see *Philos. Mag.*, Vol. XXX, and *Chem. Gazette*, 1855). Purree comes in dark-brown balls, yellow within, weighing about a quarter pound. It has a castor-like odor. Stenhouse found it to be composed mainly of the magnesium salt of *purreic acid*. *Purreic acid* (*euxanthic acid*, Erdmann) occurs in the amount of half the weight of purree, forming small, pale-yellow crystals, resembling berberine, and having a sweetish and afterward bitterish taste. Hot alcohol readily dissolves it. In hot water it is quite soluble, but sparingly so in cold water. Nitric acid converts it into yellow needles of *oxypicric acid* (Erdmann).

MAGNESII CARBONAS (U. S. P.)—MAGNESIUM CARBONATE.

FORMULA: "Approximately $([MgCO_3]_4.Mg[OH]_2+5H_2O)$"—(*U. S. P.*). MOLECULAR WEIGHT: 484.62.

SYNONYMS: *Carbonate of magnesia*, *Carbonicus magnesicus*, *Magnesia hydrico-carbonica*. *Magnesia alba*, *Magnesiæ carbonas*.

Source and History.—Native carbonate of magnesium, or *magnesite* ($MgCO_3$, in its purest form), has been found in Moravia; the vicinity of Turin, Piedmont; in the East Indies; and in the island of Eubœa. It constitutes a range of low hills in Hindustan; also in Eubœa there are entire hills of it. At one time, upward of 2000 tons are said to have been annually exported to Smyrna and England. The Eubœan magnesite is almost pure magnesium carbonate. In England, carbonate of magnesium is found in combination with carbonate of calcium, forming what is called magnesian limestone or *dolomite* ($CaCO_3.MgCO_3$). This mineral is also found abundantly in some portions of the United States, notably in the New England and New York states. *Kieserite* ($MgSO_4+H_2O$), found in the Stassfurt salt-beds in Germany, is also a source from which artificially prepared carbonate of magnesium is derived. The preparation magnesium carbonate, the *Magnesia alba* of *Pharm. Lond.*, 1787, formerly bore the name at Rome, of Count Palma's powder, and was kept a secret for many years. The mode of preparation was probably carried from Germany to Italy. Lancisi, in 1717 (and it is said, Valentini, in 1707), and afterward Hoffman, in 1722, made public the process of manufacture. At that time it was extracted from the mother liquor which remains after the crystallization of rough niter (chloride of magnesium) by precipitation with a solution of carbonate of potassium or sodium. The name *Miraculum Chemicum*, was given to it from the circumstance of a precipitate being formed by the mixture of two clear solutions.

Preparation.—Magnesium carbonate may be prepared in several ways, dependent mainly upon the source from which the magnesia is derived, as each mineral requires a different mode of treatment according to its composition. In this connection the reader is referred to an exhaustive article on the occurrence and commercial production of magnesium carbonate in *Pharm. Jour. Trans.*, Vol. XIV, 1855, p. 221. The largest producers of magnesium carbonate in this country are the Keasbey & Mattison Company, of Philadelphia, who prepare it from *dolomite* and *kieserite*. When magnesium is in solution as chloride or sulphate, the carbonate is prepared by precipitating with sodium carbonate. By precipitating magnesium sulphate, for example, with sodium carbonate, the neutral compound $MgCO_3$ is never formed; basic carbonates are invariably precipitated (that recognized by the *U. S. P.*), having the composition $(MgCO_3)_4.Mg(OH)_2+5H_2O$. The process is represented by the following equation: $5MgSO_4+5Na_2CO_3+6H_2O=Mg(CO_3)_4.Mg(OH)_2+5H_2O+5Na_2SO_4+HCO_2$. If the liquid is warm, the carbonic acid gas escapes; if cold it remains and holds magnesium in solution in the form of the soluble *bicarbonate* $Mg(CO_3H)_2$.

The *British Pharmacopœia* (1898) recognizes a *heavy magnesium carbonate* (*Magnesii Carbonas Ponderosus*), and a light magnesium carbonate (*Magnesii Carbonas Levis*), both of the composition $3(MgCO_3)Mg(HO)_2 4H_2O$. *Heavy Carbonate of Magnesium* is directed to be prepared as follows: "Magnesium sulphate, 10 ounces (Imp.) [125 Gm., metric]; sodium carbonate, 12 ounces (Imp.) [150 Gm., metric]; distilled water, boiling, a sufficient quantity. Dissolve the magnesium sulphate and the sodium carbonate, each, in a pint (or 250 Cc.) of the distilled water, mix the solutions, and evaporate to dryness; digest the residue for ½ hour with 2 pints (or 500 Cc.) of the distilled water, and, having collected the insoluble matter on a calico filter, wash it repeatedly with the distilled water, until the washings are free from sulphates; dry the product at a temperature not exceeding 100° C. (212° F.)"—(*Br. Pharm.*, 1898).

Light Magnesium Carbonate is directed to be prepared by using the same materials and amounts as in the preceding case, and dissolving "the magnesium sulphate and the sodium carbonate, each in ½ gallon (or 1 litre) of cold distilled water; mix the two solutions; boil the mixture for 15 minutes; transfer the precipitate to a calico filter; pour upon it boiling distilled water, until the washings are free from sulphates; dry the product at a temperature not exceeding 100° C. (212° F.)"—(*Br. Pharm.*, 1898).

Description.—The official salt is described as "light, white, friable masses, or a light, white powder, without odor, and having a slightly earthy taste; permanent in the air. Almost insoluble in water, to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol, but soluble in diluted acids with active effervescence. When strongly heated, the salt loses water and carbon dioxide, and is converted into magnesia. A filtered solution of the salt in diluted sulphuric acid, when mixed with ammonium chloride T.S. and an excess of ammonia water, yields with sodium phosphate T.S., a white, crystalline precipitate"—(*U. S. P*). Carbonate of magnesium is loose and granular if dense, but somewhat coherent, like starch, if light; more readily soluble in cold than hot water; if the water be charged with carbonic acid, it is rendered much more soluble, requiring only 48 parts of this fluid for its solution. As before stated, it exists in this solution as magnesium bicarbonate. When this solution is heated, carbonic acid is evolved, and basic magnesium carbonate precipitated. "The *incompatible* substances with this salt are acids and acid salts, alkalies and neutral salts, alum, cream of tartar, nitrate of mercury, acetate of mercury, bichloride of mercury, acetate of lead, sulphates of zinc, iron, and copper" (Coxe).

Impurities and Tests.—The impurities of carbonate of magnesium are similar to those of magnesia, and usually occur from carelessness in the process of manufacturing. It is liable to contain traces of sodium carbonate, calcium, iron, sulphates and chlorides, etc., which are detected by employing the following tests of the *U. S. P.*: "If the salt be boiled with water, the filtered liquid, when evaporated to dryness, should not leave more than a very slight residue. A 2 per cent solution of the salt prepared by the addition of acetic acid, should not be rendered more than slightly opalescent by ammonium oxalate T.S. (limit of calcium); nor by barium chloride T.S. (limit of sulphate); nor after the addition of a few drops of nitric acid, by silver nitrate T.S. (limit of chloride). If 0.4 Gm. of the salt be dissolved in 5 Cc. of diluted hydrochloric acid, the solution should be colorless, and should not be affected by hydrogen sulphide T.S., nor, after the addition of an excess of ammonia water, should it be immediately affected by ammonium sulphide T.S. (absence of metallic impurities). If 1 Gm. of the salt be ignited in a porcelain crucible, the residue should weigh not less than 0.4 Gm."—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Carbonate of magnesium is antacid, antilithic, and purgative when it meets with an acid in the alimentary canal, but not without. Hence, it is always useful to give it in combination with lemonade or lemon juice. It has the same uses as magnesium oxide. It has proved useful in cases of *acid stomach*, *gout*, and where the urine contains an *excess of uric acid;* but from its liability to occasion flatus, owing to the escape of its carbonic acid gas, when in the intestines, it is inferior to calcined magnesia, especially for use in children. Doses of a teaspoonful of magnesium carbonate, night and morning, continued for a length of time, are said to be efficient in removing *cutaneous warts.* Dose, as an antacid and antilithic, 1 to 40 grains; as a cathartic, 1 or 2 drachms in water or milk. In preparing camphor, and other medicated waters, carbonate of magnesium by trituration, aids materially in diffusing the essential oils, etc., through the water. Its use for this purpose, however, has been discarded by the Pharmacopœia in favor of precipitated phosphate of calcium.

Magnesium and Its Compounds.—*Magnesium, Magnium, Manganesium.* Symbol: Mg. Atomic weight: 23.94. This element is very abundant in nature, occurring in the form of carbonates, as *magnesite* ($MgCO_3$); *hydromagnesite* (basic carbonate, $3MgCO_3.Mg[OH]_2+3H_2O$); *dolomite* ($MgCO_3.CaCO_3$); as sulphate in *kieserite* ($MgSO_4+H_2O$), and in *Epsom salts* ($MgSO_4+7H_2O$) from bitter-water springs; as an aluminate in *spinell*, and in a great number of silicates, *e. g.*, asbestos, talcum, tourmaline, etc. In the form of magnesium chloride the element exists in comparatively large quantity in sea water, and is also a constituent of the organic world.

Metallic magnesium was first isolated by Davy. Subsequently it was obtained by reduction of molten magnesium chloride with metallic sodium. In more recent years it is prepared by electrolytic decomposition of magnesium chloride (Bunsen), or certain magnesium minerals, *e. g.*, *carnallite.* Magnesium is a silver-white metal, permanent in dry air, but oxidizes on its surface when exposed to moist air. It has the specific gravity 1.75, and melts at slightly below 800° C. (1472° F.) (Victor Meyer, 1887). In commerce it is found both in ribbon and in powder form. When held in a flame, the ribbon ignites and burns with a brilliant white light, rich in chemically active (actinic) rays; hence its use in flash-light photography. White magnesium oxide (MgO) is formed in the combustion of the metal. Magnesium is also used in pyrotechnics as an ingredient of white and red fire. (See formulæ in *Amer. Jour. Pharm.*, 1885, p. 605.) It is likewise recommended as a substitute for zinc in the testing for arsenic, by Marsh's test, on account of its being free from contaminating arsenic. Magnesium decomposes water slowly at boiling temperature, and dissolves in diluted acids with evolution of hydrogen gas, forming a line of salts which is of importance in medicine. Magnesium, under certain conditions, also combines with nitrogen, forming the nitride Mg_3N_2. This reaction became prominent by the part it played in the isolation of argon by Lord Rayleigh and Prof. Ramsay, in 1895. Magnesium also forms alloys with metals and an amalgam with mercury, which is used in analytical chemistry as a reducing agent.

Other Magnesium Compounds.—MAGNESII SALICYLAS, *Magnesium salicylate* ($[C_6H_4.OH.COO]_2MgH_2O$). This salt forms in elongated colorless needles, hygroscopic, and soluble in alcohol and water, and of bitterish taste. B. Fischer (*Pharm. Ztg.*, 1888) prepares it by saturating a solution of salicylic acid in boiling water with magnesium carbonate. It has been used in *typhoid fever*, but has not become popular.

MAGNESII CHLORIDUM, *Magnesium chloride*, $MgCl_2$. This salt is a by-product of the potash and bromine works at Stassfurt. It is a bitter, very deliquescent compound, acting as a mild purgative. It is said to augment the appetite, and promote an increased flow of bile. Dose, ½ to 1 ounce, well diluted.

MAGNESII LACTAS, *Magnesium lactate*, ($Mg[C_3H_5O_3]_2.3H_2O$).—Dissolve separately, in hot water, magnesium sulphate, 5 parts, and calcium lactate, 6 parts. Mix the solutions and filter from the precipitated calcium sulphate. To insure a complete precipitation digest with a small quantity of magnesium carbonate, filter again, evaporate, and crystallize. Or it may be prepared by saturating an aqueous dilution of lactic acid (1 in 10) with an excess of carbonate of magnesium. Filter and evaporate to crystallization. White, crystalline granules or needles, soluble in cold (30), and in boiling water (6), but not soluble in alcohol. It decomposes upon heating.

Asbestos.—A compound of silicon, calcium, and magnesium, most largely of magnesium silicate, occurring in many sections of Europe, and in Canada and the United States. It consists of parallel aggregations of long, silky fibers, which are insoluble, incombustible, and is a poor conductor of heat. Formed into paper, or into pulp-like masses, it is used to protect structures from fire and to retain heat in steam pipes. It is also an excellent filtering substance for fluids which can not be passed through paper. In a finely divided state it is known as *mineral wool.*

MAGNESII CITRAS EFFERVESCENS (U. S. P.)—EFFERVESCENT MAGNESIUM CITRATE.

Preparation.—"Magnesium carbonate, ten grammes (10 Gm.) [154 grs.]; citric acid, forty-six grammes (46 Gm.) [1 oz. av., 272 grs.]; sodium bicarbonate, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; sugar, in fine powder, eight grammes (8 Gm.) [123 grs.]; alcohol, distilled water, each, a sufficient quantity. Mix the magnesium carbonate intimately with thirty grammes (30 Gm.) [1 oz. av., 25 grs.] of citric acid and four cubic centimeters (4 Cc.) [65 ♏] of distilled water, so as to form a thick paste. Dry this at a temperature not exceeding 30° C. (86° F.), and reduce it to a fine powder. Then mix it intimately with the sugar, the sodium bicarbonate, and the remainder of the citric acid previously reduced to a very fine powder. Dampen the powder with a sufficient quantity of alcohol, so as to form a mass, and rub it through a No. 6 tinned-iron sieve. Then dry it, and reduce it to a coarse granular powder. Keep the product in well-closed vessels"—(*U. S. P.*).

Care must be taken to observe these proportions exactly, and especially not to exceed the temperature indicated, in order to obtain a soluble product. In the first part of the process, an acid-soluble magnesium citrate is formed, and the final product is a mixture of acid magnesium citrate, sodium bicarbonate, some slight excess of citric acid, and sugar.

Description and Tests.—"A white, coarsely granular salt, without odor, and having a mildly acidulous, refreshing taste. Deliquescent on exposure to the air. Soluble, with copious effervescence, in 2 parts of water at 15° C. (59° F.), and very soluble in boiling water; almost insoluble in alcohol. The aqueous solution (1 in 20) has an acid reaction, and, after the addition of ammonium chloride T.S. and a slight excess of ammonia water, it yields with sodium phosphate T.S., a white crystalline precipitate. If to another portion of the aqueous solution a little calcium chloride T.S. be added, and then a slight excess of ammonia water, the filtered liquid will deposit a white precipitate on boiling. A saturated, aqueous solution of the salt, when mixed with potassium acetate T.S., and a small quantity of acetic acid, should not yield a white, crystalline precipitate (absence of tartrate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—A mild laxative. Dose, 2 drachms to 1 ounce, well diluted.

MAGNESII SULPHAS (U. S. P.)—MAGNESIUM SULPHATE.

Formula: $MgSO_4+7H_2O$. Molecular Weight: 245.84.

Synonyms: *Epsom salt, Sulphate of magnesia, Sal Epsomense, Sal Sedlicense, Sal amarum, Sal anglicum, Sulfas magnesicus.*

Source and Preparation.—Sulphate of magnesium, commonly known as *Epsom salt*, exists abundantly in sea water, and in some mineral springs. It was discovered in 1694 by Nehemias Grew, who prepared it from the saline waters of Epsom, in England, from whence it has derived its familiar name *Epsom salt;* it also occurs in the form of the mineral *kieserite* ($MgSO_4+H_2O$), which is found in the celebrated salt-beds of Stassfurt, Germany, with other magnesium-bearing minerals, such as *kainite, polyhalite*, etc. Magnesium sulphate may be prepared from various sources: From the natural bitter-waters by evaporation and recrystallization; from the mother liquors in the preparation of salt from sea water; from *dolomite* (magnesium calcium carbonate); from *kieserite*, by calcination, solution in hot water and crystallization, etc. In large quantities it is obtained as a by-product in the manufacture of carbonic acid gas from *magnesite* ($MgCO_3$) with sulphuric acid.

Crab Orchard Salt, obtained by evaporating the water of certain wells in Kentucky, is an impure magnesium sulphate, its off-color being due to impurities, iron compounds probably contributing somewhat to the discoloration. Wiley (1871) found it to contain magnesium sulphate to the extent of nearly 65 per cent (*Amer. Jour. Pharm.*, 1871, p. 209; also see *ibid.*, 1874, p. 5, and 1875, p. 229).

Description.—Magnesium sulphate occurs in "small, colorless, rhombic prisms, or acicular crystals, without odor, and having a cooling, saline, and bitter taste; slowly efflorescent in dry air. Soluble in 1.5 parts of water at 15° C. (59° F.), and in 0.7 part of boiling water; insoluble in alcohol. When heated to 52° C. (125.6° F.), the salt loses 1 molecule of water, and is converted into a white powder. At about 132° C. (269.6° F.), it still retains 1 molecule of water, and at a temperature of 200° to 238° C. (392° to 460.4° F.), it is rendered anhydrous. The aqueous solution is neutral to litmus paper. When mixed with ammonium chloride T.S. and ammonia water, it yields with sodium phosphate T.S., a white, crystalline precipitate. With barium chloride T.S. it yields a white precipitate insoluble in nitric acid"—(*U. S. P.*). Magnesium sulphate should be kept in well-closed containers to prevent it from efflorescing. Magnesium sulphate is decomposed by the hydroxides of barium, strontium, the alkalies, and all the salts formed by these bases, excepting the alkaline chlorides, nitrates, and sulphates; and by the nitrate, chloride, and carbonate of calcium. Caustic potash and soda, also lime water and aqua ammoniæ precipitate white magnesium hydroxide ($Mg[OH]_2$), which forms a soluble compound with ammonium chloride or any of the other salts of ammonium; hence the precipitation with ammonia water is incomplete, sulphate of ammonium being formed in the reaction. Alkali carbonates precipitate basic magnesium carbonate (see *Magnesium Carbonate*).

The afore-mentioned crystalline precipitate with sodium phosphate in solution of magnesium sulphate to which previously ammonia and ammonium chloride were added, is characteristic for magnesium. It has the composition $PO_4(NH_4)Mg+6H_2O$, and is insoluble in water containing ammonium hydroxide. Heated to redness, it loses ammonia and water, and is transformed into magnesium pyrophosphate ($P_2O_7Mg_2$).

Impurities and Tests.—This salt is liable to various impurities, the most probable being iron and chloride of magnesium. When iron is present the solution gives a violet or bluish-black precipitate with tannic acid, and a blue or bluish-white precipitate with ferrocyanide of potassium. The latter reagent produces a red-brown precipitate if copper is present. If contaminated with chloride of magnesium, the salt will be more or less deliquescent, according to the amount of chloride contained in it. If chloride of calcium be present, oxalate of ammonium will cause a precipitate in the salt solution acidulated with acetic acid. The presence of chlorides may be known by the evolution of hydrochloric acid gas when the sulphate is acted on by sulphuric acid. If the salt is of acid reaction, contamination with zinc sulphate or with oxalic acid may be looked for.

The *U. S. P.* directs the following tests: "When a small portion of the salt is introduced, on a clean platinum wire, into a non-luminous flame, it should not impart to the latter a persistent yellow color (limit of sodium). A 5 per cent aqueous solution of the salt should not be affected by hydrogen sulphide T.S. (absence of metallic impurities); nor produce more than a slight opalescence with silver nitrate T.S. (limit of chloride); nor should 20 Cc. of the same solution give any coloration or precipitate on the addition of 0.5 Cc. of potassium ferrocyanide T.S. (absence of iron, zinc, or copper). If 1 Gm. of the powdered salt be shaken with 3 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), a small piece of pure tin-foil added, and the test-tube then set aside no coloration should appear within 1 hour (limit of arsenic)"—(*U. S. P.*). The arsenic test is officially given to guard against arsenic being introduced into the salt through the sulphuric acid used in its manufacture.

Action, Medical Uses, and Dosage.—Refrigerant, cathartic, and diuretic. Sulphate of magnesium produces copious and repeated watery evacuations, depending in character largely upon the amount of water in which it is administered. If taken when the stomach is empty, it is prompt in action, and when it can be retained in hot solution a quick action results. Diuresis accompanies the cathartic action and is often quite pronounced if the drug be in small amount and the skin kept cool. Owing to its marked refrigerant properties it should not be given to delicate individuals, except in hot weather. Concentrated doses of 2 ounces have caused death. Collapse without purgation has resulted from its administration in this manner. Chiefly used in *febrile* and *inflammatory affections*, or in cases where a refrigerant, mild, laxative effect is desired. It is specially adapted to *summer disorders* requiring catharsis, though it is lacking in cholagogue properties. It may be dissolved in eight times its quantity of water. The addition of 4 or 5 drops of sulphuric acid to the dose covers the bitter taste of the salt, causes it to sit easier on the stomach, counteracts its refrigerant effects, does not impair its energy, completely removes its tendency to gripe or irritate the rectum, and prevents it from interfering with the appetite or digestion.

Magnesium sulphate is not so extensively used as a cathartic as it was formerly. It is one of the hydragogue cathartics which may be used for a continued length of time, and for that reason it has been of service in *dropsy*. Prof. Locke recommends the following combination: ℞ Magnesium sulphate, potassium bitartrate, aa ℥i; sulphur, ʒi; oil of peppermint, gtt. iij. Mix. Sig. One teaspoonful in plenty of water, every 2 or 3 hours. These doses should be followed by smaller doses after a free evacuation has been provoked. Magnesium sulphate in doses of from 10 grains to 1 drachm, should be frequently repeated for *impacted feces* in any part of the intestinal tract. It is particularly useful where impaction in the right iliac region threatens to provoke inflammatory action, and there is a rise of temperature. Ten-grain doses should be frequently given where other remedies are vomited in these cases. It is a remedy for *constipation*, being given in full laxative doses.

Sulphate of magnesium is one of the most certain of the specific agents employed for the relief of *dysentery*. Occasionally, if the patient has been very costive, the larger dose will be required. But for ordinary cases of dysentery, and for dysentery following diarrhœa, the small doses gradually and surely bring about a cure. The proper dose is about 1 or 2 grains in a tablespoonful of water, every hour. Aconite and ipecac also aid its action, and may be given with it or in alternation. ℞ Magnesium sulphate, grs. xxx to ʒi; specific aconite, gtt. iij; specific ipecac, gtt. x; aqua, fl℥iv. Mix. Sig. Dose, a teaspoonful every hour. This overcomes the derangement of the upper bowel, allays the fever and the inflammation of the lower bowel, checks the outflow of mucus, allays the tormina, and promptly arrests the hemorrhagic manifestations when present. For *acute lead poisoning* or *lead colic*, large doses acidulated with sulphuric acid act specifically. Magnesium sulphate is contraindicated and dangerous in concentrated doses and when the patient is suffering from chills, cholera, or wasting diseases, and in the cases of the old and debilitated. Webster (*Dynam. Therap.*) states that doses of $\frac{1}{10}$ to $\frac{1}{2}$ grain of magnesium sulphate, continued for 2 or 3 weeks are effectual in removing *warts*.

The dose of this salt for its full purgative effect is about 1 ounce, well diluted; for its specific purposes in dysentery and fecal impactions, from 1 to 10 grains to 1 drachm may be employed, though in the former conditions the smaller the dose the better the action. M. Combes states that the bitterness of this salt may be removed by the following means: Take of sulphate of magnesium, 1 ounce; powder of roasted coffee, 2½ drachms; water, about 16 ounces. Place in a vessel (not a tin one), and boil for 2 minutes; remove from the fire, and let the mixture infuse for some minutes, so as to allow time for the development of the aroma; then strain and sweeten to the taste. By this process the salt is not decomposed. Should it be required to increase the amount of the sulphate without augmenting the proportion of coffee, 2 or 3 grains of tannic acid should be added to the boiling decoction.

Specific Indications and Uses.—Dysenteric, mucoid, or muco-sanguineous alvine discharges, with tormina and tenesmus; fecal obstructions; acute lead poisoning or "painters' colic."

Related Preparation.—MAGNESII SULPHAS EXSICCATUS. The *Magnesium Sulphuricum Siccum* of the *German Pharmacopœia* is made by exposing crystalline magnesium sulphate in a warm situation until it loses in weight from 35 to 37 per cent, and then passing it through a sieve. Its properties are those of the crystalline salt, being, of course, of greater strength, bulk for bulk. It is hygroscopic, and consequently should be preserved in well-stoppered bottles.

MAGNESII SULPHIS.—MAGNESIUM SULPHITE.

FORMULA: $MgSO_3.6H_2O$. MOLECULAR WEIGHT: 255.76.

SYNONYM: *Sulphite of magnesium.*

Preparation.—"Dissolve 136 parts of freshly prepared crystallized sulphite of sodium, free from carbonate and sulphate, in the smallest quantity of hot water; filter into this hot liquid a concentrated solution of 123 parts of Epsom salt, and stir the mixture till cold. Drain the mass of fine crystals on a strainer, press, and dry them at a moderate heat. The product should weigh 69 parts (J. C. Sticht in Wittstein's *Vierteljahrsschrift*, 1867, p. 49).

Prof. Joseph P. Remington obtained better results by the following process, published in *Amer. Jour. Pharm.*, 1868, p. 97: Take of pure calcined magnesia, 8 ounces (av.), and make into a paste with distilled water, 1 pint, and then add sulphurous acid (*U. S. P.*), sp. gr. 1.035, stirring constantly until the liquid gives a slight acid reaction; allow the crystals that form to subside, and then decant the clear liquid. Drain the sulphite of magnesium on a muslin strainer, and wash with distilled water until free from impurities, then drain again and dry on bibulous paper. The yield should be 1 pound and 8 ounces of dry crystals.

Description.—Sulphite of magnesium prepared by the above process is obtained in small, white crystals having the peculiar taste of the sulphites, mild and earthy at first, but afterward sulphurous They are soluble in 20 parts of water at 15.5° C. (60° F.); the solution on exposure to air gradually absorbs oxygen and is converted into the sulphate; by exposure to heat they soften, become ductile like gum, and lose 0.45 part in weight; strong heat sets the acid free, leaving pure magnesia behind. The specific gravity of sulphite of magnesium is 1.3802. Chloride of barium produces a precipitate with it which should be completely soluble in hydrochloric acid (absence of sulphate). Sulphite of magnesium destroys the color of a solution of permanganate of potassium, reduces the ferric to ferrous salts, forms a white precipitate of sulphite of silver with the nitrate, and reduces the chloride of gold from its acid solution. It does not so readily become converted into a sulphate, on exposure to the air, as the sulphite of sodium or of calcium, has the least taste of either, and contains a larger proportional quantity of acid than the sodium salt, and hence is more useful and valuable as an internal remedy when the action of the acid is particularly desired. Material in the dissecting room can be preserved for many weeks in a solution of one of these sulphites, without any change being induced in it, and without acting upon the instruments employed, in dissecting it.

Action, Medical Uses, and Dosage.—The sulphites of magnesium ana sodium were introduced to the profession as active azymotic agents, by Prof. Giovanni Polli, of Milan; and his statements of their efficacy have been confirmed by numerous physicians in this country and Europe. Their efficacy is due not wholly to the base, but in part at least to their sulphurous acid radical, which is set free in the stomach, and permeates the whole system, and that without any injury or destruction to the vital principles; though owing to their deoxidizing qualities, their long-continued use is apt to induce œdema and diseases of debility. They are supposed to act by destroying vegetable organisms when present, and by preventing the peculiar fermentation that develops zymotic phenomena; and which prevention may be due either to destruction of the fermentable material, or to a modification effected in its composition. After having taken them they appear in the urine in 20 minutes, but are gradually changed in the system into sulphates. Under ordinary circumstances they are not decomposed in the stomach, but when they are there, there is a manifest production of sulphurous acid gas; when this is the case, the acids of the stomach must be neutralized by a little magnesia.

The hyposulphites are less efficient than the sulphites, are less active azymotics, are more rapidly oxidized in their passage through the system, and hence appear in the urine as sulphates, and often occasion a troublesome diarrhœa, which is not the case with the sulphites. The earlier these are administered in the diseases for which they are used, before the blood corpuscles lose the greater part of their vitality, the more prompt will be their salutary influences. The diseases among others in which they have been found of specific application are *hospital fever*, *puerperal peritonitis*, *pyemia*, *septicemia*, and all *fevers with putridity and purulent absorption; measles*, *scarlatina*, *smallpox*, *erysipelas*, *endemic* or *miasmatic fevers*, *typhus fever*, *irritative fever* from absorption of pus, *infection from wounds* in the dissecting room, *pertussis*, *dysentery*, *diarrhœa*, *cholera*, *influenza*, *diphtheria*, *plague*, *malignant sore throat*, and externally in the dressing of *foul ulcers* or *wounds*, *ichorous*, *gangrenous*, *phagedenic ulcers* or *sinuses*, *indolent ulcers*, and *parasitical* and other *cutaneous diseases*. In fevers they do not cut them short, but gradually diminish the intensity of the symptoms. They are likewise used as prophylactics against zymotic action. These remedies are borne well by the stomach, and to obtain their curative effects rapidly and promptly, the system must be saturated with them as speedily as possible, giving moderately large doses daily, so that the fluids of the body, urine, saliva, and sweat, will contain some of the sulphite. As they are decomposed by all vegetable acids and many of deoxidizing agents, however weak these may be, their use is contraindicated when the sulphites are being taken; such as citric, malic, tartaric, oxalic, nitric, and hydrochloric acids, or food or drinks containing them, as fruits, oranges, lemons or lemonade, apple water, acid jellies, and the like.

For internal use the sulphite of magnesium is an excellent form; it may be given in powder in doses of from 1 to 30 grains, and repeated according to the urgency of the case, every 1, 2, 3, or 4 hours; it may be taken in water, syrup, or other vehicle not contraindicated. Unlike sodium sulphite, which is indicated by the broad, pallid tongue with white, pasty coat, magnesium sulphite is indicated by the deep-red or dusky tongue, with a dark-brown fur, or a smooth, glistening surface. If diarrhœa or vomiting be present, these must be relieved, otherwise the system will not be saturated; or else injections of the solution must be employed. The sulphite may be combined with opium for diarrhœa, pain, etc.; with quinine in cases of obstinate periodicity; with iron when anemia is present, and so on. If the remedy is likely to be efficient, a change for the better will occur in a few days (see *Sulphite of Sodium*).

Specific Indications and Uses.—Typhoid and septic states with deep-red, dusky tongue, coated with a brown fur, or smooth and glistening without the brown coating.

MAGNOLIA.—MAGNOLIA.

The bark of *Magnolia glauca*, Linné; *Magnolia acuminata*, Linné; *Magnolia Umbrella*, Lamarck, and other species of *Magnolia*.

Nat. Ord.—Magnoliaceæ.

COMMON NAMES: (See below.)

Botanical Source and History.—Besides the species herein described, there are four other native species of Magnolia, all probably possessing the same medicinal properties as those herein mentioned. These four are: *Magnolia grandiflora*, Linné; *Magnolia cordata*, Michaux; *Magnolia macrophylla*, Michaux; and *Magnolia Fraseri*, Walter. The *M. macrophylla* and *grandiflora* (fruit only), are figured in Lloyd's *D. and M. of N. A.*, Vol. II. The *Magnolia grandiflora* is the most magnificent forest tree of the extreme south. Its flowers are large and very beautiful. The *M. macrophylla* has the largest leaves of any native tree, they being from 2 to 3 feet in length (C. G. Lloyd).

MAGNOLIA GLAUCA.—This tree is known by several names, as *White bay*, *Beaver-tree*, *Sweet magnolia*, *Swamp sassafras*, *White*, or *Red laurel*, etc.; it varies in height from 6 feet to 30 or more, being taller in the south and shorter in the north; its average height is about 25 feet. Bark of the trunk smooth, ash-colored, that of the young twigs a bright, smooth green, scarred with rings at the insertion of the leaves by the fall of the deciduous stipules. Branches crooked, spreading. Leaves alternate, petioled, regularly elliptical, entire, smooth, thick; their under side, except the midrib, of a pale, glaucous color; when young covered with a silken pubescence. Flowers large, solitary, terminal, cream-colored, of a grateful odor, on a short incrassated peduncle. Calyx composed of 3 spatulate, obtuse, concave sepals; corolla of 8 to 14 obovate, obtuse, and concave petals, contracted at their base. Stamens very numerous, inserted in common with the petals on the sides of a conical receptacle; filaments very short; anthers linear, mucronated, 2-celled, opening inwardly. Ovaries collected into a cone, each divided by a furrow, tipped with a brownish, linear, recurved style. Fruit a cone, consisting of imbricated cells, which open longitudinally at the back for the escape of the seed. Seeds obovate, scarlet, connected to the cone by a funiculus, which suspends them some time after they have fallen out (L.—B.). It is found in swamps and morasses from Massachusetts to the Gulf of Mexico, and always in maritime districts; flowering from May to August, according to the climate in which it is located. At the south it is known as *White-bay*, or *Sweet-bay*. Although the flowers yield a delicate, agreeable odor, yet it sometimes occasions unpleasant symptoms, as difficult breathing, tendency to faint, etc.

MAGNOLIA ACUMINATA, or *Cucumber tree*, sometimes called *Blue*, and *Mountain magnolia*, is a tree reaching from 60 to 80 feet in height, and 4 or 5 feet in diameter, with a perfectly straight trunk. Leaves oval, acuminate, green, a little pubescent beneath, scattered, about 6 inches long, half as broad. Flowers 5 to 6 inches in diameter, bluish, sometimes yellowish-white, numerous, faintly fragrant; petals 6 to 9, obovate, obtusish. Cones about 3 inches long, cylindric, bearing some resemblance to a small cucumber. This tree grows near the Falls of Niagara, and in the mountainous regions in the interior of the country from New York to Georgia; it is more abundant in the southern states. It is most abundant, however, "in the moist valleys in the northern Allegheny Mountains" (C. G. Lloyd). Its flowers appear in May and June (W.—G.—B.).

MAGNOLIA UMBRELLA, Lamarck, or *Umbrella tree*, the *Magnolia tripetala*, of Linne, is a small tree not exceeding 30 feet in height, generally having a sloping trunk. Leaves 16 to 20 inches long, by 6 or 8 in width, obovate, lanceolate, pointed at both ends, silky, when young, soon smooth, often appearing whorled at the ends of the branches in the form of an umbrella, displaying a surface 30 inches or more in diameter. Flowers terminal, white, 7 or 8 inches in diameter, with 5 to 12 narrow, lanceolate, acute petals, the 3 outer curved. Fruit conical, rose-colored, 4 to 5 inches in length. This tree is found growing in shady situations, in strong, deep, fertile soil, in the same range of country as the *M. acuminata*, being, however, more generally confined to the lower grounds. It also flowers in May and June (W.—G.—B.).

Description.—All the species of these trees possess similar therapeutical virtues, which are found especially in the bark and fruit. The bark, either of the trunk or root, is the medicinal part; its odor is aromatic, and its taste warm, bitterish, and pungent, though these properties, with the exception of the bitterness, are lost by age. The bark is taken off during the spring and summer; it is ashen, smooth, and silvery externally, white and fibrous internally. The appearance of the bark varies much, depending upon the species. Magnolia, from these three species, was formerly official. Water or alcohol extracts its virtues.

Chemical Composition.—The various species of Magnolia probably have analogous composition. From the bark of *Magnolia Umbrella* and *M. acuminata*, John Floyd, in 1806, obtained small amounts of an aromatic, volatile oil, a resin, and bitter principles. Dr. Stephen Procter (1842) analyzed the bark of *M. grandiflora* in search for a substance analogous to liriodendrin of Emmet, and found numerous acicular crystals, a resinous body, and volatile oil. W. H. Harrison (1862) obtained from the bark of *M. glauca* a resin, volatile oil, and a crystallizable substance; from the fruit, ether extracted much fixed oil, and a pungent and acrid resin.

Wallace Procter (*Amer. Jour. Pharm.*, 1872, p. 145), observed a deposit of colorless crystals in an evaporated tincture of the fruit of *M. Umbrella* (umbrella tree), which substance he called *magnolin*, having ascertained it to be different from liriodendrin of Emmet. Petroleum benzin readily removed it from the extractive and coloring matters. It is a neutral body, insoluble in cold, crystallizable in small quantity from hot water, freely soluble in alcohol, ether, chloroform, carbon disulphide and petroleum benzin. When pure the crystals are tasteless. A soft, pungent resin, gum, glucose, etc., were likewise found by the author.

Prof. J. U. Lloyd separated from the bark of *Magnolia glauca*, three uncrystallizable resins, differing in their behavior toward solvents; furthermore, a crystallizable glucosid, and a fluorescent substance, probably a product of decomposition. The filtrate from the resins and the glucosid gave reactions for alkaloids, but no alkaloid could be isolated. (See *D. and M. of N. A.*, Vol. II, pp. 42–45, for the early chemical history.) Mr. W. F. Rawlins (1889) obtained from the leaves of *Magnolia glauca* a glucosidal, occasionally crystallizable substance, by abstracting an evaporated alcoholic extract with water and shaking out with chloroform. It is noteworthy that the leaves of *M. glauca* produce upon linen an indelible stain (C. E. Hornberger, *Amer. Jour. Pharm.*, 1876, p. 279). Analysis of the bark of *M. grandiflora*, by B. A. Randolph (1891), showed the presence of volatile oil, tannin, starch, saccharine, and coloring matter; upon incineration, 6½ per cent of ash was left.

Action, Medical Uses, and Dosage.—Magnolia bark is an aromatic tonic bitter, of reputed efficacy, and appears likewise to possess antiperiodic properties. *Intermittent fevers* have been cured by it after cinchona had failed. It is not so apt to disagree with the stomach and bowels, nor to induce fullness of the head as cinchona, and can be continued a longer time with more safety in all respects. Its curative agency is said to be favored by the diaphoretic action which generally follows its administration. In *dyspepsia*, with loss of tone in the stomach, it is very useful as a tonic, and has also proved of much service in the treatment of *remittents with typhoid symptoms*. A warm infusion acts as a gentle laxative and sudorific; a cold one as a tonic and antiperiodic, as does also the tincture and powder. The powder is considered the preferable form of administration. The bark of the *M. Umbrella*, chewed as a substitute for tobacco, has cured an inveterate tobacco chewer of the filthy habit, and deserves a further trial among those who wish to break up the pernicious practice. The bark in powder may be administered in ½-drachm or drachm doses, to be repeated 5 or 6 times a day; the infusion may be taken in wineglassful doses, repeated 5 or 6 times a day. It is used in the above forms of disease, as well as in *chronic rheumatism*. The tincture, made by adding an ounce of the powder to a pint of brandy, and allowing it to macerate for 10 or 12 days, may be given in tablespoon doses 3 times a day, for the same purposes. A tincture made by adding 2 ounces of the cones to a pint of brandy, has long been used as a domestic remedy for *dyspepsia* and *chronic rheumatism;* it is given 3 or 4 times a day in doses of from 1 to 4 fluid drachms. Magnolia is contraindicated whenever inflammatory symptoms are present. Though possessing undoubted tonic properties, magnolia is now seldom employed.

Related Species.—*Telauma mexicana*, Don. This is called, in Mexico, where it abounds, the *yoloxochitl*. *Quercetrin*, volatile oil, resin, tannin, etc., have been found in the fragrant white blossoms, which are reputed antispasmodic and tonic. Antiperiodic virtues are ascribed to the bark.

MALTUM.—MALT.

"The seed of *Hordeum distichum*, Linné (*Nat. Ord.*—Graminaceæ), caused to enter the incipient stage of germination by artificial means and dried"—(*U. S. P.*, 1880).

SYNONYMS: *Maltum hordei, Barley malt.*

Preparation.—If barley, or any other grain, be soaked (steeped) in water and thrown into heaps (couched), it will spontaneously generate heat. By frequent turning, the heat is prevented from becoming too great. The barley is then spread upon the floors (floored), whereupon germination takes place. The grain, after its germ has attained a certain length (usually one-third the length of the seed), is quickly dried in kilns at a temperature not above 71° C. (160° F.), and constitutes what is termed *malt*. What are known as the varieties—*pale malt, pale-amber, amber*, and *amber-brown malt*—is the malt to which different degrees of heat have been applied in drying. For medicinal uses only the *pale malt* or *pale-amber malt* should be employed. *Black*, or *roasted malt*, is that kind, the integuments of which are deep-brown in color, made so by roasting in rapidly revolving cylinders. Should the interior of the grain be of the same hue it is then called *crystal-*

lized malt. (For a very readable, short article on malt and malting, by F X Moerk, see *Amer. Jour. Pharm.*, 1884, p. 305; also see special treatises on the fermentation industries.)

Description and Chemical Composition.—Malt should have a pale or amber color, a sweetish taste, and a somewhat pleasant odor. Its aqueous infusion should be of a deep-yellowish or brown color. Besides the constituents of barley, malt contains the ferment *diastase*, dextrin, and sugar. Diastase resembles *ptyalin*, in that it changes starch into dextrin and sugar (*maltose*), and is, therefore, considered by some as identical with that salivary ferment (also see under *Hordeum*).

Action, Medical Uses, and Dosage.—(For uses of extract of malt, see *Extractum Malti.*) Starchy food is rendered more easily digested by malt and its preparations, which act similarly to *ptyalin*, converting amylaceous matter into sugar and dextrin, and preventing fermentation. An excellent diastatic agent for addition to farinaceous foods, for those suffering from wasting disorders, where nutriment is either passed undigested or is vomited, and especially useful in the *summer disorders of infants*, and for *marasmic and tubercular patients*, is the following cold infusion of malt: Mix 1½ ounces of crushed malt with 4 fluid ounces of cold water. Allow it to stand a half day, then filter it through paper until of a perfectly clear, sherry-brown color. Maltose and diastase are its principal constituents, and it readily ferments, hence but small amounts should be prepared, and those daily. A half ounce of this sweetish infusion added to half pint of any farinaceous gruel, at a moderately warm temperature, will cause the amylaceous products to be converted into glucose and dextrin.

MANGANI DIOXIDUM (U. S. P.)—MANGANESE DIOXIDE.

FORMULA: MnO_2. MOLECULAR WEIGHT: 86.72.

"Native crude manganese dioxide, containing at least 66 per cent of the pure dioxide ($MnO_2 = 86.72$)"—(*U. S. P.*).

SYNONYMS: *Mangani oxidum nigrum* (*U. S. P.*, 1880), *Black oxide of manganese*, *Pyrolusite*, *Manganese peroxide*, *Manganum hyperoxydatum*, *Manganesia vitriariorum*, *Deutoxide of manganese*, *Binoxide of manganese*, *Permanganic oxide*.

Source and History.—Dioxide (also called deutoxide, binoxide, peroxide, or black oxide) of manganese (MnO_2) occurs in considerable abundance, and constitutes the mineral which Haidinger termed *pyrolusite*, from whence all the oxide of manganese used in the arts is obtained. It exists in various parts of Europe, and some in the United States, as in Vermont, Massachusetts, and on Red Island in the Bay of San Francisco; also in Nova Scotia. The purest varieties are found in Great Britain and Germany. Usually it is more or less impure from the presence of lime, alumina, baryta, silica, oxide of iron, and brown *manganite*.

Description.—Manganese dioxide occurs in nature in the form of right rhombic prisms, or needles, or in amorphous masses. The official article is described as follows: "A heavy, grayish-black, more or less gritty powder, without odor or taste; permanent in the air. Insoluble in water or alcohol. It is not affected by cold, concentrated sulphuric acid, but when heated with the latter it is converted into manganous sulphate, with the evolution of oxygen. When heated with hydrochloric acid, it is converted into manganous chloride, with the development of chlorine. At a red heat, the dioxide gives off oxygen gas, and is converted into reddish-brown manganoso-manganic oxide (Mn_3O_4)"—(*U. S. P.*). It is infusible before the blow-pipe, dissolves in fused borax with effervescence, and gives to the globule an amethyst color.

Its specific gravity is stated to vary from 4.7 to 4.9. Chlorine is also evolved when manganese dioxide is heated with a mixture of common salt and sulphuric acid, the reaction taking place as follows: $MnO_2 + 2NaCl + 2H_2SO_4 = MnSO_4 + Na_2SO_4 + 2H_2O + Cl_2$. On a large scale, the manganous salt formed in this reaction is not thrown away, but is converted back again by oxidation into manganese dioxide by Weldon's process, which was introduced in 1867. (For its detailed description, see Roscoe & Schorlemmer's *Chemistry.*)

Tests.—Iron is almost always present in this oxide, the crystals being the most free from it. If the dioxide be digested in hydrochloric acid until chlorine ceases to be evolved, the addition of ferrocyanide of potassium will color it green or blue if iron be present. The *U. S. P.* directs the following tests: "On intimately mixing 1 part of the dioxide with 1 part of potassium hydrate and 1 part of potassium chlorate, introducing the mass into a crucible, moistening with water, drying, and igniting, a dark fused mass is obtained, which yields, with water, a green solution, changing to purplish-red on being boiled, or on the addition of diluted sulphuric acid. If a portion of the dioxide be strongly heated in a dry test-tube, no combustion should ensue, nor should any carbon dioxide be evolved (absence of organic impurities). If to another portion of the dioxide, contained in a test-tube, a small quantity of diluted hydrochloric acid be added, no odor of hydrogen sulphide should be developed, nor should a strip of paper moistened with lead acetate T.S., and suspended over the mixture, become blackened (absence of metallic sulphides). After the mixture of the dioxide with hydrochloric acid has been raised to boiling and filtered, the filtered liquid should not give, with hydrogen sulphide T.S., an orange-colored precipitate (absence of antimony sulphide). If 1 Gm. of the finely powdered dioxide, contained in a small, long-necked flask, be mixed with 5 Cc. of water, then 4.22 Gm. of ferrous sulphate, in clear crystals, added, and subsequently 5 Cc. of hydrochloric acid, the mixture digested for about 15 minutes at a gentle heat, and finally heated to boiling, the cooled filtrate, when immediately tested with freshly prepared potassium ferricyanide T.S., should not acquire a blue color (presence of at least 66 per cent of pure manganese dioxide)"—(*U. S. P.*). Some other methods for the valuation of manganese dioxide are based on the fact that oxalic acid is quantitatively and readily oxidized to carbonic acid by a mixture of manganese dioxide and sulphuric acid according to the equation: $C_2O_4H_2+MnO_2+H_2SO_4=MnSO_4+2H_2O+2CO_2$.

Action, Medical Uses, and Dosage.—The actions of this oxide upon the system are but imperfectly understood. Dr. Coupar, of Glasgow, considered it to act as a cumulative poison, producing paralysis of the motor nerves, but without causing colic, constipation, or tremors. It has been used internally in many cutaneous diseases, as *herpes*, *scabies*, and in the *scorbutic diathesis*. It has likewise been found efficient in *scrofula*, *chlorosis*, *syphilis*, and in *anemia*. The gastro-intestinal membranes are said to absorb but very little of the salt, but if it be injected into parenchymatous tissues, it is readily taken up and excreted with the feces (Cahn). From 3 to 20 grains may be given, in pill form, every 3 or 4 hours. Externally, 1 drachm mixed with ½ ounce of lard, has been found advantageous as an application to *itch*, *porrigo*, and *old ulcers*. One part of binoxide of manganese, added to 5 or 10 parts of chlorate of potassium, and subjected to a moderate heat in a glass or iron retort, gives out a rapid flow of oxygen gas, which may be collected for various purposes.

Dr. J. Kovascy recommends the following formulæ: Take of binoxide of manganese, 4 grains; extract of savin, extract of aloes, each, 10 grains. Mix, and divide into 6 pills, of which 1 pill may be given 3 times a day. (2) Take of binoxide of manganese, 3 grains; powdered leaves of digitalis, 1 grain; sugar of milk, 8 grains. Mix, and divide into 6 powders, of which 3 are to be taken daily, preferably after meals. These are said to be useful in properly selected cases of *chlorosis* and *amenorrhœa*.

MANGANI SULPHAS (U. S. P.)—MANGANESE SULPHATE.

FORMULA: $MnSO_4+4H_2O$. MOLECULAR WEIGHT: 222.46.

SYNONYMS: *Manganesii sulphas*, *Manganous sulphate*, *Sulfas manganosus*, *Manganum sulfuricum*.

Preparation.—This salt may be formed by adding to carbonate of manganese diluted sulphuric acid, as long as effervescence continues, then filtering and evaporating the solution to crystallization. Another method is to heat a thin, magma-like mixture of manganese dioxide and sulphuric acid. Evaporate to dryness, heat to redness in a crucible to decompose the ferrous sulphate present. Dissolve out the manganese sulphate with water, and heat the solution with a little carbonate of manganese to precipitate the last traces of iron, filter, evaporate, and allow to crystallize.

Description.—"Manganous sulphate varies in properties according to the water of crystallization present. If the salt is crystallized at a lower temperature than 6° C. (48.8° F.), it will have the composition $MnSO_4.7H_2O$; between 7° and 10° C. (44.6° and 50° F.), it is represented by $MnSO_4.5H_2O$; and at from 20° to 30° C. (68° to 86° F.), by $MnSO_4.3H_2O$"—(Lloyd's *Chem. of Med.*, p. 320). The *U. S. P.* describes it as in "colorless, or pale rose-colored, transparent, tetragonal prisms (crystallized at a temperature between 20° and 30° C. [68° and 86° F.], and containing 4 molecules, or 32.29 per cent of water of crystallization), odorless, and having a slightly bitter and astringent taste. Slightly efflorescent in dry air. Soluble in 0.8 part of water at 15° C. (59° F.), and in 1 part of boiling water; insoluble in alcohol. The aqueous solution is neutral, or very slightly acid to litmus paper, and yields, with ammonium sulphide T.S., a flesh-colored precipitate soluble in dilute acids; with potassium ferrocyanide T.S., a reddish-white precipitate; and with potassium ferricyanide T.S., a brown precipitate. With barium chloride T.S., it yields a white precipitate insoluble in hydrochloric acid. If a fragment of the salt be mixed with a little sodium hydrate T.S., and the mixture then dried and fused, it will yield a dark-green mass, dissolving in water with a green color"—(*U. S. P.*). When the water of crystallization is driven off by heat, a white, friable mass is formed. Sulphate of manganese should be preserved in well-stoppered bottles.

Tests.—"A 5 per cent, aqueous solution of the salt, after being heated with a few drops of hydrochloric acid and a little chlorine water, should not be colored red by potassium sulphocyanate T.S. (absence of iron), and should not be affected by hydrogen sulphide T.S. (absence of copper or arsenic). If the manganese be completely precipitated from an aqueous solution of the salt by ammonium carbonate T.S., the filtrate, on evaporation and gentle ignition, should leave no residue (absence of salts of the alkalies, or of magnesium). A solution of 1 Gm., each, of the salt, and of sodium acetate, in 10 Cc. of water, to which a few drops of acetic acid are added, should not be affected by hydrogen sulphide T.S. (absence of zinc). If 1 Gm. of the salt be gently ignited, in a porcelain crucible, it should lose not more than 0.323 Gm. in weight (distinction from manganese sulphate containing a larger amount of water of crystallization)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sulphate of manganese appears to be a stimulant to the lymphatic system of vessels and glands, and has been found valuable in *anemic conditions* of the system, accompanied with a deficiency of the white corpuscles of the blood. It acts as a powerful cholagogue, causing a profuse secretion of bile, and has been used with efficacy in *scrofula*, *chlorosis*, *jaundice*, *torpid liver*, *diseases of the spleen*, and *cachexia*. Prof. Scudder praised this remedy for its effects in *ascites*, due to hepatic disease and particularly in old topers. He directed from ¼ to 1 grain as the proper dose. In *jaundice*, with *hepatic enlargement*, with sense of weight and fullness in the hypogastrium, he considered it a useful remedy. He believed small doses to be curative in disorders where the chief symptoms were a pallid, dirty, leaden tongue, gastric fullness, sluggish bowels, and lax, pendulous abdomen. Minute doses, as of the first and second decimal trituration, were recommended by him where the tissues were old and feeble, and the cardiac action and circulation weak. A high dilution (6 x trituration) of manganese, has been recommended by Webster in doses of 2 to 3 grains, every 4 hours, in *painful affections of the periosteum*, associated with subacute inflammation. The dose for its gross action is from 2 to 20 grains, 3 times a day; for specific purposes, from $\frac{1}{50}$ to 1 grain. One or 2 drachms dissolved in ½ or 1 pint of water, will act as a prompt purgative, with scarcely any depression of the system. Large doses, or its long-continued use in small doses, injures the tone of the stomach One drachm of the sulphate mixed with 1 ounce of lard, has been used externally, as an ointment, in *buboes*, *chancres*, *indolent ulcers*, and some *diseases of the skin*.

Specific Indications and Uses.—Ascites, with hepatic disease, especially the result of spirituous beverages; lax, pendulous abdomen; pale, dirty, leaden-hued tongue; diarrhœa; small mucous passages, with tormina and tenesmus.

Manganese and Its Compounds.—MANGANESE, *Manganesium*, *Manganum*. Symbol: Mn. Atomic weight: 54.8. Manganese, in the form of dioxide, has long been known and used in the manufacture of glass, and was commonly considered an iron ore until 1775, when Gahn succeeded in extracting a peculiar metal from it. The element is widely distributed in the soil and in the vegetable kingdom. According to Flückiger (*Amer. Jour. Pharm.*, 1886, p. 147), certain species and natural orders—*e. g.*, Zingiberaceæ—are remarkable for their power of assimilating manganese. *Trapa natans*, or *Water-nut*, a marsh plant growing in some parts of Germany, France, and Italy, is another example of these "manganivorous" plants. The element may be obtained by the reduction of pure oxide or carbonate of manganese with charcoal, flux material being added and the whole exposed, in a covered crucible, to a very violent heat for several hours. It will then be reduced to the metallic state and fused into a solid mass. Thus obtained it has a gray color, somewhat whiter than cast iron, finely granular in texture, hard, and so brittle that it can be reduced to powder in a mortar. Manganese is an important factor in the production of white cast iron (see *Ferrum*). Its specific gravity is 8.013 (7.13 to 7.21, Brunner). It has strong affinity for oxygen, quickly absorbing it from the atmosphere, and, in consequence, must be kept like sodium and potassium, under naptha or benzin: but if it contains iron it will be permanent in the air. It decomposes water rapidly at a red heat, hydrogen being disengaged.

Manganese combines with oxygen in several proportions, forming chiefly the following oxides: (1) MnO, *manganese monoxide*, or *manganous oxide;* (2) Mn_2O_3, *manganese sesquioxide*, or *manganic oxide;* (3) Mn_3O_4; (4) MnO_2, *manganese dioxide* (which see); (5) MnO_3, *manganese trioxide;* and (6) Mn_2O_7, *manganese heptoxide*. (1) The oxide MnO is strongly basic, dissolving in acids and forming salts with them, known as *manganous salts*, which are analogous to ferrous salts. Their solutions are of a rose-red or flesh color. The oxide, its hydroxide ($Mn[OH]_2$), and the carbonate, when moist, easily oxidize when exposed to the air. Solutions of manganous salts become turbid upon standing if exposed to air and light (A. Gorgeu, *Amer. Jour. Pharm.*, 1889, p. 522). (2) The oxide Mn_2O_3 remains as residue when manganese dioxide (MnO_2) is heated in oxygen gas. It occurs in nature as the mineral *braunite;* its hydrate ($Mn_2O_2[OH]_2$) as *manganite*. The oxide and its hydrate have weak basic properties; dissolved in acids they yield *manganic salts*, which are analogous to ferric salts, but rather unstable. (3) The red oxide of manganese (Mn_3O_4) occurs in nature as the mineral *hausmannite*. It is the form into which the lower and the higher oxides of manganese are converted upon being heated (the lower, when in contact with air). In some respects it is analogous to *red lead* (*minium*, Pb_3O_4). (4) Manganese dioxide (MnO_2) has weak basic and weak acid properties. It forms several salts of (the hypothetical) *manganous acid* ($Mn_5O_{11}H_2$). (5) Manganese trioxide (MnO_3) (see Watts' *Dictionary*, 1892, Vol. III, p. 184) is the anhydride of *manganic acid* (MnO_4H_2), which is not known in the free state. Its salts (the *manganates*) are green and are stable only when in contact with an excess of caustic alkali. Manganates may be formed from any manganese compound, by fusing it with oxidizers—*e. g.*, saltpeter and soda, or potassium chlorate and caustic potash. The green mass is called *chameleon mineral* (Scheele), because it undergoes a change of color from green to blue, violet, and red upon the addition of an excess of water. When the green, fused mass is treated with diluted acids—*e. g.*, acetic or even carbonic acid—it likewise turns red, being decomposed into insoluble hydrate of manganesium dioxide and soluble permanganate of potassium. This is a delicate reaction for manganese. (6) Manganese heptoxide (Mn_2O_7) is the anhydride of the dark-red liquid and powerfully oxidizing *permanganic acid* (MnO_4H). Its potassium salt is the well-known *potassium permanganate* (which see), used as an oxidizing agent, being especially employed in analytical and organic chemistry. When heated with caustic potash, the solution of permanganate turns green; potassium manganate is formed with evolution of oxygen as follows: $2KMnO_4+2KOH=2K_2MnO_4+O+H_2O$.

Mangani Iodidum, *Manganous iodide* (MnI_2+4H_2O).—This salt may be prepared by adding manganese carbonate (to saturation) to solution of hydriodic acid, thus: $MnCO_3+2HI=MnI_2+H_2O+CO_2$. It forms very deliquescent, unstable crystals. A syrup of this salt is used in medicine.

Syrup of Iodide of Manganese has been used in the same class of diseases as syrup of iodide of iron and manganese. Prof. Procter (*Amer. Jour. Pharm.*, 1850, p. 300) directs it to be made as follows: Take of sulphate of manganese, 16 drachms; iodide of potassium, 19 drachms. Dissolve these salts separately, each, in 3 fluid ounces of water, to which 2 fluid drachms of syrup have been previously added. Mix these two solutions in a glass-stoppered bottle, and when the resultant crystals of sulphate of potassium are all precipitated, filter the supernatant liquor, through a fine muslin strainer, into a vessel containing 12 ounces of pulverized sugar. Add to this sufficient water to make the whole measure 16 fluid ounces. A fluid ounce of this syrup contains about 60 grains of iodide of manganese. Its dose is from 10 drops to ½ fluid drachm, repeated 3 or 4 times a day. Combined with cinchona, it is very efficient in *ague-cake*, or *diseased spleen*, following *intermittent fevers*.

Syrup of Iodide of Iron and Manganese has been recommended in *anemia*, *scrofula*, *cancer*, and *glandular enlargements*. Prof. W. Procter, Jr., gives the following formula for its preparation: Take of iodide of potassium, 1000 grains; sulphate of iron, 630 grains; sulphate of manganese, 210 grains; iron filings (free from rust), 100 grains; coarsely-powdered white sugar, 4800 grains; distilled water, a sufficient quantity. Triturate the sulphates and the iodide separately to powder, mix them with the iron filings, and add ½ fluid ounce of distilled water, triturate, and allow it to rest 15 minutes. A third addition of water should now be made and mixed. The sugar should then be introduced into a bottle capable of holding a little more than 12 fluid ounces, and a small funnel, prepared with a moistened filter, inserted into its mouth. Remove the magma of salts from the mortar to the filter, and when the dense solution has drained through, add carefully, and in small portions, some distilled water, until the solution of the iodides is displaced and washed from the magma of crystals of sulphate of potassium. Finally, finish the measure of 12 ounces by adding sufficient distilled water, and agitate the bottle until the sugar is dissolved. The solution of the sugar may be facilitated, when desirable, by placing the bottle in warm water for a time, then agitating. Each fluid ounce of this syrup contains 50 grains of the mixed anhydrous iodides in the proportion of the 3 parts of iodide of iron to 1 part of iodide of manganese, and the dose is from 10 to 30 drops (*Amer. Jour. Pharm.*, 1853, p. 199). Another formula by Prof. Lloyd is recorded, *ibid.*, 1874, p. 6.

Mangani Chloridum, *Chloride of manganese, Manganese dichloride* ($MnCl_2.4H_2O$).—Formed by dissolving pure dioxide of manganese in hydrochloric acid, evaporating the solution to dryness, and exposing the white salt that remains to a red heat in a glass tube with a very narrow orifice. This compound is also obtained as a by-product in the manufacture of chlorine gas from manganese dioxide and hydrochloric acid. Thus made it is impure, however, and must be deprived of the ferric chloride it contains by proper precipitation with sodium carbonate. From the chloride most of the manganese salts are prepared, the carbonate being made the intermediary product.

Manganous chloride consists of thin, broad, delicate, light-pink plates, which fuse in close vessels without alteration, at a red heat, and, when exposed to the air, deliquesce. Sometimes the salt is granular. They are very soluble in water and alcohol, and have the specific gravity 1.56. They are inodorous, and have a saline, astringent taste. This salt has been recommended in *chronic diseases of the skin*, in *scorbutic affections*, and *syphilitic diseases*, in doses of from 3 to 10 grains in watery or alcoholic solution. A drachm or 2 dissolved in 1 pint of water, has been used as a gargle in *syphilitic ulceration of the mouth and throat*. The alcoholic solution has been used internally to check *epistaxis*, giving 10 or 20 drops every 4 hours, until a feeling of giddiness is perceived.

Mangani Carbonas, *Manganese carbonate* ($MnCO_3$).—This forms a white precipitate when solutions of either chloride or sulphate of manganese are mixed with solution of sodium carbonate. The presence of a little syrup is desirable. Wash with boiling distilled water, and dry quickly at a moderate temperature. It is a tasteless, buff-colored salt, soluble in about 8000 parts of water, and readily soluble in water containing carbonic acid (Roscoe & Schorlemmer). Acids dissolve it readily with formation of salts. By oxidation at ordinary temperature, the carbonate yields no higher oxide than Mn_2O_3; when exposed to a heat of 200° C. (392° F.), 92 per cent of manganese dioxide (MnO_2) is formed.

Various other preparations of manganese have been used and recommended by physicians for nearly similar purposes, as the malate, tartrate, phosphate, lactate, etc., but their therapeutical actions appear to be very nearly alike. Dr. T. S. Speer gives the following formula for a *Saccharine carbonate of iron and manganese*, which has proved very useful in *anemia*. Take of finely powdered sulphate of iron, 25 drachms; carbonate of sodium, 5 ounces; sulphate of manganese, 500 grains; dissolve these, each, in 1½ pints of water (Imperial measure), then add the solutions together and mix them well. Collect the precipitate on a filter of cloth and immediately wash it with cold water, squeeze out as much of the water as is possible, and, without delay, triturate the pulp with sugar, previously reduced to a fine powder. Dry it at a temperature of about 48.8° C. (120° F.). It forms a reddish-brown powder, having only a saccharine taste, and may be given in doses of 5 grains, 3 times a day, gradually increased to 20 grains. It should be given immediately after each meal (*Amer. Jour. Pharm.*, 1854, p. 127). The compounds of iron and manganese have cured cases of anemia in which iron alone failed.

Mangani Phosphas, *Manganese phosphate* ($Mn_3[PO_4]_2+7H_2O$).—Produced when sodium phosphate solution is precipitated with solution of manganese sulphate, or chloride. A white, or faintly reddish, crystalline powder. A syrup may be made by dissolving the salt in diluted phosphoric acid and adding to the cold solution enough sugar to form a syrup.

Mangani Lactas, *Manganese lactate.*—Shining, pale-rose crystals, produced by adding to hot lactic acid manganese carbonate. Soluble in cold water (12 parts) and boiling alcohol, from which the salt crystallizes on cooling.

Mangani Tannas, *Manganese tannate.*—Prepared by adding manganese carbonate (freshly precipitated and wholly free from iron) to a hot solution of tannic acid, in distilled water, until it ceases to be dissolved. Filter and dry by evaporation. Soluble in water. Its solution should not be of an inky color (absence of iron).

Mangani Tartras.—Take of Rochelle salts, 10 parts; dissolve in its weight of boiling water. Likewise dissolve manganese sulphate, 8 parts. Mix the solutions. When cool, wash the salt with cold water. Decomposition results if hot water be employed to wash the product. White or faintly red, small crystals.

MANGIFERA.—MANGIFERA.

The inner bark of the root and tree of *Mangifera indica*, Linné.

Nat. Ord.—Anacardiaceæ.

Common Name: *Mango.*

Illustration: *Botanical Magazine*, Plate 4510.

Botanical Source, History, Description, and Chemical Composition.—A tall tree, native of the East Indies, but cultivated in most parts of the tropics for its edible fruit. It has "become thoroughly naturalized in the West Indies, and is forming large groves in waste places in Jamaica, where negroes, horses, pigs, and fowls feed upon the fruit for nearly four months of the year" (D. Morris, *Amer.*

Jour. Pharm., 1886, p. 444, from *Gard. Chronicle*). The leaves are alternate, lanceolate, entire, from 6 to 8 inches long, and one-quarter as wide. They are petioled, and borne in clusters near the end of the branches. The flowers are small, yellowish, and disposed in large, loose, terminal panicles. The calyx-lobes and petals are 5. The stamens are 5, alternate with the petals, and all but one abortive. The fruit is a reddish-yellow drupe, about the size of a quince, and kidney-shaped; it consists of a hard, fibrous nut, which is surrounded by edible flesh in a manner like the peach, and is known as "mango fruit." It is largely consumed in tropical countries, and forms one of the most highly esteemed fruits. The natives of India use the leaves and leaf-stalks to harden the gums; the wood, together with sandal wood, is used by the Hindus for burning their dead, and an infusion of the bark is employed for various skin diseases. When incisions are made into the bark of the tree, a soft, reddish-brown gum-resin exudes, which hardens by age, and resembles bdellium; this dissolves in spirits and partly in water, forming milky solutions; when chewed, it softens, adheres to the teeth, and gives a pungent and slightly bitter taste (Roxburgh).

Sir J. D. Hooker reports (*Pharm. Jour. Trans.*, 1883, Vol. XIV, p. 501), that the yellow pigment known as *piuri* or *Indian yellow* (compare *purree*) is produced in India by evaporating the urine of cows which are fed exclusively on mango leaves. This is said to increase the secretion of the bile pigment, and to impart to the urine of the animal a bright yellow color; the yield of the pigment is 2 ounces a day, but the animal becomes very unhealthy under this treatment. There is another *piuri*, of mineral origin, but less valued.

In 1877, Dr. M. F. Linquist, New Haven, Conn., introduced the bark of the mango tree to the medical profession, having found it beneficial in a number of diseases. The bark was imported under the name "*mango*," for the purpose of removing incrustations from steam boilers, it having been stated that when a small amount of a strong solution of the bark is added to the water within the boiler, the saline deposit quickly separates. The bark is very astringent, and this property suggested to Dr. Linquist its appropriate application in a therapeutical sense. As found in market it is a coarse powder, of a deep brownish-red color, none of the bark, entire, having come under our observation. The odor is peculiar, being, in a very slight degree, terebintheous. The taste resembles that of rhatany. According to Dragendorff (*Heilpflanzen d. versch. Völker u. Zeiten*, 1898), the bark contains 16.7 per cent of tannic acid and an acrid oil; the fruit contains much sugar, citric acid, mucilage, and yellow coloring matter.

Action, Medical Uses, and Dosage.—Mango bark has been recommended in the treatment of *nasal catarrh*, *diarrhœa*, *dysentery*, *vaginitis*, *metritis*, *diphtheria*, *hemorrhages*, etc. Dr. Linquist, in writing to me concerning its use, makes the following statement: "I have used it for upward of eight years, and have largely experimented with it. It is an astringent of peculiar power upon the mucous membrane. I first employed it in certain uterine diseases, with marked benefit. In *catarrh*, with the spray atomizer, I have used it with better success than any other agent. In *diphtheria*, and other malignant diseases of the throat, its effect has been truly marvelous. During last year I have had several cases of diphtheria, that I have treated exclusively with the fluid extract, penciling the fauces with it, of full strength, and also using it as a gargle in the proportion of 2 fluid drachms of the fluid extract to 4 fluid ounces of water. As an internal remedy in *hemorrhages* from the uterus, bowels, or lungs, or in *muco-purulent discharges* from either the bowels or uterus, I know of no agent equal to it. It appears to have the following advantages: The dose is small, is easily taken, has no disagreeable taste, does not derange the stomach, is rapid in its action, and more certain in its effects than other medicines." Prof. A. J. Howe, M. D., writes me as follows: "During the past year I have prescribed a tincture of Mangifera indica on many occasions; and I find it most useful in lessening *leucorrhœal discharges*, and in diminishing too *profuse menstrual evacuations*. The agent exerts an astringent action, but not to the extent of constipating the bowels. It assuages catamenial pains to an appreciable degree, and corrects menstrual disorders in general. I consider the medicine a valuable adjutant to gynæcological therapeutics. I have also prescribed it in the treatment of *chronic diarrhœa*, and in *obstinate gleet*, and have obtained quite satisfactory results, though not better than from extract of logwood, or from pinus canadensis In a case of albuminuria, the remedy, for a week or two, greatly lessened the amount of albumen discharged; yet it made no decided change for the better. The dose of the fluid extract is from 15 minims to 1 fluid drachm. Dr. Linquist adds from 2 to 4 fluid drachms of the fluid extract to 4 fluid ounces of water, and this mixture he administers in teaspoonful doses, repeated every hour or two (J. King). In Brazil, the flowers of the mango are used either in the form of tea or powder for *catarrh of the bladder* (G. Peckolt, *Amer. Jour. Pharm.*, 1884, p. 622).

Specific Indications and Uses.—Feeble relaxed tissues; mucous profluvia; chronic dysentery with muco-purulent passages.

MANIHOT.—TAPIOCA.

The fecula of the root of *Manihot utilissima*, Pohl (*Jatropha Manihot*, Linné; *Janipha Manihot*, Kunth).

Nat. Ord.—Euphorbiaceæ.

COMMON NAMES: *Tapioca, Tapioca meal, Brazilian arrow-root.*

Botanical Source.—This plant is a native of Brazil, and is cultivated in various parts of South America. It has a large, fleshy, oblong, tuberous root, often weighing 30 pounds, and full of a wheyish, venomous juice. The stems are white, crooked, brittle, jointed, pithy, and usually 6 or 7 feet high, with a smooth, white bark. The branches are crooked, and have on every side, near their tops, leaves irregularly placed on long, terete petioles, broadly cordate in their outline, divided nearly to their base into 5 spreading, lanceolate, entire lobes, attenuated at both extremities. The leaves are dark green above, and pale glaucous beneath; the midrib is strong, prominent, and yellowish-red below with several oblique veins, connected by lesser transverse ones, branching from it. The stipules are small, lanceolate, acuminate, and caducous. The flowers are borne in axillary and terminal racemes, the pedicels having small, subulate bracts at their base. Male flowers smaller than the female. The calyx is campanulate, and divided into 5 spreading segments, purplish externally, fulvous-brown within. The disk is orange-colored, fleshy, annular, 10-rayed; the stamens number 10, alternating with the lobe of the disk. The filaments, which are shorter than the calyx, are white, filiform, and free, the anthers yellow and linear-oblong. The female flowers have the same color as the male, and are deeply 5-parted, the segments being lanceolate-ovate and spreading. The disk has an annular, orange-colored ring, in which the purple ovate, furrowed ovary is imbedded; the style is short. Stigmas 3, reflexed, furrowed and plaited, and white. The capsule is ovate, 3-cornered, and tricoccous; the seeds are elliptical, black, and shining, with a thick, fleshy funiculus (L.—W.).

History.—*Manihot utilissima*, formerly designated by botanists as *Jatropha Manihot*, furnishes a large amount of food to the inhabitants of southern America, under the names of *mandioc*, *tapioca*, or *cassava starch*. The juice, mixed with molasses, and fermented, produces an intoxicating liquor which is much relished by the negroes and Indians of the West Indies. According to Pohl, there are two distinct species, the *bitter* and the *sweet cassara.* The bitter is the more common species, *Manihot utilissima* above described; its root is much larger, knotty, black externally and contains a bitter and poisonous milky juice. The root of sweet cassava (*Manihot palmata*, of J. Mueller; *Manihot Aipi*, Pohl; *Jatropha dulcis*, Gmelin) is fusiform, brown externally, not exceeding 6 ounces in weight, with a sweet, amylaceous taste, and it is stated that it may be eaten with impunity see *Chemical Composition*).

Preparation.—Tapioca is prepared from the bitter cassava. The large, fleshy, and tuberous root is reduced to a pulp, this is washed with cold water in funnel-shaped mat-filters, the starch is allowed to subside in the milky fluid which passes through, and is then elutriated in the usual manner, and finally converted into the granular form by drying it on hot plates. Should any of the volatile poisonous principle remain in the meal previous to drying it, the heat employed for this purpose entirely removes it. *Cassara meal*, which is obtained by pressing out the poisonous juice from the grated root, drying the remaining solid portion, and finally grinding it, is made into *cassava bread* by the natives, who bake it in thin loaves. Large quantities of tapioca are now prepared by steam in Malacca.

Description.—Tapioca is a very pure starch in the form of irregular, warty grains, seldom larger than a pea, white, tasteless, and inodorous. Boiling water dissolves it almost entirely, or, if in small proportion to the tapioca, it forms with it a translucent, tasteless jelly, and firmer than is made with most varieties of starch. Cold water partially dissolves it, forming a liquid which yields a blue precipitate with iodine. Under the microscope it is found to consist of aggregated starch globules, about $\frac{1}{2000}$ of an inch in diameter, partly broken, partly entire, the broken ones only being soluble in cold water, more uniform than the granules of most other varieties of fecula, with a distinct hilum, which is completely surrounded by rings, and bursts in a stellate manner. The rupture observed in some of the granules is owing to the heat employed in drying (C.—P.). (See also an interesting article on *Manioc* or *Cassava*, by Dr. E. Chenery, in *Amer. Jour. Pharm.*, 1890, p. 359.) Tapioca of commerce is frequently prepared from domestic sources, such as potatoes, etc.

Chemical Composition.—The poisonous principle in cassava juice was suspected to be *hydrocyanic acid* as early as 1796, by Dr. Clark, of Dominica, who pronounced the toxic symptoms caused by it in negroes to be similar to those caused by prussic acid. Dr. Fennor, of Cayenne, shortly afterward isolated the poison by distillation. Subsequently, Messrs. Henry and Boutron-Charlard identified the poison in a specimen of cassava juice as hydrocyanic acid by chemical tests. In recent years, Mr. E. Francis (*Amer. Jour. Pharm.*, 1883, p. 35, from *Chem. and Drug.*, 1882), found hydrocyanic acid not only in the bitter but also in the sweet cassava, the latter (15 samples from Trinidad) containing on an average 0.0168 per cent, the former (10 samples), 0.0275 per cent of prussic acid.

Dr. Eberhard, of Blumenau, Brazil (*Amer. Jour. Pharm.*, 1869, p. 301), found the root of *Manihot utilissima* to be composed of starch (13.63 per cent), water (61.7 per cent), lignin (23.49 per cent), and ash (1.18 per cent). The starch flour obtainable from cassava is very pure, being nearly all starch (99.1 per cent), with only about 0.5 per cent of protein substances. Dr. H. W. Wiley (*U. S. Dep. of Agr.*, 1895, Bull. No. 44; also see *Amer. Jour. Pharm.*, 1895, p. 262), found in sweet cassava, growing in southern Florida, about 20 to 25 per cent of starch (referred to fresh root), and recommends the cultivation of this root for the economic production of tapioca, glucose, alcohol, and probably cane sugar.

Action and Uses.—Nutritive and demulcent. Used as a light and agreeable nourishment for the sick. It makes an excellent nourishment for infants about the time of weaning, and is less apt to turn sour on their stomach than any other farinaceous food. For the sick and convalescent, its flavor may be improved by raisins, sugar, prunes, lemon-juice, wine, spices, etc., as may be required.

MANNA (U. S. P.)—MANNA.

The concrete, saccharine exudation of *Fraxinus Ornus*, Linné (*Ornus europaea*. Persoon).

Nat. Ord.—Oleaceæ.

COMMON NAME: *Manna*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 170.

Botanical Source.—The manna tree, or *Flowering ash*, is a small tree, usually 20 or 30 feet high, with a close, round head; the bark is smooth and grayish. The leaves are opposite, unequally pinnated in 3 or 4 pairs; the petioles furrowed; the leaflets petiolate, oblong, acute, serrated, and very hairy, at the base of the midrib on the under side. The flowers are white, in dense, terminal, nodding panicles, and appear with the leaves. Calyx very small and 4-cleft. Corolla divided to the base into linear, drooping segments. Stamens 2; anthers yellow and incumbent. The pericarp is a winged key, not dehiscing (L.). The leaves on the same tree are said to be variable.

History and Description.—The manna tree is a native of most parts of southern Europe. The official part is the juice of the tree, known in commerce as "*manna*." Manna issues from the tree in part spontaneously from fissures, partly from punctures produced by an insect, but more generally from incisions daily made in the tree (one above another during the warm summer months, from which the viscous, brown, bluish fluorescent, bitterish juice flows out, and speedily hardens, losing thereby its bitterness and becoming white. These incisions are repeated annually, and alternately upon opposite sides of the tree, each season, so long as it yields manna. One tree may yield manna for 20 years. There are several varieties of manna, which chiefly differ from one another in quality according to the season and mode of gathering. The *Sicily manna* (*manna gerari*) is the most esteemed. It is also called *flake manna* (*manna cannulata*)—*large and small flake*—and is procured from the incisions on the upper part of the tree, during the height of the season, when the juice flows vigorously. It is collected on straws or twigs, etc., upon which it concretes in stalactitic masses. Long keeping deepens its color. Its fracture is somewhat crystalline, due to the presence of crystals of mannite. The *U. S. P.* describes good manna as "in flattish, somewhat 3-edged pieces, occasionally 20 Cm. (8 inches) long and 5 Cm. (2 inches) broad, usually smaller; friable; externally yellowish-white; internally white, porous, and crystalline; or in fragments of different sizes, brownish-white and somewhat glutinous on the surface, internally white and crystalline; odor honey-like; taste sweet, slightly bitter and faintly acrid. On heating 5 parts of manna with 100 parts of alcohol to boiling, and filtering, the filtrate should rapidly deposit separate crystals of mannite. Manna consisting of brownish, viscid masses, containing few or no fragments of a crystalline structure, should be rejected"—(*U. S. P.*). The ordinary quality is *common manna*, or *manna in sorts;* this is gathered late in the season when the temperature is diminishing, so that the juice imperfectly concretes, and has to be exposed to the action of the sun to complete its drying. Pieces of manna picked up from the ground form part of this sort of manna. It is in masses of a similar color to, but of less size than the flake manna—joined by a soft, adhesive substance of a dark, yellowish-brown color; its taste is rather unpleasant. A third variety, termed *fat manna*, is gathered in the latter part of autumn, when the season is wet and cool, and, in consequence of which, it does not readily concrete. A fatty manna is also said to be procured from the incision made in the lower part of the tree, during the warmer months. Fat manna is less solid than the preceding varieties, adhesive, not brittle, of a yellowish-red or yellowish-brown color, of a strong honey odor, a mawkish, sweet, unpleasant taste, and mixed with sand, pieces of bark, and other foreign substances. There is not so much mannite present in this grade, but more of sugar, gum, etc. This is the kind of manna rejected by the Pharmacopœia.

Manna softens with the heat of the hand, melts at a temperature somewhat higher, and is inflammable, burning with a blue flame, throwing out yellow sparks. Pure manna is almost entirely dissolved in 3 parts of water at 15.5° C. (60° F.), and 1 part at 100° C. (212° F.). From the latter solution it is deposited, on cooling, in crystalline forms. In consequence of the sugar contained in manna it is capable of undergoing fermentation.

Chemical Composition.—The principal constituent of pure manna is *mannite* ($C_6H_8[OH]_6$), 90 per cent, with 11 per cent of sugar and about 0.75 per cent of impurities (Flückiger, *Pharmacognosie*, 1891, p. 27). Inferior sorts of manna contain mucilage, cane-sugar, lævulose, dextrin (Buignet, 1868; doubted by Flückiger), bitter substances soluble in ether, and *fraxin* ($C_{16}H_{18}O_{10}$), a fluorescent glucosid resembling *æsculin*.

Mannite (*mannitol*) ($C_6H_8[OH]_6$, or $C_6H_{14}O_6$) may be readily prepared from manna by digesting it in hot alcohol; on cooling, the mannite forms in tufts of silky, quadrangular prisms. C. T. Bonsall's method consists in dissolving manna in boiling water (3 parts by weight), precipitation of the gum, etc., by lead subacetate, removal of lead with sulphuric acid or hydrogen sulphide, concentration, and pouring the hot solution in cold alcohol (2 parts), from which the mannite is deposited on cooling. Mannite is sweet, odorless, requiring about 6 parts of water to dissolve it, is readily dissolved in boiling alcohol, much less so in cold, deliquesces in the air, and does not dissolve in ether. Its solution possesses a feebly lævo-rotatory polarization. Mannite combines with bases, dissolves lime, reduces gold from its chloride solution, does not reduce Fehling's solution, forms oxalic and saccharic acids when heated with nitric acid, does not ferment when its solution is mixed with yeast, though it ferments when in contact with old cheese and chalk at 40° C. (104° F.), alcohol, lactic, butyric, acetic, and carbonic acids and hydrogen being produced. Unlike cane-sugar, mannite does not char under the action of sulphuric acid, and does not become, like grape-sugar, brown when heated with alkaline solutions. It fuses at about 165° C. (329° F.), without losing weight, and, on cooling, the colorless solution forms a mass of radiated crystals. At about 200° C. (392° F.), it sublimes partially unchanged, but a large portion of it becomes a sweetish, viscid liquid, *mannitan* ($C_6H_{12}O_5$). It is also changed into fermentable *mannitose* ($C_6H_{12}O_6$) and *mannitic acid* ($C_6H_{12}O_7$) when in contact with moistened platinum black (Gorup-Besanez). Mannite also exists in *Laminaria saccharina*, onions, asparagus tops, celery, unripe olives, certain fungi, etc. It has also been procured from beet root, and the juice exuding from apple and pear trees. One or 2 ounces will, it is stated, act as a gentle laxative.

Action, Medical Uses, and Dosage.—Manna is nutritive in small doses, and mildly laxative in large ones. It operates without causing any local excitement or uneasiness, and is useful as a laxative for young infants, children, females during pregnancy and immediately after, *inflammation of the abdominal viscera*, *disorders of childhood*, *hemorrhoids*, *costiveness*, etc. It is accredited with cholagogue properties, and has a somewhat beneficial action upon the respiratory tract. It is commonly added to other purgatives to improve their flavor, as well as to increase the purgative effect. One or 2 ounces may be taken by an adult; 1, 2, or 3 drachms by a child, according to its age. Two or 3 parts of manna to 1 of senna may be made into a laxative infusion for children. Sometimes manna causes flatulency and griping, which may be obviated by combining it with any grateful warm aromatic.

False Mannas.—Various other trees of the family *Ornus* and *Fraxinus* furnish manna, as the *O. rotundifolia*, *O. parvifolia*, *O. subrufescens*, *O. lentiscifolia*, *F. excelsior*, etc. The *Abies* or *Pinus Larix* (*Larix europæa*) yields a sweet exudation called Briançon Manna, or European False Manna, but which contains no mannite, but a principle called *melezitose* ($C_{18}H_{32}O_{16}.2H_2O$). The *Alhagi Camelorum* (*Hedysarum Alhagi*), of Syria, yields the Manna Mereniabin, an inferior manna. The *Larix Cedrus* produces the Manna of Lebanon; the *Tamarix gallica*, of North Africa, the Manna of Mount Sinai; it also yields tamarisk galls; and the *Eucalyptus mannifera*, a kind of manna called New Holland Manna, containing a saccharine principle, but no mannite. Other species of *Eucalyptus* yield Australian Manna. There are several other mannas, such as Persian Manna, Oak Manna, Oriental Manna, Lerp, etc., for description of which see works specially treating on the subject. The manna of Scripture is now thought possibly to be the lichen *Lecanora esculenta*, which sometimes falls in showers from Persia to the Desert of Sahara. It makes a fairly good bread, and is eaten by the people. It is called *manna*. An American Manna, so called, is the product of an Oregon tree—the *Pinus Lambertiana*. It contains a non-fermentable, very sweet body called *pinite* ($C_6H_{12}O_5$). The California Manna, described, in 1702, by the Jesuit Father Picolo, is most likely an exudation of the reed grass, *Phragmites communis*, caused by insects (see J. U. Lloyd, *Amer. Jour. Pharm.*, 1897, p. 329).

MARANTA.—ARROW-ROOT.

The fecula of the rhizome of *Maranta arundinacea*, Linné.

Nat. Ord.—Marantaceæ.

Common Names: *Arrow-root*, *Bermuda arrow-root*.

Botanical Source.—This plant has a perennial rhizome, which is fibrous, producing numerous fusiform, fleshy, scaly, pendulous tubers from its crown. The stems are 2 or 3 feet high, much branched, slender, finely hairy, and tumid at the joints. The leaves are alternate, with long, leafy, hairy sheaths, ovate-lanceolate, slightly hairy underneath, and pale-green on both sides. The flowers are white, and disposed in a long, lax, spreading, terminal panicle, with long, linear, sheathing bracts, at the ramifications. The calyx is green and smooth; the corolla white, small, unequal, with one of the inner segments in the form of a lip. The ovary is 3-celled and hairy. The fruit is nearly globular, with 3 obsolete angles, and the size of a small currant (L.).

History, Description, and Chemical Composition.—This plant, originally from the West Indies, has been introduced into several parts of the world, in warm latitudes and moist climates, where it is extensively cultivated. It has also been raised in South Carolina and Georgia. The plant is developed by planting portions of the root-stock, which gradually increases in size, and throws out leaves.

which wither when the plant is mature. Arrow-root is prepared from the root when nearly a year old. The tubers are washed, beaten in large, deep vessels to a pulp, this is well stirred in clean water, the fibrous parts being separated by hand and thrown away. The milky liquor, which holds the starch in suspension, is passed through a fine sieve, the starch allowed to subside, the supernatant clear fluid is poured off, the starch is again washed in clean water and drained, and is then dried on sheets in the sun. This constitutes West India arrow-root, of which the finest comes from the Bermudas. The crop of the root on this island in 1891, amounted to 180,000 pounds, yielding 12 per cent of arrow-root. Bermuda arrow-root is now getting very scarce, the attention of the Bermuda planters having turned toward raising early vegetables for the New York market. The island of St. Vincent, in the West Indies, is now the leading district where arrow-root from *Maranta arundinacea* is produced (see J. W. McDonald, *Pharm. Jour. Trans.*, 1887, Vol. XVII, p. 1042). Arrow-root is likewise obtained from other plants, as the *M. nobilis*, *M. Allouia*, *M. indica*, Tussac (regarded merely as a variety of *Maranta arundinacea*) (L.), and *Curcuma angustifolia*, and *C. leucorrhiza*, Roxburgh, the last three furnishing the East India arrow-root.

West India Arrow-root is in the form of a light, opaque, white powder, consisting of irregular, friable grains, varying in size from that of a millet-seed to a pea. It is inodorous, nearly tasteless, and crackles when rubbed between the fingers. Musty arrow-root should never be purchased (see Prof. Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1841, Vol. XIII, p. 188). Examined by the microscope, arrow-root is found to consist of minute, pearly globules, or granules, which are spherical or ovate, and have a diameter varying from 7 to 50 micromillimeters. The rings are said to be distinct, though fine. In polarized light, very distinct crosses are seen, the junction of the arm of the cross indicating the position of the hilum.

Arrow-root presents all the chemical relations of wheat and potato-starch, though it makes a firmer jelly with the same quantity of boiling water, 9 parts in this respect being equivalent to 14 parts of common starch. According to J. W. McDonald, the tuber consists of 27 per cent starch, 63 per cent water, 1.56 per cent albumen, 4.10 per cent sugar, gum, etc., 0.26 per cent fat, 2.82 per cent fiber, and 1.23 per cent ash. Arrow-root starch, according to the same authority, contains 15.87 per cent water and 83.70 per cent starch. West India arrow-root is sometimes adulterated with wheat or potato starch, or with starches from sago and tapioca. The *German Pharmacopœia* of 1872 (see C. L. Lochman's translation, 1873) recommended the test to shake 1 part of arrow-root for 10 minutes with 10 parts of a mixture consisting of 2 parts of hydrochloric acid and 1 part of water; the greater part of the powder should separate unchanged, and should not become mucilaginous nor yield an herbaceous odor similar to that of green, unripe bean-pods. According to Prof. Schaer (see *Amer. Jour. Pharm.*, 1875, p. 503), potato-starch in this process readily yields a thick, almost clear jelly, of a strong, herbaceous, bean-like odor, and may thus be easily recognized. (For the microscopical differentiation of genuine arrow-root from adulterations, see the afore-mentioned pharmacopeial authority; also see literature on this phase of the subject in Flückiger, *Pharmacognosie*, 1891, p. 244.)

East India Arrow-root is chiefly prepared from plants growing throughout India, and particularly on the Malabar coast, the *Curcuma angustifolia* and *Curcuma leucorrhiza*, and to some extent from the *Maranta indica;* it is prepared by a process similar to that followed in the West Indies. It is commonly white, sometimes pale-yellow, less crackling between the fingers than the best West Indian kind, more frequently damaged by impurities, and composed of rather larger globules, unequal in size, egg-shaped, compressed, faintly rugous at their larger end, and with little projections attached to their sides. It is lighter than Maranta arrow-root, does not so quickly make a jelly, and is of inferior value.

Action and Medical Uses.—Arrow-root is nutritive, and is used as an agreeable, non-irritating diet in certain chronic diseases, during *convalescence from fevers*, in *irritations of the alimentary canal*, *pulmonary organs*, or of the *urinary apparatus*, and is well suited for infants to supply the place of breast-milk, or for a short time after having weaned them. It may be given in the form of jelly, variously seasoned with sugar, lemon-juice, fruit jellies, essences, or aromatics. Potato-starch is sometimes substituted for it, but it is more apt to cause acidity. Arrow-root is superior to every other kind of farinaceous food, except tapioca and tous-les-mois. Its jelly has no peculiar taste, and is less liable to become acid in the stomach, and is generally preferred by young infants to all others, except tapioca. *Tous-les-mois* makes a stiffer jelly. Two or 3 drachms of arrow-root may be boiled in a pint of water or milk, and seasoned as may be desired, if allowable.

Other Varieties of Arrow-root.—A product termed ZAMIA ARROW-ROOT, *Florida arrow-root*, *Indian bread root*, or *Koonti*, is prepared in Florida by the Seminole Indians from the rhizome of the *Zamia integrifolia* (see *Amer. Jour. Pharm.*, 1898, p. 213), and a kind of arrow-root that came from Chili under the name *Talcahuana arrow-root*, proved to be the product of *Alstrœmeria ligtu*. Other species of *Alstrœmeria* also yield a starchy material which is used in South America, like arrow-root. *Brazilian arrow-root* is derived from *Manihot utilissima* (which see). *Arrow-root* of *Tahiti* is derived from *Tacca oceanica*; *Australian arrow-root* (of Queensland) is yielded by *Canna edulis* (see *Canna*). The *Colocasia esculenta*, *Dioscorea sativa* (Common yam) and fruit of the bread-fruit tree (*Arctocarpus incisa*), have also yielded a fecula which has been substituted for true arrow-root.

Related Substance.—*Lewisia rediviva*, *Chita*, *Spathum*, *Bitter root*. Northwestern United States. Roots largely used as a food by the American Indians of that locality.

MARMOR ALBUM.—WHITE MARBLE

FORMULA: $CaCO_3$. MOLECULAR WEIGHT: 99.76.

A nearly pure, native, white crystalline, or granular calcium carbonate.

SYNONYMS: *Marble*, *Marmor* (*U. S. P.*, 1870).

History and Description.—White marble is distinguished from most minerals by its pure white color, its crystalline structure, and the effervescence it presents when touched with nitric or hydrochloric acids. It is tasteless, inodorous, friable, easily powdered, and is not dissolved by water or alcohol; but water saturated with carbonic acid gas, dissolves $\frac{1}{1500}$ part of it. From this solution it gradually precipitates, as the acid leaves it, in the form of a white powder. Its specific gravity is 2.717. Heat causes it to decrepitate, and, as the heat is increased, the carbonic acid gas is driven off and caustic lime remains ($CaCO_3 = CaO + CO_2$). Marble dissolves less rapidly in acetic acid than in nitric or hydrochloric. It also dissolves with effervescence in sulphuric acid, and forms nearly insoluble calcium sulphate.

It is sometimes rendered impure by the presence of magnesia. To detect this dissolve the marble in diluted hydrochloric acid, neutralize with ammonia, and precipitate the calcium by adding ammonium carbonate. Boil and filter, and to the cold filtrate add solution of sodium phosphate (PO_4HNa_2). If magnesium is present, a crystalline precipitate of ammonium-magnesium phosphate ($PO_4NH_4Mg + 6H_2O$) will be formed. Marmor album was formerly official in the *U. S. P.* (1870) and the *Br. Pharm.* (1885).

Uses.—Marble is used for several purposes in pharmacy, the principal of which is to furnish carbonic acid gas. It is also used in preparing Liquor Calcii Chloridi. For pharmaceutical purposes, the purest marble is required, but for procuring the acid gas, ordinary marble will answer. The *Dolomitic marble* contains more or less magnesia, and is, therefore, unfit for pharmaceutical use. The finest and best variety of marble is the *Carrara* or *Statuary marble*.

MARRUBIUM (U. S. P.)—MARRUBIUM.

"The leaves and tops of *Marrubium vulgare*, Linné"—(*U. S. P.*).

Nat. Ord.—Labiatæ.

COMMON NAMES: *Horehound*, *Hoarhound*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 210.

Botanical Source.—Hoarhound has a perennial, fibrous root and numerous, annual, bushy stems, which are erect, quadrangular, leafy, clothed with fine, woolly pubescence, branching from the bottom, from 1 to 2 feet in height. The leaves are roundish-ovate, crenate dentate, rough and veiny above, woolly on the under surface, 1 or 2 inches in diameter, and supported in pairs upon long petioles; upper ones nearly sessile. The flowers are small, white, in sessile, axillary, hairy dense whorls. Calyx tubular, 5 to 10-nerved, nearly equal, with 5 or 10 recurved, acute, spiny teeth, alternate ones shorter; orifice of the tube hairy. The corolla is tubular, upper lip erect, flattish, and notched; lower spreading and trifid; middle lobe broadest. Stamens 4, didynamous, included beneath the upper lip of the corolla; anthers with divaricating, somewhat confluent lobes, all nearly of the same form. Style with short, obtuse lobes. Achenia obtuse. Seeds 4, in the base of the calyx (L.—W.—G.). A synoptical key to various genera belonging to the natural order Labiatæ, based upon the microscopic appearance of the nutlets, by S. E. Jelliffe, is given in the *Druggists' Circular*, 1897, p. 34.

Fig. 167.

Marrubium vulgare.

History and Description.—Hoarhound is indigenous to Europe, but is naturalized in this country, where it is very common. It grows on dry, sandy fields, waste grounds, roadsides, etc., flowering from June to September. The entire plant has a white, hoary appearance. The whole herb is medicinal, and should be gathered before its inflorescence. It has a peculiar, rather agreeable, vinous, balsamic odor, and a very bitter, aromatic, somewhat acrid and persistent taste. Its virtues are imparted to alcohol or water. The *U. S. P.* describes the drug thus: "Leaves about 25 Mm. (1 inch) long, opposite, petiolate, roundish-ovate, obtuse, coarsely-crenate, strongly rugose, downy above, white-hairy beneath; branches quadrangular, white, tomentose; flowers in dense, axillary, woolly whorls, with a stiffly 10-toothed calyx, a whitish, bilabiate corolla, and 4 included stamens; aromatic and bitter"—(*U. S. P.*).

Chemical Composition.—J. A. McMaken, in 1845 (*Amer. Jour. Pharm.*, Vol. XVII, p. 1), isolated from the herb of *M. vulgare* a peculiar crystalline, bitter principle of neutral reaction, insoluble in water, soluble in ether, and more soluble in hot than in cold alcohol. The principle was again discovered, in 1855, by Mein, who named it *marrubiin*. It was subsequently investigated by Harms (1855), Kromayer (1861 and 1863), and more recently by Hertel (*Amer. Jour. Pharm.*, 1890, p. 273), J. W. Morrison (*ibid.*, p. 327), and Harry Matusow (*ibid.*, 1897, p. 201). The latter, by extraction with acetone, obtained a yield of 0.8 per cent, referred to air-dried herb, and gives *marrubiin* the formula $C_{30}H_{43}O_6$. The reactions generally confirm those given by Kromayer, only the melting point he found to be at 154° to 155° C. (309.2° to 311° F.), while Kromayer finds 160° C. (320° F.). The substance is not a glucosid. According to Morrison, several distinct bitter principles appear to exist in the plant. The latter also contains traces of volatile oil.

Action, Medical Uses, and Dosage.—Hoarhound is a stimulant tonic, expectorant, and diuretic. Its stimulant action upon the laryngeal and bronchial mucous membranes is pronounced, and it, undoubtedly, also influences the respiratory function. It is used in the form of syrup, in *coughs, colds, chronic catarrh, asthma*, and all *pulmonary affections*. The warm infusion will produce diaphoresis, and sometimes diuresis, and has been used with benefit in *jaundice, asthma, hoarseness, amenorrhœa*, and *hysteria;* the cold infusion is an excellent tonic in some forms of *dyspepsia*, acts as a vermifuge, and will be found efficient in checking *mercurial ptyalism*. In large doses it purges. It enters into the composition of several syrups and candies. Dose of the powder, 1 drachm; of the infusion, or syrup, from 2 to 4 fluid ounces; specific marrubium, 1 to 30 drops.

MASSÆ PILULARUM.—PILL MASSES.

Three pill masses that may be kept in stock, are recognized by the *U. S. P.*

Massa Hydrargyri (*U. S. P.*), *Mass of mercury, Pilula hydrargyri, Blue mass, Blue pill, Massa cærulea.*—"Mercury, thirty-three grammes (33 Gm.) [1 oz. av., 72 grs.]; glycyrrhiza, in No. 60 powder, five grammes (5 Gm.) [77 grs.]; althæa, in No. 60 powder, twenty-five grammes (25 Gm.) [386 grs.]; glycerin, three grammes (3 Gm.) [46 grs.]; honey of rose, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Triturate the mercury with the honey of rose and glycerin until it is extinguished. Then gradually add the glycyrrhiza and althæa, and continue the trituration until globules of mercury are no longer visible under a lens magnifying at least 10 diameters. If a portion of the mass be triturated, in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide). If another portion of the mass be digested with warm, diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hydrogen sulphide T.S., or by stannous chloride T.S. (absence of mercuric oxide)"— *U. S. P.*).

A powder of blue mass is prepared by using the same ingredients as above, except that sugar of milk and a drop of oil of rose are employed in place of glycerin and honey of rose. By means of alcohol, to give moisture, rub the whole to a uniform mass, and allow the alcohol to evaporate. Reduce to powder. It is known as PULVIS MASSÆ HYDRARGYRI, *Powdered blue mass*, or *Æthiops saccharatus*. PILULÆ HYDRARGYRI, or *Blue pills*, of the *U. S. P.*, 1870, contained 1 grain, each, of mercury. (For uses, see *Hydrargyrum.*) Not employed in Eclectic practice.

MASSA COPAIBÆ (U. S. P.)—MASS OF COPAIBA.

SYNONYMS: *Pilulæ copaibæ, Solidified copaiba.*

Preparation.—"Copaiba, ninety-four grammes (94 Gm.) [3 ozs. av., 138 grs.]; magnesia, six grammes (6 Gm.) [93 grs.]; water, a sufficient quantity. Triturate the magnesia with a little water, in a capsule, until the powder is uniformly dampened throughout. Then gradually incorporate with it the copaiba, so that a uniform mixture may result, place the capsule on a water-bath, and heat during half an hour, frequently stirring. Lastly, transfer the mixture to a suitable vessel, and set this aside until the mass has acquired a pilular consistence"—(*U. S. P.*).

Anhydrous magnesia does not easily combine with the resin of copaiba, hence the direction to sprinkle water upon the magnesia, thus hydrating it, in which state it more readily unites with the resin (*copaivic acid*) to form magnesium copaivate. The volatile oil is simply absorbed. The above proportions will form the proper mass, provided too much volatile oil be not present. If such should be the case, evaporation or exposure will reduce the quantity of oil. For this reason *Para copaiba*, which is thin, has to be prepared in this manner before a good result can be obtained, while, on the other hand, *Maracaibo copaiba*, being much thicker on account of its greater abundance of resin, unites to form a hard compound, a sort of resin-soap. Hence the preference for the latter variety. Fresh calcium hydrate will produce similar results. Wax or spermaceti have been advised in making pills of copaiba, as well as pills of copaiba and cubebs. Vegetable powders, as powdered liquorice root, may be combined with the wax in the mass if desirable. This method has the advantage of producing a pill which remains plastic.

Action and Medical Uses.—Same as for *Copaiba*. It should be made into 5-grain pills, 2 or 3 of which is the ordinary dose.

MASSA FERRI CARBONATIS (U. S. P.)—MASS OF FERROUS CARBONATE.

SYNONYMS: *Vallet's mass, Vallet's pill-mass.*

Preparation.—"Ferrous sulphate, in clear crystals, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sodium carbonate, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; clarified honey, thirty-eight grammes (38 Gm.) [1 oz. av., 149 grs.]; sugar, in coarse powder, twenty-five grammes (25 Gm.) [386 grs.]; syrup, distilled water, each, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the ferrous sulphate and the sodium carbonate, each separately, in two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of boiling distilled water, and, having added twenty cubic centimeters (20 Cc.) [325 ♏] of syrup to the solution of the iron salt, filter both solutions, and allow them to become cold. Introduce the solution of sodium carbonate into a bottle having a capacity of about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏], and gradually add the solution of the iron salt, rotating the flask constantly or frequently, until carbonic acid gas no longer escapes. Add a sufficient quantity of distilled water to fill the bottle, then cork the bottle and set it aside, so that the ferrous carbonate may subside. Pour off the supernatant liquid, and, having mixed syrup and distilled water in the proportion of 1 volume of syrup to 19 volumes of distilled water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the water as possible. Lastly, mix the precipitate at once with the honey and sugar, and, by means of a water-bath, evaporate the mixture in a tared capsule, with constant stirring, until it is reduced to one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]"—(*U. S. P.*).

Description.—By this process the iron salt is almost completely prevented from oxidation by the presence of the saccharine matter. The finished product, through some loss by washing, contains but about 35 or 36 per cent of ferrous carbonate. If well made, it will be completely and easily dissolved by acids. When recently prepared, *Mass of ferrous carbonate* (*U. S. P.*) is a greenish-gray, soft mass, of a pilular consistence, which becomes, superficially, greenish-black or blackish on exposure. Its taste is strongly ferruginous.

Medical Uses and Dosage.—(See *Ferrous Carbonate.*) Dose, 3 to 5 grains in pill.

MASTICHE (U. S. P.)—MASTIC.

"A concrete, resinous exudation from *Pistacia Lentiscus*, Linné"—(*U. S. P.*).

Nat. Ord.—Anacardiceæ.

COMMON NAMES: *Mastic, Mastich.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 68.

Botanical Source.—The *Lentisk*, or Mastic-tree, is a mere bush, rarely attaining a height greater than 12 feet, and from 6 to 10 inches in diameter. The leaves are evergreen, and equally pinnate; the leaflets, 8 to 12 in number, usually alternate, with the exception of the two upper, which are opposite, oval, lanceolate, obtuse, often mucronate, entire, and perfectly smooth. The flowers are very small, in axillary panicles, and diœcious; the raceme of the males is amentaceous with 1-flowered bracts; calyx 5-cleft; stamens 5; anthers subsessile and 4-cornered; the females' raceme more lax; calyx 3-cleft; ovary 1 to 3-celled; stigmas 3, and rather thick. The fruit is a very small, pea-shaped drupe, reddish when ripe, with a smooth, somewhat bony nut (L.).

History and Description.—This plant inhabits the south of Europe, north of Africa and the Levant, and abounds particularly on the island of Chios, where it is called "shinia," and from whence the bulk of the drug comes; about 120,000 pounds annually. *Pistacia Lentiscus* also grows in the island of Cyprus, where the leaves are collected and exported for the purposes of tanning and dyeing. They contain from 10 to 12 per cent of tannic acid. The seeds are eaten by goats and pigs, and yield a fatty oil used for burning purposes. When transverse incisions are made into the bark of the male plant, in the month of August, a fluid exudes, which soon concretes into yellowish, translucent, brittle grains.

There are two kinds of mastic in commerce, the picked mastic and mastic in sorts. The former is the finer variety. Good mastic is described by the *U. S. P.* as being in "globular or elongated tears, of about the size of a pea, sometimes covered with a whitish dust, pale-yellow, transparent, having a glass-like luster and an opalescent refraction; brittle; becoming plastic when chewed; of a weak, somewhat balsamic, resinous odor, and a mild, terebinthinate taste. Mastic is completely soluble in ether, and, for the most part, soluble in alcohol"—(*U. S. P.*). It is also soluble in oil of turpentine, or chloroform, insoluble in water. Boiling alcohol dissolves from it a resinous acid to the amount of eight-tenths of its weight, and leaves a white, ductile substance possessing properties similar to caoutchouc, and which is soluble in ether, or boiling absolute alcohol. Carbon disulphide dissolves about 75 per cent of mastic. At a moderate heat (below 120° C. or 248° F.), it melts, and at a higher temperature it burns with a clear flame and balsamic fumes. It has a specific gravity of 1.074. The mastic in sorts is a coarser kind, and is composed of many tears agglutinated together, varying in color from pale-yellow to grayish-brown and black, together with pieces of wood, bark, and sand.

Chemical Composition.—Mastic contains 2 per cent of an essential oil; according to Flückiger, it is dextro-rotatory and chiefly composed of a terpene ($C_{10}H_{16}$), boiling from 155° to 160° C. (311° to 320° F.). The principal constituent of mastic is a resin which was differentiated by Johnston (*Phil. Trans.*, 1839) into alcohol-soluble *alpha-resin* (*mastichic acid*), about 80 per cent, and alcohol-insoluble *beta-resin* (*masticin*), the latter being tough and elastic, soluble in ether and in absolute alcohol, also in alcoholic solution of mastichic acid. According to E. Reichardt (*Archiv der Pharm.*, 1888, p. 158), benzin effects the differentiation of mastic resin more readily and more completely than alcohol. Old mastic yielded to benzin 66 per cent, while new mastic yielded 90 per cent. Analysis showed that the insoluble resin is formed by the gradual oxidation of the soluble portion. Mastic also contains a bitter principle, soluble in boiling water; it is precipitated by solutions of tannic acid.

Action and Medical Uses.—Mastic is seldom employed in medicine, though it was formerly employed in *renal* and *bronchial catarrhs*. The Turks used it as a masticatory to sweeten the breath and strengthen the gums. It is sometimes employed by dentists to fill the *cavities of decayed teeth*. The following preparation is recommended for this purpose: Take of pulverized mastic, 9 parts; sulphuric ether, 4 parts; mix, and digest for several days, strain it through a cloth, and add native alum, in fine powder, a sufficient quantity to form a plastic mass, with which vials holding about 2 drachms are to be filled, having first poured into each about 30 grains of camphorated alcohol, and 15 grains of essence of cloves. This substance, introduced into the cavity of a carious tooth, first well cleansed and dried, is extremely useful on account of the great degree of hardness it acquires, An ounce of mastic, and ½ drachm of caoutchouc, dissolved in 4 fluid ounces of chloroform, and then filtered under cover to prevent the evaporation of the chloroform, forms an elegant microscopic cement. Another formula for dental mastic is as follows: Dissolve 4 parts of mastic and 2.5 parts of balsam of Peru in 7 parts of chloroform (*Amer. Jour. Pharm.*, 1885, p. 241, from *L'Union Pharm.*, 1885). A solution of mastic in alcohol, or oil of turpentine, forms an elegant varnish. Such a solution may be used to arrest slight *hemorrhages from wounds*, *leech bites*, etc.

Related Products.—BOMBAY MASTIC, or *East Indian mastic*. This exudes from the *Pistacia Khinjuk*, Stocks, and the *Pistacia cabulica*, Stocks (*Pistacia Terebinthus*, Linné of Kabul, Beloochistan, and Sind. In the Indian bazaars it is known as *Mustagi-rúmi* or *Roman mastich*. It very much resembles true mastic, but is usually more opaque and not so clean as that product. The same species, *Pistacia Terebinthus*, also grows in the islands of Chios and Cyprus, and yields *Chian turpentine*. The mode of its cultivation, etc., is described in *Proc. Amer. Pharm. Assoc.*, 1897, p. 563. Chian turpentine contains from 9 to 12 per cent of volatile oil (Wigner, 1880). The Arabs of North Africa gather from an Algerian plant, the *Pistacia Terebinthus*, Linné, var. *Atlantica*, Desfontaines, a product similar to mastic.

SANDARACH.—*Sandaraca*, *Sandarac*. A northwest African tree, the *Callitris quadrivalvis*, Ventenat (*Thuja articulata*, Vahl), *Nat. Ord.*—Coniferæ, yields tears of sandarac by spontaneous exudation. They are brittle, elongated, light-yellow, and have a dusty appearance. When masticated they crumble to a powder, are translucent, have a vitreous fracture, and are almost completely dissolved by alcohol. Sandarac is also soluble in ether, amyl alcohol and acetone, partly soluble in chloroform and essential oils, insoluble in low-boiling petroleum benzin, and in benzol, partly soluble in carbon disulphide, also soluble in considerable quantity in hot solution of caustic soda. The freshly exuding resin contains notable quantities of essential oil which evaporates, however, as the tears are exposed (Flückiger, *Pharmacognosie*, 1891, p. 108). Their odor is therefore feeble, unless the product be heated when it becomes balsamic; the taste is resin-like and subacrid. It is inflammable. Sandarac is said to be composed of 3 resins, which may be differentiated by their behavior toward solvents. One of these resins is Giese's *sandaracin*. Like mastic, sandarac resin contains small quantities of a bitter principle.

Australian sandarach is physically very similar to the foregoing. It is obtained in Tasmania and Australia.

PSEUDO-MASTICH.—*Acantho-mastich*. Agglutinated tears of an exudation from the *Atractylis gummifera*. It comes in masses about the size of a small egg. It is employed in Greece.

MATICO (U. S. P.)—MATICO.

"The leaves of *Piper angustifolium*, Ruiz et Pavon"—(*U. S. P.*). (*Piper elongatum*, Vahl; *Stephensia* [*Steffensia*] *elongata*, Kunth; *Artanthe elongata*, Miquel

Nat. Ord.—Piperaceæ.

COMMON NAMES: *Matico*, *Matico-leaves*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 242.

Botanical Source.—This plant is the *Artanthe elongata* of Miquel, and the *Stephensia elongata* of Kunth; it is described as a tall shrub, presenting a singular appearance from the segmentary character of its stems and branches. The leaves are harsh, short-stalked, oblong-lanceolate, acuminate, pubescent beneath, tessellated or rough on the upper side on account of the sunken veins. The spikes are solitary, cylindrical and opposite the leaves; the bracts lanceolate; the flowers hermaphrodite, yellow, minute, and numerous. The fruit consists of small, almost black seeds.

History and Description.—This is a Peruvian plant, which was brought into notice among the profession of this country by Dr. Ruschenberger, a member of the United States Navy. The dried leaves are the parts used; they have a strong, rather fragrant odor, not unlike that of cubebs, and a warm, aromatic, somewhat feebly astringent taste. They are easily reduced to a powder of a color similar to that of senna leaves. Water takes up their aroma and a slight pungency, but no astringency. Infusion of galls produces a gray precipitate with infusion of matico; iron causes a deep-green one; tartar-emetic, corrosive sublimate, and gelatin scarcely affect it.

The official description of matico is as follows: "From 10 to 15 Cm. (4 to 6 inches) long, short-petiolate, oblong-lanceolate, apex pointed, base unequally heart-shaped, margin very finely crenulate, tessellated above, reticulate beneath, meshes small, and the veins densely-brownish-hairy; aromatic, spicy, and bitterish"—(*U. S. P.*).

Chemical Composition.—Dr. Hodges, in 1844, found in the leaves a bitter principle which he called *maticin*, an aromatic, volatile oil nitrate of potassium, a soft, dark-green resin, etc. T. S. Wiegand (1846) and John J. Stell (1858), and more recently, Prof. Flückiger, doubt the existence of Hodge's maticin; Flückiger (*Pharmacognosie*, 1891, p. 748) was also unable to verify the existence of Marcotte's crystallizable *artanithic acid* (1869). Tannin is present in the leaves. The *volatile oil* of matico is pale yellow and thick, and exists to the extent of 2.7 per cent. Its optical rotation is slightly right-handed. Most of the oil distills between 180° and 200° C. (356° and 392° F.). From the thick residue Prof. Flückiger obtained upon cooling, large crystals of a peculiar camphor; Kügler (1883) ascribes to the purified substance the formula $C_{10}H_{15}(C_2H_5)O$. It melts at 94° C. (201.2° F.), and is devoid of odor and taste.

Action, Medical Uses, and Dosage.—Matico is an aromatic bitter stimulant, whose virtues reside in its resin, volatile oil, and bitter principle. It has been highly reecommended in *bleeding from the lungs*, *stomach*, or *kidneys*, and in *dysentery*, but its use is doubtful in these cases. It has, however, been found advantageous in *leucorrhœa*, *gonorrhœa*, *piles*, and *chronic mucous discharges;* also in *dyspepsia*, owing to chronic mucous affections of the stomach. Externally, the leaves are used for arresting *hemorrhages from wounds*, *leech-bites*, etc.; the downy part of the leaf is said to be the most active part. Also applied to *ulcers*. A tincture is also used, made with 2½ ounces of the leaves to 1 pint of diluted alcohol, of which the dose is from 1 to 3 fluid drachms. The infusion is made by macerating ½ ounce of the leaves in ½ pint of boiling water for 1 hour; dose, from 1 to 2 fluid ounces, 3 or 4 times a day.

Related Species.—*Piper aduncum*, Linné (*Artanthe adunca*, Miquel), abundant in Tropical America, furnishes a leaf which was substituted for matico, and was detected by Prof. Bentley in 1864. It differs but little in odor, shape, or color, from matico, though it does not appear tessellated like the latter. The parallel ascending nerves are more prominent on the under surface, and the spaces are nearly smooth, instead of rugose, and not hairy like the same surface of matico leaves. Chemically, it resembles matico, and therapeutically, it is probably not less effective.

Artanthe lanceæfolium, Miquel (*Piper lanceæfolium*, H. B. K.), yields a *matico* which is employed in New Granada (*Pharmacographia*). The leaves of *Eupatorium glutinosum*, Kunth (the *Chusalonga*) (*Nat. Ord.*—Compositæ), and *Waltheria glomerata*, Presl (*Nat. Ord.*—Sterculiaceæ) of Central and South America, are known also as matico. It appears that the terms *Matico* and *Yerba* (*palo*) *del soldado* (*Soldiers' herb* or *tree*), both Spanish names, are applied to these plants as well as to true matico, on account of their styptic qualities. The *Piper aduncum* is used in Brazil as a stimulant only, styptic properties not being mentioned. The fruit of the same is employed like cubebs. The leaves of the Eupatorium and Waltheria are sufficiently different as not to be confounded with matico.

Piper Carpunya, Ruiz et Pavon. Peru and Chili. Glossy, leathery leaves used in *gastric disorders*.

Piper umbellatum, Linné; *Piper peltatum*, Linné. Tropical America. The *caapeba* or *pariparobo.* Rhizomes, diuretic; leaves employed for *tumors* and *cutaneous diseases*. See also *Areca*, *Piper methysticum*, and *Piper Betle*.

MATRICARIA (U. S. P.)—MATRICARIA.

"The flower-heads of *Matricaria Chamomilla*, Linné"—(*U. S. P.*). (*Chamomilla officinalis*, Koch; *Chrysanthemum Chamomilla*, Bernhardi.)

Nat. Ord.—Compositæ.

COMMON NAME: *German chamomile.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 155.

Botanical Source.—A branching annual, having a stem from 1 to 2 feet high, with alternate, smooth, deep-green, pinnate, or bi- or tri-pinnate leaves, the leaflets of which are small and linear. The numerous small branches bear single, terminal flowers, about ¾ inch in breadth, with spreading rays. The calyx-scales are obtuse, whitish, translucent, and membranaceous near the margins, but green in the center. The white ray-florets are spreading at first, finally becoming reflected. The disc is convex primarily, and later becomes prominently conical and hollow.

History and Description.—This plant is found in wastes and fields in Europe northward to Finland, and is cultivated in this country by our German population. It is likewise found in Asia in the temperate localities, and, through naturalization, has become one of the plants of Australia. All parts of the plant are medicinal, but the flowers are generally employed. When dried they are much smaller than the fresh heads. Matricaria is described by the *U. S. P.* as follows: "About 15 to 20 Mm. (½ to ⅘ inch broad), composed of a flattish, imbricate involucre, a conical, hollow, naked receptacle, which is about 5 Mm. (⅕ inch) high, about 15 white, ligulate, reflexed ray-florets, and numerous yellow, tubular, perfect disk-florets without pappus; strongly aromatic and bitter. The similar flower-heads of *Anthemis arvensis*, Linné, and *Maruta Cotula*, De Candolle (*Nat. Ord.*—Compositæ), have conical, solid, and chaffy receptacles"—(*U. S. P.*). (See *Anthemis*.)

Chemical Composition.—In addition to the ordinary constituents of plants, matricaria contains a small portion of tannin and tannates, malates, bitter extractive, and a volatile oil. The latter, known as *Oleum Chamomillæ Æthereum*, may be obtained, by distillation in a suitable apparatus, in the quantity of 0.45 per cent (Schimmel & Co.). It has an aromatic, warm taste, and a pronounced odor of matricaria. It is thick, somewhat viscid, opaque in bulk, but in layers transparent, and has a rich, dark-blue color which, on exposure to air and light, gradually becomes green, and, lastly, brown. Its density is 0.93; its congealing point, —20° C. (—4° F.). It consists of a colorless oil having the composition $C_{10}H_{18}O$, and a terpene ($C_{10}H_{16}$). *Azulene* (of Piesse), or *cærulein* (of Gladstone), a volatile body said to be present in all blue or green oils, gives to it its blue coloration. It was investigated by Kachler (1871), and occurs only in the highest fractions of the oil. An *Oleum Chamomillæ Citratum*, sometimes met with, is prepared by adding oil of lemon (1 part) to recently gathered matricaria (480 parts), and distilling. It is thinner than the true oil, and its blue color changes more readily. Werner, in 1867, states to have obtained from *Matricaria Chamomilla* the crystallizable, bitter *anthemic acid*, isolated by Pattone (1859) from the flowers of *Anthemis arvensis*, Linné; and a crystallizable alkaloid, which he called *anthemidine*. Flückiger (1891) doubts the correctness of these results.

Action, Medical Uses, and Dosage.—Matricaria is usually listed as having properties similar to anthemis, but of less activity. It has, however, come to be preferred over the latter by Eclectic practitioners, and is now an important remedy with us, particularly in affections of young children. It has two particular specific fields of action—one upon the nervous system, subduing nervous irritability, and the other upon the gastro-intestinal tract, relieving irritation. Upon the nervous system its action is most pronounced, affecting both the sensory and motor nerves. It is peculiarly adapted to the *nervous manifestations of dentition*, and in other affections where there seems to be a *morbid susceptibility to pain. Earache, rheumatic* and *neuralgic pains, abdominal neuroses*, etc., are relieved by it when the nervous apprehension is all out of proportion to the actual amount of pain experienced. A matricaria patient is restless, irritable, discontented, and impatient, and, if a child, is only appeased when continually carried. In *pregnancy*, it relieves nervous twitching, cough, false pains, etc., accompanied by great unrest. It should be borne in mind, however, that it is not the gross dose of matricaria that will overcome these morbid, nervous phenomena, but the small, or almost minute dose. It is one of those agents, and we have many, that exert their peculiar effects only in small doses, yet can be used without harm in large doses, but without the peculiar benefit derived from the smaller amounts. It relieves the erethism producing *hysteria*—a little slowly, perhaps, but its effects are lasting—and for the conditions that threaten *infantile convulsions*, during dentition, it is one of the most certain of drugs. After the spasms have supervened, it is not equal to gelsemium or lobelia.

While it has been said that it has two specific fields of action—upon the mental and nervous, and upon the digestive tract—it must be remembered that the nervous manifestations calling for matricaria, are nearly always present in the disorders of the latter, while, on the other hand, the nervous phenomena may occur without any disturbance of the latter. Hence the references to the nervous symptoms of stomach and bowel disorders, given as specifically calling for the drug. In the *summer diarrhœa* of irritation (not of atony), it becomes an important remedy. The condition will probably not be without call for other specifics, but the indications for matricaria will be distinct. There is marked irritability, the child is peevish and fretful, the stools extremely fetid, and may excoriate around the anus more or less. In appearance they vary—may be watery and green, or slimy, perhaps in yellow and white lumps, or it may be of undigested curds of milk, imbedded in a green mucus—an appearance aptly compared by Prof. Bloyer to "chopped eggs and greens." In *subacute inflammation* and in *congestion of the liver*, small doses of matricaria are very efficient when the bowels are costive, the urine voided with difficulty, the child fretful and peevish, and the right hypochondrium tender. If fever is present, aconite may be associated with it. It corrects the skin eruptions and rashes due to these disorders. Alone, or associated with phytolacca, it relieves *soreness and swelling of the breasts in infants*, and is useful in *suppression of the lacteal secretion*. It is a remedy for *flatulent colic* with distension.

Either small or large doses of matricaria (specific or infusion) are of value in *amenorrhœa*, with sense of weight and heaviness in the womb, and bloating of the abdomen, accompanied with sudden nervous explosions of irascibility. The infusion, given to the extent of producing free diaphoresis, relieves *dysmenorrhœa*, with labor-like pains, and tends to prevent the formation of clots. Various painful conditions, due to contracting *colds*, are relieved by matricaria infusion associated with aconite. Among these may be mentioned *earache*, *rheumatism*, *catarrhal affections of the bowels*, *ears*, *nose*, and *eyes*. Locally, it has been used as a wash for *leucorrhœa*, *mammary abscess*, *ulcerating bubo*, and *catarrhal conjunctivitis*.

For topical application and internal administration, an infusion (℥ss to water Oj) may be used. For its gross action, it may be given freely, but for specific purposes, teaspoonful doses of an infusion of half the above strength will give the best results. Specific matricaria is given in doses of a fraction of a drop to 30 drops.

Specific Indications and Uses.—Nervous irritability, with peevishness, fretfulness, discontent, and impatience; sudden fits of temper during the catamenial period; muscular twitching; morbid sensitiveness to pain; head sweats easily; alvine discharges, fetid, greenish and watery, and of green mucus with curds of milk, or of yellow and white flocculi, associated with flatulence, colic, and excoriation of the anal outlet; a remedy particularly fitted for the disorders of dentition, and to correct the condition threatening to end in dentition convulsions.

Related Species.—*Anthemis arvensis*, Linné. America and Europe. The flowers of this species have no odor, but have a bitter, acrid taste. They are possessed of medicinal qualities similar to anthemis and matricaria, but are regarded less valuable. Pattone ([illegible]) found the flowers to contain bitter and crystallizable *anthemic acid*, and a crystallizable alkaloid, *anthemine*. Flückiger (*Pharmacognosie*, 3d ed., 1891, p. 832) doubts the correctness of these statements.

MEL (U. S. P.)—HONEY.

"A saccharine secretion deposited in the honeycomb by *Apis mellifica*, Linné" (*U. S. P.*).

Class: Insecta. *Order:* Hymenoptera.

Source and History.—The *Apis mellifica*, or honey-bee, belongs to the order *Hymenoptera*, of the class of insects. In the wild state it dwells in the hollows of trees in large communities, consisting of males, females, and neuters. Honey is a saccharine matter secreted by the nectariferous glands of flowers, which is collected by the working bees, and deposited in their *crop* or *honey-bag*, from which it is ejected when the insect reaches its hive. The taste, odor, and quality of honey varies according to the age of the bees and the character of the flowers from which it is gathered. The presence of pollen grains in honey mostly permits the identification of the flowers from which the honey is taken. There is no doubt but the secretions of the crop of the insect, somewhat alter the properties of the honey received into it from the nectaries. It is established, for example, that these secretions contain a ferment which readily converts cane sugar and starch into *invert-sugar*. *Virgin honey* is the best kind, and is procured by dripping honeycomb from a hive of young bees before they have swarmed. Honey of a superior quality is obtained by allowing it to ooze from the honeycomb. After the first honey is thus procured, by subjecting the honeycomb to compression, an inferior variety may be expressed; or it may be obtained by fusion in the vapor-bath. Although a large amount of honey is supplied in our own country, yet a great quantity is also imported from some of the West Indian islands. A plea for California honey was made by J. E. S. Bell, in *Amer. Jour. Pharm.*, 1888, p. 126. The best honey is stated to be produced from linden flowers. On the other hand, certain poisonous plants, especially of the natural order of Ericaceæ, yield poisonous honey, the toxic principle very likely being *andromedotoxin* (see interesting paper by L. F. Kebler, *Proc. Amer. Pharm. Assoc.*, 1896, p. 167).

Description.—The *U. S. P.* describes honey as "a syrupy liquid of a light-yellowish to pale, yellowish-brown color, translucent when fresh, but gradually becoming opaque and crystalline, having a characteristic, aromatic odor, and a sweet, faintly acrid taste"—(*U. S. P.*). (See *Mel Despumatum.*) The specific gravity of good honey, on the average, is 1.425; it should not be lower than 1.375 (*U. S. P.*). In a great measure it is soluble in water, not so readily soluble in alcohol; hot alcohol dissolves it, but on cooling deposits crystals of grape sugar.

Chemical Composition.—According to J. König (*Die Menschlichen Nahrungs- und Genussmittel*, 3d ed., 1893, p. 784), the average composition of 100 parts each, in 183 samples of honey analyzed, was as follows: Water, 20.6; nitrogenous matter, 0.76; *lævulose* (*fruit sugar*), 38.65; *dextrose* (*grape sugar* or *glucose*), 34.48; *cane sugar* (*sucrose*), 1.76; (maximum in one single instance, 12.91; the beehives in this case were situated near a cane sugar manufactory); gum, 0.22; pollen and wax, 0.71; non-sugar substances, 2.82; ash, 0.25; phosphoric acid, 0.028. Thus it is seen that the bulk of the sugar is present as *invert sugar* (equal molecules of dextrose and lævulose) with *lævulose* somewhat preponderating. Most of the genuine honey therefore, is decidedly lævo-rotatory. Still, a possible increase in cane sugar, which is dextro-rotatory, or of dextrin-like bodies (sometimes as much as 4 per cent), in natural honey is liable to change the optical rotation to the right. Pure honey, upon standing becomes semi-crystalline, crystals of *dextrose* ($C_6H_{12}O_6 + H_2O$) being deposited. A peculiar property of invert sugar, which is made use of in analysis by optical methods, consists in the fact that its optical rotation, which is to the left, becomes zero at a temperature of 87.2° C. (189° F.). Honey, diluted with water, is susceptible to the vinous fermentation, without the addition of yeast; if yeast be added, it forms the alcoholic liquor called *mead;* the presence of albuminous bodies in honey facilitates fermentation; if nitric acid be allowed to act on honey, oxalic acid results. Honey also contains *formic acid*, which the bees deposit in the honey in order to preserve it.

Adulterations and Tests.—Honey is occasionally adulterated with flour or starch, especially the inferior kinds, in order to give it a white appearance. If the honey be thin and slow to crystallize, it is probably adulterated with water. Honey is also liable to be adulterated by the addition of solution of cane sugar, or of glucose syrup. The presence and quantity of cane sugar may be established by determining the reducing power of the honey in question upon Fehling's solution before and after inversion with diluted hydrochloric acid. An increased reduction after inversion is due to the presence of cane sugar. The aforenamed adulterants are recognized by the following official tests: "When recent honey is diluted with 2 parts of water, the resulting liquid should be almost clear, not stringy, and should have a specific gravity not lower than 1.100 (corresponding to a specific gravity of 1.375 for the original honey). Honey has a faintly acid reaction toward litmus paper. If 1 part of honey be dissolved in 4 parts of water, a clear or nearly clear solution will result, which should not be rendered more than faintly opalescent by a few drops of silver nitrate T.S. (limit of chlorides), or of barium chloride T.S. (limit of sulphates). If 1 volume of honey be diluted with 1 volume of water, and a portion of this liquid gradually mixed with 5 volumes of absolute alcohol, it should not become more than faintly opalescent (as compared with the reserved portion of the solution), and should neither become opaque, nor deposit a slimy substance on the inner walls and bottom of the test-tube. And when honey is incinerated, in small portions at a time, in a platinum crucible, it should not leave more than 0.2 per cent of ash (absence of glucose and foreign inorganic substances). On boiling 1 part of honey with 5 parts of water, the resulting solution, when cold, should not be rendered blue or green on the addition of iodine T.S. (absence of starch)"—(*U. S. P.*).

Dr. O. Haenle (*Amer. Jour. Pharm.*, 1890, p. 445), employs dialysis and subsequent polarization of the residual liquid to prove the presence of glucose syrup in honey; the residue is optically active if glucose (which always contains dextrin-like bodies) is mixed with the honey in question. Yet, genuine honey, being of variable composition, may contain, as stated before, large quantities of dextrin as a natural constituent. In this connection, see the elaborate researches on the chemistry of honey, by O. Künnmann and A. Hilger, in *Forschungsberichte*, 1896, pp. 211–226.

In testing honey for chlorides, an excess of chlorides present may in some cases be accounted for by the gathering of honey from flowers grown in "salt marshes" (see L. F. Kebler, *Amer. Jour. Pharm.*, 1895, p. 27). The so-called *Eucalyptus honey* of Australia, for which its discoverer, D. Guilmeth, and his followers, claimed the virtue of containing large amounts of eucalyptol, proved to be a misrepresentation. (Compare *Amer. Jour. Pharm.*, 1887, p. 471, and 1891, p. 517.

Action, Medical Uses, and Dosage.—Honey is nutritious, antiseptic, diuretic, and demulcent. Used in *urinary affections*, and as an addition to gargles, lotions, injections, etc. A very excellent preparation for *coughs*, especially during *febrile* or *inflammatory attacks*, is composed of honey, olive-oil, lemon juice, and sweet spirits of niter, each 1 fluid ounce, to be taken several times a day, in half fluid-drachm or fluid-drachm doses. Honey sometimes enters into the formation of cataplasms for *diminishing the lacteal secretion*, and for the treatment of *fissured nipples*, *carbuncles*, and *boils*. Several preparations, as honey of borax, honey of rose, etc., are used as local applications in *aphthous sore throat and mouth*, and to *local disorders of the female genitalia*. It is said that the Indians make an infusion of the honey bee, and give 1 gill of it every half hour, in *strangury*, *suppression of urine*, etc. (see *Apis*), and it is further added, that this infusion has the power of destroying the sexual propensity. The latter statement requires confirmation. A tincture of honey bees is made by collecting a quantity of the living insects in a vial, agitating them roughly so as to irritate them, and while in that condition they are to be covered with alcohol; in a few days it will be ready for use. In small doses, several times a day, this is a highly useful remedy in many *diseases of the bladder* and *kidneys*, as well as in some *uterine affections* (see *Apis*). Some practitioners assert that it will produce abortion in the pregnant female, if its use be too long continued, or when employed too freely. Though extensively used as a food, honey occasionally causes, in susceptible individuals, unpleasant head symptoms, and more often flatulent colic of a peculiar character, and will sometimes produce diarrhœa.

MEL BORACIS.—BORAX HONEY.

SYNONYMS: *Mel sodii boratis*, *Honey of sodium borate*.

Preparation. Mix 60 grains of finely powdered borax with 30 grains of glycerin, and 480 grains of clarified honey. This accords with the *British Pharmacopeia*. The parts used are respectively 2, 1, and 16. This is extemporaneously prepared as needed. (See an interesting article on the chemistry of mel boracis, by W. R. Dunstan, in *Amer. Jour. Pharm.*, 1883, p. 453, from *Pharm. Jour. Trans.*, 1883.)

Action and Medical Uses.—Its uses are practically those of each of the ingredients composing it. It is especially applicable to *aphthous conditions* in young children.

MEL DESPUMATUM (U. S. P.)—CLARIFIED HONEY.

Preparation.—"Honey, a convenient quantity; glycerin, a sufficient quantity. Mix the honey intimately with two (2) per cent of its weight of paper-pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then apply the heat of a water-bath, and, as long as any scum rises to the surface, carefully remove this. Finally, add enough distilled water to make up the loss incurred by evaporation, strain, and mix the strained liquid with five (5) per cent of its weight of glycerin"—(*U. S. P.*). Some older processes employed for purification of honey, at boiling heat, the white of eggs, animal charcoal, gelatin, with subsequent addition of tannic acid, etc. (see description of these processes in this *Dispensatory*, preceding editions). "Clarified honey should conform to the tests of purity given under honey (see *Mel*)"—(*U. S. P.*).

Pharmaceutical Uses.—Honey is used in the preparation of pills, confections, oxymels, and medicated honeys.

MELLITA.—*Medicated honeys.* Simple mixtures of drugs with honey, prepared extemporaneously on account of their liability to decompose.

OXYMELLITA.—*Oxymels.* Medicated honeys, containing vinegar, or acetic acid (see *Oxymel*).

MEL ROSÆ (U. S. P.)—HONEY OF ROSE.

Preparation.—"Fluid extract of rose, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]: clarified honey, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Into a tared vessel introduce the fluid extract of rose, then add enough clarified honey to make the contents weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and mix them thoroughly"—(*U. S. P.*).

Action and Medical Uses.—Useful and pleasant addition to mouth-washes and gargles. It is slightly stimulant and astringent, and is adapted to *inflammatory ulcerations of mouth and throat.*

MELILOTUS.—MELILOT.

The leaves and flowering tops of *Melilotus officinalis*, Willdenow (*Melilotus vulgaris*, Eaton and Wright; *Trifolium officinale*, Linné).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Sweet clover*, *Yellow melilot*, *Yellow melilot clover.*

ILLUSTRATION: Johnson, *Med. Bot. of N. A.*, Fig. 120.

Botanical Source, History and Description.—Yellow melilot has an erect, sulcate stem, about 3 (2 to 4) feet high, with spreading branches. The leaves are pinnately trifoliate; the leaflets obovate-oblong, obtuse and smooth, with remote, mucronate teeth. The flowers are yellow, in one-sided, spicate, axillary, loose, paniculate racemes; the calyx half as long as the corolla; the legume ovoid and 2-seeded. The petals in this species are of about equal length. It is an indigenous annual, growing in alluvial meadows, and flowering in June. The whole plant is scented, having nearly the odor of the sweet-scented vernal grass, *Anthoxanthum odoratum*. The taste of the plant, when dried, is somewhat pungent, aromatic, and bitterish. A closely related species, the *Melilotus officinalis* of Desrousseaux (*M. diffusa*, Koch; *M. arvensis*, Walroth) of Europe, is collected also with the foregoing species. It has light-yellow flowers having short carinas, while the fruit is a transversely-rugose, obovate, usually 1-seeded legume. An American species, having white flowers, probably has virtues similar to yellow melilot. It is the *Melilotus alba*, Lamarck (*Melilotus officinalis*, Pursh; *Melilotus officinalis*, var. *alba*, Nuttall; *Melilotus leucantha*, Koch). In this species the standard is longer than the other petals. It is known as *White melilot*, *White melilot clover*, or *Sweet-scented clover*, and is a biennial, with an erect, robust, very branching, sulcate stem, 4 to 6 feet high. The leaflets are variable, oval, ovate, ovate-oblong, truncate, and mucronate at the apex, remotely serrate, and 1 or 2 inches long; stipules setaceous. The flowers are white, numerous, the racemes more loose and longer than in the first species. The petals are unequal, the banner longer than wings or keel, and the calyx shorter than the corolla by more than one-half. This plant grows in similar situations with *M. officinalis*, flowering in July and August, and having a sweet fragrance, which is improved upon being dried—(W.).

Chemical Composition.—The characteristic constituent of melilotus is the aromatic, crystallizable *coumarin* ($C_9H_6O_2$), which is the anhydrid of *ortho-coumaric acid* ($C_6H_4OH.CHCHCOOH$). The latter, and *hydrocoumaric (melilotic) acid* ($C_6H_4OH.CH_2CH_2COOH$) likewise occur in the plant. Cumarin forms with melilotic acid a crystallizable compound (Zwenger and Bodenbender). *Melilotol* of Phipson (1875), is a volatile oil, probably the anhydrid (*lactone*) of melilotic acid. As much as 0.2 per cent has been obtained by distilling the fresh herb with water. *Chenopodin*, a crystallizable principle occurring quite frequently in various plants, was observed by Reinsch (1867) as a deposit from an alcoholic extract of *Melilotus alba;* it is probably identical with *leucin* (*amido-caproic acid*, $C_5H_{10}NH_2COOH$) (Flückiger, *Pharmacognosie*, 1891).

Coumarin is also the odoriferous principle of many other plants, occurring, *e. g.*, in *Tonka beans* where it was first discovered; in *Liatris*, *Asperula odorata*, etc. (see list of coumarin-bearing plants in Husemann and Hilger, *Pflanzenstoffe*, p. 1037). It was found in melilotus only in small quantity (about 0.04 per cent, in combination with melilotic acid). *Coumarin* is now obtained synthetically by the action of acetic anhydrid and sodium acetate upon the sodium compound of salicylic aldehyde (C_6H_4OHCHO). It forms hard, colorless prisms, melting at 67° C. (152.6° F.), and boiling at 291° C. (608° F.). It sublimes, however, at ordinary temperature, in the form of white needles; sometimes it is found in crystals on the herb. Coumarin is soluble in ether, volatile and fatty oils, in acetic and tartaric acids, also soluble in boiling alcohol, and requires 400 parts of cold, and 45 parts of hot water for solution. Hot alkalies convert it into ortho-coumaric acid.

Action, Medical Uses, and Dosage.—Melilotus (species), placed between woolen clothing, is used in Europe to guard against the ravages of the moth. The medicinal properties of melilotus are undoubtedly chiefly due to coumarin. Many observers have found it peculiarly effective in certain *painful disorders*, particularly *neuralgias* of long standing and associated with debility. It is adapted to idiopathic *neuralgic headaches*, and to *neuralgic affections* not depending upon reflex causes, although it has given good results in headaches arising from painful disorders of the stomach. *Recurring neuralgia*, especially from cold or fatigue, have been promptly relieved by small doses of the drug. It relieves *ovarian neuralgia* sometimes as if by magic, and in *dysmenorrhœa* its beneficial effect is observed when lameness and soreness are prominent symptoms, and particularly when the trouble seems to follow the great sciatic nerve. Rheumatic cases, showing marked lameness, are also said to be cases for its exhibition. It is likewise of value in *painful dysuria*, *colic*, *painful diarrhœa*, and *menstrual colic*. *Gastralgia*, *neuralgia of the stomach*, and other *abdominal viscera*, have been promptly relieved by it, and a prominent symptom in these disorders, that has been met by the drug, is the coldness of the extremities. We should remember melilotus in painful states, with coldness, and marked soreness or tenderness to the touch. Dose of specific melilotus, 1 to 10 drops; of a strong tincture, 1 to 20 drops. The leaves and flowers of these two plants (*M. officinalis* and *M. alba*) are boiled in lard, and formed into an ointment, which is found of utility as an application to all kinds of *ulcers*. The *Vanilla*, or *Seneca grass*, used for a stimulant purpose, is the *Hierochloë borealis*.

Specific Indications and Uses.—Idiopathic headaches; long-standing neuralgias; coldness, tenderness, lamenesss or marked soreness of parts; painful menstruation with lameness or sensation of cold; menstrual colic; ovarian neuralgia; colic with diarrhœa and much flatus.

Related Drugs. Tonka Beans. These are derived from the *Dipteryx odorata*, Willdenow (*Coumarouna odorata*, Aublet), a large, papilionaceous tree inhabiting Guiana. The fruit consists of an oblong-ovate, 1-seeded legume. The seed, or part employed, is somewhat 2-edged, appearing compressed, blackish-brown in color, and has a brittle, shining, or fatty-like skin, is deeply rugose, and has an oily, pale-brown kernel. The seeds possess an aromatic, bitterish taste, and a balsamic, agreeable, vanilla-like odor. The chief constituent, and the one upon which its odor depends, is *coumarin* (see *Melilotus*), which is often found between the two halves of the seeds, and upon the surface, as an efflorescence. Coumarin was first observed in Tonka beans, in 1820, by Vogel, who held it to be benzoic acid. Guibourt soon afterward declared it to be a different substance, and gave it its present name. Tonka beans are about 2 inches long. A variety known as *English Tonka beans*, are smoother, smaller, and do not contain as much coumarin as the preceding, 108 grains having been yielded by 1 pound of true Tonka beans. The English Tonka bean is the seed of *Dipteryx oppositifolia*, Willdenow. Tonka depends undoubtedly upon coumarin for its virtues. Pronounced narcotic effects have been observed from coumarin, which is also a cardiac stimulant, and finally paralyzes the heart. Dr. Laurence Johnson attributes the evil effects of cigarette smoking to this principle, for among the substances used in preparing cigarettes are plants containing coumarin, notably *Liatris odoratissima*. A fluid extract of Tonka bean has been used in *pertussis*.

FAHAM LEAVES.—The leaves of *Angræcum fragrans*, belonging to the Orchidaceæ. They have a strong and delicious aroma, and a sharp, aromatic taste. Introduced at one time in France as a substitute for ordinary tea. Fifteen grains are infused in a cup of cold water, brought to a boil for 10 minutes, poured into a closed container, and sweetened when partaken of. It comes from Mauritius and the Isle of Reunion, and contains *coumarin*.

MELISSA (U. S. P.)—MELISSA.

"The leaves and tops of *Melissa officinalis*, Linné"—(*U. S. P.*).

Nat. Ord.—Labiatæ.

COMMON NAMES: *Balm, Lemon balm.*

Botanical Source.—Balm is a perennial herb, with upright, branching, 4-sided stems, 10 to 20 inches high. The leaves are opposite, broadly ovate, acute, coarsely crenate-serrate, rugose, petioled, and more or less hairy. The flowers are pale-yellow, in axillary dimidiate verticils, and subsessile; the bracts are few, ovate-lanceolate, and petiolate. The calyx is slightly gibbous at base, 13-ribbed, flattish above, upper lip 3-toothed, lower one bifid. Corolla with a recurved-ascending tube; upper lip erect, flattish, lower lip spreading, 3-lobed, middle lobe mostly broadest. Stamens ascending (W.—G.).

History and Description.—Balm is a native of southern France, but is naturalized in various parts of Europe and the United States. It grows in fields, along roadsides, and is well-known as a garden plant, flowering from May to August. The whole plant is medicinal, and should be collected previous to its flowering. In the recent state, it has a lemon-like odor, which is nearly lost by drying. Boiling water extracts its virtues. It is officially described as follows: "Leaves about 5 Cm. (2 inches) long, petiolate, ovate, obtuse, rounded or subcordate at the base, crenate, somewhat hairy, glandular; branches quadrangular; flowers in about 4-flowered cymules, with a tubular, bell-shaped, 5-toothed calyx, a whitish or purplish bilabiate corolla, and 4 stamens; fragrant, aromatic; somewhat astringent and bitterish"—(*U. S. P.*).

The *Nepeta Cataria*, Linné, var. *B. citriodora*, a powerful emmenagogue, is sometimes cultivated and employed by mistake for balm. It has the same odor, but may be distinguished by both surfaces of its leaves being hairy.

Chemical Composition.—Balm contains a bitter substance, some tannin, gum, and a peculiar volatile oil, which is yellowish, or reddish-yellow, very limpid, about 0.89 in density, and possessing the fragrance of the plant in a very high degree. A stearopten is present in it (Bizio); the oil is soluble in 5 parts of alcohol. The yield in oil does not exceed 0.1 per cent. The infusion of balm is incompatible with nitrate of silver, acetate of lead, and sulphate of iron.

Action, Medical Uses, and Dosage.—Balm is moderately stimulant, diaphoretic, and antispasmodic. A warm infusion, drank freely, has been serviceable as a diaphoretic in *febrile diseases* and *painful menstruation*, and to assist the operation of other diaphoretic medicines; in combination with ipecacuanha and potassium nitrate, a valuable diaphoretic is formed. It is also occasionally used to assist menstruation. When given in fevers, it may be rendered more agreeable by the addition of lemon juice. The infusion may be taken *ad libitum*.

Related Species.—*Melissa cordifolia*, Persoon, is now accepted as a variety of *Melissa officinalis*. Its leaves are more woolly, larger, and have an unpleasant odor

Cedronella pallida, Lindley, and *Cedronella mexicana*, Bentham, are employed by the Mexican people as substitutes for balm.

Pogostemon Patchouly, Pelletier (*Pogostemon suave*, Tenore).—Eastern India. An aromatic plant, the dried leaves of which yield the volatile *oil of patchouly* (*patchouli*), much employed in giving lasting qualities to other odors in perfumes. The first bale of the leaves was offered in London in 1844, though the plant was known as early as 1826. Oil of patchouly is of two grades—that distilled from the selected fresh stock near the Indian plantations, and that distilled in Europe from the imported leaves. It is of a brownish-yellow color, slightly viscid. According to Gladstone (1864), the bulk of two specimens examined, boiled at 257° C. (495° F.). The residual liquid contained a strongly blue principle (*cœrulein*, or *azulene*)—of much higher boiling point, 302° C. (576° F.). It is also found in the oils of achillea, calamus, absinthium, matricaria, etc. The oil of patchouly, upon standing, deposits crystalline prisms of *patchouly camphor* ($C_{15}H_{26}O$), a stearopten which fuses at 59° C. (138.2° F.) when pure (Montgolfier). The oil has a specific gravity of 0.975 to 0.995, according to Schimmel & Co. (*Report*, April, 1897), and contains *cadinene* and *patchouly alcohol*. The leaves yield from 1.5 to 4 per cent. The oil is said to be occasionally adulterated to the extent of 60 per cent with cubeb and cedar oils (see interesting article on Patchouli, by J. C. Sawer, *Amer. Jour. Pharm.*, 1881, p. 187; also *ibid.*, 1888, p. 184, from *Kew Bulletin*). Prophylactic powers are ascribed to this plant by the Japanese, Chinese, and Arabs.

MENISPERMUM (U. S. P.)—MENISPERMUM.

"The rhizome and roots of *Menispermum canadense*, Linné"—(*U. S. P.*).

Nat. Ord.—Menispermaceæ.

COMMON NAMES: *Yellow parilla, Canadian moonseed, Moonseed sarsaparilla, Texas sarsaparilla, Vine maple.*

Botanical Source.—This plant has a perennial, horizontal, woody, very long root, of a beautiful yellow color externally, and a round, striate, climbing stem, greenish-yellow when young, 8 to 12 feet in length. The leaves are roundish, cordate, peltate, 3 to 7-angled or lobed, smooth, the petiole inserted near the base, 3 to 5 inches long, white lines radiating from the petiole on the upper surface to each angle, glaucous green above, paler below, entire, 4 or 5 inches in diameter. The flowers are small, yellow, and in axillary clusters; sepals, 4 to 8, in a double row; petals 4 to 7, minute, retuse, and shorter than the sepals. Stames 12 to 20 in the sterile flowers; anthers 4-celled. Pistils 2 to 4 in the fertile flowers, raised on a short stalk, 1 or 2 ripening into round drupes. Imperfect stamens are sometimes found in the fertile flowers. The drupes are about 4 lines in diameter, black, with a bloom resembling frost-grapes, and 1-seeded. The seeds are crescent-shaped and compressed (W.—G.).

History.—This is a valuable American remedy, not in extensive use among physicians. It grows in woods and hedges near streams, from Canada to Carolina, and west to the Mississippi, flowering in July. The rhizome, with its roots, is the official part. It has a bitter, persistent, but not unpleasant acrid taste, and yields its virtues to water or alcohol. The root of this plant has been offered in our markets as a *Texas sarsaparilla* (see *Amer. Jour. Pharm.*, Vol. XXVII, page 7).

Description.—The *U. S. P.* describes yellow parilla as follows: "Rhizome several feet long, about 5 Mm. (⅕ inch) thick, brown or yellowish-brown, somewhat knotty, finely wrinkled longitudinally, and beset with numerous thin, rather brittle roots; fracture tough, woody; internally yellowish, the bark rather thick, the wood-rays broad, porous, and longest on the lower side; pith distinct. Nearly inodorous; taste bitter"—(*U. S. P*).

Chemical Composition.—Prof. J. M. Maisch found in it a small amount of berberine, and a large quantity of a white, amorphous, bitter alkaloid, which is soluble in ether, alcohol, and in much water with alkaline reaction (*Amer. Jour. Pharm.*, 1863, p. 303). It does not dissolve in benzene or alkaline solutions, but dissolves in 20 parts of chloroform. H. L. Barber (*Amer. Jour. Pharm.*, 1884, p. 401) has shown it to differ in its properties from *menispermine* (from *Cocculus indicus*) and *oxyacanthine* (from *Berberis vulgaris*). Maisch has named it *menispine*; its taste is a pure bitter, like that of gentian. Tannin, gum, resin, and starch are also present in the drug.

Action, Medical Uses, and Dosage.—Yellow parilla is tonic, laxative, alterative, and diuretic. In small doses, no obvious effects are produced on the general system, but in larger doses, a slight increase of the volume of the pulse may be perceived, as well as increase of the appetite, and the action of the bowels. In excessive doses, purging and vomiting will follow, but no other unpleasant effect. It is a superior laxative bitter. It acts quite prominently upon the glandular structures. It was formerly much esteemed as a remedy in *scrofulous*, *cutaneous*, *arthritic*, *rheumatic*, *syphilitic*, and *mercurial diseases*. Likewise employed in *dyspepsia*, *general debility*, and *chronic inflammation of the viscera*. Externally, the decoction has been used with good effect as an embrocation in *gouty* and *cutaneous affections*. Indications seem to point to its probable value in *leucocythæmia*, especially when the spleen is prominently involved. Dose of the decoction, from 1 to 4 fluid ounces, 3 times a day; of the extract, from 2 to 6 grains, 3 or 4 times a day; or the saturated tincture, from ½ to 1 fluid drachm.

Specific Indications and Uses.—"Skin brown, tongue coated at the base, tip red, irregular appetite, constipation" (Scudder, *List of Specific Indications*).

Related Drug.—*Pangium edule*. East India. Contains an alkaloid which has been compared to *menispermine*. Anthelmintic and narcotic, and, in large doses, toxic.

MENTHA PIPERITA (U. S. P.)—PEPPERMINT.

"The leaves and tops of *Mentha piperita*, Smith"—(*U. S. P.*).

Nat. Ord.—Labiatæ.

COMMON NAME: *Peppermint*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 203.

Botanical Source.—This herb is a perennial, with procumbent, ascending, branched, reddish stems, quite smooth, or fringed, with a few spreading hairs, furrowed and quadrangular, and 2 or 3 feet in height. The leaves are ovate-oblong, or somewhat lanceolate, rounded at the base, deep-green, smooth or hairy on the under side, serrate, and borne on ciliated petioles. The flowers are in whorls, small, and purplish; upper floral leaves small, lanceolate-subulate, shorter than the flowers. The whorls are few, lax, uppermost in a short, oblong, obtuse, reddish spike; lowermost remote, with the cymes shortly stalked. Bracts subulate, outer ones as long as the calyx. Pedicels quite smooth. Calyx 5-toothed, teeth hispid, subulate, erect. The corolla is 4-cleft, tubular, with the broadest segment emarginate. Stamens 4, awl-shaped, straight, and distant; anthers with 2 parallel cells. Achenia smooth (L.—W.—G.).

Fig. 168.

Mentha piperita.

History, Description, and Chemical Composition.—Peppermint is indigenous to England, and has been extensively cultivated in various parts of Europe and throughout the United States. It grows wild in damp places, and flowers from July to September. In order to preserve the fragrance of this plant, the roots require to be reset triennially, perhaps oftener. Care must also be taken to keep out the weeds, especially *Erigeron canadense*, Linné; *Erechtites hieracifolia*, Rafinesque, and *Ambrosia trifida*, Linné. The entire herb is medicinal; it should be collected as soon as the flowers begin to develop, and be carefully dried in the shade. The whole plant has a peculiar, aromatic, diffusive odor, and an agreeable, warm, burning, bitter taste, followed by a feeling of coolness during inhalation. These properties are more marked in the fresh than in the dried plant. Both the odor and taste are retained when the plant is dried, and may be preserved for a long time. The *U. S. P.* describes it as follows: "Leaves about 5 Cm. (2 inches) long, petiolate, ovate-lanceolate, acute, sharply serrate, glandular, nearly smooth, the few hairs containing crystals of menthol in one or more thin cells; branches quadrangular, often purplish; flowers in terminal, conical spikes, with a tubular, 5-toothed, often purplish calyx, a purplish, 4-lobed corolla, and 4 short stamens; odor aromatic; taste pungent and cooling"—(*U. S. P.*). Its virtues are due to a volatile oil (see *Oleum Menthæ Piperitæ*), which is contained in little vesicles existing throughout the plant, and visible in the leaves; the oil may be obtained by distillation with water. The plant also contains tannic acid, as its infusion becomes dark-green with ferric salts. Its virtues are taken up in infusion by water, and still better by alcohol. As regards the treatment and distillation of peppermint plants, see two interesting papers by W. M. L. Weills, *Proc. Penn. Pharm. Assoc.*, 1887, p. 147, and A. M. Todd, *Amer. Jour. Pharm.*, 1888, p. 328.

Action, Medical Uses, and Dosage.—Peppermint is a powerful diffusive stimulant, antispasmodic, carminative, stomachic, and weak anodyne. It undoubtedly possesses marked antiseptic properties. Used in the treatment of *gastrodynia*, *flatulent colic*, *hysteria*, *spasms* or *cramps of the stomach*, to allay the griping of cathartics, to check *nausea and vomiting*, and to disguise the unpleasant taste of other medicines. Equal parts of the essence and alcohol, used by atomization, relieve the *cough of bronchitis* and *pneumonia*. The fresh herb, bruised and applied over the bowels, will often allay *sick stomach*, and is efficient in *cholera infantum*. The same kind of application sometimes relieves *headache*. The infusion may be drank freely; but the most usual form of administration is the essence, made by dissolving 1 fluid drachm of the oil in 1 fluid ounce of alcohol. Dose, from 10 to 60 drops, in sweetened water.

Specific Indications and Uses.—Gastrodynia, flatulent colic, and difficult digestion

MENTHA VIRIDIS (U. S. P.)—SPEARMINT.

"The leaves and tops of *Mentha viridis*, Linné"—(*U. S. P.*). (*Mentha sylvestris*, var. *glabra*, Koch.)

Nat. Ord.—Labiatæ.

COMMON NAME: *Spearmint*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 202.

Botanical Source.—Spearmint is a creeping-rooted, herbaceous plant, with erect, branching, quadrangular, smooth stems, 1 or 2 feet high. The leaves are subsessile, ovate-lanceolate, unequally serrated, and smooth; those under the flowers all bract-like, rather longer than the whorls; these last and the calyces hairy or smooth. The flowers are pale purple. Spikes cylindrical and loose. Whorls approximated, or the lowest or all of them distant; peduncles smooth, round, and shining. The calyx is bell-shaped and 5-toothed. Corolla funnel-shaped (L.—W.).

Fig. 169.

Mentha viridis.

History and Chemical Composition.—Spearmint (*Herba menthæ acutæ* [*vel Romanæ*]) is an European herb, but like the preceding species of mint, is extensively cultivated in various moist places in this country on account of its oil, and for domestic use. It flowers in July and August; the whole herb is medicinal, and should be gathered for medicinal use during dry weather and previous to the full development of the flowers. If gathered to procure its oil, it should be done after the flowers have become developed, and before the ripening of the seeds. It has a strong, peculiar, aromatic odor, and an aromatic, faintly bitter taste, followed by coolness in the mouth during inhalation. When the plant is carefully dried, these properties are preserved for a long time. Its virtues are due to a volatile oil (see *Oleum Menthæ Viridis*), which may be obtained by distillation with water. Alcohol extracts its virtues, also water by infusion. It contains a little tannin.

Description.—"Leaves about 5 Cm. (2 inches) long, subsessile, lance-ovate, acute, serrate, glandular, nearly smooth; branches quadrangular, mostly light-green; flowers in terminal, interrupted, narrow, acute spikes, with a tubular, sharply 5-toothed, calyx, a light-purplish 4-lobed corolla, and 4 rather long stamens; odor aromatic; taste pungent"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The carminative, antispasmodic, and stimulant properties of spearmint are somewhat inferior to those of peppermint;

its principal employment is for its diuretic and febrifuge virtues. As a febrifuge, it is superior to peppermint, and may be used freely in warm infusion. The cold infusion is beneficial in high color, or *scalding of urine*, *difficult micturition*, etc.; it may be used alone or in combination with marsh-mallow root. In fact, it is one of the best of simple diuretics, and acts nicely with potassium acetate. A saturated tincture of the fresh herb with gin has been found serviceable in *gonorrhœa*, *strangury*, *suppressed urine*, *gravel*, and as a local application to *painful hemorrhoids*. The oil is diuretic, stimulant, antispasmodic, and rubefacient, and is used externally in *rheumatic* and *other pains*. Dose, same as peppermint.

Specific Indications and Uses.—Scanty secretion of urine with frequent desire to urinate; simple nausea.

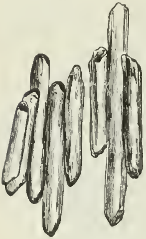
MENTHOL (U. S. P.)—MENTHOL.

Formula: $C_{10}H_{19}OH$. Molecular Weight: 155.66.

"A stearopten (having the character of a secondary alcohol), obtained from the official oil of peppermint (from *Mentha piperita*, Smith), or from Japanese or Chinese oil of peppermint (from *Mentha arvensis*, Linné, var. *piperascens*, Holmes, and *Mentha canadensis*, Linné, var. *glabrata*, Holmes. *Nat. Ord.*—Labiatæ). Menthol should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Source and Preparation.—Menthol is the solid constituent of oil of peppermint, to which its characteristic odor is due, and was formerly known as peppermint camphor. It occurs in largest quantity in the oils of peppermint known as the Chinese and Japanese oils. Our home-grown peppermint (*Mentha piperita*) yields about 20 per cent of an excellent article of menthol, of a pure mint odor, and known in trade as *pip-menthol*. It forms handsome, dry crystals, and was first prepared in this country by Mr. A. M. Todd, of Nottawa, Michigan. Analysis by the late Prof. Henry Trimble (*Amer. Jour. Pharm.*, 1884, p. 405) shows it to conform to the above formula more closely than Japanese menthol, which still contained traces of liquid hydrocarbons and also showed a slightly reduced melting point on this account. According to Mr. Todd (*Amer. Jour. Pharm.*, 1886, p. 159), menthol is obtained by subjecting the distilled oil of peppermint to a temperature of —22° C. (—7.6° F.), by the aid of a freezing mixture. The menthol crystallizes out in satiny crystals, and the mother liquor is removed while the low temperature is maintained. In rare instances, the distillate congeals at —4.4° C. (24° F.).

Fig. 170.



Crystals of Menthol.

Description.—The *U. S. P.* describes menthol as forming "colorless, acicular or prismatic crystals, having a strong and pure odor of peppermint, and a warm, aromatic taste, followed by a sensation of cold when air is drawn into the mouth. Menthol is only slightly soluble in water, but imparts to the latter its odor and taste. It is freely soluble in alcohol, ether, chloroform, carbon disulphide, or glacial acetic acid. It melts at 43° C. (109.4° F.) to a colorless liquid, boils at 212° C. (413.6° F.), and volatilizes slowly at the ordinary temperature. When it is triturated with about an equal weight of camphor, thymol, or chloral hydrate, the mixture becomes liquid. Its alcoholic solution is neutral to litmus paper, and deviates polarized light to the left"—(*U. S. P.*). Chemically, menthol is a secondary alcohol of the formula $C_6H_3(OH)CH_3C_3H_7.H_6$, or *hexa-hydro-oxy-para-cymene*, yielding, upon oxidation, a mobile, dextro-rotatory fluid (*menthone*, $C_{10}H_{18}O$), which is a ketone, and bears the same relation to menthol as Japan camphor does to *borneol* (see *Camphora*). Reversedly, menthol may be obtained from menthone by reduction with metallic sodium. The hydrocarbon (*menthene*, $C_{10}H_{18}$) is obtained by heating menthol with zinc chloride, or other dehydrating agents.

Tests.—"If a little menthol be heated in an open capsule, on a water-bath, it should gradually volatilize without leaving any residue (absence of wax, paraffin, or inorganic substances). If a few crystals of menthol be dissolved in 1 Cc. of glacial acetic acid, and then 3 drops of sulphuric acid and 1 drop of nitric acid added, no green color should be produced (absence of thymol)"—(*U. S. P.*). Cones or pencils of menthol, which are so extensively sold as a remedy for headache, neuralgia, etc., are usually largely mixed with wax, paraffin, or other foreign admixture, the presence of which is recognized by the above test.

Mr. L. F. Kebler (*Amer. Jour. Pharm.*, 1897, p. 189) recommends the quantitative determination of menthol by a modification of the process given by Prof. Power and Dr. Kleber in *Pharm. Rundschau*, 1894, p. 157. According to this process, the *combined* menthol—*i.e.*, occurring in the form of esters—is first determined by saponification of the oil with a known amount of caustic soda solution. The *total* menthol is then determined by forming an acetyl ester of menthol, and saponifying the product by a known excess of caustic soda. The amount of *free* menthol is then represented by the difference between the total and the combined menthol. (For the details of this process, consult the interesting papers quoted.)

Action, Medical Uses, and Dosage.—Menthol possesses the general properties of peppermint oil somewhat intensified. It undoubtedly has active germicidal and pronounced tonic properties. It exerts considerable anæsthetic power over parts to which it is applied, and is frequently added to ether, chloroform, etc., when they are to be used in spray for the relief of *local pains*. Paralysis of the spinal nerve centers and nerves, involving a loss of both sensation and motion, has resulted from large doses of menthol. When applied in solid form to the skin or mucous tissues, it first produced a sharp, burning sensation, soon followed by a sense of coldness with decreased sensibility of the parts. It forms a good application to *itching surfaces*, and in *pruritis vulvæ* a weak solution in olive oil has given us excellent satisfaction. It is largely used for *itching of the surface*, *cellular inflammations*, and *local pains*—such as occur in *burns*, *scalds*, *insect bites and stings*, *eczema*, *ringworm*, *urticaria*, *toothache*, *earache*, *neuralgia*, *sciatica*, *boils*, *carbuncles*, etc. In *boils of the external auditory canal*, a 20 per cent solution in oil may be applied on cotton, renewing every 24 hours. A petrolatum ointment of menthol (20 per cent) has been recommended as a stimulating agent where there is a lack of secretion of cerumen. *Coryza* and *hay fever* are frequently treated with the vapor or the direct application of a 10 to 20 per cent solution to the nostrils, and a solution of the latter strength has been recommended where thickening of the membranes give rise to *obstruction* or *stenosis of the Eustachian tubes*. *Ozæna*, *catarrhal sore throat*, *and chronic inflammation of the pharynx* are treated with the solution, while it has been used by atomization with success in *pertussis*, *asthma*, and *bronchitis of a chronic type*. Its vapor relieves irritable bronchial *cough*. Extraordinary claims regarding its effects in nebulized spray, have been advanced concerning its retarding influence and even arresting power over both *pulmonary* and *laryngeal phthisis*. These claims, however, require substantiation. Small doses sometimes allay *vomiting*, as of pregnancy, etc. The dose of menthol for internal use is from $\frac{1}{2}$ to 2 grains in pill, capsule, trituration, or olive oil; for local uses, ointments, liniments, and solutions are employed in strength ranging from 5 to 20 per cent.

Specific Indications and Uses.—Topically, to pruritic surfaces.

Related Product.—Menthiodol. Heat carefully in a capsule menthol, 4 parts, and add iodol, in fine powder, 1 part, and triturate until a uniform mass is obtained. Mold into suitable pencils or cones. If too hard, soften by remelting with a small quantity of gum camphor. A local application for *neuralgia*.

MENYANTHES.—BUCKBEAN.

The leaves and rhizome of *Menyanthes trifoliata*, Linné.

Nat. Ord.—Gentianaceæ.

Common Names: *Buckbean*, *Bogbean*, *Marsh-trefoil*, *Water-shamrock*.

Illustration: Bentley and Trimen, *Med. Plants*, 184.

Botanical Source.—This plant is perennial, has a blackish rhizome, about 5 or 6 lines in diameter, penetrating horizontally in the earth to a great distance, regularly intersected with joints at the distance of about half an inch from each other; these joints are formed by the breaking off of the old petioles and their sheaths. The leaves proceed from the end of the rhizome on long stalks furnished with broad, sheathing stipules at the base; are trifoliate, nearly oval, glabrous somewhat fleshy, slightly repand, or furnished with many irregular [illegible] at the edge, which hardly prevent them from being entire. The scape is round, ascending, smooth, about a foot high, bearing a conical raceme of flowers. Peduncles straight, supported by ovate, concave bracts. Calyx erect, somewhat campanulate, 5-parted and persistent. Corolla white; its tube short, border 5-cleft, spreading, at length revolute, and clothed on the upper part with a coating of dense, fleshy, obtuse hairs. Stamens 5, shorter than the corolla, and alternate with its segments; anthers oblong, arrow-shaped. Ovary ovate; stigma bifid and compressed. Capsule ovate, 2-valved, and 1-celled; seeds numerous and minute (L.). Its flowers are flesh color or pale lilac.

History.—Buckbean is indigenous to this country and Europe, growing in spongy, boggy soils, swamps, ditches, etc., flowering from April to August. The whole plant possesses medicinal properties, but the root and leaves are the parts more generally employed. The whole plant is nearly odorless, but has a very bitter, somewhat aromatic taste. Water, or alcohol, takes up its active properties. Infusions of the leaves, saccharated by adding simple syrup, gelatinize through the presence of pectin; if the latter is removed by alcohol, no gelatinization takes place (see *Amer. Jour. Pharm.*, 1881, p. 360).

Chemical Composition.—*Menyanthes trifoliata* contains a bitter, glucosidal principle, first isolated, in 1861, by Ludwig and Kromayer, and called *menyanthin.* Karl Lendrich, in 1892, gave an improved method of obtaining menyanthin (*Archiv der Pharm.*, 1892, p. 38), and found it to have the formula $C_{33}H_{50}O_{14}$. It is a neutral body of bitter taste, and yellow color, soluble in alcohol and hot water; soluble with difficulty in cold water and ether. Although menyanthin contains no nitrogen, it strangely enough responds to alkaloidal reagents, such as Mayer's solution, tannic acid, etc. Diluted alkalies or acids cause it to split into a resinous product, a lævo-rotatory sugar, and a volatile, sweetish, aromatic oil, *menyanthol* $(C_7H_{11}O_2)_n$, which is both an aldehyde and a phenol. Contrary to some statements, it has not the odor of bitter almond oil.

Action, Medical Uses, and Dosage.—Buckbean, when recent, and given in large doses, usually causes emesis. It is, when dried, tonic and astringent, or purgative, according to the dose. It is valuable as a tonic where digestion and blood making are impaired, and particularly when there is an associated *uterine disease* or irregularity, or when following the use of quinine in *malarial disorders* (Scudder). For this purpose, a strong tincture of the fresh leaves may be given in doses of from 1 to 10 minims. It has been given in *dyspepsia*, *intermittent* and *remittent fevers*, with advantage; and has been highly recommended in *chronic rheumatism*, *hepatalgia*, *dropsy*, *worms*, and some *cutaneous diseases*, and as a tonic in *scrofula*, and various *cachectic affections*. As a tonic, the powdered root or herb may be given in doses of from 10 to 25 grains; of the aqueous extract, 5 or 10 grains; of the infusion (made by infusing 2 drachms of the herb or root in 4 fluid ounces of water at 212° F.), a fluid ounce or two; repeating the dose of either every 3 or 4 hours. Sixty grains of the powder, or 4 fluid ounces of the infusion, produce catharsis, and sometimes emesis.

METHYLENI BICHLORIDUM.—METHYLENE BICHLORIDE.

FORMULA: CH_2Cl_2. MOLECULAR WEIGHT: 84.71.

SYNONYMS: *Methene dichloride, Bichloride of methylene, Methylene dichloride, Monochlorinated chloride of methyl, Chlorinated chloride of methyl, Dichloromethane, Dichlormethane, Chloro-methyl, Methene chloride.*

History and Preparation.—This substance may be considered the second substitution product of the action of chlorine upon methane (*marsh gas*), CH_4, the first product being gaseous methyl chloride, or chloromethane, CH_3Cl. It was discovered, in 1840, by Regnault; Dumas and Peligot having prepared chloride of methyl about five years previously. It is difficult to prepare, and is seldom found in commerce. It is formed when chlorine gas is passed into di-iodomethane covered with water, the retort containing it being at the same time heated; iodine separates in crystals, and an oily liquid (*dichloromethane*), with impurities, passes into the cooled receiver. This is purified by prolonged contact with chlorine, then distilling from solution of potash, agitating with calcium chloride, and redistilling to separate water. It may also be made (Regnault's process) by chlorination of methyl chloride (CH_3Cl), bringing the gases together in the sunlight, and afterward separating the methene dichloride by fractional condensation; also by the action of chlorine on methyl iodide, thus: $CH_3I+Cl_2=CH_2Cl_2+HI$. Another process consists in treating chloroform in alcoholic solution with zinc and sulphuric acid as follows: $CHCl_3+H_2=CH_2Cl_2+HCl$.

Description and Adulterations.—*Dichloride of methene* is a colorless liquid, of a sweet, chloroform-like odor, of specific gravity 1.360 at 0° C. (32° F.), and boiling at 40° C. (104° F.) (Butlerow). According to Watts and others, Regnault's preparation boils at 30.5° C. (87° F.), has a specific gravity of 1.344 at 18° C. (64.4° F.), is very volatile, and resembles Dutch Liquid. It is dissolved by alcohol or ether, does not affect test papers, and emits a vapor that is readily combustible.

It is stated that chloroform has been substituted for methene dichloride, but the fraud can be readily detected by the specific gravity, unless the adulterating liquid be reduced to the gravity of methene by the addition of ether. In this case, the odor of ether will be apparent. Should a mixture of chloroform and absolute alcohol be prepared and substituted, agitation with cold distilled water will separate the alcohol, and the difference in bulk will reveal the fraud, while specific gravity of the heavy liquid will be found greater than 1.360.

Action, Medical Uses, and Dosage.—Bichloride of methylene has been proposed by Richardson, Wells, and others, as an anæsthetic. The inhalation of its vapor is rather agreeable, its influence occurs without any unpleasant sensations, and the return to consciousness is rapid and without any feeling of prostration. Vomiting frequently accompanies its administration, and occasionally, a very obstinate period of agitation and struggling. It has been considered less dangerous than chloroform, though Richardson states that it is one of a dangerous family of chemical substances, involving more or less risk, unless used with great care. Spencer Wells, the celebrated ovariotomist, having employed it in nearly one thousand cases, in the course of a surgical practice of ten years, recommends it as more effective and less dangerous than any other known anæsthetic; yet, notwithstanding these commendations, and their confirmation by several other surgeons, the substance has not come into general use in surgical practice. The quantity required for inhalation varies from 20 to 40 minims; and 10 or 20 minims subsequently, if required, whenever symptoms of a return to consciousness begin to manifest themselves. The use of this vapor, undiluted, is unsafe; it should always be inhaled in association with a certain quantity of atmospheric air; and for this purpose, a hollow cone, of metal or pasteboard, perforated with numerous apertures, has been advised. The material upon which the liquid has been poured, is to be placed within the cone, and the vapor be inhaled therefrom. Wells recommends Junker's apparatus for this purpose. Messrs. Regnault and Villejean make the statement (*Amer. Jour. Pharm.*, 1884, p. 646) that the methylene chloride at one time supplied to surgeons, was often nothing but a mixture of chloroform and methylic alcohol. Pure dichloride of methylene prepared by them, differed markedly from chloroform in its physiological action, excepting that both agencies produce unconsciousness. The pure methylene chloride, however, produced constant symptoms of an alarming character.

Related Compounds.—METHYLENE, or ENGLISH METHYLENE CHLORIDE. This is not the above substance, and should not be confounded with it, as it is not a definite chemical compound, but simply a mixture of ether and methylene chloride. It has anæsthetic properties. Richardson declared it a safe anæsthetic in doses of from 1 fluid drachm to ½ fluid ounce. Others, however, regard it as a dangerous agent and one to be altogether avoided. According to Helbing, a second product has been sold as methylene chloride. It is a mixture of methyl chloride and chloroform.

METHYL CHLORIDE, *Monochlormethane* (CH_3Cl), *Chlormethyl.*—This compound is produced by the action, in the presence of a small quantity of zinc chloride, of hydrochloric acid gas upon methylic alcohol. It is also formed by heating the hydrochloride of trimethylamine ($N[CH_3]_3.HCl$) to a temperature of 260° C. (500° F.) It is thus obtained as a colorless gas, with an ethereal smell. Ignited it burns with a green-edged flame. At —23° C. (—9.4° F.) it condenses to a fluid. Likewise a pressure of 5 atmospheres, at common temperature, reduces it to a liquid. It dissolves in ether, alcohol, and chloroform, but less readily in water. By employing the condensed liquid in the form of a spray, it is used as a freezing agent to produce *local anæsthesia*. Reputed success has attended its use in *sciatica* (Debove), the parts over the nerve being treated with its spray.

METHYLI IODIDUM.—METHYL IODIDE

FORMULA: CH_3I. MOLECULAR WEIGHT: 141.50.

Preparation and History.—Equal proportions of anhydrous methylic alcohol and potassium iodide are mixed together in a retort, and a stream of dry hydrochloric acid is passed into the mixture. Upon warming, iodide of methyl distills. It is now chiefly prepared by a modification of the method employed, in 1835, by its discoverers, Dumas and Peligot—namely, by the interaction of pure wood alcohol (35 parts), iodine (100 parts), and *red* (amorphous) phosphorus (10 parts). The reaction which takes place is as follows: $10CH_3OH+I_{10}+P_2=10CH_3I+{}_2PO_4H_3+2H_2O$.

Description.—Methyl iodide is a heavy, colorless liquid, having a sweetish, ethereal odor. Its specific gravity at 0° C. (32° F.) is 2.199; at 15° C. (59° F.), 2.23; its boiling point, 42.8° C. (109° F). At a low temperature it forms, with water, a crystalline hydrate ($CH_3I.H_2O$). It gradually turns brown when exposed to light, and ignites with difficulty, burning with evolution of violet fumes of iodine.

Action, Medical Uses, and Dosage.—This agent was introduced as an anæsthetic by Richardson, in 1868. While a powerful anæsthetic, it is equally a dangerous one. It is very liable to decompose, and, when it does so, it produces the irritant effects of iodine. After anæsthesia under its use, the effects last for many days. It will not come into use for operative purposes. It has more recently (1884) been given internally as a sedative, and to quiet pain and hyperæsthesia in *cancer of the mammæ and womb*. Richardson so employed it, using 1 grain of the iodide in 10 minims of alcohol.

Related Compounds.—METHYLENI IODIDUM (*Methyleni biniodidum*), CH_2I_2. Molecular Weight: 267.03. This compound was first prepared by the interaction of sodium ethylate (C_2H_5ONa) and iodoform (Butlerow). It may conveniently be prepared by heating for some hours, at about 130° C. (266° F.), a mixture of strong hydriodic acid and chloroform. It is a yellow fluid, congealing at about 0° C. (32° F.). Its specific gravity is 3.34; its boiling point, 180° C. (356° F.). Partial decomposition ensues at the boiling point.

METHYL FLUORIDE is asserted by H. Moissan to be anæsthetic.

METHYL SALICYLAS (U. S. P.)—METHYL SALICYLATE.

FORMULA: $CH_3C_7H_5O_3$. MOLECULAR WEIGHT: 151.64.

"Methyl salicylate, produced synthetically. It should be kept in well-stoppered bottles, protected from light"—(*U. S. P*).

SYNONYMS: *Artificial* (or *Synthetic*) *oil of wintergreen*.

Preparation.—G. M. Beringer's (*Amer. Jour. Pharm.*, 1887, p. 8) method is essentially as follows: In 2 fluid ounces of absolute methylic alcohol dissolve ½ ounce of salicylic acid, and add gradually to the solution 1 fluid ounce of sulphuric acid. Heat gently for a day. Distill from a retort into which a jet of steam is injected. Wash the distillate thoroughly and decant the product. The odor of the product is said to improve by time. In the bark of *Betula lenta* methyl salicylate results from the decomposition of *gaultherin*, a bitter, crystallizable glucosid discovered, in 1843, by Prof. Procter, and recently investigated by Schneegans and Gerock. (See review by F. X. Moerk, in *Amer. Jour. Pharm.*, 1895, p. 8; also see an interesting review of the occurrence of methyl salicylate in plants, by Prof. Henry Kraemer, in *Amer. Jour. Pharm.*, 1898, p. 412).

Description and Tests.—It is asserted that artificial oil of wintergreen is more uniform in quality, and gives better results than the natural oils from birch or gaultheria. It is now very extensively used. Methyl salicylate, according to the *U. S. P.*, is "a colorless, or slightly yellowish liquid, having the characteristic, strongly aromatic odor, and the sweetish, warm, and aromatic taste of oil of gaultheria, with the essential constituent of which it is identical. It is wholly identical with volatile oil of betula (see *Oleum Betulæ Volatile*). Specific gravity 1.183 to 1.185 at 15° C. (59° F.). Boiling point 219° to 221° C. (426.2° to 429.8° F.). It is optically inactive. Soluble, in all proportions, in alcohol, glacial acetic acid, or carbon disulphide. The alcoholic solution is neutral or slightly acid to litmus paper. If a drop of methyl salicylate be shaken with a little water, and a drop of ferric chloride T.S., subsequently added, a deep-violet color will be produced. When heated on a water-bath, in a flask provided with a suitable condenser, it should yield no distillate having the characteristics of alcohol or chloroform. If to 1 Cc. of methyl salicylate, contained in a capacious test-tube, 10 Cc. of sodium hydrate T.S., be added, and the mixture agitated, a bulky, white, crystalline precipitate will be produced; then, if the test-tube, loosely corked, be allowed to stand in boiling water for about 5 minutes, with occasional agitation, the precipitate should dissolve, and form a clear, colorless, or faintly yellowish solution, without the separation of any oily drops, either on the surface or at the bottom of the liquid (absence of other volatile oils, or of petroleum). If the alkaline liquid thus obtained be subsequently diluted with about 3 times its volume of water, and a slight excess of hydrochloric acid added, a white, crystalline precipitate will be produced, which, when collected on a filter, washed with a little water, and recrystallized from hot water, should respond to the tests of identity and purity described under *Acidum Salicylicum* (absence of methyl benzoate, etc.)"—(*U. S. P.*).

Action and Uses.—Same as for oil of wintergreen (see *Oleum Gaultheriæ*)

MEZEREUM (U. S. P.)—MEZEREUM.

"The bark of *Daphne Mezereum*, Linne, and other species of *Daphne*"—(*U.S.P.*).

Nat. Ord.—Thymelæaceæ.

COMMON NAME AND SYNONYMS: *Mezereon-bark; Mezerei cortex, Cortex mezerei, Cortex thymeleæ, Cortex coccognidii.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 225, 226, 227.

Botanical Source.—DAPHNE MEZEREUM. *Mezereon*, or *Spurge olive*, is a weather-proof shrub, with a large root and bushy stem, 4 or 5 feet high, with upright alternate, smooth, tough, and pliant branches, leafy when young, and a smooth, dark-gray bark, which is not strongly attached to the wood. The leaves are terminal on the branches, scattered, stalked, lanceolate, smooth, deciduous, 2 inches long, appearing after the flowers, and soon accompanied by flower-buds for the next season. The flowers are highly fragrant, of a pale-rose color, in little clusters on the naked branches, with several brown, smooth, ovate bracteas underneath. Calyx tubular, hairy externally, like a corolla in texture, and crimson all over; limb in 4 deep, ovate, spreading, colored segments. Stamens 8; filaments short, in 2 rows, from about the middle of the tube; anthers roundish-oblong, 2-celled, simple, and inclosed within the tube. Ovary superior, ovate; style short and terminal; stigma capitate, depressed, and entire. The berry is scarlet, pulpy, oval, 1-celled, and 1-sided; the seed suspended, oval, and large, with a thin brittle skin (L.).

DAPHNE GNIDIUM is a small bush, with the leaves linear-lanceolate, clustered, acuminate, cuspidate, and quite smooth. The flowers are numerous, small, white, downy, and fragrant, in terminal, panicled racemes. The fruit is globular, dry, at first green, but ultimately black (L.).

DAPHNE LAUREOLA, or *Spurge-laurel*, is a smooth plant, with a stem 2 or 3 feet high, round, pale, brown, upright, tough, and pliant branches, crowned with tufts of evergreen leaves, elegantly drooping in all directions, about 2 or 3 inches long, lanceolate, glabrous, acute, entire and subsessile. The flowers are deep-green, with orange anthers, 4 of which are just visible in the throat of the calyx, 5 together in each axillary raceme. An oval, concave bract accompanies each short partial stalk, at the base. Berry oval and black (L.).

History and Description.—All species of Daphne possess active properties, but the bark met with in commerce is usually obtained from the three above described, that from the latter being less active than the others. The *D. Mezereum* is a native of the northern parts of Europe, where it is cultivated both as a medicine and as an ornament; it flowers very early in the spring, often before the snow has disappeared. This species is the most active plant of the genus; its bark is generally collected in the spring. It is met with in flat or quilled pieces, a few feet in length, and from 8 to 12 lines in breadth, and put up in packages which are often globular. Alcohol takes up its virtues, also boiling water. Oils or fats boiled with it, likewise take up its active principles and form ointments. The *D. Gnidium* is found in the south of France on hills and barren plains, and its bark is employed equally with that of the other kinds; the root-bark is also used in medicine. The barks of the three species constitute the official drug, which is described as follows: "In long, thin bands, usually folded or rolled into disks: outer surface yellowish or brownish-yellow, with transverse scars, and minute, blackish dots, underneath of a light-greenish color; inner surface whitish, silky; bast in transverse layers, very tough; inodorous; taste very acrid"—(*U. S. P.*). The leaves of *D. salicifolia*, Kunth, of Mexico, are used in that country as an epispastic.

Chemical Composition.—The active principle of the bark of *Daphne Mezereum* is an *acrid resin* soluble in alcohol and ether, insoluble in water Buchheim); it is probably formed by oxidation of *volatile oil* present in the bark. The latter also contains wax, yellow coloring matter, sugar, nitrogenous and gummy matter, malic acid and malates, and *daphnin*, a crystallizable odorless, neutral substance of bitter, somewhat astringent taste, discovered in 1812 by Vauquelin, in the bark of *D. alpina*, and by Gmelin and Bär (1822) in the bark of *D. Mezereum*. Zwenger (1860) found it to be a glucosid, of the formula $C_{15}H_{16}O_9+2H_2O$. It is but little soluble in cold water or alcohol, but readily soluble in hot water or alcohol, insoluble in ether. By boiling with diluted acids, or under the influence of certain ferments, daphnin is decomposed into sugar and *daphnetin*, a crystallizable body having the odor of coumarin; it was found by Stünkel (1879) to be *dioxycoumarin* ($C_6H_2[OH]_2.CHCH.COO$). *Umbelliferon* (see *Galbanum*), an isomer of daphnetin, was obtained by Zwenger (1854) upon dry distillation of mezereum-resin. In the *fruit*, A. Casselmann (*Jahresb. der Pharm.*, 1870, p. 62 determined the presence of 31 per cent of a fatty, drying oil, 5.46 per cent ash, 0.32 per cent of an acrid resin soluble in alcohol, and 0.38 per cent of *coccognin*, a crystallizable substance not identical with daphnin. It is soluble in alcohol and alkalies, soluble with difficulty in hot water, insoluble in cold water and in ether. Upon being heated it sublimes with partial decomposition, the odor of coumarin being developed.

Action, Medical Uses, and Dosage.—In large doses, mezereon is an irritant poison, causing redness and vesication of the skin when left in contact with it, and causing when swallowed, dryness and burning of the throat, vomiting, hypercatharsis, and frequently renal irritation. The berries have proved fatal to children who have eaten them; yet in some countries they are used as a purgative in doses of 8 to 12. In small doses it acts as a stimulant, alterative, diuretic, diaphoretic, in warm decoction, and cathartic. It acts favorably in *syphilis*, *mercurio-syphilis*, *scrofula*, *chronic rheumatism*, and some forms of *obstinate disease of the skin.* Dose of the decoction, from 1 to 3 fluid ounces; of the powder, 10 grains. Homœopathists regard it highly in the treatment of the *periosteal pains* and *nodes* following syphilitic infection, and in *rheumatic*, and even in *syphilitic periostitis*.

Externally, it is used occasionally; sometimes employed by practitioners to produce rubefaction and vesication, and in the form of ointment as an application to *blistered surfaces*, *indolent ulcers*, and *issues*, in order to excite suppuration. When vesication is desired, the bark is soaked in hot vinegar and water to soften it, and then applied to the part by a compress and bandage. The application is to be renewed night and morning, until vesication is produced.

MICA PANIS.—CRUMB OF BREAD.

The soft portion of bread made from wheaten flour was official under the above title in the *British Pharmacopœia* of 1885. Bread crumb is employed as a pill-excipient, and is a constituent of the former British charcoal poultice and of several emollient cataplasms. Corn meal is generally used in this country in making charcoal poultice.

MIMULUS.—HAIRY MONKEY-FLOWER.

The plant *Mimulus pilosus*, Watson.
Nat. Ord.—Scrophulariaceæ.
COMMON NAME: *Hairy monkey-flower*.

Botanical Source.—This is a small annual plant, a native of California, and found growing in damp situations. It has an erect, angular stem, less than a foot high, and much branched from near the base. The entire plant is covered with soft and sticky hairs, whence the specific name. The leaves are opposite, from 1 to 2 inches long, sessile, and entire. The flowers are small, bright-yellow, and are borne on short axillary peduncles; they appear in July and August. The corolla is about ¼ of an inch in length, and 2-lipped; it has a broad tube, a 2-lobed, erect upper lip, and a 3-lobed lower lip, bearing 2 purple spots. The calyx is bell-shaped, slightly shorter than the corolla-tube, and has 5 unequal teeth. The fruit is a dry, 2-celled capsule, containing many seeds. This plant has never been examined chemically.

Action, Medical Uses, and Dosage.—This plant is of rather recent introduction to the profession, and deserves further investigation. A local application of the plant, in the form of a cataplasm, made either by bruising the leaves, or by steeping them in hot water, is reputed very efficient in *local inflammations* and *painful affections*, as in *rheumatism, neuralgia, erysipelas, burns*, etc. A tincture of the plant, in the dose of from 3 to 10 minims, repeated 3 or 4 times a day, will likewise be found beneficial in *rheumatism, neuralgia*, and other painful disorders. In *cardiac affections*, the sequence of rheumatic attacks, it has proved very serviceable, in several cases. In *obstinate bronchial* and *laryngeal affections*, I have derived much benefit from the use of a tincture, made with diluted alcohol, in the form of spray. It is probable that some of the other species of Mimulus possess similar properties (J. King).

MISTURÆ.—MIXTURES.

Mixtures include those liquid preparations containing oleaginous, mucilaginous, albuminous, or saccharine substances, which are used internally, and can not properly be classed with infusions, decoctions, syrups, tinctures, emulsions, etc.; also pharmaceutical compounds in which insoluble substances, whether liquid or solid, are suspended in aqueous fluids by the intervention of viscid substances.

As a rule, those preparations containing oily substances in suspension belong with *emulsions*, although compounds not easily classified, as will be seen below, are included under the elastic term *mixture*. *Saturations* are effervescing draughts prepared by neutralizing with a carbonate solutions of a vegetable acid, like citric and tartaric acids, the container being tightly corked to prevent the escape of carbonic acid gas.

Guttæ are mixtures that are to be administered by drops. If designed to be taken at one or a few doses, a mixture is sometimes called a *Haustus, Potion*, or *Draught*. A sweetened, aromatic mixture, containing a medicated water or an essential oil, is denominated a *Julep* (*Julapium*); a sweet, syrupy mixture, a *Linctus*.

MISTURA ACACIÆ (N. F.)—MIXTURE OF ACACIA.

SYNONYM: *Mixtura gummosa* (*Ger. Pharm.*, I).

Preparation.—"Acacia, in coarse powder, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; sugar, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.], water, eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏]. Dissolve the acacia and sugar in the water. This preparation should be freshly made when wanted for use"—(*Nat. Form*).

Uses.—(See *Acacia*.)

MISTURA ADSTRINGENS ET ESCHAROTICA (N. F.)
ASTRINGENT AND ESCHAROTIC MIXTURE.

SYNONYM: *Villate's solution*.

Preparation.—"Solution of lead subacetate (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; copper sulphate, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; zinc sulphate, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; diluted acetic acid (*U. S. P.*), eight hundred and fifty cubic centimeters (850 Cc.) [28 fl℥, 356 ♏]. Dissolve the copper sulphate and zinc sulphate in the diluted acetic acid, add the solution of lead subacetate, and agitate thoroughly. Set the mixture aside so that the precipitate may subside. Then decant, or siphon off, the clear liquid and preserve it for use. *Note.*—In attempting to pass the liquid through a filter, it will usually be found that the finely divided precipitate of lead sulphate will partially pass along with it. This may be prevented (in this and many similar cases) by adding to the mixture a small quantity of starch, thoroughly incorporating this by agitation, and pouring the mixture on the previously wetted filter. The first portions of the filtrate are poured back until it runs through clear"—(*Nat. Form.*).

Action and Medical Uses.—This fluid mixture is designed as an astringent and escharotic.

MISTURA ALTERANTIÆ COMPOSITA.—COMPOUND TONIC MIXTURE.

Preparation.—Take of sulphate of iron, 1 drachm; phosphate of sodium, 6 drachms; sulphate of quinine, 192 grains; strychnine, 6 grains; white sugar, 14 ounces; diluted phosphoric acid, 14 fluid ounces; aqua ammoniæ, diluted sulphuric acid, water, boiling water, each, a sufficient quantity. Dissolve the sulphate of iron in 1 fluid ounce of the boiling water, also dissolve the phosphate of sodium in 2 fluid ounces of the boiling water. Mix these 2 solutions, and wash the precipitate (phosphate of iron) until the washings pass tasteless. Dissolve the sulphate of quinine in 2 fluid ounces of the water, with the aid of a sufficient quantity of the diluted sulphuric acid, and then add the solution of ammonia, a sufficient quantity, to precipitate the quinine, and thoroughly wash this precipitate. Add the phosphate of iron and the quinine thus obtained, together with the strychnine, to the diluted phosphoric acid, and when they are dissolved, add the sugar; dissolve without heat.

Action, Medical Uses, and Dosage.—Of this mixture, which is similar to the syrup of Easton, Prof. J. M. Scudder observes: "A very important object in the treatment of many forms of chronic disease, is to restore the tone of the stomach and bowels, and give better innervation through the ganglionic nerves. The loss of power in the worst cases (as in *secondary syphilis*) is sometimes so great that it requires powerful means to accomplish the object. It is in these cases especially, that this combination will be found most effective. This is one of the most powerful combinations I have ever employed to restore the action of the ganglionic system of nerves, the appetite, and the functions of digestion and nutrition. It may be employed in any *cachectic diseases*, or where the blood is deficient in quantity and quality, with imperfect innervation. It is also an excellent remedy in *periodical diseases*, as well as a prophylactic against them. The dose is from 15 minims to 1 fluid drachm."

MISTURA CAJUPUTI COMPOSITA.—COMPOUND CAJEPUT MIXTURE.

SYNONYM: *Hunn's drops.*

Preparation.—Take of oils of cajeput, cloves, peppermint, and anise, each, 1 fluid ounce; rectified alcohol, 4 fluid ounces. Dissolve the oils in the alcohol.

Action, Medical Uses, and Dosage.—This is a very valuable stimulant and antispasmodic preparation, and has been successfully used in *colic, cramp of the stomach*, or elsewhere, *flatulence, pains in the stomach* or *bowels, painful diarrhœa, cholera morbus, Asiatic cholera*, and in all cases where stimulant and antispasmodic action is desired. During the *cholera* of 1849–51, it was extensively used in Cincinnati for the purpose of overcoming violent spasmodic action, in the doses of 1 or 2 fluid drachms, every 10 or 15 minutes; 1 or 2 doses generally succeeded in relieving the pains and spasms when all other means had failed. The ordinary dose is from 10 drops to ½ fluid drachm. It should be given in simple syrup, mucilage of slippery-elm, or in hot brandy and water sweetened. Care should be taken not to give too much of this preparation, as a large amount would produce inflammation of the stomach. It is a very valuable agent when properly used, and should be kept by every physician and druggist (J. King).

MISTURA CAMPHORÆ COMPOSITA.—COMPOUND MIXTURE OF CAMPHOR.

Preparation.—Take of camphor water, peppermint water, and spearmint water, each, 1 fluid ounce; camphorated tincture of opium, 2 fluid drachms. Mix.

Action, Medical Uses, and Dosage.—This is a very efficient agent in allaying *nausea* and *vomiting*. It was extensively and successfully employed in Cincinnati in the nausea and vomiting attending *Asiatic cholera*. It possesses the virtues of the several articles entering into its composition, without the stimulating influence of the alcohol (which enters into their tinctures), upon already partially-inflamed mucous surfaces. The dose is from a teaspoonful to a tablespoonful, every 5 minutes, if the patient be vomiting, and every 10 minutes if he be only nauseated (J. King). This preparation may be employed in *painful states* due to gaseous distension of the intestines.

Other Camphor and Diarrhœa Mixtures.—Mistura Camphoræ Acida (N. F.), *Acid camphor mixture*, *Mistura antidysenterica*, *Hope's mixture*. "Nitric acid (*U. S. P.*), seventeen and one-half cubic centimeters (17.5 Cc.) [284 ♏]; tincture of opium (*U. S. P.*), twelve cubic centimeters (12 Cc.) [195 ♏]; camphor water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the nitric acid with about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of camphor-water, add the tincture of opium, and, lastly, enough camphor water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Mistura Contra Diarrhœam (N. F.), *Diarrhœa mixture*, *Cholera mixture*.—1. "Tincture of opium (*U. S. P.*), tincture of capsicum (*U. S. P.*), tincture of rhubarb (*U. S. P.*), spirit of camphor (*U. S. P.*), spirit of peppermint (*U. S. P.*), of each, twenty cubic centimeters (20 Cc.) [325 ♏]. Mix them and filter. *Note.*—The formula above given, which appears to be that in most general use, is also known under the name of 'Sun Mixture.' Of other similar preparations, in more or less general use, the following may be mentioned here:

2. *Loomis' diarrhœa mixture.*—"Tincture of opium (*U. S. P.*), twelve and one-half cubic centimeters (12.5 Cc.) [203 ♏]; tincture of rhubarb (*U. S. P.*), twelve and one-half cubic centimeters (12.5 Cc.) [203 ♏]; compound tincture of catechu (*U. S. P.*), twenty-five cubic centimeters (25 Cc.) [406 ♏]; oil of sassafras, one cubic centimeter (1 Cc.) [16 ♏]; compound tincture of lavender (*U. S. P.*), forty-nine cubic centimeters (49 Cc.) [1 fl℥, 315 ♏].

3. *Squibb's diarrhœa mixture.*—"Tincture of opium (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; tincture of capsicum (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; spirit of camphor (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 ♏]; chloroform (*U. S. P.*) seven and one-half cubic centimeters (7.5 Cc.) [122 ♏]; alcohol, thirty-two and one-half cubic centimeters (32.5 Cc.) [1 fl℥, 47 ♏].

4. *Thielemann's diarrhœa mixture.*—"Wine of opium (*U.S.P.*), twenty-five cubic centimeters (25 Cc.) [406 ♏]; tincture of valerain (*U. S. P.*), thirty-seven and one-half cubic centimeters (37.5 Cc.) [1 fl℥, 129 ♏]; ether (*U. S. P.*), twelve and one-half cubic centimeters (12.5 Cc.) [203 ♏]; oil of peppermint, three cubic centimeters (3 Cc.) [49 ♏]; fluid extract of ipecac (*U. S. P.*), three-fourths of a cubic centimeter (0.75 Cc.) [12 ♏]; alcohol, twenty-one and one-fourth cubic centimeters (21.25 Cc.) [345 ♏]. This preparation is practically identical with the Mistura Thielemanni of the *Swedish Pharm.*

5. *Velpeau's diarrhœa mixture.*—"Tincture of opium (*U.S.P.*), compound tincture of catechu (*U. S. P.*), spirit of camphor (*U. S. P.*), of each, thirty-three and one-third cubic centimeters (33.33 Cc.) [1 fl℥, 61 ♏]"—(*Nat. Form.*).

MISTURA CHENOPODII COMPOSITA.—COMPOUND WORMSEED MIXTURE.

Synonym: *Worm mixture.*

Preparation.—Take of castor oil, 1 fluid ounce; wormseed oil, anise oil, and tincture of myrrh, of each 1 fluid drachm. Mix (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This is an excellent vermifuge, and may be used in doses of one teaspoonful for an adult, to be repeated three or four times a day, and after having been taken for three successive days, to be followed by a cathartic. This somewhat resembles *Fahnestock's Vermifuge*, which is said to be composed of castor oil, 1 fluid ounce, oil of wormseed, 1 fluid ounce; oil of anise, ½ fluid ounce; tincture of myrrh, ½ fluid drachm; oil of turpentine, 10 minims; croton oil, 1 minim. Mix. The dose is a teaspoonful for an adult, every 2 hours, to be continued for 10 or 12 hours.

MISTURA CHLORALI ET POTASSII BROMIDI COMPOSITA (N. F.)

COMPOUND MIXTURE OF CHLORAL AND POTASSIUM BROMIDE.

Preparation.—"Chloral (*U. S. P.*), two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; potassium bromide, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; extract of Indian cannabis (*U. S. P.*), two grammes (2 Gm.) [31 grs.]; extract of hyoscyamus (*U. S. P.*), two grammes (2 Gm.) [31 grs.]; alcohol, sixty cubic centimeters (60 Cc.) [2 fl℥. 14♏]; tincture of quillaja (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥. 95 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the chloral and potassium bromide in six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of water, dissolve in this solution the extract of hyoscyamus, and add the tincture of quillaja. Then dissolve the extract of Indian cannabis in the alcohol, and add this solution gradually, and under shaking, to that first prepared. Finally, add enough water to make one thousand cubic centimeters This preparation should be shaken whenever any of it is to be dispensed. Each fluid drachm contains 15 grains each of chloral and potassium bromide, and ⅛ grain each of extract of Indian cannabis and of extract of hyoscyamus. *Note.*—The resinous extract of Indian cannabis, is merely held in suspension by means of the tincture of quillaja, as it is practically insoluble in the liquid. If the mixture is filtered, the resin will remain on the filter"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Chloral and Potassium Bromide.*) Dose, from ½ to 1 fluid drachm.

MISTURA CHLOROFORMI ET CANNABIS INDICÆ COMPOSITA (N. F.)

COMPOUND MIXTURE OF CHLOROFORM AND CANNABIS INDICA.

SYNONYM: *Chloroform anodyne.*

Preparation.—"Chloroform, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; ether, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; tincture of Indian cannabis (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; tincture of capsicum (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; morphine sulphate, two and one-half grammes (2.5 Gm.) [39 grs.]; oil of peppermint, two cubic centimeters (2 Cc.) [32 ♏]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; water, sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the oil of peppermint in five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of alcohol, add the chloroform, ether, and the tinctures. Mix well, and add the morphine sulphate, previously dissolved in the water and glycerin. Finally, add enough alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Each fluid drachm represents about 7½ minims of chloroform; 7½ minims of tincture of Indian cannabis; 3¾ minims of tincture of capsicum; and ⅐ of a grain of morphine sulphate"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This mixture is employed for the relief of *painful conditions*, and is similar to the various preparations that have been known as *Chlorodyne*. The average dose is 1 fluid drachm (see also *Mistura Chloroformi et Opii* [N. F.], which is also called *Chloroform anodyne*).

MISTURA COPAIBÆ COMPOSITA.—COMPOUND COPAIBA MIXTURE.

SYNONYM: *Diuretic drops.*

Preparation.—Take of spirit of nitrous ether and oil of almonds, each, 1 fluid ounce; copaiba and oil of turpentine, of each, ½ fluid ounce; camphor, in powder, 10 grains. Mix the liquids, then add the camphor, and agitate briskly (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This forms a diuretic mixture, which has been successfully and extensively used in *gonorrhœa*, *gleet*, *scalding of urine*, and *urinary affections*. The dose is 1 fluid drachm three times a day, in some tea or mucilage. It should be well agitated previous to administration.

Other Copaiba Mixtures.—There are various mixtures of copaiba in use for the cure of *gonorrhœa*, and as several of them have been found efficient, I give the formulas for preparing them:

1. Take of copaiba, spirit of nitrous ether, compound spirit of lavender, tincture of chloride of iron, of each, 1 fluid ounce. Mix. The dose is a teaspoonful three times a day.

2. Take of oil of cubebs, oil of anise, copaiba, tincture of opium tincture of chloride of iron, of each, 1 fluid ounce. Mix. The dose is a teaspoonful three times a day. The foregoing preparations are very disagreeable to the taste, but very efficient in *gonorrhœa*, after the active symptoms have subsided. They must be agitated thoroughly previous to taking each dose, and in order to protect the teeth from the injurious action of the acid in the tincture of iron, it is recommended to rinse the mouth immediately after taking each dose, with a solution of bicarbonate of potassium.

3. Take of solidified copaiba, 2 ounces; white wax, 1 ounce; oil of cubebs, oil of spearmint, of each, 1 fluid drachm; niter, finely pulverized, 2 drachms. Melt the wax, add the oils, and then the copaiba; stir all well together, and, finally, add the niter. This forms a paste once used for the cure of *gonorrhœa*. The dose is a quantity about the size of a small chestnut, three times a day.

4. Take of alum, in powder, 1 drachm; precipitated carbonate of iron, ½ ounce; pulverized cubebs, 1 ounce; copaiba, a sufficient quantity to form a kind of paste. The dose is the same as in the preceding preparation (J. King).

MISTURA COPAIBÆ COMPOSITA (N. F.), *Compound copaiba mixture*.—1. *Lafayette mixture:* "Copaiba, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; spirit of nitrous ether (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; compound tincture of lavender (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; solution of potassa (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; syrup (*U. S. P.*), three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl℥, 475 ♏]; mucilage of dextrin (F. 277), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the copaiba with the solution of potassa and the spirit of nitrous ether. Then add the compound tincture of lavender, and lastly, the syrup and mucilage of dextrin. Mix the whole thoroughly by shaking. This mixture should be well agitated whenever any of it is to be dispensed. Each fluid drachm contains 7½ minims of copaiba. *Note.*—The above mixture has usually been, and may be, prepared with mucilage of acacia; but if mucilage of dextrin be used, it will keep for a longer time without separating. A mixture of somewhat similar composition, in considerable use in some parts of the country, is the following:

2. *Chapman's mixture.*—Copaiba, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; spirit of nitrous ether (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; compound tincture of lavender (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl℥, 95 ♏]; tincture of opium (*U. S. P.*), thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; mucilage of acacia (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl℥, 109 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

MISTURA CREOSOTI.—CREOSOTE MIXTURE.

Preparation.—To a mixture of 15 minims, each, of glacial acetic acid and creosote, add gradually, 15 fluid ounces (Imp.) of distilled water. Finally, add to this 1 fluid ounce of syrup and ½ fluid drachm of spirit of juniper. This accords with the *British Pharmacopœia*, 1885.

Action, Medical Uses, and Dosage.—(See *Creosota*.) This agent is intended to check *vomiting*. Dose, ½ to 1 fluid ounce.

MISTURA CRETÆ (U. S. P.)—CHALK MIXTURE.

Preparation.—"Compound chalk powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; cinnamon water, four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the compound chalk powder, in a mortar, with the cinnamon water and about two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏] of water, gradually added, to a uniform mixture; transfer this to a graduated vessel, and rinse the mortar with enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the whole thoroughly. This preparation should be freshly made when wanted"—(*U. S. P.*). As this readily decomposes in hot weather, the addition of a little glycerin is recommended by Kennedy.

Action, Medical Uses, and Dosage.—This preparation is popular with some physicians, chiefly those of the Allopathic school, for the *diarrhœas of children* and *adults* when the dejecta are foamy and greenish, and there is *flatulence* and *gastric acidity*. It is recommended for the watery diarrhœa preceding *cholera*. Astringents and tincture of opium are often added to it. The dose is from 1 to 4 fluid drachms.

MISTURA EXPECTORANS, STOKES (N. F.)—STOKES' EXPECTORANT MIXTURE.

SYNONYM: *Stokes' expectorant.*

Preparation.—Ammonium carbonate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; fluid extract of senega (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; fluid extract of squill (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; camphorated tincture of opium (*U. S. P.*), one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl℥, 440 ♏]; water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; syrup of tolu (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏). Dissolve the ammonium carbonate in the water, add the fluid extracts and tincture, and lastly, enough syrup of tolu to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏].

Action, Medical Uses, and Dosage.—As its name implies, this preparation is intended as an expectorant mixture. Dose, 1 fluid drachm.

Other Expectorants.—MISTURA AMMONII CHLORIDI (N. F.), *Mixture of ammonium chloride, Mistura* (or *Mixtura*) *solvens simplex:* "Ammonium chloride, twenty-five grammes (25 Gm.) [386 grs.]; purified extract of glycyrrhiza (F. 158), twenty-five grammes [25 Gm.) [386 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the solids in a sufficient quantity of water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—Sometimes a Mistura (or Mixtura) Solvens Stibiata is prescribed. This may be prepared by dissolving thirty centigrammes (0.30 Gm.) of antimony and potassium tartrate in one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of mistura ammonii chloridi"—(*Nat. Form.*).

MISTURA OLEI PICIS (N. F.), *Mixture of oil of tar, Mistura picis liquidæ, Tar mixture.*—"Purified extract of glycyrrhiza (F. 158), sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; oil of tar (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; sugar, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; chloroform (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; oil of peppermint, three cubic centimeters (3 Cc.) [49 ♏]; alcohol, one hundred and sixty cubic centimeters (160 Cc.) [5 fl℥, 197 ♏], water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Add the purified extract of glycyrrhiza and sugar to six hundred cubic centimeters (600 Cc.) [20 fl℥, 138 ♏] of water, contained in a covered vessel, and heat the mixture to boiling until the extract and sugar are dissolved. Then add the oil of tar, cover the vessel, and allow the contents to cool, stirring occasionally. Next add the chloroform and oil of peppermint, previously dissolved in the alcohol, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This mixture should be well agitated, whenever any of it is to be dispensed"—(*Nat. Form.*).

MISTURA FERRI AROMATICA.—AROMATIC MIXTURE OF IRON.

Preparation.—Macerate, in a closed vessel, for 3 days, with occasional agitation, 1 ounce of powdered red cinchona bark, ½ ounce of coarsely powdered calumba root, ¼ ounce of bruised cloves, and ½ ounce of fine iron wire, in 12 fluid ounces of peppermint water. Filter, and by pouring upon the filter a sufficient quantity of peppermint water, bring the measure to 12½ fluid ounces. Then add ½ fluid ounce of tincture of orange-peel, and 3 fluid ounces of compound tincture of cardamoms. (Weight, avoirdupois; measure, Imperial.) Preserve in tightly-stoppered bottles. This accords with the formula of the *British Pharmacopœia*, 1885. It is a greenish-black fluid, and is properly a compound infusion.

Action, Medical Uses, and Dosage.—Excellent tonic for *debilitated and anemic individuals*. Dose, 1 to 2 fluid ounces.

MISTURA FERRI COMPOSITA (U. S. P.)—COMPOUND IRON MIXTURE.

SYNONYM: *Griffith's mixture.*

Preparation.—"Ferrous sulphate, in clear crystals, six grammes (6 Gm.) [93 grs.]; myrrh, in small pieces, eighteen grammes (18 Gm.) [278 grs.]; sugar, eighteen grammes (18 Gm.) [278 grs.]; potassium carbonate, eight grammes (8 Gm.) [124 grs.]; spirit of lavender, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; rose water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the myrrh, sugar, and potassium carbonate, in a mortar, with seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of rose water, at first very gradually added, so that a uniform mixture may result. Transfer this to a graduated vessel, add the spirit of lavender, then the ferrous sulphate, previously dissolved in about fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏] of rose water, and, lastly, enough rose water to make the product measure one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]. Mix the whole thoroughly. This preparation should be freshly made when wanted"—(*U. S. P.*).

By the interaction of the potassium carbonate and ferrous sulphate, potassium sulphate and ferrous carbonate result. The mixture, when freshly made, is of a greenish color, but if allowed to oxidize, as it will do if not tightly corked, the ferrous salt changes to rust-red ferric compounds. Therefore, the mixture should be extemporaneously prepared as needed.

Action, Medical Uses, and Dosage.—This agent was formerly much admired as an antihectic remedy in *purulent chronic bronchitis* with *bronchial dilatation.* The sulphate and the myrrh tend to overcome relaxation while the iron is present to fulfil the common uses of the ferruginous compounds. Dose, ½ to 1½ fluid ounces. Griffith's mixture has also been employed in *menstrual irregularities,* and in anemic and debilitated patients.

MISTURA GLYCYRRHIZÆ COMPOSITA (U. S. P.)—COMPOUND MIXTURE OF GLYCYRRHIZA.

SYNONYM: *Brown mixture.*

Preparation.—"Pure extract of glycyrrhiza, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; syrup, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; mucilage of acacia, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; camphorated tincture of opium, one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28 ♏]; wine of antimony, sixty cubic centimeters (60 Cc.) [2 fl℥, 14 ♏]; spirit of nitrous ether, thirty cubic centimeters (30 Cc.) [1 fl℥, 7 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the pure extract of glycyrrhiza, in a mortar, with five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water until it is dissolved. Transfer the solution to a a graduated vessel containing the other ingredients, and rinse the mortar with enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the whole thoroughly"—(*U. S. P.*).

This forms an unsightly mixture, yet it is very popular with some physicians. The antimonial wine contained in the preceding mixture will render it unpopular with the Eclectic profession, and the following old formula will more nearly meet with the approval of our physicians where a mixture of this kind is desired:

MISTURA GLYCYRRHIZÆ COMPOSITA, *Compound liquorice mixture.*—Take of powdered extract of liquorice, powdered gum Arabic, and white sugar, each, 2 drachms; triturate these with water, 6 fluid ounces, added to them gradually, and when these are dissolved, strain the solution, and add to it camphorated tincture of opium, 1 fluid ounce; tincture of bloodroot, ½ fluid ounce; spirit of nitrous ether, 2 fluid drachms.

Action, Medical Uses, and Dosage.—The latter preparation forms an excellent cough mixture, and may be used in *catarrhal affections* after the subsidence of the more active symptoms, and when expectoration is present. An adult may take ½ fluid ounce for a dose, and a child 3 or 4 years old a fluid drachm.

A very excellent cough remedy may be made as follows: Dissolve ammonium chloride, 2 drachms, in water, 6 fluid ounces; then add extract of liquorice, 2 drachms; extract of hyoscyamus, ½ drachm; when these are dissolved, add syrup of tolu, 1 fluid ounce. The dose is the same as the above, and may be repeated 3 or 4 times a day. A grain or two of the sulphate of sanguinarine may be added to render it more expectorant (J. King).

MISTURA GUAIACI (N. F.)—MIXTURE OF GUAIAC.

Preparation.—"Guaiac (*U. S. P.*), in powder, twenty-five grammes (25 Gm.) [386 grs.]; sugar, twenty-five grammes (25 Gm.) [386 grs.]; acacia, in fine powder, fifteen grammes (15 Gm.) [231 grs.]; cinnamon water (*U. S. P.*), one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the powdered guaiac with the sugar and acacia, then gradually add the cinnamon water, and mix thoroughly. This mixture should be well agitated, whenever any of it is to be dispensed. *Note.*—This preparation is practically identical with the *Mistura Guaiaci* of the *British Pharmacopœia*"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Same as for *Guaiacum*. Dose, ¼ to 1 fluid ounce, several times a day. Mixture of guaiac was once very popular in the treatment of *constitutional syphilis* and *syphilitic rheumatism*.

MISTURA MAGNESIÆ ET ASAFŒTIDÆ (N. F.)—MIXTURE OF MAGNESIA AND ASAFETIDA.

SYNONYMS: *Dewees' carminative, Mistura Carminativa Deweesi.*

Preparation.—"Magnesium carbonate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; tincture of asafœtida, seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏]; tincture of opium, ten cubic centimeters (10 Cc.) [162 ♏]; sugar, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Rub the magnesium carbonate and sugar, in a mortar, with the tincture of asafœtida and the tincture of opium. Then gradually add enough distilled water to make the mixture measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent was formerly much used in *infantile colic*. The average dose is from 10 to 20 minims. This preparation contains $\frac{1}{100}$ part of laudanum.

Related Preparations.—MISTURA CARMINATIVA (N. F.), *Carminative mixture, Dalby's carminative.* "Magnesium carbonate, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; potassium carbonate, three grammes (3 Gm.) [46 grs.]; tincture of opium (*U. S. P.*), twenty-five cubic centimeters (25 Cc.) [406 ♏]; oil of caraway, one-half cubic centimeter (0.5 Cc.) [8 ♏]; oil of fennel, one-half cubic centimeter (0.5 Cc.) [8 ♏]; oil of peppermint, one-half cubic centimeter (0.5 Cc.) [8 ♏]; syrup (*U. S. P.*), one hundred and sixty cubic centimeters (160 Cc.) [5 fl℥, 197 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the oils with about ten grammes (10 Gm.) [154 grs.] of magnesium carbonate, and seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of water gradually added. Then add the remainder of the magnesium carbonate and the other ingredients, and lastly, add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. This preparation should be freshly made, when wanted for use. Each fluid ounce represents about 1 grain of opium"—(*Nat. Form.*).

MISTURA SASSAFRAS ET OPII (N. F.), *Mixture of sassafras and opium, Mistura opii alkalina, Godfrey's cordial.*—"Oil of sassafras, one cubic centimeter (1 Cc.) [16 ♏]; tincture of opium (*U. S. P.*), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; alcohol, fifty cubic centimeters (50 Cc.) [1 fl℥, 332 ♏]; potassium carbonate, eight grammes (8 Gm.) [123 grs.]; molasses, three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl℥, 475 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the tincture of opium with the alcohol in which the oil of sassafras had been previously dissolved. Dissolve the potassium carbonate in about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of water, mix this with the molasses, then add the mixture first prepared, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Allow the mixture to become clear by standing, then pour off the liquid portion and preserve it for use. Each fluid drachm contains 2 minims of tincture of opium, corresponding to about ⅕ grain of opium"—(*Nat. Form.*).

MISTURA OLEORUM CAMPHORATA.—CAMPHORATED MIXTURE OF OILS.

Preparation.—Take of oils of cloves, cajeput, and amber (rectified), and camphor, each, ½ ounce. Mix the oils together, and dissolve camphor in the mixture.

Action and Medical Uses.—This is intended for the relief of *toothache.* The decayed portion of the tooth is to be cleansed and dried, and then a few drops of the mixture on cotton applied to the part; continue application 2 or 3 times in the same manner, and leave the last in the tooth. This has proved very efficient, and has been extensively sold throughout the country as "*Parisen's Vegetable Specific.*"

It will not be amiss to give at this place, another preparation for *toothache*, which I have found of service. Take of opium and saltpeter, each, 2 ounces; camphor, 1½ ounces; galls, in powder, 4 ounces; alcohol, 1½ pints. Place the articles in the alcohol, macerate for 14 days, and filter. To be applied the same as the preceding mixture. Various other agents, as solution of tannic acid, or gallic acid in alcohol, etc., have also been recommended for relieving toothache (J. King).

MISTURA OLEORUM COMPOSITA.—COMPOUND MIXTURE OF OILS.

SYNONYM: *Vermifuge oil.*

Preparation.—Take of castor oil and wormseed oil, each, 1 ounce; oil of turpentine, and oil of anise, of each, ½ ounce. Mix.

Action, Medical Uses, and Dosage.—This forms an efficient remedy for *worms*, and may be given in teaspoonful doses to an adult, and repeated every 2 hours. After its employment for 2 or 3 days, a purgative must be administered (T. V. Morrow).

MISTURA RHEI ET SODÆ (U. S. P.)—MIXTURE OF RHUBARB AND SODA.

Preparation.—"Sodium bicarbonate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; fluid extract of rhubarb, fifteen cubic centimeters (15 Cc.) [243 ♏]; fluid extract of ipecac, three cubic centimeters (3 Cc.) [49 ♏]; glycerin, three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏]: spirit of peppermint, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium bicarbonate in about four hundred cubic centimeters (400 Cc.) [13 fl℥, 252 ♏] of water. Then add the fluid extracts, the glycerin, and the spirit of peppermint, and, lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This preparation, in large doses, is purgative and carminative; in smaller amounts, it checks *diarrhœa* and *colic* accompanying *infantile dyspepsia.* Dose, ½ fluid drachms to 2 fluid ounces.

Related Preparation.—MISTURA RHEI COMPOSITA (N. F.), *Compound mixture of rhubarb, Squibb's rhubarb mixture.* "Fluid extract of rhubarb (*U. S. P.*), twelve cubic centimeters (12 Cc.) [195 ♏]; fluid extract of ipecac (*U. S. P.*), two cubic centimeters (2 Cc.) [33 ♏]; sodium bicarbonate, twenty-four grammes (24 Gm.) [370 grs.]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; peppermint water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium bicarbonate in about five hundred cubic centimeters (500 Cc.) [16 fl℥, 435 ♏] of peppermint water, then add the fluid extracts and glycerin, and lastly, enough peppermint water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]"—(*Nat. Form.*). This preparation must not be confused with the well-known neutralizing cordial, which in some respects it resembles.

MISTURA SANGUINARIÆ COMPOSITA.—COMPOUND MIXTURE OF BLOODROOT.

SYNONYM: *Cough drops.*

Preparation.—Take of syrup of ipecacuanha, syrup of squill, tincture of bloodroot, syrup of balsam tolu, camphorated tincture of opium, each, 1 ounce. Mix (J. King).

Action, Medical Uses, and Dosage.—This is a very efficient preparation in severe *coughs* from *colds*, *catarrhal*, or *bronchial irritations*. The dose is from ½ to 1 fluid drachm whenever the fit of coughing is severe. I have used it for many years in practice, with much benefit. A very pleasant preparation for cough is composed of oil of anise, oil of sweet almonds, tincture of balsam of tolu. Canada balsam, Madeira wine, each, 1 ounce. Mix (Beach's *Amer. Prac.*). The dose is from 10 to 20 drops, 3 or 4 times a day, in a little elm or flaxseed infusion. It assists expectoration, and affords great relief in tickling coughs (J. King).

MISTURA SCAMMONII.—SCAMMONY MIXTURE.

SYNONYMS: *Lac scammonii, Emulsio purgans cum scammonia.*

Preparation.—Make a uniform emulsion by triturating together 6 grains of powdered scammony and 2 fluid ounces of milk. This is really an emulsion, and has a fine appearance, and is not unpleasant to the taste. The formula accords with that of the *British Pharmacopœia*, 1885. It should be made only when needed for immediate use.

Action, Medical Uses, and Dosage.—(See *Scammonia.*) The above mixture is intended for a single dose for an adult; for a child the dose is one-third of this mixture.

MISTURA SENNÆ COMPOSITA.—COMPOUND MIXTURE OF SENNA.

Preparation.—Dissolve, by means of gentle heat, 4 ounces (av.) of magnesium sulphate in 15 fluid ounces (Imp.) of infusion of senna, and add 1 fluid ounce of liquid extract of liquorice, 2½ fluid ounces of tincture of senna, and 1½ fluid ounces of tincture of cardamoms. This is the British form (*Br. Pharm.*, 1885) of compound infusion of senna, or *black draught* (see *Infusum Sennæ Compositum* for American *black draught*).

Action, Medical Uses, and Dosage.—Same as for *Compound Infusion of Senna.* Dose, from 1 to 1½ fluid ounces (Imp.).

MISTURA SODÆ ET MENTHÆ (N. F.)—MIXTURE OF SODA AND SPEARMINT.

SYNONYM: *Soda mint.*

Preparation.—Sodium bicarbonate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; aromatic spirit of ammonia (*U. S. P.*), ten cubic centimeters (10 Cc.) [162 ♏]; spearmint water (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Dissolve the sodium bicarbonate in about seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of spearmint water, add the aromatic spirit of ammonia and enough spearmint water to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Filter, if necessary"—(*Nat. Form.*).

Action and Medical Uses.—Antacid and carminative.

MISTURA SPIRITUS VINI GALLICI.—MIXTURE OF FRENCH BRANDY.

SYNONYM: *Brandy mixture.*

Preparation.—Take of brandy, cinnamon water, each, 4 fluid ounces; the yolks of two eggs; refined sugar, ½ ounce; oil of cinnamon, 2 minims. Mix—(*Lond.*). This is identical with the present formula of the *British Pharmacopœia* (1898), excepting that the latter does not add the 2 minims of cinnamon oil.

Action and Medical Uses.—This forms a nutritive and stimulating preparation, especially adapted to the stage of prostration in *low forms of fever*, and in cases of much *debility* from various other causes.

MISTURA SULPHURICA ACIDA (N. F.)—SULPHURIC ACID MIXTURE.

SYNONYMS: *Mixtura sulphurica acida* (*Ger. Pharm.*), *Haller's acid elixir.*

Preparation.—"Sulphuric acid (*U. S. P.*), two hundred and fifty grammes 250 (Gm.) [8 ozs. av., 358 grs.]; alcohol, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Add the acid very gradually to seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.] of alcohol contained in a flask, agitating after each addition, and taking care that the temperature of the mixture be not allowed to rise above 50° C. (122° F.). When the mixture is cold, add enough alcohol, if necessary, to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. *Note.*—The same product may be obtained, approximately, by carefully and slowly adding 1 volume of sulphuric acid to 7 volumes of alcohol, and this method may be used when small quantities are required for immediate use in a prescription"—(*Nat. Form.*). The sulphuric acid gradually becomes converted into ethylsulphuric acid, of which this mixture is merely an alcoholic solution.

Action, Medical Uses, and Dosage.—(See *Acidum Sulphuricum.*) Dose, 1 to 8 minims, well diluted with water.

MITCHELLA.—PARTRIDGEBERRY.

The whole plant of *Mitchella repens*, Linné.

Nat. Ord.—Rubiaceæ.

COMMON NAMES: *Partridgeberry, Checkerberry, Squaw-vine, Squaw-berry vine, Winter clover, Deerberry,* and *One-berry.*

Botanical Source.—This is an indigenous, evergreen herb, with a perennial root, from which arises a smooth and creeping stem, furnished with roundish ovate, or slightly heart-shaped, petiolate, opposite, flat, coriaceous, dark-green, and shining leaves, usually variegated with whitish lines. The flowers are white, often tinged with red, very fragrant, in pairs, with their ovaries united. Calyx 4-parted. Corolla funnel-form, two on each double ovary, limb 4-parted, spreading, and densely hairy within. Stamens 4, short, and inserted on the corolla. Style slender; stigmas 4. The fruit is a dry, berry-like, double drupe, crowned with the calyx-teeth of the two flowers, each containing 4 small and seed-like, bony nutlets. Some plants bear flowers with exserted stamens and included styles; others, conversely, those with included stamens and exserted styles (W.—G.—T.). According to Mr. Thomas Meehan, this is a diœcious plant, having imperfect rudimentary pistils in the male plant, with the calyx-teeth coarser than in the female, the anthers on filaments projecting considerably beyond the corolla throat; in the female plant, the anthers are sessile, rudimentary, concealed in the coarse down of the corolla tube, and the pistil, with its well-developed stigma, projects beyond the throat of the corolla (*Amer. Jour. Pharm.*, 1868, p. 554).

Fig. 171.

Mitchella repens.

History.—This plant is indigenous to the United States, growing in dry woods, among hemlock-timber, and in swampy places, flowering in June and July. The leaves bear some resemblance to clover, and remain green through the winter. The fruit or berry is bright scarlet, edible, but nearly tasteless, dry, and full of stony seeds, and also remains through the winter. The whole plant is medicinal, and imparts its virtues to boiling water or alcohol.

Chemical Composition.—E. Breneiser found in this plant a saponin-like body, frothing in aqueous solution; the water-soluble part of an ether extract of the plant contained a principle forming a precipitate with tannic acid and with picric acid; but it was neither an alkaloid nor a glucosid. No volatile oil was present (*Amer. Jour. Pharm.*, 1887, p. 229).

Action, Medical Uses, and Dosage.—Partridgeberry is parturient, diuretic, and astringent. Used in *dropsy*, *suppression of urine* and *diarrhœa*, in decoction. It seems to have an especial affinity for the uterus, exerting a powerful tonic and alterative influence upon this organ, and has hence been found highly beneficial in many *uterine derangements*, as in *amenorrhœa*, some forms of *dysmenorrhœa*, *menorrhagia*, *chronic congestion of the uterus*, *enfeebled uterine nervous system*, etc. It is said that the squaws drink a decoction of this plant for several weeks previous to their confinement, for the purpose of rendering parturition safe and easy. Similar virtues have been ascribed to it by competent physicians of our time. The remedy is peculiarly American, not being noticed or used by foreign practitioners. Dose of a strong decoction, from 2 to 4 fluid ounces, 2 or 3 times a day. The berries are a popular remedy for *diarrhœa* and *dysuria*. Used as follows, partridgeberry is highly recommended as a cure for *sore nipples:* Take 2 ounces of the herb, fresh if possible, and make a strong decoction with a pint of water, then strain, and add as much good cream as there is liquid of the decoction. Boil the the whole down to the consistence of a soft salve, and when cool, anoint the nipple with it every time the child is removed from the breast.

MONARDA.—HORSEMINT.

The leaves and flowering tops of *Monarda punctata*, Linné.

Nat. Ord.—Labiatæ.

Common Name: *Horsemint.*

Illustration: Bentley and Trimen, *Med. Plants*, 208.

Botanical Source.—Horsemint is an indigenous perennial or biennial herb, with a fibrous root. The stems are obtusely angled, hoary pubescent, branched, and 2 or 3 feet high. The leaves are oblong-lanceolate to oblong, remotely and obscurely serrate, narrowed at base, punctate, and petioled. The flowers are yellow, with brown or purple spots, in numerous, dense, axillary whorls. The bracts are large, yellow, and red, lanceolate, obtuse at the base, sessile, and longer than the whorls. The corolla is nearly smooth, ringent, tubular, upper lips spotted with purple, lower lip reflexed, 3-lobed. Calyx elongated, cylindric, 15-nerved, subequally 5-toothed, and hairy in the throat; the teeth are short and rigid, awnless. Stamens 2, elongated, ascending, inserted in the throat of the corolla; anthers linear, cells divaricate at base, and connate at apex (G.—W.).

History and Chemical Composition.—This plant is found growing in sandy fields and barrens from New England to the Gulf of Mexico, and westward beyond the Mississippi, flowering during the summer. The entire plant has a rather fragrant odor, and a pleasant, pungent, slightly bitter taste. It contains an abundance of essential oil (*Oleum Monardæ*, *U. S. P.*, 1870) on which its active virtues depend. The oil may be obtained by distillation of the recent herb with water. The plant yields its virtues to alcohol, or boiling water by infusion.

Oleum Monardæ, or *Oil of horsemint*, is of a yellowish, or more often yellowish-red or brownish-red color, and has a sharp taste and an aromatic, pleasant odor. Alcohol readily dissolves it. Below 5° C. (39° F.), it deposits crystals of a stearopten once called *monardin*, but which has subsequently been shown to be *thymol* ($C_{10}H_{13}OH$). H. J. M. Schroeter (*Amer. Jour. Pharm.*, 1888) believes the oil to contain 50 per cent of a hydrocarbon ($C_{10}H_{16}$), 25 per cent of thymol, which he pronounced to be dextro-gyrate, while thymol from oil of thyme is optically inactive, and oxygenated bodies of the composition $C_{10}H_{18}O$. He also found small quantities of formic, acetic, and butyric acids in the form of esters. More recently, Prof. Edward Kremers and W. R. Schumann (*Proc. Amer. Pharm. Assoc.*, 1896, p. 238) distilled the flowering herb of *Monarda punctata* of their own collection, and obtained an amber-colored oil of 0.9307 specific gravity, at 20° C. (68° F.), which yielded to a 10 per cent caustic soda solution, 56 per cent of *thymol*. The residue distilled with water, yielded an oil containing the hydrocarbon *cymene* ($C_{10}H_{14}$), previously shown by Brennan (1895) to occur also in the oil of *Monarda fistulosa*. Another lot of the herb collected by the same authors before flowering yielded upon distillation 3.39 per cent of oil, while more recently, Kremers and W. E. Hendricks (*Pharm. Archives*, 1899, Vol. II, p. 73), obtained only 1 per cent of oil from a flowering specimen of the plant. In the latter case, 60 per cent of phenols were present, mostly thymol. Its isomer, *carvacrol*, may be occasionally present in small quantity. The non-phenol part of the oil contained 10 per cent of an alcohol; furthermore, *cymene*, and a small quantity of dextro-rotatory *limonene*.

Action, Medical Uses, and Dosage.—Horsemint is stimulant, carminative, sudorific, diuretic, and anti-emetic. The infusion or essence is used in *flatulence*, *nausea*, *vomiting*, and as a diuretic in *suppression of the urine*, and other urinary disorders. The warm infusion is a stimulating diaphoretic, and has acquired some celebrity as an emmenagogue; it may be drank freely. The oil is extremely sharp and pungent, and applied to the skin, excites heat and redness, and if too long or too closely applied, will produce a painful blister. It is used like peppermint oil internally, and is employed locally in embrocations to relieve *pain*. The full strength oil may be used upon *neuralgic parts*. The *M. didyma* and *M. fistulosa* may be used as substitutes for the above.

Related Species.—*Monarda didyma*, Linné; *Oswego tea*. This species grows in the Alleghany Mountains, from North Carolina northward to Canada. In the northern states it often grows along streams and in other wet situations. The flower is composed of a showy, large crimson corolla, and crimson-stained bracts. The stamens are much exserted. It is often cultivated in gardens.

Monarda fistulosa, Linné; *Wild bergamot*, also called *Horsemint*. From New England states west and south, growing in thickets. Flowers are in a terminal head, large, and have a greenish, white, light lilac, or blue corolla. It is a variable species. The uses of these two species are similar to those of horsemint. The chemical composition of the oil of this plant is analogous to that of *Monarda punctata*, *carvacrol* taking the place of its isomer, *thymol*, contained in the latter plant. Less than 2 per cent of thymol is present in the oil of *M. fistulosa*. The latter also contains a crystalline red coloring matter resembling alizarin (see E. J. Melzner and Edward Kremers, *Proc. Amer. Pharm. Assoc.*, 1896, p. 242, and *Pharm. Archives*, Vol. II, 1899, p. 76).

MONESIA.—MONESIA-BARK

Extract of the bark of *Chrysophyllum Glyciphlœum*, Casaretti (*Chrysophyllum Buranhem*, Riedel; *Lucuma Glycyphlœa*, Martius et Eichler).

Nat. Ord.—Sapotaceæ.

Common Name: *Monesia*.

Botanical Source.—Chrysophyllum Glyciphlœum is a common Brazilian tree known locally as *buranhem* or *guaranhem*. It is often from 40 to 50 feet in height. The genus *Chrysophyllum* comprises several species, mostly South American trees, with milky juice. The leaves are alternate, entire, and furnished with a golden-yellow pubescence underneath, hence the name. The flowers are small, and in fascicled umbels in the axils of the leaves. The corolla is bell-shaped, and has 5 stamens. The ovary has 10 1-ovuled cells, and bears a peltate 10-lobed stigma.

History and Description.—The bark is in fragments, nearly smooth, and cinnamon-colored internally. The pieces are thin, about ¼ or ½ inch in thickness; at first a sweetish taste is imparted, which subsequently becomes acrid and astringent. It has no odor. The fruit of the *C. Cainito*, and other species are called "star apples," and are eaten by the natives. Chrysophyllum Glyciphlœum is of interest from the fact that an extract from the bark is used in medicine, and known as *Monesia*.

Monesia (*Extractum Monesiæ*), the extract of the foregoing bark, was introduced to notice in 1839, in an article written by Dr. St. Ange, and published in the *Paris Medical Gazette* (*Br. Pharm. Jour.*, Vols. III and IV). The extract appeared in the form of brown, brittle cakes of about 1 pound each, insoluble in ether, partly soluble in alcohol, but more so in water; forming with the latter menstruum, a frothy, soap-suds-like solution. Monesia extract, when prepared in the cold is of a dark-red color, and is considered in Brazil to be superior in quality. T. Peckolt reports (*Pharm. Rundschau*, 1888, p. 30) that the extract is not now exported to any considerable extent.

Chemical Composition.—Shortly after the introduction of monesia bark Derosne and Henry examined it, and found it to contain chlorophyll, wax, *glycyrrhizin*, iron-bluing tannin, and red coloring matter. The supposed active principle, which is acrid, they named *monesin;* although it is probable that the tannin and other substances are of therapeutic value.

Monesin is regarded as identical with saponin ($C_{32}H_{54}O_{18}$). It forms transparent yellow scales, insoluble in ether, but soluble in water and alcohol, and produces in aqueous solution, upon shaking, an abundant froth. It is odorless, but has a bitter, acrid taste. Peckolt's analysis of the bark (*loc. cit.*) shows the presence of *monesia-tannic acid*, 6.2 per cent; red coloring matter, 2.2 per cent; starch, 1.97 per cent; *monesin*, 0.28 per cent; *glycyrrhizin*, 1.5 per cent; crystallizable *hivurahein* (*lucumin*), 0.009 per cent, etc. The latter substance is bitter, insoluble in cold water, soluble in ether and hot alcohol.

Action, Medical Uses, and Dosage.—Monesia appears to possess slightly stimulating and astringent properties. In doses of from 2 to 10 grains, repeated 2 or 3 times a day, it acts as a gentle excitant of the stomach, improving the appetite and the digestive functions. In larger doses, it causes a burning sensation in the epigastric region, gastric uneasiness, and costiveness. It has been found advantageous in certain atonic forms of *dyspepsia*, as a stimulant and tonic; and as a tonic and astringent in *diarrhœa* and *hemorrhages*, as from the lungs, stomach, and kidneys, in *hemorrhoids*, and in *profuse menstruation*. In *chronic bronchitis*, attended with considerable expectoration, and in the *catarrhal affections* and *winter cough* of persons in advanced years, it has proved useful. As an alterative, it has been advised in *scrofulous* and *scorbutic affections*, though it is somewhat doubtful as to its good effect in these cases, although it is stated to have been effectual in the *purpura of scurvy*. It has been advised as a tonic in convalescence from *malarial fevers* and in *incipient consumption*. As a local application, in the form of powder sprinkled upon the parts, in aqueous solution, tincture, or ointment, it has proven valuable in obstinate *indolent ulcers*, in *anal* and *buccal fissures*, in *scorbutic* or other *unhealthy condition of the gums*, in *vaginal leucorrhœa*, and in *nasal hemorrhage;* it may be applied on lint, as a wash, by injection, or by spray.

The dose of monesia is from 2 to 10 or 15 grains; of monesin, from $\frac{1}{4}$ to $\frac{1}{2}$ grain. These may be given in pill, or powder, and in some syrup or other convenient vehicle. The tincture may be made of any desirable strength, from 1 to 4 ounces of monesia extract to a pint of alcohol. The ointment may be made by triturating 1 drachm of the extract with 7 drachms of cerate, or purified lard.

Related Species.—*Lucuma salicifolia*, Kunth. The *Zapote amarillo* or *Z. borracho* of the Mexicans. The fruit produces sleep and the seeds are employed by the natives in *pleuritis*. Several Brazilian species yield food or medicines.

Bassia longifolia, Linné; *Elloopa-tree.*—East India. A nutritious jelly is prepared from the fruit and flowers of this tree, which also furnishes valuable timber. The bark, leaves, and a fixed oil from the seeds have antirheumatic virtues and have been used in *skin disorders*. Elloopa oil is greenish and odorous.

Bassia butyracea, Roxburgh.—The seeds yield a butyraceous substance known as *fulwa-butter*. It is used like the oil of the preceding species. *Bassia parkii* yields *Shea butter*.

Mimusops Elengi, Linné.—India. The sweet fruit of this species is eaten, and the tree furnishes an excellent timber. A pleasant perfume is obtained from the flowers, and the seeds yield a drying fixed oil. Bark and root are reported astringent and tonic, and are employed as such in India. The juice of the unripe fruit and the bark are used to fix colors in silk dyeing (Dymock).

Mimusops hexandra, Roxburgh.—Fruit eaten. Uses same as for preceding.

Mimusops Schimperi and *M. kummel* yield a variety of gutta-percha.

Achras Sapota, Linné (*Sapota Achras*, Miller); *Sapota plum* (*Zapotilla* or *Bully tree.*—West Indies, South America, and naturalized in western India, where the natives eat the quince-flavored fruit called by them *Chikku* or *Kárath*. As a preventive against *febrile* and *bilious attacks*, the inhabitants of the Concan eat the fruit which has been soaked over night in melted butter. The bark is regarded astringent, tonic, and febrifuge; the seeds diuretic and aperient. Bernou (1883) obtained a crystalline alkaloid, *sapotine*, from the bark (*Sapota Bark*); it is insoluble in water, but dissolves in alcohol, chloroform, and ether. He also found two resins, and a large amount of *sapotannic acid*, the last giving the bark its astringency (see Dymock, *Mat. Med. of Western India*). G. Michaud (1891) obtained from the seeds *sapotin* ($C_{29}H_{52}O_{20}$), a crystalline, white, acrid glucosid, insoluble in chloroform, ether, and benzol, but soluble in hot alcohol and water.

Mimusops globosa, Gaertner (*Sapota Muelleri*, Blukrode; *Achras Balata*, Aublet): *Bully tree.*—Guiana. The concrete milky juice of this tree furnishes what is variously known as *balata*, ue, *gum chicle*, *zapota gum*, or *tuno gum*. It is intermediate between gutta-percha and caoutchouc, and is used in America in manufacturing *chewing gum*. Its behavior toward solvents is like that of *gutta-percha* (see *Gutta-percha and its Related Products*; also see *Amer. Jour. Pharm.*, 1883, p. 523, on *Pseudo Gutta-perchas*).

MONOTROPA.—INDIAN PIPE.

The root of *Monotropa uniflora*, Linné.

Nat. Ord.—Ericaceæ.

Common Names: *Indian pipe*, *Ice-plant*, *Bird's nest*, *Fit-plant*, *Ova-ova*, *Pipe-plant*, etc.

Illustration: Dana's *How to Know the Wild Flowers*.

Botanical Source and Description.—This plant has a dark-colored, fibrous, perennial root, matted in masses about as large as a chestnut-burr, from which arise one or more short, ivory-white stems, 4 to 8 inches high, furnished with sessile, lanceolate, white, semi-transparent, approximate leaves or bracts, and bearing a large, white, terminal, solitary flower, which is at first nodding, but becomes upright in fruit. The calyx is represented by two to four scale-like deciduous bracts, the lower rather distant from the corolla. The corolla is permanent, of 5 distinct, erect, fleshy petals, which are narrowed below with a small, nectariferous pit at the base. Stamens 10, sometimes 8; anthers short on the thickened apex of the hairy filament, 2-celled, opening by transverse chinks. Stigma 5-crenate, depressed, and beardless. Pod or capsule 5-celled and 5-valved; the seeds numerous, and invested with an arillus-like membrane (W.—G.—Eaton).

History and Chemical Composition.—This is a singular plant, found in various parts of the Union from Maine to Carolina, and westward to Missouri, growing in shady, solitary woods, in rich, moist soil, or soil composed of decayed wood and leaves, and near the base of trees, on whose roots it is said to be parasitic. The whole plant is ivory-white in all its parts, resembling frozen jelly, and is very succulent and tender, so much so that when handled it dissolves and melts away in the hands like ice. The flowers are inodorous, and appear from June until September; their resemblance to a pipe has given rise to the names *Indian pipe* or *Pipe-plant*. The root is the part used; it should be gathered in September and October, carefully dried, pulverized, and kept in well-stoppered bottles. A. J. M. Lasché (*Pharm. Rundschau*, 1889, p. 208) has found in this plant a crystallizable poisonous principle, which also occurs in several other ericaceous plants; it is named *andromedotoxin* ($C_{31}H_{51}O_{10}$).

Action, Medical Uses, and Dosage.—Ice-plant root is a tonic, sedative, nervine, and antispasmodic. It has also been employed in *febrile diseases*, as a sedative and diaphoretic. The powder has been employed in instances of restlessness, pains, nervous irritability, etc., as a substitute for opium, without any deleterious influences. It is reputed to have cured *remittent* and *intermittent fevers*, and to be an excellent antiperiodic. In *convulsions of children*, *epilepsy*, *chorea*, and other *spasmodic affections*, its administration has been followed with prompt success; hence its common name, *Fit* or *Convulsion root*. The juice of the plant, alone, or combined with rose water, has been found an excellent application to *obstinate ophthalmic inflammation*, to *ulcers*, and as an injection in *gonorrhœa*, and *inflammation and ulceration of the bladder*. Dose of the powdered root, from ½ to 1 drachm, 2 or 3 times a day. It has been used as a substitute for opium.

This plant is undoubtedly one of value, and deserving of more confidence and attention than is at present bestowed upon it. It is, however, seldom or never used at the present day. It is not the *Mesembryanthemum crystallinum* (see *Ficus*, p. 891), or Ice-plant of Europe, which has a creeping stem a foot or more in length, with large, ovate, wavy, frosted leaves, and white flowers; and the whole plant is covered with frost-like, warty protuberances, which give it a singular aspect.

MORUS RUBRA.—RED MULBERRY.

The fruit of *Morus rubra*, Linne.

Nat. Ord.—Urticaceæ.

Common Name: *Red mulberry*.

Botanical Source.—Morus rubra, or the Red mulberry, is but a shrub in the northern and New England states, 15 to 20 feet high, but in the middle and western states it attains an elevation of 50 to 60 feet, with a diameter of 2 feet, and covered with a grayish, furrowed, much-broken bark. The leaves are alternate, rounded or subcordate at base, acuminate, equally serrate, either ovate or 3-lobed, rough above, pubescent beneath, thick, dark-green, 4 to 6 inches long, and about two-thirds as wide. The flowers are small, monœcious, rarely diœcious; sterile ones in loose spikes; calyx 4-parted; fertile ones in dense spikes; styles 2, filiform, stigmatic down the inside. The ovary is 2-celled, one of the cells smaller and disappearing. Achenium ovate, compressed, inclosed within the succulent, berry-like calyx. Fertile spikes cylindric, constituting a dark-red, thickened, oblong and juicy, compound berry or fruit. The sterile spikes are rather slender (W.—G.).

History.—The red mulberry is indigenous to the United States, growing in rich woods, flowering in May, and ripening its fruit in July. The wood of the tree is fine grained, strong, and durable. The fruit is oblong-oval, of a dark-red color, and is compounded of a great number of small berries, which are very juicy, inodorous, and of an agreeable sweetish and acidulous taste; in appearance it very much resembles the fruit of the blackberry. This species is fully equal in value to the *Morus nigra*, Linné, of Europe (figured in Bentley and Trimen, *Med. Plants*, 229), the juice of which was official in the *British Pharmacopœia*, 1885, under the title Mori Succus.

Fig. 172.

Morus nigra.

The *Morus nigra*, Linné, possesses similar properties. It is probably a native of the Levant, though cultivated in Europe, and to some extent in the United States. This species, and that following, is a tree of about 30 feet in height, and has a purplish, black, berry-like fruit. Its leaves furnish food for silk-worms. The *Morus alba*, Linné, a native of China, with white fruit which is more saccharine and less pleasant than the preceding species, is one of the trees upon the foliage of which the silk-worm feeds. This species is naturalized in this country.

Chemical Composition.—Mulberries are said to consist of bitartrate of potassium, pectin, sugar, woody fiber, coloring matter and water. They contain rather more grape-sugar than the ordinary berries, such as strawberries, blackberries, currants, etc., being exceeded only by the cherry and grape. Fresenius found mulberries of the following percentage composition: sugar, 9.19; malic acid with a little tartaric, 1.86; albuminous matter, 0.361; gum, pectin, and fatty matter, 2.31; woody fiber, 0.91; ash, 0.66; water, 84.71. Wright and Patterson (*Pharm. Jour. Trans.*, Vol. VIII, 1878, p. 540) found the solid matter in the juice of the unripe berries to amount to 70.16 Gm. to the liter. A large proportion (26.83 Gm.) of this was citric acid, and a smaller quantity (7.82 Gm.) was malic acid. G. Goldsmith (*Amer. Jour. Pharm.*, 1882, p. 456) observed *succinic acid* in the form of its calcium salt (C_4H_4OCa) in an exudation from the bark of *Morus alba*. It is the *mulberry acid* of Klaproth.

Action, Medical Uses, and Dosage.—Mulberries possess very slightly nutritive qualities; they are refrigerant and laxative, and their juice forms a pleasant and grateful drink for patients suffering under *febrile diseases*, as it checks the thirst, relieves febrile heat, and when taken freely, gently relaxes the bowels. The juice, formed into a syrup and added to water, answers the same purpose, and forms a pleasant adjunct to gargles in *quinsy*. If the berries are eaten to excess they are apt to induce diarrhœa. The bark of the tree is reputed purgative and vermifuge, having expelled *tapeworm*.

MORPHINA (U. S. P.)—MORPHINE.

Formula: $C_{17}H_{19}NO_3+H_2O=302.34$.

"An alkaloid obtained from opium"—(*U. S. P.*).

Synonyms: *Morphinum*, *Morphium*, *Morphia*.

Source and History.—Morphine, the first alkaloid identified, was discovered and its alkaline quality made known in 1816, by Sertürner, a Hanoverian chemist, though Derosne and Seguin, two French chemists, had separated it, as well as narcotine, as far back as 1803 and 1805, without recognizing, however, their differences or establishing their alkaloidal nature. Its only source thus far known, is opium, obtained by inspissation of the milky juice exuding from incisions into the unripe capsules of the poppy (*Papaver somniferum*, Linné) and its varieties. Morphine is also said to occur in the milky sap of the *Papaver orientale*, Linne, and of *Argemone mexicana*, Linné.

Preparation.—Numerous processes have been devised to isolate morphine from opium, the aim being to free it chiefly from contaminating *meconic acid*, *codeine* (methyl morphine) *narcotine*, and the other opium bases, and resinous and coloring matters. In Gregory-Anderson's process, originated by Robertson, an aqueous extract of opium is neutralized with marble dust, the fluid evaporated to a syrup, and the latter boiled for a short time with excess of solution of calcium chloride. Upon dilution with water, resin falls out; the liquid is filtered, again treated with marble dust, and concentrated by evaporation. Calcium meconate falls out, which is removed. Upon evaporation to syrupy consistence, and cooling, a mass of crystals is formed, consisting of the hydrochlorides of morphine and codeine. After removing the black mother liquor, the salts are purified by treatment with animal charcoal, dissolved in water, and treated with aqua ammoniæ which precipitates only morphine, since codeine is much more soluble in water. From the black mother liquor, aforementioned, the other opium bases may be obtained. By Merck's process, an aqueous extract of opium is precipitated by means of sodium carbonate, the morphine thus obtained is purified by washing with water and alcohol, and dissolving in acetic acid which leaves narcotine undissolved, since the latter does not easily combine with acetic acid. Or, narcotine may be dissolved out by ether, in which morphine is nearly insoluble. Mohr's process is that on which is based the assay of opium for morphine, as given in the *U. S. P.*, 1880, and the *Br. Pharm.*, 1898. It depends on the fact that morphine forms with milk of lime, in excess, a soluble compound which is decomposable by the addition of ammonium chloride, morphine being precipitated. The other opium bases are not soluble in milk of lime (see the details of this process in this *Dispensatory*, preceding editions). (For a useful review of the methods employed for abstracting morphine from opium, see Husemann and Hilger, *Pflanzenstoffe*, 1884, p. 666.) The amount of morphine obtainable from opium has been found to vary between the limits 2.7 and 22.8 per cent (Guibourt); the usual average is about 10 per cent.

Description.—As officially described, morphine occurs in "colorless or white, shining, prismatic crystals, or fine needles, or a crystalline powder, odorless, and having a bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 4350 parts of water, and in 300 parts of alcohol; in 455 parts of boiling water, and in 36 parts of boiling alcohol; also soluble in 4000 parts of ether. When heated to about 75° C. (167° F.), morphine begins to lose its water of crystallization. Heated for some time at 100° C. (212° F.), it becomes anhydrous. At 254° C. (489.2° F.) it melts, forming a black liquid. Upon ignition, it is consumed without leaving a residue. Morphine has an alkaline reaction upon litmus paper"—(*U. S. P.*). The dry crystals are first tasteless, afterward slightly bitter; in solution the taste is strongly bitter. Morphine is hardly soluble in chloroform if this is absolutely free from alcohol. According to Van der Burg, 1 part of morphine requires for solution 10,000 parts of absolute chloroform; 2000 parts if it contains 1 per cent alcohol; 222 parts if it holds 5 per cent, and 111 parts if it contains 10 per cent of alcohol. One part of morphine furthermore requires 220 parts of glycerin, 400 parts of cold, 90 parts of hot amyl alcohol, and 500 parts of acetic ether. It is nearly insoluble in alcohol-free benzol, and in carbon disulphide. It is also soluble in diluted acetic, hydrochloric, nitric, and sulphuric acids, in the fixed and volatile oils, in solutions of caustic potash and of soda, in solutions of caustic baryta, lime, and strontia, also in small quantity in aqua ammoniæ. It is precipitated from its alkaline solutions, when exposed to the atmosphere, on account of the alkalies combining with the carbonic acid to form carbonates.

In aqueous and in alcoholic solution, morphine is optically lævo-rotatory. Morphine is a tertiary amine also containing two phenol groups. Its formula is $C_{17}H_{19}NO_3+H_2O$ (Laurent), or, $C_{17}H_{17}(OH)_2NO$. Its solubility in excess of alkalies, the blue color-reaction with ferric chloride (see *Tests*), etc., are in accord with this formula. Morphine dissolves in acids, forming a series of salts. In solution it is precipitated by alkaloidal reagents (see enumeration in Charles E. Sohn's *Dictionary of the Active Principles of Plants*, London, 1894). Solutions of alkaline carbonates, like alkalies, precipitate morphine from its solutions, but it is much more slowly soluble in excess of the precipitant. Morphine, both free and in combination, is remarkable for its reducing properties. It reduces gold chloride, silver nitrate, silver oxide, chromic acid, cuprammonium sulphate, potassium ferricyanide, iodic and periodic acids, bismuth subnitrate, and the acids of tungsten, tin, titanium, vanadium, and molybdenum. Morphine, when dissolved in caustic potash solution, is oxidized upon exposure to the air, *oxydimorphine* ($C_{34}H_{36}N_2O_6$) being formed. When a salt of morphine is heated, in a closed tube, to 150° C. (302° F.), in the presence of strong hydrochloric acid, 1 molecule of water is abstracted and *apomorphine* ($C_{17}H_{17}NO_2$) is formed (which see). Morphine also stands in close connection with *codeine* ($C_{17}H_{18}[OCH_3]NO_2$), the latter being methylmorphine (see *Codeina*). Morphine, when heated with strong potassium hydroxide, yields *methylamine*, and upon destructive distillation over zinc dust, various hydrocarbons and bases are yielded, among them *phenanthren* ($C_{14}H_{10}$), *trimethylamine* ($N[CH_3]_3$), *pyrrol* (C_4H_4NH), *pyridine* (C_5H_5N), *quinoline* (C_9H_7N), etc.

Tests.—The *U. S. P.* gives the following tests for morphine: "When crystals of morphine are sprinkled upon nitric acid (specific gravity 1.250 to 1.300) they will assume an orange-red color, and then produce a reddish solution gradually changing to yellow. On shaking a small portion of morphine, in a test-tube, with 10 Cc. of chlorine water, the latter will acquire a yellowish color. On now carefully pouring a small amount of ammonia water on the surface of the liquid, a brown or reddish-brown zone will form at the line of contact of the two liquids. If to a neutral 1 per-cent solution of morphine, made by the careful addition of dilute sulphuric acid, a few drops of ferric chloride T.S. be added, a blue color will be produced which is destroyed by acids, alcohol, or heating. On treating morphine with cold, concentrated sulphuric acid free from nitric acid, the liquid should not at once acquire more than a faintly yellowish tinge (absence of more than traces of narcotine, papaverine, etc.); and the subsequent addition of a small crystal of potassium permanganate should produce only a greenish, but no violet or purple, color (difference from strychnine). On precipitating a solution of any of the salts of morphine by ammonia water, dissolving the washed precipitate in sodium hydrate T.S., shaking the solution with an equal volume of ether, and evaporating the ethereal solution, no appreciable residue should remain (absence of narcotine, codeine, etc.). On adding 4 Cc. of potassium or sodium hydrate T.S. to 0.2 Gm. of morphine, a clear, colorless solution, free from any undissolved residue, should result (absence of, and difference from, various other alkaloids)"—(*U. S. P.*). A delicate test for morphine is that with Fröhde's Reagent (a solution of 0.5 Gm. of sodium molybdate in 100 Cc. of sulphuric acid). Traces of morphine produce, with a thin layer of this solution, a beautiful violet coloration which changes to blue, olive-green, yellow, and in 24 hours to purplish-blue again. Other alkaloids, *e. g.*, codeine, produce a similar change of color with this reagent. According to Flückiger, if a trace of morphine be added to a solution of titanic acid in concentrated sulphuric acid, a brown-red to violet coloration will be produced. A sensitive test for morphine is that based on the liberation of iodine from solution of iodate of potassium, in a slight excess of acetic acid, when a small quantity of morphine is added. The liberated iodine may be recognized by the blue starch reaction. Other alkaloids, however, *e. g.*, codeine, cryptopine, eseridine, laudanine, and narcotine, behave in the same manner (see Flückiger-Nagelvoort, *Reactions*, Detroit, 1893, p. 77). The solution of morphine, in diluted nitric or acetic acid, must give no precipitate with nitrate of silver, or nitrate of barium (absence of hydrochloride or sulphate of morphine). Upon incineration of morphine, upon platinum foil, no residue should remain (absence of inorganic impurities).

Action and Medical Uses.—(See *Morphinæ Sulphas.*)

Salts of Morphine.—In addition to the salts of morphine considered herein under special headings, there are other salts, such as the *nitrate*, *phosphate* and *tartrate*; they are prepared like the acetate, by substituting the respective acids. Doses, same as acetate. The last-named salt occurs in warty, needle crystals, very soluble in alcohol and water, and preferred by some to the sulphate for hypodermatic use, on account of its greater solubility.

MORPHINÆ HYDRIODAS.—*Hydriodate of morphine* ($C_{17}H_{19}NO_3.HI.2H_2O$) may be made by mixing together strong solutions of hydrochlorate of morphine, 2 parts, and of iodide of potassium, rather more than 1 part. Wash the precipitate with a little cold water; press it between folds of blotting paper, redissolve it in hot water, and crystallize. It may also be prepared with morphine and warm hydriodic acid. Long, silky needles, sparingly soluble in water. This salt, according to E. Schmidt, is probably identical with Winckler's *Iodide of morphine* (*Morphinæ Iodas*, see directions for its preparation in this *Dispensatory*, preceding editions, and in *Amer. Jour. Pharm.*, 1853, p. 126). Doses of these, same as the acetate.

MORPHINÆ HYDROBROMAS, *Morphine hydrobromate* ($C_{17}H_{19}NO_3HBr.2H_2O$), *Morphine bromide*.—Prepared by double decomposition between alcoholic solutions of morphine sulphate (19 parts), and potassium bromide (6 parts), or by dissolving pure morphine in warmed hydrobromic acid. It forms long, white needles, soluble in 25 parts of cold water.

MORPHINÆ PHTHALAS, *Morphine phthalate.*—To a hot solution of pure phthalic acid add pure morphine as long as the latter is dissolved. Filter and evaporate. This salt dissolves in 5 parts of water, forming neutral solutions, and is recommended for hypodermatic use.

MORPHINÆ LACTAS ($C_{17}H_{19}NO_3.C_3H_6O_3$).—*Morphine lactate* crystallizes in prisms soluble in water (1 in 8), and alcohol (1 in 93) (see D. B. Dott, *Amer. Jour. Pharm.*, 1886, p. 353).

MORPHINÆ VALERIANAS.—Morphine neutralized with valerianic acid, forms *Valerianate of morphine*, a salt which is used to some extent in *nervous diseases*, restlessness in *fevers*, etc. The dose is the same as for the sulphate of morphine.

MORPHINÆ BIMECONAS, *Morphine bimeconate.*—A preparation called *Solution of Bimeconate of Morphia* was at one time introduced into this country from England, and at a very high price, and was stated to possess all the therapeutic effect of opium without any of its disagreeable influences, as well as to be serviceable in those cases where from idiosyncrasy or other causes the crude drug or its ordinary preparations could not be employed, when these were indicated (see P. Squire, *Amer. Jour. Pharm.*, Vol. XI, 1839, p. 166). In the *London Pharmaceutical Journal*, on page 288, Vol. XV, 1885, the following formula for this solution is given: "Take of bimeconate of morphine, 10 grains; alcohol, 1 fluid drachm; distilled water, 13 fluid drachms. Mix." But there is no formula for the bimeconate itself. If there be such a salt, it may probably be made by the addition of meconic acid to a solution of morphine.

According to Prof. W. Procter, Jr., the morphine bimeconate may be prepared as follows: Macerate opium in powder (or dry enough to powder) 5 troy ounces in distilled water, a pint, with agitation for three days, strain with expression, and again macerate in successive portions of distilled water, a pint each time, for 24 hours, until 4 pints have been used, and the opium is sufficiently exhausted. Evaporate the liquors carefully to the measure of a pint, filter, and add solution of acetate of lead until it ceases to produce a precipitate. Collect this on a filter, thoroughly wash it with water, suspend it in a pint of warm distilled water, pass a current of hydrogen sulphide through the mixture until the lead is entirely precipitated, heat and filter the solution of meconic acid that remains, until deprived of sulphuretted odor. Meanwhile, take the liquid filtered from the lead precipitate (containing the morphine, etc.) together with the washings, evaporate them at a gentle heat to 4 fluid ounces; drop in sufficient diluted sulphuric acid to precipitate the oxide of lead present, and filter; then mix the filtrate with an equal bulk of alcohol, and carefully add water of ammonia, with agitation, until it remains in slight excess; allowing it to rest 24 hours, that the morphine may separate. Collect the impure morphine on a filter, wash it with a little water, and dissolve it in the hot solution of meconic acid (above referred to) and filter if necessary, washing the filter with a little distilled water. Finally, add sufficient distilled water to the filtrate to make it measure 3 pints, and then stronger alcohol, 95 per cent, a pint, and mix them.

This solution is of a light, reddish-brown color, varying however, in different specimens, and which is due to adhering coloring matter, and especially to the oxide of iron with which it comes in contact during the process; its odor is that of alcohol, and its taste decidedly bitter. Its morphine strength is about 3.3 grains per fluid ounce. Prof. Procter does not believe it to possess any merit not embraced in the *Liquor Opii Compositus*, of Dr. Squibb (*Amer. Jour. Pharm.*, 1860, p. 120), and the *Deodorized Tincture of Opium* of the *U. S. P.* (*Amer. Jour. Pharm.*, 1867, p. 104). Mr. D. B. Dott (*Pharm. Jour. Trans.*, Vol. IX, 1879, p. 883, endeavoring to prepare the meconates of morphine, could obtain only one well-defined crystallizable salt, namely, the neutral *dimorphine meconate*, of the formula $(C_{17}H_{19}NO_3)_2.C_7H_4O_7.5H_2O$. It is easily prepared by dissolving the equivalent quantities of morphine and meconic acid in boiling water and allowing the solution to cool. The author was unable, however, to prepare a crystallizable *monomorphine meconate* (*morphine bimeconate*) and, therefore, doubts its existence (*Amer. Jour. Pharm.*, 1887, p. 188).

MORPHINÆ ACETAS (U. S. P.)—MORPHINE ACETATE.

FORMULA: $C_{17}H_{19}NO_3C_2H_4O_2 \cdot 3H_2O$. MOLECULAR WEIGHT: 398.12.

"Morphine acetate should be kept in dark amber-colored, well-stoppered vials"—(*U. S. P.*).

SYNONYMS: *Morphia acetas, Morphium aceticum, Morphinum aceticum, Acetate of morphia, Acetas morphicus, Acetas morphina.*

Preparation.—Wittstein's process is: "Intimately mix 2 parts of pure morphine with 2 parts of water in a mortar, warmed in a sand-bath, and then add concentrated acetic acid to it until the morphine is dissolved; 1 part of acetic acid, sp. gr. 1.045, will be sufficient. Pour the solution on a shallow porcelain plate, dry at a temperature not to exceed 48.8° C. (120° F.), powder, and preserve in a closed vessel in a cool place. The yield will be about one-eighth more than the weight of the morphine employed."

In the British process (*Br. Pharm.*, 1885) the morphine is freshly prepared from the hydrochlorate by precipitation with solution of ammonia. The well-washed morphine is then saturated with diluted acetic acid and evaporated by water-bath, keeping the acid in slight excess, until when cooled it will solidify. The product is dried at a low heat to prevent the dissipation of the acid, rubbed to a powder, and preserved in well-stopped bottles.

Description and Tests.—Morphine acetate is officially described as being "a white or faintly yellowish-white, crystalline or amorphous powder, having a faint, acetous odor, and a bitter taste. It slowly loses acetic acid when exposed to the air. Soluble at 15° C. (59° F.), when freshly prepared in 2.5 parts of water, and in 47.6 parts of alcohol; in 1.5 parts of boiling water, and in 14 parts of boiling alcohol; also soluble in about 1700 parts of ether, 2100 parts of cold chloroform, and 60 parts of boiling chloroform. On protracted exposure to the air. the salt gradually loses some acetic acid, and becomes less soluble. When heated, the salt loses water as well as acetic acid. Upon ignition, it is consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. The addition of potassium or sodium hydrate T.S. to an aqueous solution of the salt causes a white precipitate, which is soluble in an excess of the alkali, and which conforms to the reactions and tests of morphine (see *Morphina*). On adding sulphuric acid to the salt, vapors of acetic acid are evolved"—(*U. S. P.*). If a solution of the acetate is required the addition of a trace of acetic acid will render the solution clear in case the salt has lost some acid by evaporation. Its aqueous solution, moderately concentrated, is affected by nitric acid and ferric chloride in the same manner as morphine; and the alkalies and alkaline earths precipitate morphine from it, but redissolve it if added in excess.

Action, Medical Uses, and Dosage.—Acetate of morphine exerts a similar influence upon the system to the other salts of morphine, and is preferred by some practitioners to them; but I have not found the combination of any acid to appreciably affect the therapeutical influence of morphine (J. King). It may be substituted for opium, as a general rule, or for any of the other salts of morphine. The dose to produce an anodyne or hypnotic effect is from ⅛ to ¼ grain; but under certain excitable conditions of the system, even more may be required. One-sixth of a grain represents about 1 grain of opium. It is sometimes used externally, applied to vesicated surfaces, for the purpose of affecting the system. Internally, it may be given either in the form of pill or solution. A solution (*Liquor Morphinæ Acetatis*) may be formed by adding 4 grains of acetate of morphine to 4 fluid ounces of distilled water. If it does not readily dissolve, 5 minims of diluted acetic acid may be added. The dose of this is from ½ to 2 fluid drachms. A fluid drachm or two of alcohol, mixed with the water forming the solution, will prevent spontaneous decomposition. (See also *Liquor Morphinæ Acetatis* [*Br. Pharm.*], which is four times stronger, containing ½ grain of morphine to the fluid drachm.)

MORPHINÆ HYDROCHLORAS (U. S. P.)—MORPHINE HYDROCHLORATE.

FORMULA: $C_{17}H_{19}NO_3HCl+3H_2O$. MOLECULAR WEIGHT: 374.63.

SYNONYMS: *Morphiæ murias*, *Hydrochloras morphicus*, *Murias morphicus*, *Muriate of morphia*, *Morphiæ hydrochloras*.

Preparation.—"Take of pure morphine, 2 parts; rub in a porcelain dish with water, 5 parts; heat to the boiling point, and add pure hydrochloric acid until the morphine is dissolved (1 part of acid, sp. gr. 1.130, will suffice), and then allow it to cool. After standing a day, the crystals which form are separated from the supernatant liquid, which is evaporated to further crystallization. The salt is spread on filtering paper and dried; about $2\frac{1}{2}$ parts by weight should be obtained" (Wittstein). The hydrochloric acid must be added gradually, and the mixture be constantly stirred. The process of the *U. S. P.* (1870) was essentially the same.

The process of the *British Pharmacopœia* (1885) is based on Dr. Wm. Gregory's method of obtaining the hydrochlorate from opium as the starting point. By this process the meconate of morphine existing in the opium is decomposed by chloride of calcium, which forms, through double decomposition, a precipitate of meconate of calcium, leaving hydrochlorate of morphine in solution, which is obtained in crystals by evaporation; these are purified by repeated solution, concentration, and crystallization, and lastly, decolorization with animal charcoal. (Also compare *Morphina.*)

Description and Tests.—Hydrochlorate of morphine is described by the *U. S. P.* as occurring in "white, feathery needles of a silky luster, or minute, colorless, cubical crystals, odorless, and having a bitter taste; permanent in the air. Soluble at 15° C. (59° F.), in 24 parts of water, and in 62 parts of alcohol; in 0.5 part of boiling water, and in 31 parts of boiling alcohol. Very slightly soluble in ether or chloroform. When heated at 100° C. (212° F.), the salt loses its water of crystallization (14.38 per cent); at 300° C. (572° F.), it coheres slightly, but does not completely melt; and upon ignition it is consumed, leaving no residue. The salt is neutral to litmus paper"—(*U. S. P.*). Hydrochlorate of morphine also dissolves in 20 parts of glycerin and 800 parts of olive oil. This salt contains of crystallized morphine, 80.7 per cent; of anhydrous morphine, 75.9 per cent. Hydrochlorate of morphine is decomposed by diluted sulphuric acid, with disengagement of hydrochloric acid. "The addition of potassium or sodium hydrate T.S. to an aqueous solution of the salt causes a white precipitate, soluble in an excess of the alkali, and conforming to the reactions and tests of morphine (see *Morphina*). The aqueous solution of the salt yields, with silver nitrate T.S., a white precipitate insoluble in nitric acid"—(*U. S. P.*). The *British Pharmacopœia* directs that this salt should dissolve "without coloration in strong sulphuric acid; the addition of a small quantity of sodium arsenate to a portion of this solution causes a bluish-green coloration, and a small quantity of bismuth oxynitrate added to another portion, gives a purplish-brown coloration"—(*Br. Pharm.*, 1898). White sugar is said to have entered sometimes into hydrochlorate of morphine as an adulteration. The fermentation test will serve to discover it. Hydrochlorate of morphine should be entirely soluble in water, giving a colorless solution; its loss of weight at 100° C. (212° F.), should not exceed 14.38 per cent.

Action, Medical Uses, and Dosage.—Hydrochlorate of morphine possesses properties similar to the other salts of morphine, having essentially all the actions of opium. It is much more extensively used in Great Britain than in this country; and may be employed as a substitute for opium, or the acetate or sulphate of morphine. Its dose is from $\frac{1}{8}$ to $\frac{1}{2}$ grain; $\frac{1}{6}$ of a grain represents about 1 grain of opium. A solution of the hydrochlorate of morphine (*Liquor Morphinæ Hydrochloratis*) is made by dissolving 4 grains of hydrochlorate of morphine in distilled water, 4 fluid ounces. If it does not readily dissolve, 5 minims of diluted hydrochloric acid may be added. The dose is from $\frac{1}{2}$ to 2 fluid drachms. Alcohol, 1 or 2 fluid drachms, mixed with the water forming this solution, will prevent spontaneous decomposition (see also *Liquor Morphinæ Hydrochloridi* [*Br. Pharm.*, 1898], which is four times as strong as the foregoing solution.

MORPHINÆ SULPHAS (U. S. P.)—MORPHINE SULPHATE.

FORMULA: $(C_{17}H_{19}NO_3)_2H_2SO_4+5H_2O$. MOLECULAR WEIGHT = 756.38.

SYNONYMS: *Morphiæ sulphas, Sulphas morphicus, Sulphate of morphia.*

Preparation.—"Take of pure morphine, 2 parts; rub it in a porcelain dish with 5 parts of distilled water, then heat to boiling and add sulphuric acid until the morphine is dissolved, and then allow the solution to cool. After standing a day, the crystals which form are treated in the same manner as named for the crystals of hydrochlorate of morphine. The sulphuric acid must be added gradually, an excess of acid is to be tested for with blue litmus paper, and the mixture must be constantly stirred" (Wittstein). The processes of the *U. S. P.* (1870) and of the *Br. Pharm.* (1885) are essentially the same. Morphine is here saturated with sulphuric acid, of which saturation its complete solution in the water is an indication. As in the preparation of the acetate of morphine, the heat must not be too high during evaporation of this salt, else it will be decomposed.

Description and Tests.—Morphine sulphate is officially described as occurring in "white, feathery, acicular crystals of a silky luster, odorless, and having a bitter taste; permanent in the air. Soluble at 15° C. (59° F.), in 21 parts of water, and in 702 parts of alcohol; in 0.75 part of boiling water and 144 parts of boiling alcohol; almost insoluble in ether. When heated for some time at 100° C. (212° F.), the salt loses 3 molecules (7.12 per cent) of water of crystallization; the remaining 2 molecules (4.75 per cent) are gradually expelled by raising the temperature to 130° C. (266° F.). At 255° C. (491° F.) the salt melts, and upon ignition, it is consumed, leaving no residue. The salt is neutral to litmus paper. The addition of potassium or sodium hydrate T.S. to an aqueous solution of the salt causes a white precipitate, which is soluble in an excess of the alkali, and which conforms to the reactions and tests of morphine (see *Morphina*). The aqueous solution yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid"—(*U. S. P.*). Morphine sulphate is also soluble in glycerin (1 in 5). It contains of crystallized morphine, 79.94 per cent; of anhydrous morphine, 75.19 per cent. D. B. Dott (1877) found a certain commercial specimen of morphine sulphate to consist of more than one-third of anhydrous sulphate of sodium. Analysis of the mixture thrown on the market in 1898, under the name "Husa," showed that it contained large amounts of morphine sulphate (see J. U. Lloyd, *Amer. Jour. Pharm.*, 1899, p. 210).

Action, Medical Uses, and Dosage.—The effects of morphine and its salts are practically those of *opium*, which see. Being but one of the constituents of that drug, however, slight differences in action have been observed. Much depends also, upon the manner of administering it. The indications are those given under *Opium*. Morphine is not so soluble as its salts, which are usually employed; the principal ones are the sulphate, hydrochlorate, and acetate. Pereira says that in comparing the morphine salts with opium, we observe that they are less stimulant, and less disposed to cause sweating, constipation, headache, and dryness of the tongue; the feelings which they excite are less agreeable, and hence they are not adapted to be substituted for opium by the eaters of this drug; they more readily affect the bladder than opium. Morphine is more likely to provoke nausea and vomiting than opium. If given by mouth for any length of time it induces diarrhæa, while opium does not, but the bowels cease to be costive. Hypodermatically, morphine constipates. Morphine primarily diminishes the frequency of the pulse, while opium increases it. Morphine lowers the temperature, while opium often increases it. Less stimulation of the nervous and circulatory systems are observed under morphine, and itching of the surface is far more readily produced by the alkaloid. Finally, the narcotic action of the morphine is comparatively less profound than that of the parent drug. A weak and oppressed heart is always embarrassed by opium and its alkaloids.

Enormous amounts of morphine are consumed by morphine habitues (see *Opium*). Many cases are reported in which the daily allowances were 14, 16, 18, 40, 50 grains, and even 80 grains have been taken for a few days. A case is reported in which a woman took, hypodermatically, 25 grains at one time, and a case came under our care in which a one-legged habitué attempted suicide by the injection of 24 grains, besides shooting himself through the lower edge of the left lung, the bullet lodging in the skin of the back. Every inspiration forced frothy blood out of the bullet wound. He recovered. His arms, left leg, and side of body presented a tattooed appearance from the habitual injections to which he had been accustomed.

The uses of morphine have been considered mainly under the head of opium (see *Opium*). It may be well, however, to briefly enumerate some of the conditions there mentioned, and to add a few others. It should be borne in mind, however, that unless contraindicated, it is the drug for *sudden, acute pain*, and pain from *wounds*, *burns*, and *scalds*. It is useful, therefore, following the indications given under *Opium* in *puerperal convulsions*, *peritonitis*, *pleuritis*, *angina pectoris*, *ovaritis*, *metritis, appendicitis, asthma, sciatica,* to alleviate severe pain in the various forms of *neuralgia,* as *pleurodynia, gastrodynia,* etc., and in *obstinate vomiting, cholera morbus, renal* and *biliary colic, local spasms, epileptiform convulsions, lead colic,* various severe and acute *abdominal pains,* and *poisoning by belladonna* or *atropine, stramonium* or *strychnine.* In *sunstroke,* with general excitation, jactitation, and convulsions, morphine gives relief. As a stimulant in the prostrating stage of *typhus* and *typhoid fevers,* and to check unhealthy discharges, opium is to be preferred to morphine. Morphine salts are always used to relieve the excessive operation of strychnine.

The dose of morphine and its salts, is from ⅛ to ¼ grain; and ⅙ of a grain represents about 1 grain of ordinary opium. The various salts of morphine, dissolved in water, are used by subcutaneous injection. A dose of from ⅛ to ¼ grain of the selected salt, in solution, is injected at once, repeating the operation in 1 or 2 days, or even every 3 or 4 hours, if the urgency of the case requires. Vomiting, nausea, or uneasiness, sometimes follows the injection, but soon passes away without injury to the patient.

Sulphate of morphine is probably more often employed in this country than any other of the salts of this alkaloid, and is considered to be more uniform in its effects on the system. It possesses the usual properties belonging to morphine and its various salts, and is used in cases where these are indicated. The dose is from ⅛ to ¼ grain, which may be given in pill or solution, or hypodermatically. A solution of sulphate of morphine (*Liquor Morphiæ Sulphatis, U. S. P.,* 1870), is made by dissolving 4 grains of the sulphate of morphine in 4 fluid ounces of distilled water. This forms a convenient solution, in which the morphine may be administered in minute or ordinary doses to suit the occasion; it will keep for a long time unaltered. A fluid drachm of this solution is equal to about ⅛ of a grain of the sulphate (see also *Liquor Morphinæ Sulphatis* [*Br. Pharm.,* 1885], which is four times as strong as the *U. S. P.* [1870] solution.)

MOSCHUS (U. S. P.)—MUSK.

"The dried secretion from the preputial follicles of *Moschus moschiferus,* Linné"—(*U. S. P.*).

Class: Mammalia. *Order:* Ruminantia.

Source and History.—This article is obtained from the male of *Moschus moschiferus* or *Musk deer,* a wild ruminating animal, rather larger than the domestic goat, and approaching the deer in its characters, and which is an inhabitant of Central Asia. At the posterior part of its abdomen, there is a small sac situated immediately under the skin, which opens a little in front of the preputial orifice, and which is filled with a thick fluid, abounding particularly in the rutting season. This fluid, in the dried state, is musk. It is removed from the animal in its containing bag, and dried in this state for exportation. The musk-bag, or pod, is usually plano-convex; and in general the plane surface is a bare membrane, while the convex surface is covered with stiff hairs; but sometimes the hairy and membranous parts are reversed. It weighs along with its contents, between 5 and nearly 10 drachms, and contains on an average 2⅔ drachms of musk, *i. e.,* from 26 to 52 per cent. Two kinds of musk are met with in American commerce. The *Chinese, Thibet,* or *Tonquin musk* is the variety that should always be preferred. It occurs in commerce in lots of about 25 paper-wrapped sacs, shipped in lead-lined boxes (caddies). The yellowish or brownish hairs are cut short. It comes to us partly from Tonquin, but for the greater part, from the Chinese province of Yun-Nan, and is shipped from the Chinese port, Shanghai, hence the name *Chinese musk.* A consular report from Shanghai, in 1885, stated the annual export to be about 3000 caddies, each containing, on an average, 20 pods, thus representing an annual decimation of the animal by about 60,000. *Siberian musk* is also called *Russian musk;* it is exported from St. Petersburgh. It resembles the preceding, yet often is of a much inferior quality, having an ammoniacal, somewhat fetid odor.

Cabardine musk is a variety which comes in flat, ovate sacs, the hairs on which are somewhat paler and thinner, and the odor of which is feebler and far less aromatic than that of good musk, besides having a urinous smell. Two other grades, *Assam* and *Bucharian musk-sacs*, are not found in American markets. Musk is now scarcely ever prescribed, both on account of its high price, and the extreme difficulty of obtaining a pure article, as nearly all the musk in trade at the present day, is an almost uncontrollable drug (see *Adulterations;* also see an interesting article on "Musk," from the *Chemist and Druggist*, 1890, in *Amer. Jour. Pharm.*, 1891, p. 149).

Description.—"In irregular, crumbly, somewhat unctuous grains, dark reddish-brown, having a peculiar penetrating, and persistent odor, and a bitterish taste. It is contained in oval or roundish sacs about 4 to 5 Cm. ($1\frac{1}{2}$ to 2 inches) in diameter, on one side invested with a smoothish membrane, on the other side covered with stiff, appressed, grayish hairs, concentrically arranged around 2 orifices near the center. About 10 per cent of musk is soluble in alcohol, the tincture being light brownish-yellow, and on the addition of water becoming slightly turbid. About 50 per cent of musk is soluble in water, the solution being deep-brown, faintly acid, and strongly odorous. When ignited with free access of air, musk gives off a peculiar, somewhat urinous odor, and leaves behind not more than 8 per cent of a grayish ash"—(*U. S. P.*). It is very inflammable. Musk is very little soluble in ether or chloroform. The powerful odor of musk is destroyed when it is rubbed together with camphor, cinnamon, syrup or oil of bitter almonds, oil of fennel, precipitated sulphur, ergot, quinine sulphate or chloride, etc. Hence, to remove the odor from the hands, it is advised to rub the hands with some quinine, moistened with diluted sulphuric acid. On the other hand, alkalies intensify the odor of musk. The odor is also lost by drying the musk over sulphuric acid; it gradually returns, however, as moisture is reabsorbed. With some persons the odor of musk produces several unpleasant effects, as cephalalgia, fainting, etc.

Chemical Composition.—The chemical nature of the odoriferous principle is not known. Geiger and Reinmann found musk to contain a peculiar volatile substance, ammonia, a peculiar, fixed, uncrystallizable acid, stearin and olein, cholesterin, peculiar bitter resin, osmazome (see foot-note under *Ichthyocolla*), and salts. The *U. S. P.* demands that musk, upon incineration, should yield not more than 8 per cent of ash. In addition to the substances mentioned above, musk is incompatible with bichloride of mercury, sulphate of iron, nitrate of silver, and infusion of cinchona.

Adulterations.—Owing to its high price, musk is very liable to adulterations; indeed it is rare that the pure article can be obtained in commerce. In 1889, a consular report from Shanghai states that the article comes into the Chinese market in simple wood cases of 9 to 14 caddies; every parcel contains a number of adulterated sacs, which must be bought along with the good ones. About 50 per cent seems to be adulteration. The parcels are then, as a rule, broken up by the exporter and sorted for the London market. He divides the lot into three grades, all of which are probably thrown on the market. "The sophistication consists of earth, rasped wood, and small pieces of leather or skin, which are inserted in the pods after the musk has been removed. Less frequently the sophistication is effected with lead, heavy pieces of flesh, or paper inserted between the thin inner and thick outer skin, which can only be discovered upon cutting it. In the last year or two, the adulteration has gone up to 80 per cent, but in the absence of better qualities, even such an article has found buyers" (*Amer. Jour. Pharm.*, 1889, p. 376).

These adulterations are very difficult to detect. Musk which is not readily inflammable, whose odor is weak, which is of a black or pale color, very damp, or gritty to the touch, should be rejected as containing impurities. By incineration, genuine musk leaves behind a grayish-white ash, whereas blood leaves a reddish one. It is probably advisable to insist on buying the musk in its containing bag. False pods may be distinguished from the genuine ones, by their ammoniacal odor, by the absence of any aperture in the middle of the hairy coat, by the hair not being arranged in a circular manner, and by the absence of the remains of the penis, which accompanies every genuine musk-sac. False sacs may often be known by being stitched together, because a genuine sac may be opened to introduce foreign matter; such a sample becomes suspicious, and invites further analysis.

To test a bag for lead inserted through its aperture, exposing the specimen to the action of the Roentgen rays will reveal the fraud without the necessity of cutting open the bag (see interesting shadowgraph of an adulterated musk-bag, by E. Wolff, *Pharm. Centralh.*, 1896, p. 827).

Action, Medical Uses, and Dosage.—Musk is a stimulant to the nervous and vascular systems, acting much after the manner of the alcoholics, and an irritant to the stomach, deranging its functions; also said to possess narcotic properties secondarily. From its influence on the nervous system it is termed a powerful antispasmodic; and has been used with advantage in *typhus* and *low forms of fever*, *obstinate hiccough*, *pertussis*, *epilepsy*, *chorea*, *hysteria*, *asthma*, *palpitation of the heart*, *colic*, *convulsions of infants*, all *spasmodic affections*, etc. (see *Specific Indications* below). United with ammonia, it has been used with success in stopping the progress of *gangrene*. Fifteen grains of musk, combined with extract of valerian, and alcoholic extract of cimicifuga, of each, 15 grains, and divided into 15 pills, will be found beneficial in *pneumonia* accompanied by delirium, and in the involuntary movements observed in *low typhoid fevers*. One pill may be given every 1 or 2 hours, until there is a marked improvement in the symptoms. In small doses musk is hypnotic. If its use is long continued, it imparts its peculiar odor to the secretions. It should always be given in substance, either in the form of pill or emulsion. Dose, from 5 to 20 grains, every 2 or 3 hours. Niter, cochineal, of each, 2 grains; musk, 1 grain; mix and form a powder. This powder, given and repeated every 2 or 3 hours, is said to be very useful in some low forms of fever, and in *febrile* or *inflammatory affections* with spasmodic action or delirium.

Specific Indications and Uses.—Hiccough; muscæ-volitantes, subsultus tendinum, low muttering delirium, and stupor; pulse small, quick, irregular, or tremulous; muscular spasm; insomnia from physical or mental fatigue.

Related Products.—A naturalist found in Central Africa numerous flocks of a small ruminant of the gazelle family, the excrement from which exhaled so decided an odor of musk that be thought it might be advantageously used. M. Stanislas Martin formed a tincture with some of it, using alcohol of 80 per cent. It had a greenish color. This excrement, powdered and macerated with glycerin, lard, or fixed oils, forms a powerful musky odor, answering all the purposes of musk as a perfume, and being decidedly cheaper (*Bull. de Thérap.*, 1868). The species probably referred to is the *Antilope Dorcas*, Linné, or *Algerian gazelle*. The excrements are small and globular. Jacqueme obtained an alcoholic extract (7 per cent) from them, which contained calcium, ammonium, and sodium salts, a resinous body of musky odor, and an acid capable of crystallization.

HYRACEUM.—Probably derived from the *Hyrax capensis*, Cuvier (*Order:* Hyracoidea), or *Badger*, a South African mammal. The drug comes in brittle, resinous, irregular, blackish-brown fragments, of a nauseously bitter taste. When heated it becomes soft and evolves a castor-like odor; further heated it burns, evolving acrid fumes. Water does not wholly dissolve it, and it is still less soluble in alcohol or ether. It is collected on mountain sides in Africa, and is either a fecal or urinous product. Analyses of Wm. H. Greene and A. J. Parker (*Amer. Jour. Pharm.*, 1879, p. 363), show this substance to yield, upon incineration, 34 per cent of ash, chiefly containing chlorides and carbonates of sodium, calcium, potassium, and magnesium. The organic matter constitutes about 52 per cent, containing traces of urea, uric acid, hippuric and benzoic acids. Hyraceum is said to resemble the American castor in physiological action. A similar dried body, renal and fecal, is found in rock-fissures in New Mexico, and is believed to be the product of the *Neotoma* or *Wild rat* (Cope).

CIVETTA, or ZIBETHUM, *Civet*, *Zibeth.*—An unctuous, musky secretion, collected from receptacles between the anus and genitalia of both male and female of the *Viverra Civetta*, Schreber (*Civet cat*), of Africa, and *Viverra Zibetha*, Schreber, of the East Indies. The animals are kept in captivity for the purpose of obtaining the drug. It was formerly employed in medicine, but is now wholly consumed in the perfumer's art. It is semisolid, yellowish, changing to brown, unctuous, not so diffusible nor agreeable as musk, of an unpleasant, subacrid, bitter, greasy taste, soluble in part in hot alcohol and in ether, but not in water. It is fusible, and burns without leaving much residue. It contains salts, resin, coloring bodies, various fats, and a volatile oil.

AMERICAN MUSK.—The musk-sacs of the *Musk-rat* (*Fiber zibethicus*) have been substituted for musk under the name *American musk*. Its odor differs somewhat from that of musk, but it may be advantageously employed in perfumes (see *Amer. Jour. Pharm.*, 1881, p. 397, and 1886, p. 550).

ARTIFICIAL MUSK.—An *artificial musk* is prepared, by carefully adding, drop by drop, 3 parts of fuming nitric acid to 1 of unrectified oil of amber. The acid is decomposed and the oil converted into an acid resin, which must be kneaded under pure water until all excess of acid is removed. The substance which remains is of a yellowish-brown color, viscid, and of an odor similar to musk, for which it may be used as a substitute, in doses of from 15 to 30 grains.

Moschus Factitius, *Artificial musk.*—The artificial musk introduced by Dr. A. Baur, and known commercially as "*Musk Baur,*" is *trinitroso-butyl-toluene* ($C_6H.CH_3.C[CH_3]_3.[NO_2]_3$), prepared by the interaction of tertiary butyl-toluene ($C_6H_4.CH_3.C[CH_3]_3$), and a mixture of sulphuric and nitric acids. It forms yellowish-white needles melting at 96° to 97° C. (204.8° to 206.6° F.), insoluble in water, but soluble in alcohol, chloroform, ether, benzol, and light petroleum ether (see *Amer. Jour. Pharm.*, 1890, p. 489, and 1892, p. 31). The action of this body is similar to, but less energetic, than that of musk. The dose for a small child is from ⅛ to 1 grain, every 2 or 3 hours; for an adult, 10 grains. Of a tincture (ʒj to ℥x of alcohol), the dose is 1 fluid drachm. Hauner, of Munich, praises it in *spasm of the glottis* in children.

Vegetable Musk.—On account of the high price of musk, and its liability to adulteration, Dr. Hannon (*Jour. de Pharm.*, 1854) sought for a vegetable substitute, which he thinks he has found in a Columbian plant, cultivated in Belgium, *Mimulus moschatus*, which plant yields an essential oil by distillation. In doses of 2 or 3 drops, this oil exerts an energetic, excitant action on the intestinal canal, and on the brain. In a state of health it caused vertigo, cephalalgia, dryness in the fauces, epigastric weight, and eructations. He believes it may replace the animal musk, and may be given in *hysteria* and analogous complaints, in doses of from 2 to 4 drops in 24 hours. He calls it *vegetable musk*.

Nearly all of the preceding products are used in the manufacture of perfumes and not, at the present time, in medicine.

MUCILAGINES.—MUCILAGES.

Mucilages are viscid, somewhat tenacious, and generally adhesive liquids, prepared with water as a solvent. As represented by the preparations of the *U. S. P.* they are usually solutions of gums, or closely related bodies. The official mucilages gradually decompose and become acid, thinner, and offensive in smell. Such changes may often be checked or entirely prevented by glycerin, alum, or creosote. The majority of the mucilages should be prepared only as wanted.

MUCILAGO ACACIÆ (U. S. P.)—MUCILAGE OF ACACIA.

Synonym: *Mucilage of gum Arabic.*

Preparation.—"Acacia, in small fragments, three hundred and forty grammes (340 Gm.) [11 ozs. av., 435 grs.]; water, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Wash the acacia with cold water, and let it drain. Then add to it enough water to make the mixture weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], agitate or stir occasionally until the acacia is dissolved, and strain. Keep the product in well-stoppered, completely filled bottles, in a cool place"—(*U. S. P.*). Clear, white pieces of gum acacia should be selected for this mucilage. By rapid washing of the fragments first with cold water, much of the impurities may be removed. The mucilage becomes thick and dense during preparation, making it somewhat difficult to stir or agitate, and it has been proposed to make the solution by suspending the gum in a loose-textured bag, which should be moved occasionally from place to place in order to bring it into contact with successive portions of water. In our experience, however, no difficulty is experienced in making it by the usual method. It should be at once put into well-filled bottles, and even then it readily sours with the development of acetic acid. Mucilage of acacia should be a colorless, or but faintly yellowish, transparent, nearly tasteless, viscid fluid, with a faint, although not disagreeable odor. Aluminum sulphate (1 to 125 parts) is said to increase its adhesiveness. Heat should not be employed in the preparation of this mucilage as it is said to promote the formation of acetic acid.

Action, Medical Uses, and Dosage.—This flavored and sweetened, diluted mucilage forms an agreeable and soothing drink for *febrile* and *inflammatory conditions*, being particularly applicable in *gastric* and *respiratory inflammations*. It is probably nutritive. In pharmacy it is employed to give adhesiveness in pill masses, and in mixtures to hold in suspension insoluble ingredients. It is sometimes used in making troches. It may be freely given.

MUCILAGO AMYLI.—MUCILAGE OF STARCH.

Preparation.—To 120 grains of starch gradually add 10 fluid ounces (Imp.) of distilled water, with constant trituration. Boil for a few moments, with continual stirring. This accords with the *British Pharmacopœia*, 1885. It should be prepared only when needed. This mucilage is of proper consistence for an enema, being opaline and gelatinous.

Action and Medical Uses.—This is employed for its demulcent effects in *rectal* and other *intestinal inflammations* that can be reached by an enema. It is chiefly employed as a vehicle for anodyne applications (as laudanum) in *dysentery*, and for this purpose but small quantities, 2 or 3 fluid ounces, should be employed so that the patient may be able to retain the medicament until its effects are produced.

MUCILAGO CHONDRI (N. F.)—MUCILAGE OF IRISH MOSS.

Preparation.—"Irish moss, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Wash the Irish moss with cold water, then place it in a suitable vessel, add one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water, and heat it, on a boiling water-bath, for 15 minutes, frequently stirring. Then strain it through muslin, and pass enough water through the strainer to make the liquid, when cold, measure one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mucilage of Irish moss may also be prepared in the following manner: Irish moss gelatin (F. 184), twenty grammes (20 Gm.) [309 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Heat the Irish moss gelatin with one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water, at a boiling temperature, until it is completely dissolved. Then allow the solution to cool, and add enough water, if necessary, to make up the volume to one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. *Note.*—Mucilage of Irish moss, thus prepared, is well adapted for the preparation of emulsions of fixed oils. If it is, however, required for admixture with clear liquids, it should be diluted, when freshly made, and while still hot, with about 3 volumes of boiling water, filtered, and the filtrate evaporated to the volume corresponding to the proportions above given. The filtration may be greatly facilitated by filling the filter loosely with absorbent cotton, and pouring the liquid upon the latter.

"Mucilage of Irish moss may be preserved for some time by transferring it, while hot, into bottles, which should be filled to the neck, then pouring a layer of olive oil on top, securely stoppering the bottles, and keeping them, in an upright position, in a cool place. When the mucilage is wanted for use, the layer of oil may be removed by means of absorbent cotton"—(*Nat. Form.*).

Medical Uses.—(See *Chondrus.*)

MUCILAGO CYDONII (N. F.)—MUCILAGE OF CYDONIUM.

Synonyms: *Mucilage of quince-seed, Mucilago cydoniæ.*

Preparation.—"Cydonium, two grammes (2 Gms.) [31 grs.]; distilled water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Macerate the cydonium for half an hour, in a covered vessel, with the distilled water, frequently agitating. Then drain the liquid through muslin without pressure. This preparation should be freshly made, when required for use"—(*Nat. Form.*). An identical preparation was official in the *U. S. P.*, 1880. Rose-water is employed by the *German Pharmacopœia.* The hair-dressing mucilage known as *Bandoline*, is prepared by macerating, in 1 pint of water, 2 drachms of quince-seeds (unbroken), and adding cologne water, 1 ounce. Other perfumes may be substituted, if preferred.

Action, Medical Uses, and Dosage.—Quince-seed mucilage is soothing and protecting, and adapted for *inflammations of mucous surfaces.* It is therefore valuable in *gastro-intestinal inflammations, irritation of broncho-pulmonary tract*, with *cough, cystitis* and other *acute urinary disorders*, and *cutaneous* and *conjunctival inflammations.* It may be freely used.

MUCILAGO DEXTRINI (N. F.)—MUCILAGE OF DEXTRIN.

Preparation.—"Dextrin, three hundred and thirty-five grammes (335 Gm.) [11 ozs. av., 357 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix them in a tared vessel, and heat the mixture, under constant stirring, to near boiling, until the dextrin is dissolved and a limpid liquid results. Then restore any loss of water by evaporation, strain the liquid through muslin, and allow it to cool short of gelatinizing, when it will be ready for immediate use. *Note.*—If the mucilage is not at once to be used for preparing emulsions or other mixtures, transfer it, while hot, to bottles, which should be filled to the neck. Then pour into each bottle a sufficient quantity of olive oil to form a protecting layer, and when the mucilage has gelatinized, securely cork the bottles, and keep them in a cool place, in an upright position. When gelatinized mucilage of dextrin is to be used for the preparation of emulsions and other mixtures, pour off the protecting layer of oil from the surface, remove the remainder of the oil by a pellet of absorbent cotton, and warm the bottle gently, until the mucilage is liquefied. Then allow it to cool short of gelatinizing. The kind of dextrin suitable for this preparation is the commercial, *white* variety, provided it still contains some unaltered or only partially altered starch, and forms a jelly on cooling, when made into a mucilage after the formula above given. The yellow variety, which is completely soluble in about 2 parts of cold water, will not answer the purpose"—(*Nat. Form.*).

MUCILAGO SALEP (N. F.)—MUCILAGE OF SALEP.

Preparation.—"Salep, in fine powder, ten grammes (10 Gm.) [154 grs.]; cold water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]; boiling water, nine hundred cubic centimeters (900 Cc.) [30 fl℥, 208 ♏]. Place the powdered salep into a flask containing the cold water, and shake until the powder is divided. Then add the boiling water, and shake the mixture continuously until it has cooled to 25° C. (77° F.), or below this temperature. The cooling may be hastened by frequent and brief immersion of the flask in cold water. Mucilage of salep should be freshly made, when wanted for use. *Note.*—If sugar or syrup is prescribed in the same mixture with mucilage of salep, it is preferable to triturate the required quantity of powdered salep with either of the former, as the case may be, and then to add rapidly the proportionate amount of boiling water"—(*Nat. Form.*).

Action and Medical Uses.—(See *Salep.*)

MUCILAGO SASSAFRAS MEDULLÆ (U. S. P.)—MUCILAGE OF SASSAFRAS PITH.

Preparation.—"Sassafras pith, two grammes (2 Gm.) [31 grs.]; water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Macerate the sassafras pith in the water during 3 hours, and strain. This preparation should be freshly made, when wanted"—(*U. S. P.*). Sassafras mucilage has a bland taste, is thickish, colorless, and transparent.

Action, Medical Uses, and Dosage.—This is a soothing and refreshing drink for *inflammatory conditions of mucous surfaces* and in *febrile disorders.* It is especially applicable in *dysentery.* Locally, it is applied in *conjunctivitis* (acute), *erythema*, and various *inflammatory skin disorders.* It may be freely used.

MUCILAGO TRAGACANTHÆ (U. S. P.)—MUCILAGE OF TRAGACANTH.

Preparation.—"Tragacanth, six grammes (6 Gm.) [93 grs.]; glycerin, eighteen grammes (18 Gm.) [278 grs.]; water, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix the glycerin with seventy-five cubic centimeters (75 Cc.) [2 fl℥, 257 ♏] of water in a tared vessel, heat the mixture to boiling, add the tragacanth, and let it macerate during 24 hours, stirring occasionally. Then add enough water to make the mixture weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.], beat it so as to make it of uniform consistence, and strain it forcibly through muslin"—(*U. S. P.*). Tragacanth is but partly soluble in water. The mucilage is viscid and thick.

Action and Medical Uses.—This has been applied locally to *burns, scalds, ulcers*, etc., for its protective purposes. It is employed as an excipient where a slowly dissolving preparation is desired, as in troches, and in laxatives and non-irritating mixtures. It is also used as a pill excipient.

MUCILAGO ULMI (U. S. P.)—MUCILAGE OF ELM.

Preparation.—"Elm, bruised, six grammes (6 Gm.) [93 grs.]; water, one hundred cubic centimeters (100 Cc.) [3 fl℥, 183 ♏]. Digest the elm with the water, on a water-bath, in a covered vessel, during 1 hour, then strain. This preparation should be freshly made, when wanted"—(*U. S. P.*). Though this fulfils the idea of the framers of the Pharmacopœia, inasmuch as it produces what is understood by the term "mucilage," it does not produce the kind of a mucilage most useful and most grateful to the patient. By a mucilage, the *U. S. P.* refers to a kind of opaque semifluid, gelatinous product, having more or less of a viscid or adhesive quality. It is often a solution in water of a gum, or some material closely related to it. The substance wanted in this mucilage is the mucilaginous constituent of the elm-bark, and that is best extracted by means of *very cold water*. Therefore, the best method to pursue in making mucilage of slippery-elm for the patient, is as follows: Take fresh slippery-elm, or, if it can not be obtained direct from the trees, use the dried strips as found in the drug houses. Shred these, longitudinally, so that the individual pieces will be about the width of an ordinary lead pencil. Now, after bundling together the smaller strips, tie them at one end so that the other ends may be left free after the manner of a whisk-broom. In tying the pieces together leave a long piece of cord by which to suspend the bundle of shreds. Prepare a pitcher of ice-cold water, and place a stick across the top of the vessel and from the stick suspend the shredded bark in the water. If particles of ice be floating in the water, so much the better. In a short time the water will be found to have assumed a thick, ropy, mucilaginous consistence. This preparation should be prepared often, and kept in an ice-cold condition. Furthermore, it should be placed in a situation remote from the sick-room, outdoors if necessary, on account of the great facility with which it absorbs gases and noxious emanations of the sick-chamber.

Action, Medical Uses, and Dosage.—Prepared by the second method, a *good* mucilage of slippery-elm is obtained, and will be found a grateful drink for patients undergoing *febrile* and *inflammatory diseases*, as well as those who *cough* much and complain of *dryness of the mouth and fauces*. It is regarded as particularly useful in *catarrhal* and *inflammatory diseases of the stomach* and *genito-urinary tract*. Locally, it is serviceable as a cooling and soothing application to *cutaneous diseases*, especially the various forms of *dermatitis, erysipelas, furuncles*, and *carbuncle*. Besides being a good demulcent, its nutritious value is considerable. It may be freely administered.

MUCUNA.—COWHAGE.

The hairs from the pods of *Mucuna pruriens*, De Candolle (*Mucuna prurita*, Hooker; *Dolichos pruriens*, Linné; *Stizolobium pruriens*, Persoon; *Carpopagon pruriens*, Roxburgh).

Nat. Ord.—Leguminosæ.

Common Names: *Cowhage, Cowage* (*Seta siliquæ hirsutæ*).

Illustration: Bentley and Trimen, *Med. Plants*, 78.

Botanical Source.—This is a perennial plant, with a fibrous root and a twining, herbaceous, much-branched stem, and of considerable length. The leaves are alternate, pinnately trifoliate, distant, and on long petioles; leaflets entire, ovate, acute, smooth above, hairy beneath; lateral ones oblique at the base, middle one slightly rhomboidal. The flowers are rather large, have a disagreeable, alliaceous odor, are disposed in axillary, lax, many-flowered, interrupted racemes, 1 to 1½ feet long. The corolla is papilionaceous; vexillum cordate, incumbent on the wings, much shorter than they and the keel, without callosities, and flesh-colored; wings oblong-linear, connivent, purple, or violet; keel or carina straight below, slightly falcate in the upper part, terminated by a smooth, polished. acute beak, and greenish-white. Stamens diadelphous (9 and 1), alternately longer; anthers alternately longer and ovate. Calyx campanulate, bilabiate, with 2 very caducous bracteoles as long as the tube, hairy, pink, bilabiate, with narrow lanceolate segments; upper lip broad, entire, or emarginate; lower, trifid, middle segment the largest. Style long, slender, and hairy below; stigma small. The legume is about 3 inches long, as thick as the finger, and closely covered with strong, brown, stinging hairs. The seeds are oblong and variegated, with a white hilum (L.).

History, Description, and Chemical Composition.—This plant inhabits the West Indies, and other tropical parts of South America; it is found in woods, along river courses, upon fences, and in waste, neglected places. The medicinal part of the plant is the hair of the pods, which are generally imported into this country attached to the pod, and from which they are carefully removed, so that they do not fasten to the operator's hands. They are straight, about ⅛ of an inch in length, quadrangularly prismatic, with upper half retrorsely serrated, and acutely pointed at the apex. They are brown and glossy, and inclose a granular, brown substance, which but partially fills the hair. Mucuna, according to Martius (1827), contains resin and a small amount of tannin. The shorter, darker-hued spicula of the *Stizolobium urens*, Persoon (*Mucuna urens*, De Candolle; *Dolichos urens*, Linne), is used for the same purposes as cowhage. The seeds of this species are employed in dysuria in the West India Islands. In India the root of the cowhage plant is a reputed remedy for cholera. Mucuna was first introduced to the notice of English physicians by Bancroft, about the year 1769 (see Dymock's *Vegetable Materia Medica of India*, p. 229).

Action, Medical Uses, and Dosage.—Cowhage was formerly regarded as a mechanical anthelmintic, acting by irritating the body of the worms; its decoction or tincture has no anthelmintic properties. It was used in the treatment of *intestinal worms*, which are expelled alive. It is very probable, however, that its setæ did very little mechanical harm to the worm, for when the spiculæ are moistened, they largely lose their irritating properties. It has no effect on tænia, but appears more serviceable in removing the *lumbrici* and *ascarides*. Dose, from 1 drachm to ½ ounce, in syrup or molasses, and followed a few hours afterward by a purgative. The application of oil is the best to allay the heat and itching it produces when rubbed on the skin. Cowhage has been recommended in the form of an ointment, as a cutaneous irritant, in the place of croton-oil and tartar-emetic; also as a good medium for the endermic application of various substances, as hydrochlorate of morphine. The proportions are, 7½ grains of the hairs of cowhage to 1 ounce of lard. This must be rubbed in from 10 to 20 minutes; 7 or 8 grains are usually sufficient. The immediate effect is the production of a sensation resembling stinging with nettles; but the burning sensation, and the itching diminish during the friction, and entirely pass off in less than half an hour. The skin generally becomes covered with white, flat papulæ, which soon disappear, leaving a sensation of heat. It produces no inconvenience, and children bear it easily. It is seldom used.

Related Species.—The following species of Corylus are indigenous to (one cultivated in) the United States, one of which has covering the involucre spiculæ, which are employed like mucuna, as a vermifuge. They belong to the natural order *Cupuliferæ*.

Corylus rostrata, Aiton, *Beaked hazel.*—Canada, northern United States, and along the Appalachian ranges. Shrub 2 to 5 feet high. Fruit inclosed in a long, scaly involucre, which is hirsute, and terminates in a prolonged, tube-like beak. The spiculæ are reputed to act as a mechanical vermifuge.

Corylus americana, Walter.—North American thickets. Fruit wide and long, surrounded by an involucre at least double the length of the fruit.

Corylus avellana, Linné, *Hazel.*—Europe, North Asia, in wood and thickets. Cultivated in the United States. A shrub, from 10 to 15 feet high, flowering in early spring and bearing fruit in the autumn. The fruit is known as the *filbert*, and is a hard nut, with a pale-brown, ligneous shell, surrounding a sweetish, oleaginous, white kernel. It is about an inch long. The seeds yield about 50 per cent of *hazelnut oil*, a light-yellow, fixed oil, without odor, but tasting somewhat like the nuts. It is composed of olein, palmitin, arachin, and stearin, freezing at near the zero point, 0° F. (—17.8° C.).

MYRICA.—BAYBERRY.

The bark and wax of *Myrica cerifera*, Linné.

Nat. Ord.—Myricaceæ.

COMMON NAMES: *Wax-myrtle, Bayberry, Candle berry, Waxberry.*

Botanical Source.—This plant is a branching, half-evergreen shrub, 1 to 12 feet in height, and covered with grayish-bark. The leaves are glabrous, cuneate-lanceolate, rather acute or obtuse, distinctly petiolate, margin entire, but more frequently remotely dentate, particularly toward the end, paler, with distinct veinlets beneath, generally twisted or revolute in their mode of growth, shining, resinous, dotted on both sides, 1½ to 2½ inches in length, and from ½ to ¾ of an inch wide. The flowers appear in May, before the leaves are fully expanded. The males grow in aments, are sessile, erect, 6 to 9 lines in length; originating from the sides of the last year's twigs. Every flower is formed by a concave, rhomboidal scale, containing 3 or 4 pairs of roundish anthers on a branched foot-stalk. Females on a different shrub, less than half the size of the males, consist of narrower scales, with each an ovate ovary, and 2 filiform styles. To these aments succeed clusters or aggregations of small globular fruits, resembling berries, which are at first green, but finally become nearly white, and consist of a hard stone inclosing a dicotyledonous kernel, studded on its outside with small, black grains, resembling fine gunpowder, over which is a crust of dry, greenish-white wax, fitted to the grains, giving the surface of the fruit a granulated appearance. The fruit is persistent for 2 or 3 years (L.—P.—W.—G.).

History and Description.—This plant is found in dry woods, or in open fields, from Canada to Florida. The bark of the root is the preferred part; boiling water extracts its astringent and alcohol its stimulating principles.

BAYBERRY BARK.—As met with in commerce, the bark is in curved or quilled pieces, from 1 to 6 or 7 inches long, covered with a thin, grayish, mottled epidermis, with slight transverse fissures, beneath which the true bark is of a dull reddish-brown color, rugged, darker internally, breaking rapidly with a short fracture, and giving, when pulverized, a light brown powder, of a pungent, peculiar, spicy odor, a bitter taste succeeded by astringency, acridity, and a stinging sensation which gradually extends to the fauces, where it leaves an unpleasant feeling and a sense of constriction; it is powerfully sternutatory, excites cough, and forms a dense froth when briskly agitated with water. Water takes up its active properties; diluted alcohol is its best menstruum. The root should be collected late in the fall, cleansed from dirt and foreign substances, and then, while fresh, pounded with a hammer or club to separate the bark, which should be thoroughly dried without exposure to a wet or moist atmosphere, then pulverized, and kept in darkened and well-closed vessels.

BAYBERRY-TALLOW, or MYRTLE WAX *(Bayberry wax.)*—This substance is yielded by the berries and is obtained by boiling them in water, upon the top of which it floats, and from which it is removed when it has become cold and hardened; it is a concrete oil or fatty substance of a pale-green color, with a tendency to dirty gray, of moderate hardness and consistence, having the tenacity of beeswax, but more brittle and not so unctuous to the touch, of a faintly balsamic and pleasant odor which is increased by burning it, and of an astringent, bitterish taste. It fuses at a temperature of from 47° to 49° C. (116.6° to 120.2° F.) (Moore), burns with a clear, white flame, producing little smoke, and has the specific gravity 1.004 to 1.006. Water does not act upon it; boiling alcohol dissolves about four-fifths of its weight, but deposits it again upon cooling; but ether also dissolves it, and on cooling deposits it in crystalline plates like spermaceti; the ether becomes green, leaving the wax nearly white; oil of turpentine, aided by heat, dissolves it sparingly; alkalies and acids act upon it nearly as upon beeswax. Sulphuric acid, assisted by heat, dissolves about one-twelfth of its weight, and converts it into a thick, dark-brown mass. A bushel of bayberries will yield about 4 pounds of the wax.

Chemical Composition.—According to George M. Hambright (1863), bayberry bark contains albumen, tannic and gallic acids, starch, gum, red coloring matter, traces of oil, an acrid resin soluble in alcohol or ether, an astringent resin soluble in alcohol, insoluble in ether; *myricinic acid*, etc. The latter substance is granular, and when shaken with water, produces a bulky froth, hence is analogous to *saponin*. It is persistently acrid in taste. Ammonia, added to its aqueous solution produces a rapid change of colors from deep green to red, and finally to yellow (*Amer. Jour. Pharm.*, 1863, p. 193). The fruit yielded (Dana) solid fat, 32 per cent; starch, 45 per cent; and resin, 5 per cent. According to G. E. Moore (1852), *bayberry-tallow* is composed of *palmitin*, 1 part, and *palmitic acid*, 4 parts, with a little *lauric acid* (*laurin*). A more recent analysis by G. Schneider (1890) shows this wax to be chiefly composed of palmitin (70 per cent), myristin (8 per cent), and lauric acid (4.7 per cent), mostly in the free state (see G. M. Beringer, *Amer. Jour. Pharm.*, 1894, p. 221).

Action, Medical Uses, and Dosage.—Bayberry bark is astringent and stimulant, and as such is valuable in debilitated conditions of the mucous membranes; in drachm doses, it is apt to occasion emesis. It was largely employed by the followers of Samuel Thomson, in *catarrhal states of the alimentary tract*. The bark has been successfully employed in *scrofula*, *jaundice*, *diarrhœa*, *dysentery*, *aphthæ*, and other diseases where astringent stimulants were indicated. Specific myrica, in small doses (2 to 5 drops) will be found a good stimulant to the vegetative system of nerves, aiding the processes of digestion, blood making, and nutrition. In larger doses (5 to 20 drops) it is a decided gastric stimulant. In small doses it has been found advantageous in *chronic gastritis*, *chronic catarrhal diarrhœa*, *muco-enteritis*, and in *dysentery* having a typhoid character. It is said to restore *arrested lochial discharges*. Cases calling for myrica show feeble venous action, while the pulse is full and oppressed. It is not adapted to acute disorders of the alimentary tract, as a rule. A weak infusion used as an injection, is an admirable remedy in *amenorrhœa* and *atonic leucorrhœa*. Use the specific medicine or tincture internally also. In *scarlatina* in the latter stages, when the tissues are swollen and enfeebled, it may be used both for its antiseptic and stimulating effects (Locke).

The powdered bark, combined with bloodroot, forms an excellent application to *indolent ulcers*, and has likewise been employed as a snuff for the cure of some forms of *nasal polypus*. In the form of poultice, with elm or alone, it is a valuable application to *scrofulous tumors* or *ulcers*. The decoction is beneficial as a gargle in *sore mouth* and *throat*, and is of service in injection, in *leucorrhœa* and *fistula*, and also as a wash for *ulcers*, *tinea capitis*, etc. It also forms an excellent gum wash for *tender*, *spongy*, and *bleeding gums*. The leaves are reputed astringent, and useful in *scurvy* and *spasmodic affections*. Probably the *M. pennsylvanica*, *M. carolinensis*, and *M. Gale*, possess similar properties. Bayberry or myrtle wax, has been used by Dr. Fahnestock in *epidemic dysentery* with typhoid symptoms, with considerable success; it possesses mild astringent, with some narcotic properties. It is also used in the form of plaster, as an application to *scrofulous* and *other ulcers*. Dose of the powdered bark, from 20 to 30 grains; of the wax, 1 drachm; of the decoction of the leaves or bark, from 2 to 4 fluid ounces; specific myrica, 2 to 20 drops. Bayberry bark was a constituent of "*Thomson's Composition Powder* or No. 6."

Specific Indications and Uses.—Profuse mucous flows; catarrhal states of the gastro-intestinal tract; atonic diarrhœa, typhoid dysentery, atony of the cutaneous circulation; full oppressed pulse. Locally and internally—sore mouth; spongy, flabby, bleeding gums; sore throat of scarlet fever when enfeebled and swollen.

Related Species.—*Myrica Gale*, Linné. *Sweet gale*, or *Dutch myrtle*, a smaller plant than the bayberry, is found in swampy places in northern portions of Asia and Europe, and in the United States from the Carolinas to Canada. Its subcoriaceous leaves, pubescent-downy beneath, and its fruit are dotted with a yellow resin. The taste of the leaves and twigs is aromatic, bitterish, and astringent; the odor strongly balsamic. A volatile oil, seven-tenths of which is a stearopten, was obtained in small quantity by Ravenhorst (1836) from sweet-gale leaves. It solidifies at 12° C. (53.6° F.).

Myrica ocuba, a widely distributed shrub, in the Brazilian province of Para, furnishes a fruit whose seeds yield *Ocuba wax*. It has been used in Brazil in the manufacture of cheap candles.

Myrica jalapensis, Kunth.—A solid fat, is obtained from the fruit by boiling it with water, and the bark of the root is astringent and acrid, and in larger doses emetic. The fat is readily saponifiable with alkalies, has probably the same composition as myrtle wax from *Myrica cerifera*, and is given internally in powder for *diarrhœa* and *jaundice* (Prof. J. M. Maisch, *Amer. Jour. Pharm.*, 1885, p. 339).

MYRISTICA (U. S. P.)—NUTMEG.

"The seeds of *Myristica fragrans*, Houttuyn," "deprived of its testa"—*U.S.P.*

Nat. Ord.—Myristicaceæ.

COMMON NAME: *Nutmeg* (*Nux moschata*).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 218.

Botanical Source.—This is a tree from 20 to 25 feet high, having a grayish-brown, somewhat smooth bark, abounding in a yellow juice; the branches are spreading, in whorls. The leaves are alternate on petioles from ½ to ¾ of an inch long, plane above, or oblong, approaching to elliptical, subbifarious, glabrous, rather obtuse at the base, acuminate, quite entire, aromatic, dark-green and somewhat glossy above, paler beneath, and from 3 to 6 inches long. The flowers are diœcious, small, in axillary, subumbellate racemes, sometimes forked, or compound. The peduncles and pedicels are glabrous, the latter having a quickly deciduous, ovate bract at its summit, often pressed close to the flower. Male flowers, 3 to 5, or more, on a peduncle. Calyx urceolate, thick, fleshy, clothed with a very indistinct, reddish pubescence, dingy pale-yellow, cut into 3 erect, or erecto-patent teeth. The filaments are incorporated into a thickened, whitish cylinder, about as long as the calyx, the upper half covered by about 10 linear-oblong, 2-celled anthers, free at their base, opening longitudinally. The female flowers are scarcely different from the male, except that the pedicel is very frequently solitary. Pistils solitary, shorter than the calyx, broadly-ovate, a little tapering upward into a short style, bearing a 2-lobed, persistent stigma. The fruit is a fleshy pericarp, nearly spherical, of the size, and somewhat of the shape, of a small pear; flesh astringent, yellowish, almost white within, 4 or 5 lines thick, opening into 2, nearly equal, longitudinal valves. The arillus (mace) is thick, between horny and fleshy, much laciniated, folded and anastomosing toward the extremity, almost enveloping the nut, and so tightly as to form inequalities on its surface; when fresh, brilliant scarlet; when dry, much more horny, of a yellowish-brown color, and very brittle. The nut is oval or broadly-ovate, with a hard, rugged, dark-brown, glossy shell, pale, smooth within, about half a line thick. The seed, or nutmeg, is oval, pale-brown, quite smooth when fresh, but soon becomes shriveled, with irregular, vertical lines or furrows on its surface. Its substance or albumen is firm, fleshy, whitish, being traversed by veins of a red brown color, abounding in oil. Near the base of the albumen, imbedded in a cavity in its substance, is the embryo, which is small, fleshy, yellowish-white, rounded below, and where is found the hemispherical radicle; cotyledons of 2, large, somewhat foliaceous, plicate lobes, in the center of which is seen the plumule (L.).

Fig. 173.

Myristica fragrans.

History and Description.—This tree has received several botanical names, as *M. officinalis*, Linné, *M. moschata*, Thunberg, *M. aromatica*, Lamarck, and *M. fragrans*, Houttuyn; this last is the one now generally adopted by botanists. The nutmeg tree is indigenous to the Molucca Isles, and is raised in Sumatra, French Guiana, the Mauritius, and various West Indian Islands. The nutmeg tree is propagated by planting the uninjured seed; when it has attained the age of about 9 years, it commences to blossom, and continues to yield fruit for about three-quarters of a century, requiring hardly any attention from its cultivators. The seeds are frequently spread in the Banda Isles by certain species of pigeons, which thus contribute to the propagation of the tree. In the eighteenth century this was the cause of much disaster to the natives of these islands in their dealings with the Dutch East Indian Company who endeavored to limit and monopolize the plantation of the nutmeg tree, by prohibiting its being planted on certain isles (A. Tschirch, *Indische Heil-und Nutzpflanzen*, Berlin, 1892, p. 104). In the Banda Isles there are three harvests annually, the principal one in July or August, in November, and in March or April. The ripe fruit is gathered by means of a barb attached to a long stick; the mace or arillus separated from the nut, and both separately cured (P.). The kernel of the fruit, or *nutmeg*, and the arillus of the nut, or *mace* (see *Macis*), are the official parts; they are imported from the East Indies, from Europe, and a small portion from the West Indies.

The nutmegs, previous to exportation, undergo a process of curing to preserve them, and protect them from the attacks of insects; the nuts are exposed to the sun for 4 or 6 days, and afterward smoke-dried for several weeks at about 60° C. (140° F.); when thoroughly dried, the kernel rattles in the shell, which is then cracked with a wooden mallet, and the perfect nuts selected; these are then covered with dry lime, or steeped for a time in a thick mixture of lime and water; the former is considered the preferable plan. Nutmegs are officially described as follows: "Oval or roundish-ovate, about 25 Mm. (1 inch) long, light-brown, reticulately furrowed, with a circular scar on the broad end; internally pale-brownish, with dark orange-brown veins, and of a fatty lustre; odor strongly aromatic; taste aromatic, warm, and somewhat bitter"—(*U. S. P.*). From the interior veins mentioned, an oil may be easily expressed with the point of a warm knife. The virtues of nutmegs are extracted by alcohol or ether. The small, round, heavy nutmeg is esteemed superior to those which are larger, longer, lighter, less marbled, and not so oleaginous. It produces a grayish-brown, somewhat fatty powder. Singapore and Penang nutmegs are unlimed; those from the Dutch colonies are limed. (For botanical and anatomical studies of various species of Myristica, see A. Tschirch [*Jahresb. der Pharm.*, 1885, p. 98, and 1887, p. 108, and *Archiv der Pharm.*, 1895, p. 443]; also J. Moeller [*Pharm. Centralhalle*, 1880, pp. 453, 465 and 473], and W. Busse [*Jahresb. der Pharm.*, 1895, p. 113].) An exhaustive and classical monograph, on the history, botany, commercial aspect, etc., of nutmeg, was written quite recently by O. Warburg (1897).

Chemical Composition.—Nutmegs contain 8 to 10 per cent of volatile oil (see *Oleum Myristicæ*), 30 to 40 per cent of fatty oil (see *Oleum Myristicæ Expressum*), from 9 to 13 per cent of water, and about 5 per cent of ash; furthermore, nitrogenous matter, starch, gum, woody fiber, etc. The fatty oil of nutmeg contains as the characteristic constituent, about 12 per cent of *myristin*, the glycerin ester of *myristic acid* ($C_{14}H_{28}O_2$), discovered by Playfair, in 1841. Stearic and oleic acids are likewise present in the fatty oil.

Action, Medical Uses, and Dosage.—Both nutmeg and mace possess aromatic stimulating properties, and are occasionally used to remove *flatulency*, correct the nausea arising from other drugs, and to allay *nausea* and *vomiting*. It may be used in *gastrodynia* and *atonic diarrhœa*. The nutmeg forms a very agreeable addition to various drinks for convalescents, as well as to some articles of diet; it is generally grated over them, or mixed with them. Applied locally, grated nutmeg, mixed with lard, has been found an excellent application in *piles*, and the nutmeg roasted is used internally in some parts of the country, as a domestic remedy for *leucorrhœa*. I have known the following preparation to cure several cases of *intermittent fever*, and have been assured of its almost universal success in this disease. It is also recommended for the cure of other forms of *fever*. Char a nutmeg by holding it to the flame, and permitting it to burn by itself without disturbance; when charred, pulverize it, combine it with an equal quantity of burnt alum, and divide the mixture into three powders. On the commencement of the chill, give a powder—if this does not break it, give the second powder on the approach of the next chill, and if not cured, the third powder must be given as the succeeding chill comes on. Usually the first powder effects a cure, and it is seldom that the three powders are required. The bowels should be acted upon by a purgative previous to the administration of the powders. It is certainly deserving attention, though I do not pretend to account for its action (J. King). Nutmeg occasionally controls passive *uterine hemorrhage*. The powder, dusted upon a larded cloth, is effectual as an application to the chest in *pneumonic complaints* and *colds*, and to the bowels in *cholera infantum*, and over the stomach to allay *vomiting*. Dose of nutmeg or mace, from 5 to 20 grains. Larger doses possess decided narcotic qualities, and in doses of 2 or 3 drachms, dangerous symptoms have been produced. Death followed the eating of two nutmegs by a boy of 4 years. The symptoms produced in various cases of nutmeg poisoning vary. The chief symptoms, however, are headache, coldness and collapse, drowsiness, indisposition to muscular movement, and increased diuresis. In [illegible] cases the urine has been suppressed (see case of *Myristica poisoning*, *Ec. Med. Jour.*, 1891, p. 125; also *Amer. Jour. Pharm.*, 1885, p. 23).

Related Species and False Nutmegs.—*Myristica argentea*, Warburg, grows in New Guinea; its leaves are silvery below, hence the name. The nutmeg is longer and narrower than that of *M. fragrans*, after which it ranks next in commercial importance. Instead of this species *M. fatua*, Houttuyn, growing in the Molucca Islands, has for a long time been erroneously believed to yield the long nutmeg of commerce. The seed of *M. fatua* (*Male nutmeg*, *Mannetjes-noote*) soon loses its already weak aroma.

M. madagascariensis, Lamarck, growing in Madagascar, and cultivated in the French island of Bourbon, is probably identical, according to Warburg (*Ber. d. Deutsch Pharm. Ges.*, 1892, p. 211), with *M. fragrans*.

M. officinalis, Martius, growing in Brazil, yields the solid *Bicuyba oil* of the Brazilians. The seed is but faintly aromatic, and yields 72 per cent of oil (see analysis by A. Stutzer, *Jahresb. der Pharm.*, 1887, p. 108).

M. bicuhyba, Schott, growing in Brazil, produces a seed of an agreeable, cacao-like odor. H. Nördlinger (*Amer. Jour. Pharm.*, 1886, p. 88) found the dried kernels to yield 73.7 per cent of an aromatic fat, chiefly the glycerides of myristic and oleic acids with free myristic acid.

M. surinamensis, Roland.—Reimer and Will found in the seeds 73 per cent of a slightly aromatic fat, melting at 45° C. (113° F.), and consisting of myristin and 6.5 per cent of myristic acid (*Amer. Jour. Pharm.*, 1886, p. 88).

M. malabarica, Lamarck, is believed to yield *Bombay mace* (see *Macis*). Prof. Schaer (1896) found in the inspissated extract of the bark a new kino (see *Kino*).

Calabash Nutmeg, or Jamaica Nutmeg, is the product of *Monodora Myristica*; Plume, or New Holland Nutmeg, from *Atherosperma moschata*; and Clove Nutmeg, from *Agathophyllum aromaticum*. For species yielding oils, see also *Oleum Myristicæ Expressum*.)

California Nutmeg.—The seed of a California conifer, the *Torreya californica*, Torrey (*Torreya Myristica*, Hooker). It has a terebinthinate taste, is oblong, its testa smooth, brown and thin, and the seed upon cross-section is marbled.

MYROBALANUS.—MYROBALAN.

The fruit of *Terminalia Chebula*, Retzius; *Myrobalanus Chebula*, Gaertner.

Nat. Ord.—Combretaceæ.

Common Name: *Myrobalans.*

Botanical Source.—Terminalia Chebula is a tree whose trunk towers from 40 to 70 feet, its verticillate branches giving the tree a symmetrical head. The leaves are short-petioled, alternate, entire, or slightly dentate, arranged on the ends of the branches (hence the name *Terminalia*), coriaceous and spotted. The 10-stamened flowers are white or yellowish, and borne in racemes or spikes. The fruit is a drupe about the size of a large plum.

History.—Several other species yield commercial myrobalans, but the fruit is almost unknown in Western commerce. In India and China, where the spespecies are indigenous, the fruit is highly valued for almost every ill that flesh is heir to. The hard wood takes a fine polish and is useful in cabinet work. The creamy, fragrant juice of the *T. angustifolia*, Wight, when dried, is used in Indian temple worship as an incense. The tree is regarded sacred, and has interesting historical and mythological connections. The celebrated *India Ink* is the product of the bark and leaves of *T. cattapa*, Linné. All the species yield a tanning bark. The leaves, bark, and fruit yield a dye, which with iron gives a rich black, and with alum a fine yellow color.

Description.—*Chebula myrobalans* are ovoid or oblong, about the size of the prune, yellow-brown, marked with 5 or 6 obtuse angles, and ribbed. The light-brown endocarp is resin-dotted. The single seed is white. The *Myrobalani citrina*, or *Yellow myrobalans*, are smaller, orange or yellow-hued, and of a more pronounced bitter taste. They have been sold as *white galls*. The unripe fruit is known as *Myrobalani nigræ*, or *Black myrobalans*. They are blackish, shrivelled and brittle, glossy on fracture, and contain either none or an imperfect seed. They are astringent and somewhat sour.

Chemical Composition.—The fruit, as well as all other parts of the tree, contains tannin. According to E. Mafat (*Pharm. Jour. Trans.*, Vol. XXIII, 1892, p. 145), the amount of tannin in chebulic myrobalans varies from 18.2 to 52 per cent. Stenhouse (1843) found 45 per cent of tannin, gallic acid, mucilage, and a brown-yellow coloring matter. The black variety contains much sugar. Apéry (1888) isolated from black myrobalans a green oleoresin soluble in alcohol, ether, petroleum spirit, and oil of turpentine. He named it *myrobalanin*. A. Campbell Stark (*Pharm. Jour. Trans.*, 1892, Vol. XXIII, p. 253) making a complete analysis of myrobalans, observed the same oil and obtained only 20.6 per cent of tannin. Dr. G. Zölffel (*Archiv der Pharm.*, 1891, p. 123) found the tannin matter of myrobalans to be identical with that of *algarobilla*, the astringent fruit of *Cæsalpinia brevifolia*, Bentham, a Chilenian plant. It consists of two principles which differ in both plants only with regard to their relative proportions. Accordingly, the tannin matter of myrobalans is a mixture of predominating *ellaggen-tannic acid* ($C_{14}H_{10}O_{10}$, Loewe, 1875, or $C_6H_2.COOH.[OH]_2 O.O.CO.C_6H_2.[OH]_3$, Zölffel), and a smaller quantity of *gallic acid glucosid*, yielding, upon hydrolysis, gallic acid and dextrose. Gallic acid also preexists in part in myrobalans. *Ellaggen-tannic acid*, isolated by Loewe (1875) from the fruits of *Cæsalpinia Coriaria*, Willdenow (*Divi-divi*), as well as from myrobalans, decomposes, upon hydrolysis, into water and *ellagic acid* ($C_{14}H_6O_8+2H_2O$). Fridolin's crystallizable *chebulinic acid* (1884), upon hydrolysis, splits into 2 molecules of gallic, and 1 molecule of tannic acid. It is no doubt closely related to the tannic principles aforenamed.

Action, Medical Uses, and Dosage.—Myrobalans were known to the ancients who appear to have valued them highly in innumerable complaints for which they are never now employed. They impart a green color to the saliva, and have an astringent, sourish taste. Like rhubarb, they have been found to possess both cathartic and astringent properties (Apéry), and are reputed of some value in the chronic forms of *diarrhœa*, *dysentery*, and *catarrhal diseases of the bowels*. The dose is from 2 to 5 grains, in pill or capsule, every 2 to 4 hours.

Other Myrobalans.—Belleric Myrobalans. Subglobular, smaller than the chebulic myrobalans, short-stalked, tomentose, and of a red-brown color. The putamen is light-brown, 5-sided, odorless, bitter, and astringent. The fleshy part of the fruit is resinous. It is the product of *Terminalia bellerica*, Roxburgh (see its analysis in *Pharmacographia Indica*, Vol. II, 1890, p. 7). Several other species of *Terminalia* yield astringent barks and are employed in tanneries.

Emblic Myrobalans.—This is furnished by an entirely different plant from the Terminalia, the *Phyllanthus Emblica*, Linné (*Emblica officinalis*, Gaertner); *Nat. Ord.*—Euphorbiaceæ. India. Subglobular, drupaceous fruit, having 6 grooves, deeply furrowed between grooves, 3-celled, each cell enclosing 2 glossy, brownish-red seeds. The taste of this fruit is astringent and sour.

MYRRHA (U. S. P.)—MYRRH.

"A gum-resin obtained from *Commiphora Myrrha* (Nees), Engler"—(*U. S. P.*). (*Balsamodendron Myrrha*, Nees.)

Nat. Ord.—Burseraceæ.

Common Name: *Myrrh* (*Gummi-resina myrrha*).

Illustration: Bentley and Trimen, *Med. Plants*, 60.

Botanical Source.—The *Commiphora Myrrha* (*Balsamodendron Myrrha*), has a shrubby, arborescent stem, with squarrose, spinescent branches, a very pale-gray bark, and a yellowish-white wood. Its leaves are ternate, on short petioles; leaflets obovate, obtuse, somewhat tooth-letted at the apex, the lateral smooth. The flowers are unknown. The fruit is ovate, smooth, brown, somewhat larger than a pea, surrounded at base by a 4-toothed calyx, and supported on a very short stalk (Nees—De Candolle).

Fig. 174.

Commiphora Myrrha.

History.—Until recent years much doubt was entertained as to the true botanical source of myrrh. Nees von Esenbeck examined specimens of the supposed myrrh tree brought from Ghizan (Arabia), in 1826, by Ehrenberg, and named it *Balsamodendron Myrrha*. D. Hanbury, in 1873 (see his *Science Papers*, p. 378), described four districts, all situated around the Gulf of Aden and the Red Sea, which have been mentioned by various travelers as being the home of the myrrh tree. Still the species from which the bulk of commercial, especially Somali, myrrh is derived, is not as yet known with exactness. Authorities, including the *U. S. P.*, however, accept that the drug is derived from *Commiphora Myrrha* (Nees), Engler. Mr. E. M. Holmes (see *Amer. Jour. Pharm.*, 1897, p. 110) believes that Arabian myrrh at least is derived from *Balsamodendron Myrrha*, Nees, and that in tracing the botanical origin of other commercial varieties, the taste and peculiar odor of myrrh may reasonably serve as a guide, since these qualities undoubtedly exist in the plants themselves. An exceedingly useful description of the plants possibly yielding myrrh and bdellium, by Mr. E. M. Holmes, is recorded in *Pharm. Jour. Trans.*, 1898, Vol. VII, p. 547, and 1899, Vol. VIII, pp. 26 and 77.

The region south of the gulf of Aden, the country of the Somalis, furnishes almost the entire commercial drug. Formerly, myrrh was known in commerce as *Turkey myrrh*, as it formerly entered commerce from Egypt and the Mediterranean ports; but now it goes first to Berbera (ancient Mosylon) and Aden, and from thence to Bombay, where the bags are opened and sorted; the best grades going into European and American commerce, while the inferior sorts are sent to China to be used as incense. What was formerly known as *India myrrh* is the *bissa bol* of the Somalis (see *Other Myrrhs*). True myrrh is known in its native country as *Mur* (Arab). *Mulmul* (Somali), *Heerabole* (Indian), names also applied to an Arabian product from the tree known as *Didthin*, a tree identical with that furnishing African myrrh. (Also see commercial classification and description of the drug, by Mr. E. M. Holmes, in *Pharm. Jour. Trans.*, 1898, Vol. VII, p. 547.) The juice flows naturally from the myrrh tree, like cherry-tree gum upon the bark; at first it is soft and pale-yellow, but by drying becomes hard, darker and redder, and forms the medicinal gum myrrh. Myrrh varies in size from that of a pea to that of a large walnut, and may be even larger.

Description.—Myrrh is "in roundish or irregular tears or masses, dusty, brownish-yellow or reddish-brown; fracture waxy, somewhat splintery, translucent on the edges, sometimes marked with whitish veins; odor balsamic; taste aromatic, bitter and acrid. When triturated with water, myrrh yields a brownish-yellow emulsion; with alcohol it yields a brownish-yellow tincture which acquires a purple tint on the addition of nitric acid. Dark-colored pieces, the alcoholic solution of which is not rendered purple by nitric acid, and pieces of gum which dissolve completely, as well as those which merely swell in water, should be rejected"—(*U. S. P.*). Myrrh is friable and readily powdered in cold weather, but in a warm atmosphere it is difficultly pulverized, unless some of its oil and water have been extracted from it. When heated it softens, then froths up and at length ignites and burns with difficulty. Its proper solvent is rectified spirit. It is not wholly dissolved by water, ether, or proof spirit; water dissolves its gum, and the mucilage retains the oil and part of the resin in the state of emulsion; proof-spirit dissolves some of its resin. The tincture is transparent, and when poured into water forms a yellow opaque fluid, but does not form a precipitate, while the watery solution is always yellow and opaque. Alkaline solutions are good solvents for myrrh.

Chemical Composition.—Myrrh is composed of *gum*, 40 to 60 per cent, insoluble in alcohol; *resin*, about 27 to 40 per cent, soluble in alcohol, and *volatile oil*, 2.18 per cent, Ruickholdt; 7 to 8 per cent, O. Köhler, 1890. Upon incineration, myrrh leaves about 3.5 per cent of ash, principally calcium carbonate. O. Köhler (*Archiv der Pharm.*, 1890, p. 291) found 57 to 59 per cent of gum which was ascertained to be a carbohydrate of the formula $C_6H_{10}O_5$. The resins (*myrrhin* and *myrrhic acid*, of Ruickholdt) were separated by Köhler into an indifferent resin ($C_{26}H_{34}O_5$) soluble in alcohol and ether, and having three replaceable hydroxyl groups, and two dibasic resin-acids. The essential oil (*myrrhol*, or *myrrhin* of older observers) contains a volatile compound ($C_{10}H_{14}O$) not identical with thymol or carvol. The volatile oil of myrrh is lævo-rotatory. When exposed to air and light, it resinifies by oxidation and acquires the appearance and consistence of myrrh. Formic acid is said to be developed in this process.

Myrrhol, dissolved in carbon disulphide and subsequently treated with bromine or nitric acid, gradually assumes a permanent violet-blue coloration. The resin gives the same reaction due to the presence of some volatile oil. Fluckiger also abstracted, by means of water, a *bitter glucosid* from the resin as obtained by alcohol. It is amorphous, brittle, and brown, and sparingly soluble in water, producing an exceedingly bitter, yellowish solution (*Pharmacographia*). Small amounts of pyrocatechuic acid and pyrocatechin are formed when myrrh is fused with potassium hydroxide. The gum makes a good non-decomposing adhesive paste, which is still more adhesive if molasses be added to it (Shuttleworth, 1871).

Action, Medical Uses, and Dosage.—Myrrh is stimulant, especially to mucous tissues. It also exerts an antiseptic influence, and is used to promote expectoration, as well as menstruation. It has also been used as a vermifuge. Internally, the smaller doses promote digestion. Large doses accelerate the pulse, augment the heat of the body, cause gastric heat and burning, great sweating and marked prostration; occasionally it causes nausea, vomiting, and purgation. It is not antispasmodic, and is contraindicated in internal inflammations. It is generally used in enfeebled conditions of the body, and has been found useful in cases of *excessive mucous secretion*, as in *gleet*, *chronic gonorrhœa*, and *chronic catarrh*; also in *laryngitis*, *bronchitis*, *humoral asthma*, and other diseases of the air-tubes accompanied with profuse secretion, but expelled with difficulty. Its property of restraining the mucous discharges is observed to be most pronounced upon the renal and bronchial tract. As an expectorant, it acts best by combining it with such agents as squill, giving to both an increased force possessed by neither alone. *Chronic respiratory disorders* are the cases for its exhibition, it being indicated in *chronic bronchitis* with unhealthy and exhausting secretions, relaxed mucous tissues, and difficulty in raising the sputa. It is contraindicated by arterial excitement or fever. For use in the above condition, the following combination, an excellent alterative expectorant and stimulating tonic, is recommended by Prof. Locke: ℞ Syr. prunus virg., syr. senega, āā fl℥ij; Comp. tinct. of myrrh and capsicum fl℥ij. Mix. Sig. Teaspoonful every 3 hours. The same may also be used in the *asthma* of the aged. Cough and expectoration are lessened, the secretions reduced in quantity, and the consequent exhaustion incident to profuse expectoration prevented. Besides, it acts kindly on the stomach, and otherwise sustains the strength of the patient.

Myrrh has some reputation as an emmenagogue. It is adapted to female disorders accompanied with weight, dragging, and *leucorrhœa*. It is reputed useful in *suppressed menses*, and in some cases of *anemia*. In either instance, however, it is not efficient unless exhibited with some form of iron, aloes, etc. Locke recommends for *amenorrhœa*, and particularly if the uterine torpor be associated with constipation, the following prescription: ℞ Pulv. myrrh, grs. xxx; aloes, grs. x; macrotin, grs. x. Mix. Make 20 pills. Sig. Dose, 1 or 2 pills three times a day.

Myrrh is of value in *chronic gastritis* and *atonic dyspepsia* with full, pallid tongue and mucous tissues, and with frequent, mucous alvine discharges accompanied with flatulence. Here myrrh and gentian act well, and if nervous symptoms are prominent, an equal quantity of valerian may be used with them. The dose of the combination of equal parts of these tinctures is from 5 to 20 drops. *Chronic mucous fluxes*, from the bowels or urinary tract, are benefited by myrrh.

Myrrh was formerly used as a dressing for *indolent ulcers* to promote granulation and alter the character of the discharges. It was at the same time given internally also. Topically, it is a very useful application to *indolent sores*, *gangrenous ulcers*, and *aphthous* or *sloughy sore throat*, *spongy* or *ulcerated conditions of the gums*, *caries of the teeth*, etc. In *chronic pharyngitis*, with tumid, pallid membranes, elongated uvula, and spongy, enlarged tonsils, it is an exceedingly useful topical agent. It overcomes the *bad breath of dyspeptics* and *scorbutics*. It is sometimes combined with hydrastis and capsicum, in *aphthæ*. The dose of myrrh, in powder or pill, is from 5 grains to ½ drachm; of the tincture, from 20 drops to 2 fluid drachms.

Specific Indications and Uses.—Chronic bronchitis, with profuse secretion of mucus or muco-pus, with difficult expectoration; membranes lax and pallid, tonsils enlarged and spongy, throat pale and tumid; soreness and sponginess of the gums; reproductive disorders of women, with weight and dragging in the parts, and leucorrhœa.

Other Myrrhs.—BISSA BOL (*Bysabole, Bhesabol*), *Hebbakhade, Habaghadi*. This species of myrrh was formerly known as *East Indian myrrh*, and is regarded in eastern commerce as a very inferior quality of myrrh. The plant yielding it is now known as *Balsamea erythræa*, Engler (see Flückiger, *Pharmacognosie*, 3d ed., 1891, p. 43). This product resembles *Herabol* or true myrrh, but has a somewhat different odor, recalling that of the mushroom. Its taste is almost acrid, and its resin is paler than that of myrrh. Carbon disulphide but sparingly dissolves it; it is almost insoluble in petroleum ether. Besides it differs from myrrh in being unaffected by bromine, the latter producing an intense violet hue with myrrh in carbon disulphide solution. W. Tucholka (*Archiv der Pharm.*, 1897, p. 290) proposes the following characteristic test for Bisabol myrrh: 6 drops of a petroleum ether extract (its concentration not to exceed 1:15) are mixed in a test-tube with 3 Cc. of glacial acetic acid, and 3 Cc. of concentrated sulphuric acid are cautiously added so as to form a lower layer. A beautiful rose-red color becomes apparent at the zone of contact; shortly afterward the whole acetic layer will be of a permanent rose-red. If the petroleum ether extract is more concentrated, the resultant color is brown. True myrrh, under the same conditions, produces merely a faint rose-red coloration of the acetic layer, and a green coloration at the zone of contact, turning brown with green fluorescence upon standing. Analysis of bisabol showed the following percentage composition: Gum, soluble in water, 22.1; gum, soluble in soda solution, 29.85; resin, 21.5; bitter principle (crude), 1.5; ethereal oil, giving the above reaction plainly, 7.8; water, 3.17; vegetable and inorganic matter, 13.4.

ARABIAN MYRRH.—This product occurs in irregular pieces very much resembling common myrrh, though it lacks the whitish markings on fracture, is less unctuous, and has a gummy appearance externally. With bromine it reacts like myrrh. It comes from Aden, being collected in Arabia by the Somalis.

Related Drugs.—BDELLIUM. Chiefly two varieties of this product are known in commerce, *Indian* and *African*. *Indian bdellium*, or *East Indian bdellium*, is believed to be the product of *Balsamodendron Mukul*, Hooker (*Balsamea Mukul*, Engler), of India, and possibly Arabia. It forms large, rounded, dusty fragments; has a flattish shell-like fracture; in thin section translucent, but in mass dark, even deep-brown, and possesses the odor and taste of myrrh in a lesser degree. Nitric acid does not impart a purplish color to the tincture of this or the next variety.

African bdellium is the product of *Balsamodendron africanum*, Arnott (*Commiphora africana*, Engler), of western Africa. It occurs in oval, or roundish, irregular translucent tears, breaking with a wax-like fracture, and ranging in color from yellowish to brownish-red. It also has a cedar-like odor and a slightly bitter taste. Bdellium is infusible, but inflammable. It consists of resin, 59 per cent; bassorin, 30.6 per cent; gum, 9.2 per cent; and volatile oil, 1.2 (Pelletier). The French use the African variety in plasters. Bdellium was once used for purposes similar to myrrh.

BALSAMUM GILEADENSE, *Balsam of Gilead*, *Balm of Gilead*, *Opobalsamum*, *Mecca balsam*.—This product is referred to a small, evergreen, non-thorny tree, the *Balsamodendron Opobalsamum*, Kunth (*Commiphora Opobalsamum*, Engler). The dried fruit of this species formerly went by the name *carpobalsamum*; the dried branchlets *xylobalsamum*; and the exudation, as *opobalsamum*. As it spontaneously exudes from the tree it is a whitish or yellowish opaque, viscid fluid, having considerable fragrance. By exposure, it solidifies. Bonastre found in it volatile oil, 10 per cent (Trommsdorff, 30 per cent); adhesive resin, 70 per cent, and hard resin, 12 per cent. Trommsdorff obtained of hard resin, 64 per cent. It is seldom found in commerce.

Balsamodendron Berryi.—An Indian thorn-tree, *Mulu Kilirary*, yielding a gum-resin in abundance, which contains 84 per cent of gum, soluble in water. This gum-resin is devoid of fragrancy and bitterness (see D. Hooper, *Amer. Jour. Pharm.*, 1889, p. 508, from *Pharm. Jour. Trans.*, 1889).

MYRTUS.—MYRTLE.

Myrtus communis, Linné.

Nat. Ord.—Myrtaceæ.

COMMON NAMES: *Myrtle*, *Common myrtle*, *European myrtle*.

Botanical Source.—The myrtle is an evergreen shrub, whose stem is from 6 to 8 feet in height and covered with a deep-grayish, fissured bark. The stem is branched, and bears opposite, ovate, lanceolate leaves of variable width, short-petioled, closely pellucid-punctate, smooth, glossy, and evergreen. The flowers are solitary, axillary, and white, or pale-pinkish, and have many stamens. The fruit is a 2 or 3-celled bluish-black, fleshy berry, subglobular, each cell containing 4 or 5 reniform, whitish seeds. The flowers, leaves, and berry are all very fragrant. The bark is astringent.

Fig. 175.

Myrtus communis.

History.—The myrtle grows in tropical and subtropical climes, often being cultivated. It is thought to be a native of the south-eastern portion of Italy, and now grows abundantly throughout the borders of the Mediterranean. Florists consider five varieties of this species. The myrtle has been held as the emblem of honor and authority, and was worn by the Athenian judges in the exercise of their functions. It constituted the wreaths of the Grecian and Roman victors, in the Olympian and other festivities. Scriptural allusions to it are abundant,, and to the Jews it was a token of peace, and entered into bridal decorations. It is a Mohammedan tradition that it was among the pure things carried by Adam from out the Garden of Eden. The leaves, berries, and twigs have been employed in flavoring food and wines, and the leaves are said to furnish a good tea (see Willis, *Practical Flora*).

The French distill an aromatic water from the leaves and flowers which they call *eau d'ange.* Myrtle was one of the medicinal plants of the ancients, and was practically obsolete in modern therapeutics until revived, in 1876, by Delioux de Savignac. In Mexico the *Myrtus Arroya*, Kunth, is substituted for myrtle. Its leaves contain a volatile oil and tannin.

Chemical Composition.—The ripe fruit of myrtle yielded Riegel (1849) resin, sugar, citric and malic acids, tannin, and volatile oil. P. Bartolotti obtained by distillation of the leaves and twigs 0.56 per cent of an emerald-green volatile oil (*Jahresb. der Pharm.*, 1891, p. 452). It is dextro-rotatory, and has a specific gravity of 0.895 to 0.915. *Myrtol* was at one time supposed to be its chief constituent; however, it is not a simple body, and consists of a mixture of pinene, cineol, and dipentene, boiling between 160° and 180° C. (320° and 356° F.) (*Amer. Jour. Pharm.*, 1891, p. 48).

Action, Medical Uses, and Dosage.—Myrtle has recently been revived as a remedy for relaxation of parts with mucous and other profluvia. The oil and the alcoholic solution of the same possess anodyne properties, less in degree, however, than that of menthol and peppermint oil. The powder, sprinkled upon cotton first impregnated with glycerin, has been applied with marked advantage to *uterine ulcerations*. *Suppurative wounds* and *ulcers*, *intertrigo*, and *eczema* have been treated in the same manner, omitting the glycerin, while in cases with *offensive discharges* and *threatened gangrene*, a wine of myrtle has been employed with the result of correcting the fetor and inducing granulation. An infusion of the leaves or the tincture, diluted, may be used for the above-named purposes, and has given excellent results when used as an injection in *uterine prolapse*, *lax vaginal walls*, and *leucorrhœa*. An infusion is likewise valuable as a topical agent in *catarrhal conjunctivitis*, *pharyngitis*, and *bronchitis*. Made into a bolus with Venice turpentine, it has some reputation as a curative agent in *hemorrhoids*. An infusion injected is said to relieve *dysentery*, while the powder in doses of 15 to 40 grains is asserted useful in *renal* and *cystic catarrh*, and *colliquative sweating of phthisis*, and in doses of 10 to 30 grains, to check the wasting in *menorrhagia*. The oil stimulates the gastric, renal, and pulmonic membranes, increasing their functions, and is reputed to possess decided antiseptic and deodorant powers. In doses of 2 minims, the oil (in capsules) every 2 or 3 hours, is asserted prompt and curative in *fetid bronchitis* and *pulmonary gangrene*. The chief advocates of the use of myrtle are Delioux de Savignac and Eichhorst. Infusion (leaves or berries, ʒii to ʒiv to water Oj) locally; for internal use should be diluted, and even then it is very unpleasant to take. A much stronger infusion of the bark may be prepared (℥i to ℥ii to water Oss). Dose, of the fine powder, 5 to 40 grains; of the oil (in capsules), 1 to 5 minims.

Related Species.—*Myrtus Chekan*, Sprengel (*Eugenia Chekan*, Molina). This Chilian shrub is known in its native land as *cheken*, *chequen*, or *chekan*. The rough brownish bark is astringent, and the leaves almost sessile, nearly an inch long, elliptic or ovate-lanceolate, smooth, pale-green, with slightly revolute margins, and beset with oil-glands, are gathered with the branchlets, for medicinal use. The leaves have a feeble, aromatic fragrance, and a bitter, pungent, aromatic taste. The leaves contain volatile oil (2 per cent, J. W. England, *Amer. Jour. Pharm.*, 1883, p. 248), soluble in alcohol, ether, chloroform, and amylic alcohol; insoluble in water. It burns with a brilliant white flame, and becomes oxidized when exposed to the air. Fritz Weiss (*Jahresb. der Pharm.*, 1888, p. 80) found it to consist of about 75 per cent of *pinene* ($C_{10}H_{16}$), 15 per cent of *cineol* ($C_{10}H_{18}O$), and 10 per cent of undetermined higher boiling fractions. The leaves, freed from the essential oil, yielded to the author the following substances: Crystallizable *chekenon* ($C_{40}H_{44}O_8$), insoluble in water, soluble in hot alcohol; amorphous, non-poisonous *cheken bitter*, soluble in all ordinary solvents except water and petroleum-ether; *chekenin* ($C_{12}H_{11}O_3$), crystallizing in yellowish plates, and probably being a di-phenol, and *chekenetin* ($C_{11}H_7O_6+H_2O$), forming yellowish, olive-colored crystals, probably related to quercetin. The mother liquor finally contained large amounts of sugar and a small amount of *choline*, which tends to explain the formation of the volatile base *chekenine*, observed by Mr. England (*loc. cit.*) upon distillation of the leaves with alkali after they were deprived of their essential oil. The leaves were also found to contain about 4 per cent of tannin (J. W. England, *loc. cit.*, and J. Hoehn, *ibid.*, p. 253). Cheken was brought forward as an efficient remedy for *catarrhal disorders of the broncho-pulmonic tract*, and similar conditions of the urinary organs. It is claimed to be a good remedy for *winter cough* and oppressed breathing. The dose of the fluid extract is a fluid drachm, 3 times a day.

Jambosa vulgaris, De Candolle (*Eugenia Jambos*, Linné; *Jambosa malaccensis*, De Candolle).—India. The flowers, leaves, and bark are used medicinally by the natives. The bark of jambosa root is astringent, and is used in India in *leucorrhœa*, *diarrhœa*, and *dysentery*. A minute portion of alkaloid (Lyons), a crystalline, non-glucosidal body *jambosin* ($C_{10}H_{15}NO_3$), and an oleoresin have been found in it (A. W. Gerrard, *Pharm. Jour. Trans.*, 1884 Vol. XIV, p. 717). The fruit is rose-flavored and pleasantly acid, and is known as *rose-apple*.

Psidium Guajava, Linné (*Psidium pomiferum*, Linne, and *Psidium pyriferum*, Linné).—West Indies and the tropics. The acidulous fruit of these species is the *guava*, much employed by the natives in jellies, etc. The aromatic leaves and astringent bark are reputed febrifuge. They contain 12 per cent of tannin, and a resinous substance *guavin* (Bertherand, 1888); the latter is believed to be the active principle.

Eugenia Jambolana, Lamarck (*Syzygium Jambolanum*, De Candolle; *Calyptranthes Jambolana*, Willdenow). *Nat. Ord.*—Myrtaceæ. *Jambul*, *Jambu*, *Java plum*.—The seeds of this plant are reputed a remedy for *diabetes*. The subacid fruit is largely eaten by the natives, and a vinegar prepared from it is regarded as carminative, stomachic, and diuretic. The whole plant is astringent, the bark being employed where astringents are indicated. The bark externally is fissured and gray: internally fibrous and red. It has a very astringent taste and the odor of oak-bark (Dymock). The fruit is purple, of the shape and size of an olive, and excessively astringent unless altered by cultivation. The fruit is employed in India in *bilious diarrhœas*, *sore throat*, and *ringworm*. The seeds have been highly lauded as a remedy for *diabetes*, the amount of sugar being appreciably reduced in a marvelously brief space of time, the patients at the same time being able to partake of amylaceous food without ill effects. It appears, however, that the opinions as to the efficacy of this remedy are divided (see *Chemist and Druggist*, 1892, Vol. XLI, p. 319). The seeds are nearly ½ inch long, and ⅓ inch wide, gray-black in color, cylindrical in shape, with one truncated and one dome-shaped extremity, very hard and nearly tasteless. Analysis by Mr. W. Elborne (1888) showed the presence of a trace of essential oil, fat, chlorophyll, gallic acid (1.65 per cent), colored extractive soluble in water, albumen, and resin soluble in ether and alcohol, all in small amounts, together with a large proportion of insoluble matter (*Pharm. Jour. Trans.*, Vol. XVIII, p. 921). The fluid extract of the seeds is administered in doses of from 30 minims to 1 fluid drachm a day, beginning with 10-drop doses 3 times a day at first, and gradually increasing each day.

NABALUS.—LION'S FOOT.

The plant *Nabalus albus*, Hooker (*Prenanthes alba*, Linné).

Nat. Ord.—Compositæ.

COMMON NAMES: *Lion's foot*, *Rattlesnake root*, *White lettuce*, *Gall of the earth*, *Cancer weed*.

Botanical Source.—This plant is an indigenous, perennial herb, with a smooth, somewhat glaucous stem, corymbose-paniculate at the summit, stout purplish, often deeply so in spots, from 2 to 4 feet in height. The radical leaves are angular-hastate, often more or less deeply 3 to 5-lobed; the uppermost cauline ones lanceolate; between these the intermediate forms hastate and ovate, petiolate, and all irregularly dentate. The heads are pendulous and glabrous; the involucre of 8 linear scales, and from 9 to 12-flowered; the scales purplish, and the corollas whitish. Pappus brown (W.—G.).

There is a variety of the above plant *Nabalus Serpentaria* (or *Prenanthes Serpentaria*), with rough, dentate leaves, of which the radical are palmate, the cauline with long foot-stalks, sinuate-pinnatifid, disposed to be 3-lobed, with the middle lobe 3-parted, the upper lanceolate. The racemes are terminal, somewhat panicled, short, nodding, with an 8-cleft calyx, and 12 florets; it is about 2 feet high, with purple flowers (W.—G.).

History and Chemical Composition.—This plant is found in moist woods and shades, in rich soils, from New England to Iowa, and from Canada to Carolina, flowering in August. The variety *N. Serpentaria* is common to the mountainous districts of Virginia, North Carolina, and other sections of the United States, and is considered more active than the *N. albus*. The root, leaves, and juice of the plant are employed. According to N. B. Williams (*Amer. Jour. Pharm.*, 1887, p. 117), the rhizome contains tannin, gum, resins, etc., and the leaves 12 per cent of ash.

Action, Medical Uses, and Dosage.—Nabalus is said to be an antidote to the *bite of the rattlesnake*, and other *poisonous serpents*. The milky juice of the plant is taken internally, while the leaves steeped in water are to be applied to the wound, and frequently changed. A decoction of the root, which is bitter, has been successfully used in the bite of the rattlesnake, also in *dysentery*. This plant is deserving further and more accurate investigation, possessing undoubted power over the nervous system. A strong tincture of the green plant (℥viii to alcohol, 76 per cent, Oj) should be employed in doses of from 1 to 20 drops in experimenting for its effects in nervous disorders.

NAPHTALINUM (U. S. P.)—NAPHTALIN.

FORMULA: $C_{10}H_8$. MOLECULAR WEIGHT: 127.7.

"A hydrocarbon obtained from coal-tar. It should be kept in well-stoppered bottles"—(*U. S. P.*).

SYNONYMS: *Naphtalene, Naphtaline.*

History and Preparation.—Naphtalin was first observed, in 1819, in the products of the distillation of coal, by A. Garden, and believed by him to be a camphor. J. Kidd (1821) gave it its present name. T. Thomson showed that it was a hydrocarbon, and M. Faraday ascertained its correct percentage composition. The view of Dumas that naphtalin exists ready-formed in coal was refuted by Reichenbach. E. Erlenmeyer established its graphic formula, the correctness of which was experimentally proved by Gräbe and others (Roscoe and Schorlemmer's *Chemistry*, Vol. III, 1892).

Naphtalin is formed by the dry distillation of wood and coal, and is obtained by fractional distillation of the resulting wood- or coal-tar, the latter containing from 5 to 10 per cent of naphtalin. It is also formed when certain organic substances, *e. g.*, oil of turpentine, camphor, even alcohol, acetic acid, etc., are allowed to pass in vapor form through red-hot metallic tubes. Naphtalin may also be obtained from the Baku and Burmese petroleum. Naphtalin is contained in that fraction of the distillation of coal-tar which distills over between 180° and 250° C. (356° and 482° F.). The condensing pipes must be kept warm in order to prevent the naphtalin from crystallizing. Upon cooling the distillate, dark-colored crude naphtalin crystallizes and is separated by straining. It is then deprived of its mother liquor (containing phenols) by pressure, and is purified by treatment with solution of caustic soda, which removes phenol; then washed with water and treated with sulphuric acid, whereby some bases (*aniline*, etc.) are removed. After washing out the acid, and drying, naphtalin is finally obtained almost pure by sublimation. Still, owing to the presence of certain phenols, it has a tendency, when exposed to light and air, to become darker in color. A mixture of manganese dioxide and sulphuric acid is then made to act upon it for about a quarter of an hour, at the heat of a water-bath; this oxidizes and removes the phenols, after which the product is washed with water and caustic soda solution, and lastly sublimed. For pharmaceutical purposes this product should then be recrystallized from alcoholic solution.

Description.—Naphtalin is officially described as occurring in "colorless, shining, transparent laminæ, having a strong, characteristic odor resembling that of coal-tar, and a burning, aromatic taste; slowly volatilized on exposure to air. Insoluble in water, but when boiled with the latter imparting to it a faint odor and taste. Soluble in 15 parts of alcohol at 15° C. (59° F.), and very soluble in boiling alcohol; also very soluble in ether, chloroform, carbon disulphide, and fixed or volatile oils. Naphtalin volatilizes slowly at ordinary temperatures; rapidly when heated. It also volatilizes with the vapors of water or alcohol. At 80° C. (176° F.) it melts, and at 218° C. (424.4° F.) it boils. Its vapor is inflammable, burning with a luminous and smoky flame. When ignited, it is consumed, leaving no residue. Naphtalin is neutral to litmus paper moistened with alcohol. On shaking a small portion of naphtalin with concentrated sulphuric acid, the acid should remain colorless; nor should it acquire more than a pale reddish tint if the mixture be heated, for 5 minutes, on a water-bath (absence of contaminations derived from coal-tar)"—(*U. S. P.*). Naphtalin is heavier than water, its specific gravity at 4° C. (39.2° F.) being 1.145.

The graphic formula for naphtalin, as given by Erlenmeyer, suggests the possibility of a number of substitution products, which are considered in detail in every text-book of organic chemistry. Diluted nitric acid converts naphtalin into phtalic acid; with concentrated nitric acid it yields *nitronaphtalenes* ($C_{10}H_7.NO_2$); these in turn are converted by reduction into crystallizable *naphtylamines* ($C_{10}H_7.NH_2$). With sulphuric acid it yields sulpho-acids. By substituting naphtalin hydrogen by one or more phenol groups (OH), the various *naphtols* are obtained (see *Naphtol*).

Action, Medical Uses, and Dosage.—Naphtalin destroys vegetable and animal parasites. It forms a popular material for protecting woolens from the moth, sometimes being called "tar camphor," "moth balls," etc. It also finds extensive application in the preparation of a great number of organic dye-stuffs (see *Aniline Colors*). Applied to the sound integument it exerts no action upon it, but if the skin be broken it causes heat and smarting, and if the raw surfaces are secreting, decomposition of the discharges is prevented. Some contend that as high as 75 grains may be taken day after day for a long time without any untoward results, owing to its limited absorption into the system. On the other hand it is claimed that even 5 grains have produced unpleasant urinary symptoms and positive suffering, with frequent, burning, painful micturition, tenesmic pain in the bladder, and a reddening of the meatus urinarius has been induced by 15-grain doses. Collapse with facial pallor has been observed in its employment for the *diarrhœa* of infants. To the taste it is sharp, acrid, and burning, and occasions an abundant secretion of froth-like or ropy sputa, on which account Dupasquier, a half century ago, brought the drug forward as an expectorant in *chronic bronchitis*. It is now used in vapor form in the *bronchorrhœa* and *chronic bronchial inflammations* of the aged, and in *pertussis*. Naphtalin possesses decided antiseptic properties. It is for this action that it has been valued in *diarrhœas* caused by fermentative changes and catarrhal states, and by the ulcerations of Peyer's patches in *enteric fever*. *Intestinal worms* have been expelled under its influence. Externally and to mucous tracts the drug has been applied for the purpose of preventing putrescency. In this manner *wounds* and *foul ulcers* have been treated with it. An ointment of lard, green soap, chalk, and naphtalin is used in *scabies*, and a 5 per cent ointment has been lauded in *prurigo* and other skin affections, while *sprains, bruises*, etc., have been treated with its alcoholic solution. A watery emulsion of naphtalin is occasionally employed in *purulent ophthalmia*, reducing the redness and swelling of the eyelids, without however, materially lessening the discharge. For local use, an ointment containing from 15 to 25 grains to the ounce of lard or other base may be used; for internal use the powder should be given in capsules in doses ranging from 3 to 30 grains. It has been very little used in Eclectic medicine.

Related Product.—DIOXY-NAPHTALENE ($C_{10}H_8O_2$). Several isomers of this body are known, all being di-phenols. The chief are *alpha-* and *beta-dioxy-naphtalenes*. Lepine found it to be active in the lower animals, producing severe convulsions. Three grains of it a day are said by Lepine to increase power in asthenic individuals.

NAPHTOL (U. S. P.)—NAPHTOL.

FORMULA: $C_{10}H_7OH$. MOLECULAR WEIGHT: 143.66.

"A phenol occurring in coal-tar, but usually prepared artificially from naphtalin. Naphtol should be kept in dark, amber-colored, well-stoppered bottles"—(*U. S. P.*).

SYNONYMS: *Beta-naphtol, B-naphtol, Iso-naphtol, Naphtol.*

Preparation.—Schäffer first prepared naphtol in 1869. By acting upon naphtalene at 200° C. (392° F.) with strong sulphuric acid, beta-naphtalene sulphonic acid ($C_{10}H_7.HSO_3$) is formed. This high temperature insures the conversion into the beta variety. At a low temperature, near 80° C. (176° F.), the *alpha* acid is chiefly produced, and is converted into the *beta* acid by elevation of the temperature. The product is dissolved in water, milk of lime added to saturation, and the calcium compound crystallized out and redissolved, this aqueous solution being then acted upon by sodium carbonate, yielding sodium naphtalene sulphonate ($C_{10}H_7SO_3Na$). The sodium compound is then added to melted caustic soda, sodium naphtol ($C_{10}H_7ONa$) and sodium sulphite (Na_2SO_3) resulting. To the sodium naphtol hydrochloric acid is added, resulting in the production of sodium chloride and naphtol. To purify the beta-naphtol it is sublimed and recrystallized from hot water or petroleum ether (benzin).

Description and Tests.—"Colorless, or pale buff-colored, shining, crystalline laminæ, or a white or yellowish-white, crystalline powder, having a faint phenol-like odor, and a sharp and pungent, but not persistent taste. Permanent in the air. Soluble at 15° C. (59° F.), in about 1000 parts of water, and in 0.75 part of alcohol; in about 75 parts of boiling water, and very soluble in boiling alcohol. Also very soluble in ether, chloroform, or solutions of caustic alkalies. When heated, naphtol sublimes easily. It is also volatilized with the vapors of alcohol or water. It melts at 122° C. (251.6° F.), and boils at 286° C. (546.8° F.). On ignition, it is consumed, leaving no residue. It is neutral to litmus paper moistened with alcohol. A cold, saturated, aqueous solution of naphtol, when mixed with ammonia water, exhibits a faint bluish fluorescence. Chlorine or bromine water, added to the aqueous solution, produces a white turbidity, which disappears on adding ammonia water in excess. On adding about 0.1 Gm. of naphtol to about 5 Cc. of an aqueous solution (1 in 4) of potassium hydrate, then about 1 Cc. of chloroform, and gently warming, the aqueous layer will acquire a blue tint, changing after a while to green and brown. Ferric chloride T.S. colors the aqueous solution of naphtol greenish, and after some time, causes the separation of white flakes, which turn brown upon the application of heat. A piece of pine wood, dipped into an aqueous solution of naphtol, and afterward moistened with diluted hydrochloric acid, becomes green on exposure to daylight. Naphtol should dissolve in 50 parts of ammonia water without leaving a residue (absence of naphtalin), and the solution should not have a deeper tint than pale yellow (absence of various other organic impurities). If 0.1 Gm. of naphtol be mixed, in a test-tube with 1 drop of syrup and 5 Cc. of water, and about 3 Cc. of concentrated sulphuric acid be then poured into the tube held in a slanting position, so that the liquids may form separate layers, a yellowish-brown color will appear at the zone of contact, which becomes darker on standing (absence of, and distinction from, alpha-naphtol, which produces at once a crimson color, turning deep blue in the upper part of the zone on standing)"—(*U. S. P.*). By E. Leger's test, the presence of *alpha-naphtol* in *beta-naphtol* may be ascertained by the following delicate reaction: Rub the naphtol in a mortar with water, until a saturated solution is obtained; then add to 10 Cc. of this solution 2 drops of a solution of *sodium hypobromite* prepared by adding 30 Cc. of soda solution, 36° B., to 100 Cc. of water, and adding 5 Cc. of bromine. The *alpha-naphtol* produces a violet color and precipitate which is still noticeable in dilution, while *beta-naphtol* merely turns yellow, then greenish, and finally yellow again (*Amer. Jour. Pharm.*, 1897, p. 369).

Action, Medical Uses, and Dosage.—Beta-naphtol is deodorant, antiseptic, antifermentative, and stimulant. Unless in strong solution, it does not stain the integument nor hair, and may be readily washed from garments. Strong solutions in water and alcohol fissure the skin, slightly staining the epidermis brown-yellow. By absorption when applied in skin affections, it has produced a sort of intoxication. A 10 to 15 per cent ointment is efficient in *itch*, *pruritis*, *prurigo*, *acne*, *morbus pediculosis*, *ichthyosis*, *herpes*, and *lupus erythematosus*, when not actively inflamed, but has proved irritating in *eczema* (Kaposi). A soapy solution has been applied in *ozœna*, *otitis*, *conjunctivitis*, etc., and the drug is given internally in *typhoid fever*, *diarrhœa*, *dysentery*, *dyspepsia*, and *cardiac dilatation*, all with fermentative changes. The dose is from 3 to 5 grains.

Beta-naphtol (5 per cent solution) has been beneficially employed once a day in *trachoma*, both acute and chronic. For a few minutes considerable irritation is produced, but this may be subdued by the application of cold water. A solution (1 in 2500) has been found efficient in *purulent ophthalmia*, but the drug is contraindicated when the cornea is ulcerated (Foltz).

Related Products.—Camphorated Naphtol. Beta-naphtol, 1 part; camphor, 2 parts. Mix. A transparent, brownish, syrup-like fluid. *Coryza*, *furunculous inflammations*, etc., are painted with this preparation which causes considerable pain.

Alpha-naphtol.—This body, as has been stated above, is produced in the same manner as *beta-naphtol*, except that a lower temperature, 80° to 90° C. (176° to 194° F.), is employed (see *Naphtol*). It is isomeric with beta-naphtol, but is more toxic, dissolves more easily in water, fuses at 94° C. (201.2° F.), and boils near 280° C. (536° F). A collyrium (1 to 5000) is employed in *purulent ophthalmias*.

Hydronaphtol.—A derivative of beta-naphtol, produced by acting upon the latter with reducing substances. It is stated to crystallize in silver-white laminæ of a slight, aromatic odor, dissolving readily in alcohol, ether, chloroform, glycerin, benzol, and fixed oils, less soluble in water (1 in 1000). It melts at about 117° C. (242.6° F.). The hydronaphtol of commerce is said to be merely impure beta-naphtol (see *Amer. Jour. Pharm.*, 1886, pp. 93 and 158). This agent was recommended as a substitute for carbolic acid, having much greater antiseptic power, is non-corrosive, non-toxic, and not destructive to garments. Organic matter is said not to decompose it. The usual antiseptic wash consists of an aqueous solution of 1 part in 1000 of water. It is said to destroy the parasite producing *tinea tonsurans*.

Benzo-naphtol, or B-naphtol Benzoate ($C_{10}H_7.O.COC_6H_5$).—This compound of benzoic acid and beta-naphtol is produced by acting upon beta-naphtol with benzoyl chloride ($C_6H_5CO.Cl$). A crystalline white powder or long, acicular, tasteless and odorless crystals, insoluble in cold water, soluble in chloroform and hot alcohol, little soluble in ether. It melts at 110° C. (230° F.). This agent slows the action of the heart and lungs, reduces temperature, and increases the renal secretions. It is used as an antiseptic and diuretic. The dose has been variously given as from 4 to 8 grains, suspended in water or syrup, while others give, as the daily dose, 30 to 70 grains. Care should be exercised in its use, as it is somewhat toxic.

B-naphtol Salicylate ($C_6H_4OH.COO.C_{10}H_7$), *Betol*, *Naphtalol*, *Salinaphtol*, *Naphtosalol*. This body is analogous to salol, splitting up in the intestines by action of the alkaline pancreatic fluid into beta-naphtol and salicylic acid. Comparing molecular weights, betol contains about 10 per cent less of salicylic acid than salol. It has a higher fusing point, 95° C. (203° F.), salol at 43° C. (109.4° F.), and is prepared like salol (which see), excepting that sodium naphtol is substituted for sodium phenol. An odorless and nearly tasteless, lustrous, crystalline powder, soluble in ether, boiling alcohol, benzol, and warm linseed oil, soluble with difficulty in cold alcohol and turpentine; not at all soluble in hot or cold water and glycerin. Cold concentrated acids or diluted alkalies scarcely affect it, but when heated with concentrated alkaline solutions, it is saponified into beta-naphtol and salicylic acid. Concentrated sulphuric acid, when pure, produces with betol a lemon-yellow solution. This, upon the addition of a minute quantity of nitric acid, becomes an olive- or brownish-green. No such changes take place with salol under like treatment. This agent is pleasant to the taste, and is not considered toxic. In doses of 4 to 8 grains, in syrup or mucilage, it is administered in *rheumatism of the joints*, *cystic catarrh*, *gonorrhœal cystitis* when the urine is ammoniacal, and in *intestinal disorders*, chiefly of children. It is eliminated by the urine, which, when treated with ferric chloride, exhibits a violet color.

Diiodo Beta-naphtol (Naphtol-aristol).—A solution of iodine and potassium iodide (2.4 parts each) is mixed with a solution containing beta-naphtol (11 parts), and sodium carbonate (4 parts). A solution of sodium hypochlorite precipitates the naphtol-aristol from the mixture. A greenish-yellow, tasteless, and odorless compound, evolving violet vapors when heated. Chloroform dissolves it freely; alcohol, acetic acid, and ether sparingly; it is insoluble in water.

Microcidin. A non-caustic, antiseptic compound, varying somewhat in composition, but containing most largely sodium-naphtol. By melting together 1 part of beta-naphtol and ½ part of caustic soda, it is obtained as a white powder. Antiseptic; said to be twenty-fold more active than boric acid, and ten-fold more prompt than phenol. A solution (1 to 5 parts in 1000 of water) is used upon *gangrenous* and *other ulcers*, and *discharging wounds*.

Alpha-oxynaphtoic acid ($C_{10}H_6OH.COOH$).—Prepared by acting upon sodium alpha-naphtol with carbonic acid gas. Crystallizes in colorless needles, in odor resembling that of naphtol; they melt at 185° C. (365° F.). Quite readily soluble in hot water; sparingly in cold water, glycerin, alcohol, and ether. It unites with alkalies to form soluble compounds. Antiseptic and disinfectant. Used in *scabies* and *other skin affections*, employed as an ointment containing 10 per cent of the acid.

Alumnol.—*Aluminum naphtolsulphonate*. Probably obtained by the double decomposition of barium naphtolsulphonate and aluminum sulphate. A non-hygroscopic, white powder, easily soluble in glycerin and cold water, less soluble in alcohol, and insoluble in ether. Its solutions in alcohol and water are acid and exhibit blue fluorescence. A solution prepared with hot water will remain clear if not containing more than 40 per cent of alumnol. It precipitates albumen and gelatin, but excess of the latter redissolves the precipitate. Ferric chloride strikes blue with the aqueous solution. Introduced in 1892 as an astringent antiseptic by Heinz and Liebrecht.

Asaprol, *Calcium beta-naphtol-alpha-monosulphonate* ($[C_{10}H_6.OH.SO_3]_2Ca+3H_2O$).—This is prepared by neutralizing its component acid with chalk, evaporating, and crystallizing the product. A neutral, crystalline, colorless powder soluble in water (1 in 1½), and alcohol (1 in 3). Introduced, in 1892, as an antiseptic by Stackler and Dubief. Used in *enteric fever*, *la grippe*, and *acute rheumatism*. Doses, increasing gradually daily, amounting to 30, 40, 50 grains a day, being given in divided quantities with plenty of water,

Cresol-naphtol.—A viscid tarry-brown liquid recommended by Guinard as an active germicide. Water produces with it an emulsion, but does not dissolve it. Though toxic poisoning is said to be seldom produced in animals, when given by mouth, from the fact that speedy emesis occurs to eject the poison. When mixed with water and applied surgically, it is apt to be deposited in the wounds, making it an undesirable remedy.

NARCISSUS.—DAFFODIL.

The bulb of *Narcissus Pseudo-Narcissus*, Linné.

Nat. Ord.—Amaryllidaceæ.

Common Name: *Daffodil.*

Botanical Source and History. This is a perennial, bulbous plant, native of the central and northern parts of Europe, and a common plant in moist woods in England. It is often cultivated in this country, especially the form with double flowers, and is among the first of spring flowers. The bulb is globular, white internally, and has a blackish coat. The leaves are all radical, linear, and about a foot long. The scape, which is a little longer than the leaves, is erect, and bears a large, terminal, nearly nodding flower of a yellow color. The flower is inclosed in bud in a membranous spathe, which splits lengthwise when the flower expands, and remains persistent at the base. The perianth has a funnel-form tube and six acute segments, about an inch long; near the mouth of the tube is borne a large bell-shape cup, about the length of the perianth segments, and with a crisped, 6-lobed margin. The stamens are 6, attached to the perianth tube, and included in the flower. The pistil consists of a 3-celled, inferior ovary, a slender style, and a 3-lobed stigma. The seeds are numerous.

Narcissus poeticus, Linné, *Poet's narcissus*, is an allied species, native of central Europe, and naturalized in many places in England; it is one of the most common of spring flowers in cultivation in this country. The ovate bulb has a brown skin, and possesses medicinal properties similar to the bulbs of *N. Pseudo-Narcissus*. The perianth segments are spreading, and of a pure white color. The cup is very short, and has a crenate, crimson margin.

Narcissus Jonquilla, Linné.—Jonquil has a scape bearing from 2 to 5 fragrant, yellow flowers.

Chemical Composition.—M. Jourdan has described a white, deliquescent, active principle, possessing emetic properties, which he named "*narcitine*," and M. Caventou obtained from the flowers an odorous, yellow coloring matter, which he termed "*narcissine*." From the bulbs, Mr. A. W. Gerrard (*Pharm. Jour. Trans.*, 1877, Vol. VIII, p. 214) obtained a small amount of a neutral crystalline body, and a non-crystalline alkaloid, somewhat analogous to atropine, to which the name *pseudo-narcissine* has been given. The flowers of the jonquil yielded Robiquet, by extraction with ether, a volatile, butyraceous, yellow oil, very fragrant, from which *jonquil camphor* crystallized out, upon cooling, in the form of yellowish, warty crystals, volatile by heat. Louis Robechek found the bulbs of *Narcissus orientalis* (Chinese lily) to contain 0.02 per cent of an alkaloid, and 0.2 per cent of a glucosid; furthermore, resin, pectin, sugar (3 per cent), mucilage (9.5 per cent), ash (3 per cent), etc. (*Amer. Jour. Pharm.*, 1893, p. 369).

Action, Medical Uses, and Dosage.—The flowers and bulbs of this plant are the parts that have been employed, and the recent, wild plant appears to possess more active properties than the cultivated. Internally, in large doses, it is an active and even dangerous article, occasioning severe emeto-catharsis and gastro-intestinal inflammations, and its local application to the surface of ulcers and wounds is stated to occasion similar results, and, in addition thereto, serious depressing effects upon the nerve centers. The alkaloid from the bulb is a mydriatic, and, in many respects, resembles atropine in action. As a medicine, narcissus is rarely employed in this country, but is said to possess emetic, cathartic, antispasmodic, and narcotic properties. It has been used in *epilepsy*, in *hysteria*, and other *spasmodic affections*. Laennec employed it with success in *pertussis*, and other European practitioners have accorded to it an efficient action in *intermittent fever*, *diarrhœa*, *dysentery*, *worms*, etc. It has likewise been found of prompt benefit in severe *catarrh*. The cases for narcissus are those exhibiting epileptoid movements of the muscles, in *chorea*, in *rheumatism*, showing muscular contractions, and in *cerebral diseases*, with dull eyes and dilated pupils. A tincture of the bulbs by maceration in 98 per cent alcohol, may be given in doses of ½ drop to 10 drops. Dose of dried flowers or bulbs, in powder, from 10 to 60 grains; from 1 to 3 grains of the aqueous extract provokes vomiting. A syrup, ethereal oil, and acetous tincture have also been employed.

Specific Indications and Uses.—Epileptiform movements and muscular contractions; eyes dull, pupils dilated.

NECTANDRA.—BEBEERU-BARK.

The bark of *Nectandra Rodiæi*, Schomburgk.

Nat. Ord.—Lauraceæ.

Common Names: *Bebeeru*, *Bebeeru-bark*, *Greenheart-bark*, *Bibiru*, *Sipiri*, (*Cortex beberu*, or *bibiru*, *Nectandra cortex* [*Br.*]).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 219.

Botanical Source.—This is a magnificent forest tree, growing from 60 to 80 feet in height, branching near the summit, and covered with a smooth, ash gray bark. The leaves are nearly opposite, smooth, shining, coriaceous, 5 or 6 inches long, and 2 or 3 broad. The flowers are obscure, whitish-yellow, cordate, and disposed in axillary panicles. The fruit is a globular berry, about 6 inches in circumference, having a woody, grayish-brown, speckled pericarp, and a seed with 2 large, plano-convex cotyledons, which is yellow when freshly cut, and possesses an acid reaction and an intensely bitter taste. The fruit abounds in bitter starch (Schomburgk).

History and Description.—This tree is a native of British Guiana. Its bark was introduced by Dr. Rodie as an energetic tonic and febrifuge. It is in flat pieces of 1 or 2 feet in length, from 2 to 6 inches broad, and about 4 lines in thickness, dark, heavy, brittle, with a rough, fibrous fracture, dark cinnamon-brown, and rather smooth internally, and covered externally with a brittle, grayish-brown epidermis. It has little or no odor, but a strong, persistent, bitter taste, with considerable astringency. The fruit is about the size of a small peach, somewhat heart-shaped, or inversely ovate, slightly flattened, the outside coat being frangible, and the kernel pulpy. It is exceedingly bitter. The sulphate of beberine is obtained from the bark and seeds.

Chemical Composition.—The bark of nectandra contains starch, iron-greening tannin, deliquescent *bebiric acid*, melting at 150° C. (302° F.), subliming at 200° C. (392° F.), and has two alkaloids—*bebeerine* (*bibirine* or *beberine*) and *nectandrine* (*sipeerine* or *sipirine* of Maclagan, 1845). The *British Pharmacopœias* of 1867 and 1885, indicate an elaborate process for the preparation of beberine sulphate from nectandra bark. The product is probably a mixture of sulphates of *beberine* ($C_{36}H_{42}N_2O_6$), *nectandrine* ($C_{40}H_{46}N_2O_8$), and other alkaloids (Maclagan and Gamgee, *Pharm. Jour. Trans.*, 1869, Vol. XI, p. 19).

BEBERINE ($C_{18}H_{21}NO_3$, von Planta, Flückiger) is identical with the alkaloids *buxine* and *pelosine* (see *Buxus* and *Pareira brava*). It is an amorphous substance, very soluble in alcohol, soluble in ether, sparingly soluble in water.

NECTANDRINE ($C_{20}H_{23}NO_4$, Maclagan and Gamgee) is a white, amorphous powder of an intensely bitter taste, fuses in boiling water, is very soluble in chloroform, but is much less soluble in ether than beberine. One part beberine requires 104.2, 1 part nectandrine, 2500 parts of ether. When heated with strong sulphuric acid and manganese dioxide, a magnificent green color is developed, which changes to violet (similar to the analogous strychnine reaction).

Action, Medical Uses, and Dosage.—The sulphuric acid salt of the alkaloid *beberine* is employed as a substitute for quinine, in preference to the bark itself (see *Beberinæ Sulphas*).

Related Species.—*Ocotea opifera*, Aublet (*Oreodaphne opifera*, Nees). Brazil. Source of *canella de cheiro*. The fruit yields a volatile, aromatic oil, used as a liniment.

Ocotea guianensis, Aublet. Bark employed in decoction for *abscesses*.

Cryptocarya australis, Bentham, *Laurel, Moreton bay laurel, Gray sassafras.*—Australia. Insects dislike the wood on account of its odor. Bark persistently bitter through the presence of an alkaloid, which crystallizes from solution in stellate masses. It is toxic, producing in warm-blooded animals difficult respiration, ending in asphyxia and death (Bancroft, 1887; see *Useful Native Plants of Australia*, by Maiden).

Mespilodaphne pretiosa, Nees (*Cryptocaria pretiosa*, Martius).—Brazil. Source of *casca pretiosa*. A warty, cinnamon-colored bark, having a combined cinnamon-sassafras odor, and a warm, aromatic, sweetish taste.

Nectandra puchury major, Nees, and *Nectandra puchury minor*, Nees, *Pichury beans*, *Pichurim bean*, *Sassafras nuts.*—Brazil. The halves, or cotyledons, of the two sizes (one about 1½ inches long by ½ inch thick, the other about one-half that size) are oblong or round-ovate, convex on one side, flat-concave on the other, having a depressed radicle scar at one end, deep-brown or chocolate-colored externally, pale-brown internally, interspersed with oil cells, and yellow in color. The small seed are darkest in color. Both taste and odor are aromatic, recalling the combined characteristics of sassafras and nutmeg. Starch, gum, butyraceous fat (*pichurim fat*) containing laurostearin, solid fat, and volatile oil, possibly containing safrol. The "native oil of sassafras or laurel," from Venezuela, an oleoresin, described by Procter (1851) as having a pale-amber color, a penetrating, peculiar odor, and a pungent, bitter, aromatic, camphoraceous taste, and thought to be the substance employed to adulterate Maracaibo copaiva, is referred, by Prof. Carson, to this species (*Amer. Jour. Pharm.*, 1855, p. 387). Used for same purposes as the ordinary aromatics. In doses of from 10 to 20 grains, in powder or infusion, pichurim beans are given as a stimulant tonic in [illegible], as [illegible] *diarrhœa* and *dysentery* of a subacute or chronic character, and in *intestinal weakness with flatulence.* The bark, in doses of from 20 to 40 grains, has been employed in *typhoid disorders, chronic vomiting, dyspepsia, intermittents,* and *atonic menstrual derangements.*

NICCOLI SULPHAS.—NICKEL SULPHATE.

FORMULA: $NiSO_4.7H_2O$. MOLECULAR WEIGHT: 280.14.

Preparation and Description.—This salt is easily formed by dissolving metallic nickel or carbonate of nickel in diluted sulphuric acid, and concentrating the solution. When the solution contains an excess of acid, the crystals are bluish-green, quadratic pyramids of the composition $NiSO_4+6H_2O$. When it is neutral, the crystals are rhombic prisms, isomorphous with Epsom salts, sulphate of zinc, ferrous sulphate, etc., and having the composition $NiSO_4+7H_2O$. The color of the salt is a fine, deep emerald-green, its taste is sweetish, styptic, slightly acrid and persistent. At 15.5° C. (60° F.), 100 parts of water dissolve 75.6 parts of these crystals. Neither alcohol nor ether dissolves them. Exposed to the air, the rhombic prisms lose a little water, but the square prisms do not. When heated, they swell up but do not melt. At 100° C. (212° F.) a salt of the composition $NiSO_4+H_2O$ remains. The last molecule of water can not be expelled under temperatures above 280° C. (536° F.).

Nickel-ammonium sulphate ($[NH_4]_2Ni[SO_4]_2.6H_2O$) is precipitated when nickel sulphate solution is mixed with an excess of saturated ammonium sulphate solution. It is a blue-green compound, chiefly employed in the electroplater's art.

Action, Medical Uses, and Dosage.—Nickel sulphate has been asserted to act much like iron and manganese compounds, and to be less apt to nauseate than the corresponding salts of copper and zinc. However, in doses of 5 grains, both nausea and giddiness were produced by it. It appears to be a mild tonic, and pain-relieving agent, though soporific properties are not attributed to it. Sulphate of nickel was recommended by Prof. Simpson, of Edinburgh, as a tonic, in doses of from ½ grain to 1 grain, repeated every 4 or 5 hours, and given in pill form. He found it quite efficient in *periodical cephalalgia* (Braithwaite's *Retrospect*, Vol. XXVII, p. 446). *Chronic catarrh of the stomach, irregular heart action* due to valvular lesions, *diarrhœa,* and *rheumatic pains,* are other conditions in which it has been thought useful. The dose should not exceed 3 grains.

Nickel and Its Compounds.—NICCOLUM, *Nickel.* Symbol: Ni. Atomic Weight: 58.6. Nickel was first prepared from *niccolite* (*kupfer-nickel,* NiAs), a mineral known since 1694. The metal was discovered in 1751, by Cronstadt, and the discovery confirmed in 1774, by Bergmann. Nickel occurs to a slight extent in the waters of certain mineral springs, and in combination with sulphur, iron, cobalt, antimony, and arsenic, in various ores in several parts of Europe, as well as in the United States and Canada. The ore from New Caledonia is free from cobalt. It is a silicate of nickel and magnesium, and is called *garnierite.* Nickel is prepared from its ores by converting them into oxides by roasting and calcinating, and subsequently reducing the oxide formed by strongly heating with charcoal. A purer product is obtained when proceeding in the wet way (see Roscoe and Schorlemmer's *Chemistry,* Vol. II, p. 144). A remarkable method for obtaining pure nickel is that recently devised by Ludwig Mond, of England. "When nickel is heated to 80° C. (176° F.) in the presence of carbon monoxide, it is combined with the latter to nickel-carbonyl, and the latter is again decomposed into its constituent parts at 150° C. (302° F.). Mond has turned this knowledge to practical account to separate nickel from cobalt in the ore. Passing carbon dioxide over the warmed nickel (previously obtained from the ore by calcination and reduction as stated above) gaseous nickel-carbonyl is formed, while cobalt remains behind. On heating the gas, pure nickel separates, while the reformed carbon monoxide is used over and over again. A curious fact about this metallic compound is that it forms a colorless fluid which boils at a temperature lower than chloroform, 43° C. (109.4° F.)." (Adapted from *Western Druggist,* 1896, p. 120; also see *Pharm. Jour. Trans.,* 1898, Vol. VII, p. 525.) Nickel is also a constituent of meteoric masses.

When pure, nickel is white, resembling silver, is softer than iron, has the specific gravity 8.27 to 8.93, is malleable, attracted by the magnet, is not altered by the action of the air or of water, is soon tarnished when moderately heated, and forms two oxides, the *monoxide* (NiO), and *per-oxide* (*sesquioxide*) (Ni_2O_3). Only the monoxide forms salts. Nickel is used in electroplating, and forms an essential part in certain alloys, *e. g., German silver* (copper, nickel, and zinc, in the proportion of about 5:3:2), and the lower coins in some countries, including the United States. Our 5-cent coin consists of 25 parts of nickel and 75 parts of copper. Nickel is also used in the manufacture of *nickel-steel.* Its preparations are said to be poisonous. The sulphate, chloride, and bromide have been recommended for medicinal use.

NICCOLI BROMIDUM, *Nickel bromide* ($NiBr_2.3H_2O$).—Molecular Weight: 272. Prepared by digesting nickel with an aqueous solution of bromine, or by the interaction of hydrobromi acid and nickel carbonate. It forms deliquescent, green prismatic, or acicular crystals, soluble in water, alcohol, and ether. Its aqueous solution decomposes on exposure, with the deposition of nickel hydroxide. It has a sharp, hot taste. It has favorably influenced the seizures of *epilepsy*, in several instances having been effective as a nerve sedative when the alkali bromides failed, and may be used in only a third as large a dose. The dose is about 10 grains.

NICCOLI CHLORIDUM, *Nickel chloride*. This salt is prepared by dissolving the oxide or carbonate of nickel in diluted hydrochloric acid, and evaporating to dryness. The anhydrous salt is yellow; when hydrated (with $6H_2O$), it forms deliquescent, green crystals. Heated in the presence of air, it evolves chlorine, leaving nickel oxide as residue; if the air is excluded, the salt can be sublimed without decomposition. Two-grain doses have been successfully given in *anemia* and *amenorrhœa*.

NICCOLI CARBONAS, *Nickel carbonate*.—Prepared by precipitating with sodium or potassium carbonate an aqueous solution of salts of nickel. It forms a compound of uncertain basic composition, having a light or very dark-green color.

NICKEL-CARBONYL, *Carbonic oxide of nickel* ($Ni[CO]_4$).—This compound is not employed in medicine, and is extremely toxic, vapors of it producing very violent headache. It reduces bodily temperature, and is thought to act upon the blood, destroying the hæmoglobin.

NITROBENZENUM.—NITROBENZENE.

FORMULA: $C_6H_5NO_2$. MOLECULAR WEIGHT: 122.75.

SYNONYMS: *Nitrobenzol, Oil of mirbane*, etc. (see below).

Preparation and History.—This article is prepared (impure) in quantities for the purpose of manufacturing aniline colors, by acting upon benzene with a mixture of nitric and sulphuric acids, at a temperature not exceeding 50° C. (122° F.); or, by decomposing nitrate of sodium in contact with benzene, by means of sulphuric acid. In the former case, the sulphuric acid seems to concentrate the nitric acid, by abstracting water from it; and, in the latter case, it liberates nitric acid from its combination with sodium. It was discovered by Mitscherlich (1834), and was originally made by slowly adding benzene to warm, fuming nitric acid. An oily liquid separates on cooling, which is washed with water, then with caustic soda, and then distilled from chloride of calcium.

Description and Tests.—Nitrobenzene is a yellowish, oily liquid, having the odor of bitter almond oil, and a sweet but burning taste. Its specific gravity is 1.208 at 15° C. (59° F.), and its boiling point is 206° to 207° C. (402.8° to 404.6° F.) (Prof. S. P. Sadtler, *Handbook Indust. Org. Chem.*, 1895, p. 391). It is insoluble in water, but dissolves in all proportions in ether and alcohol. It forms acicular crystals at 3° C. (37.4° F.); dissolves in fuming nitric acid and in concentrated sulphuric acid, and, upon heating, is then converted into *dinitrobenzene* ($C_6H_4[NO_2]_2$).

Nitrobenzene is used in the arts for preparing aniline, and by soap manufacturers for scenting soap, under the name, oil or essence of mirbane. It is called artificial oil of bitter almonds, and has been used to adulterate the genuine bitter almond oil. Various methods have been proposed to detect the presence of nitrobenzene in oil of bitter almonds; one of these is as follows: "2 Cc. of the suspected oil are well shaken with 34 Cc. of 45 per cent alcohol. Pure oil of bitter almond will dissolve completely; but nitrobenzol or mirbane oil will gradually subside from the liquid in the course of 24 hours" (*Amer. Jour. Pharm.*, 1887, p. 557). Another process is as follows: "Warm with a little sodium hydrate, and add ferrous sulphate to destroy odor of hydrocyanic acid; an addition of considerable excess of potassium permanganate will now remove the odor of oil of bitter almond by oxidizing this compound to benzoic acid, while the treatment does not affect the nitrobenzol, which can now be easily detected by its odor" (Dr. K. List, *Chem. Ztg.*, 1888, p. 1727; also see *Amer. Jour. Pharm.*, 1889, p. 77).

Action and Medical Uses.—Nitrobenzol is a very poisonous agent, causing death in very small doses (Letheby, *Lond. Pharm. Jour.*, Sept., 1863), and whether its toxical effects be due to internal or external employment, occasioning vertigo, nervous and muscular prostrations, spasms, convulsions, dilatation of the pupils, dyspnœa, irregular action of the heart, and eventually death; consciousness being retained the most of the time. These symptoms vary in severity and in rapidity of appearance, according to the amount of the dose employed, and are supposed to be owing to the conversion of the nitrobenzol in the system into aniline. The pathological conditions after death are, congestion of the lungs, heart, and brain, and a dark, tarry appearance of the venous blood. It should never be employed in therapeutics, though it has been advised as a local remedy in the treatment of *itch* and *parasitic cutaneous maladies;* but even in these affections dangerous symptoms have followed its employment. The best means to employ in cases of poisoning by this agent, are stimulants internally, as carbonate of ammonium, etc., and externally, electro-magnetism, frictions, and baths as hot as can be used without impairing the integrity of the skin, together with the application, at the same time, of cold douches to the head and along the vertebral column.

NITROGENII MONOXIDUM.—NITROUS OXIDE.

FORMULA: N_2O. MOLECULAR WEIGHT: 43.98.

SYNONYM: *Laughing gas.*

Source, History, and Preparation.—Nitrous oxide was discovered by Priestley, in 1776. It remained of interest to the experimental chemist only until some time after Davy, in 1800 (*Elements of Chemistry*, by Lavoisier, 1802, Vol. II), discovered its wonderful action when inhaled. Then it became a curiosity, and under the name of *laughing gas*, remained such until a recent period. At present it is in extensive use throughout civilized countries for the purpose of producing temporary insensibility in dental operations. It is best to prepare it from fused nitrate of ammonium. At a certain temperature this substance splits up into water and nitrous oxide gas ($NH_4NO_3=N_2O+2H_2O$). If the nitrate of ammonium be free from chloride, no special precautions are necessary further than washing the gas with warm water; but if, as is often the case, the ammonium nitrate is impure, precautions must be taken to separate the impurities. For this purpose the following process is recommended:

Into a spacious retort introduce fused nitrate of ammonium to one-third its capacity. Connect it by means of glass tubes, with two consecutive wash bottles. The first bottle should be half filled with solution of sulphate of iron, the second with solution of caustic potash. Connect the latter bottle with the gas bag, or with a pneumatic trough containing warm water. Apply heat to the retort, and, when the temperature approaches 200° C. (392° F.), nitrous oxide gas will be abundantly disengaged. As the reaction progresses the temperature may be cautiously increased. The traces of nitric oxide will be retained by the solution of ferrous sulphate, and the free chlorine (if present) by the solution of caustic potash.

Description.—Nitrogen monoxide, or nitrous oxide, is a colorless gas, having a sweet taste and a pleasant odor. Its specific gravity is 1.52 (Colin), 1.6 (Dalton). It is somewhat soluble in cold water, and more so in alcohol. When the gas is compressed by 30 atmospheres, at 0° C. (32° F.), it liquefies to a colorless liquid. Wills has solidified it to a snow-like formation (*Jour. Chem. Soc.*, 1874). The gas supports combustion, in consequence of its ready decomposition at higher temperatures, with liberation of oxygen, which, in reality, is the combining agent. It derived the name *laughing gas*, from the curious effect it produced upon the system when mixed with oxygen and inhaled. At present, nitrous oxide gas may be obtained in our cities compressed into cylinders, and ready for use, and for dental purposes it is extensively employed in this form, and the dentist is thus saved the trouble of its preparation. *Oxygenous aerated water* is a solution of this gas in water, prepared under a 5-atmosphere pressure.

Action, Medical Uses, and Dosage.—Sir Humphrey Davy (1800) discovered that nitrous oxide possessed anæsthetic properties, and Dr. Horace Wells (1844), of Hartford, Conn., first used it to annul pain during the *extraction of teeth.* Among anæsthetics it stands remarkable for its quickness and brevity in action, and its comparative safety. The death rate from this agent is estimated at 1 in 100,000. Though seldom fatal, occasionally untoward results follow its administration, among them being convulsions, coma lasting several days, paralysis, hysteria, and albuminuria, though these effects are exceedingly rare. The first effect of the inhalation is a general stimulation of the body with accelerated, strong pulse, quick, shallow breathing, a tingling sensation throughout the system, uncommon mental activity, and a pale countenance. After inhaling the gas for a period les-than 2 minutes in duration, stertorous breathing ensues, the face becomes cyanotic, and loss of consciousness and sensation follows. If the inhalation be withdrawn before the latter effects are produced, a stage of intoxication is produced. Muscular rigidity or twitchings are sometimes observed under this agent, and occasionally hysterical manifestations and even erotic actions are observed. The high state of excitement produced, causing the individual to sing, make speeches, or to laugh immoderately, has given to this agent the popular appellative of "laughing gas." Occasionally one becomes violent under its influence. Its effects are quickly over as soon as the agent is withdrawn.

Nitrous oxide is obviously employed only where transient or quick *operations* are to be performed. It may be safely administered to young or old, and scarcely any condition contraindicates its use. The operative stage may be known by the loss of sensation when the conjunctiva is touched, and by the stertorous breathing. It is best inhaled by a mouth-piece having a valve to permit expiration, the apparatus being connected by tubing to the container, which is generally a rubber bag, or wrought-iron cylinder. The nostrils should be held closed. The chief use to which it has been put is in dentistry to allay the pangs of teeth extraction. Opening of *abscesses*, operations for *cataract*, and other operations requiring not more than 20 minutes' time, may be performed under its influence. It has been used to mitigate the sufferings of *labor*, to relieve *neuralgia* and other *painful affections*, but is now seldom employed outside of operative dentistry.

NUX VOMICA (U. S. P.)—NUX VOMICA.

"The seed of *Strychnos Nux vomica*, Linné"—(*U. S. P.*).

Nat. Ord.—Loganiaceæ.

COMMON NAMES: *Nux vomica, Nux vomica seed, Quaker buttons, Poison nut (Semen nucis vomicæ)*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 178.

Botanical Source.—This is a moderate-sized tree, with a short, pretty thick, often crooked trunk. The branches are irregular, covered with smooth, ash-colored bark; the young shoots deep-green and highly polished. The wood is white, hard, close-grained, and bitter. The leaves are opposite, short-stalked, oval, shining, smooth on both sides, 3 to 5-nerved, or rather between that and triple, or quintuple, differing in size from 1½ to 4 inches long, and from 1 to 3 broad. The flowers are small, greenish-white, funnel-shaped, in small, terminal cymes, with a disagreeable odor. Calyx 5-toothed; corolla also 5-parted. Filaments scarcely any, or exceedingly short, inserted over the bottom of the divisions of the corolla; anthers oblong, half within the tube, and half without. Ovary superior, roundish, 2-celled, with many ovules in each cell, attached to the thickened center of the partition. Style as long as the tube of the corolla; stigma capitate. The fruit is a berry, round, about the size of a large apple, covered with a smooth, hard rind, of a rich-orange color when ripe, and filled with a white, soft, gelatinous pulp. The seeds are 5, nidulant, discoidal, with a central prominence, covered with a fine woolly substance but whitish and hard like horn internally (L.).

Fig. 176.

Strychnos Nux vomica.

History and Description.—The nux vomica tree inhabits India, along the Coromandel coast, Ceylon, and other parts of the East Indies. The wood is exceedingly bitter, especially that of the root, which is said to cure intermittent fevers and bites of venomous snakes. The pulp of the fruit is greedily eaten by various birds. The *Lignum colubrinum*, or *Snake-wood*, which is generally referred to the *Strychnos colubrina*, is also derived from the nux vomica wood. The bark contains a large proportion of brucine and some strychnine, and is said to be identical with the false angustura bark, which at one time appeared on the market. The characteristic seeds are the parts used in medicine, the Bombay variety being considered the best commercial sort. As described by the *U. S. P.*, nux vomica is "about 25 Mm. (1 inch) in diameter, orbicular, grayish or greenish-gray; soft-hairy, of a silky lustre, with a slight ridge extending from the center of one side to the edge; internally horny, somewhat translucent, very tough, with a large circular cavity, into which the heart-shaped, nerved cotyledons project. It is inodorous and persistently bitter"—(*U. S. P.*). The seeds are with difficulty reduced to a powder. An efficient method is that of the former *Edinburgh Pharmacopœia*, which directs them to be softened well with steam, and then sliced, dried, and ground. By another process the seeds may be dried whole for a few days in a drying oven, and, after breaking them into fragments, dried again by the action of warm air, and lastly powdered. The powder has a fallow-gray color, a bitter taste, and a peculiar odor, similar to that of liquorice. Concentrated sulphuric acid blackens it; nitric acid renders it a deep, orange-yellow color. Hot water and diluted alcohol dissolve the bitter, active ingredients; the last solvent acts most energetically. Ether takes up a concrete oil and some wax. The aqueous decoction is of a pale, grayish-yellow color, and intensely bitter, and becomes orange-yellow on the addition of nitric acid, and emerald-green by sesquioxide of iron, the color disappearing on the addition of hydrochloric acid. Tannic acid, or infusion of nutgalls, produces in the aqueous decoction a copious precipitate.

Fig. 177.

Seed of Strychnos Nux vomica.

Chemical Composition.—The chief constituents of nux vomica are *strychnine* (see *Strychnina*) and *brucine*, both existing in combination with *igasuric acid* (Pelletier and Caventou), a tannic principle identical with *caffeo-tannic acid* (G. Sander, 1897). A crystallizable glucosid (*loganin*, $C_{25}H_{34}O_{14}$) was discovered by Dunstan and Short (*Pharm. Jour. Trans.*, 1884, Vol. XIV, p. 1025), in the pulp surrounding the seeds, the dried pulp containing between 4 and 5 per cent. Loganin was also found in the seeds in small amounts. When gently heated with a few drops of strong sulphuric acid, a handsome red color is developed, changing to purple on standing. When boiled with diluted acids, it splits into glucose and *loganetin*. Loganin is readily dissolved by alcohol or water, but is less soluble in ether, chloroform, and benzene. A supposed third alkaloid, *igasurin* (Desnoix, *Amer. Jour. Pharm.*, 1854, p. 31), according to Shenstone (*ibid.*, 1881, p. 610) is probably nothing but impure brucine. The seeds also contain a fatty substance (3 to 4 per cent), yellow coloring matter, nitrogenous matter (11 per cent), gum, sugar, and about 1.5 per cent of ash. The amount of total alkaloids in the seeds, usually containing strychnine and brucine in about equal proportions, has been found to vary from about 2 to 5 per cent. Dunstan and Short (*Pharm. Jour. Trans.*, 1884, Vol. XV, p. 6) found specimens of Ceylon nux vomica especially rich in alkaloids, the latter amounting on an average to 1.7 per cent of strychnine and 3.2 per cent of brucine; the total amount in one instance was 5.34 per cent.

BRUCINE ($C_{23}H_{26}N_2O_4+4H_2O$) was discovered by Pelletier and Caventou in 1819. It exists in the bark and seeds of nux vomica, and in St. Ignatius' bean (see *Ignatia*). It was obtained by its discoverers from false angustura bark (formerly thought to be the bark of *Brucea antidysenterica*, Miller—hence the term *brucine*), but is now obtained as a by-product in the preparation of strychnine from nux vomica (see *Strychnina*). Shenstone (*loc. cit.*) prepared it pure by converting the base (contaminated with small amounts of strychnine) into the hydriodide, and recrystallizing the latter from alcohol repeatedly. *Brucine* slowly crystallizes in colorless, transparent, oblique, 4-sided prisms, or by rapid evaporation in pearly scales. It is odorless, intensely and persistently bitter, slightly efflorescing in the air, and fusible a little above 100° C. (212° F.). When anhydrous, it is soluble in alcohol (1.5 parts), chloroform (7 parts), and glycerin (70 parts), in 850 parts of cold water, and 500 parts of boiling water; the hydrous alkaloid ($4H_2O$) is soluble in 320 parts of cold and 150 parts of hot water and in aqua ammonia; sparingly soluble in fixed and volatile oils, and insoluble in ether. Brucine forms crystallizable salts with acids. In chlorine water brucine entirely dissolves, assuming a rose color, which ammonia converts to a dirty yellow. Nitric acid dissolves it, also with decomposition, forming a deep rose-scarlet or blood-red color, which, on warming, becomes yellow; if stannous chloride is now added a purple-violet color and precipitate is formed. This behavior toward stannous chloride distinguishes brucine from morphine. Strychnine can be quantitatively separated from brucine by Gerock's process, which consists in converting the mixture of strychnine and brucine into picrates, and warming with nitric acid of specific gravity 1.056, which destroys the picrate of brucine only. Brucine may likewise be destroyed in its mixture with strychnine by merely warming it for half an hour with nitric acid of the strength mentioned (see J. B. Nagelvoort-Flückiger, *Reactions*, Detroit, 1893, p. 137; and *Proc. Amer. Pharm. Assoc.*, 1893, p. 165).

Action, Medical Uses, and Dosage.—Nux vomica is an energetic poison, exerting its influence chiefly upon the cerebro-spinal system; it affects the spinal cord principally because the division of this cord does not prevent its poisonous influence, and, again, because when the cord is destroyed by the introduction of a piece of whalebone into the spinal canal, the convulsions immediately cease. In poisonous doses, nux vomica produces violent tetanic convulsions, without impairing the functions of the brain, with asphyxia and death. When given in doses sufficiently large to influence the system, a sensation of debility and heaviness is experienced, the spirits become depressed, the limbs tremble, and a slight rigidity or stiffness comes on when it is attempted to move. Frequently, the person can not stand erect; he staggers, and if at this time he be suddenly tapped on the ham while standing, a slight convulsive attack will often ensue, with an inability to stand. In the most severe paroxysms caused by this medicine, the patient retains his mental faculties, and the slightest motion, noise, or even a breath of wind passing over him, will excite convulsions anew, every time these occur. Sometimes, even with small doses, there will be sudden starts resembling shocks of electricity, which will be more or less severe, occasioning him to jerk the muscles acted on in this manner. It frequently occasions priapism. Of course, these symptoms vary with different persons, in proportion to their susceptibility to the influence of the medicine, and to the quantity swallowed. The usual effects of nux vomica are about as follows: in poisonous doses, stiffness, weariness, pain or rending in the limbs, violent tetanic convulsions, with short intervals of repose, acute sensibility, dreadful alarm, and finally death; in small doses, twitching of the muscles, restlessness, anxiety, and increase of urine, perspiration, etc.; when the doses are rather large, there will be more active spasm of the muscles, a tendency to lockjaw, with the preceding symptoms more or less severe. Heat in the epigastric region, constriction of the throat, headache, dizziness, and impairment of vision with closely contracted pupils, are often caused by small doses; and more especially with the corpulent and apoplectic, there will be painful sensations in the skin compared to an electric shock, or to the creeping of insects over the surface, with more or less perspiration, slight involuntary spasms of the muscles, and a very disagreeable, dreamy or vague condition of the brain. The pulse may or may not be increased in frequency. Chloroform is beneficial in poisoning by nux vomica. (For other effects, and treatment of poisoning by nux vomica and strychnine, see also *Strychninæ Sulphas*.)

In medicinal doses, nux vomica is tonic, and increases the action of the various excretory organs; it should always be given, as well as its alkaloids, in doses to fall short of any immediate sensible effects upon the system. The key-note to its use is *atony*. It was formerly employed in cases where there is a want of nervous energy, as in the treatment of *paralysis*, especially when this has been of some standing, and not occasioned by hemorrhage in the nervous centers, or inflammatory conditions of them. Strychnine is now generally used in its stead. It must not be used in recent cases, or while reaction prevails, or when signs exist either of local irritation in the brain or spinal cord, or of determination of blood toward the head.. Congestion or inflammation must always be removed before employing it. It is said to be more beneficial in *general paralysis* and *paraplegia* than in *hemiplegia*, and also in *local paralyses*, as of the *bladder*, in *amaurosis*, *impotence*, *spermatorrhœa*, *tremor of the muscles* produced by habitual intoxication, etc. It has also been beneficially employed in *neuralgia*, *chorea*, *prolapsus of the rectum*, *borborygmi of females*, *colica pictonum*, etc. A small quantity added to cathartics frequently increases their energy. *Rheumatism*, *hysteria*, *mania*, and *worms* have been successfully treated by the use of this agent.

As a remedy for *atony of the gastro-intestinal tract*, few agents equal, and none exceed nux vomica in value. The condition must not be one of irritation or inflammation, though it may be one of irritability due to atony. Often there is an enfeebled spinal innervation. The tongue is pallid and expressionless, there is *nausea* or *vomiting*, a yellow or sallow circle is about the mouth, and there is evidence of a disordered liver. There may be a yellow, pasty coating upon the tongue, yellowness of the conjunctiva, pain or fullness in the hepatic region, pain in shoulder, and colicky pains pointing to the umbilicus. With any or all of these symptoms it becomes a remedy of first importance, both for the ailments of adults and children. When nausea is due to irritating material in the stomach, nux will not be apt to relieve, but if due to simple atony, it is a positive agent. Used as above indicated, it is very valuable in *cholera infantum*, *cholera morbus*, *Asiatic cholera*, *constipation*, *chronic dysentery*, *diarrhœa of atony*, *nervous debility of the stomach*, the *gastric irritability of the dipsomaniac* (with good food and capsicum), and in *chronic non-inflammatory infantile diarrhœa*. It is especially used in *obstinate* and *habitual constipation* due to atony. A drop of nux vomica should be taken in a glass of cold water upon rising in the morning, and a regular habit of going to stool be encouraged. Nux relieves constipation due to spasmodic conditions of the bowels, and to some extent, that arising from the effects of lead. Nux is a remedy for *heartburn*, *flatulent colic*, *colic of atony* in infants, in all of which the pain centers near the umbilicus. It relieves the *vomiting of pregnancy*, of *hysteria*, and of *phthisis pulmonalis*. In *chronic dyspepsia* of an atonic character, or associated with dilatation, or flatulent distension, it is one of our best remedies. Drop doses are of great benefit in the *dyspepsia of inebriates*. Though usually contraindicated by congestion, it is nevertheless a remedy for *hepatic* and *splenic congestion*, or other parts supplied by the cœliac axis. It stimulates the sluggish portal circulation and thereby relieves the congestion dependent thereon. It is the remedy for "*biliousness*," for *hepatic colic*, when not due to calculi, and for *chronic jaundice* due to atony.

In *stomach* and *liver disorders* requiring nux, there is always a feeble and sluggish circulation, and enfeebled spinal and sympathetic innervation. These conditions are overcome by nux vomica more quickly than by any other agent. Nux vomica is more largely used in disorders of the gastro-hepatic tract than strychnine, while strychnine is generally preferred in nervous, sexual, and bladder disorders. Nux vomica frequently acts as a sedative and antiperiodic. This it does when the conditions above referred to are present. Thus it has proved exceedingly useful when nerve force was low, as in *typhoid fever*, and in *asthmatic seizures*, in both of which there was impaired spinal innervation and difficulty in breathing. It is adapted to cases where the patient awakens suddenly from sleep, with a sense of suffocation; where breathing seems to depend largely on the will power. Here strychnine is valuable. When respiration flags in *pneumonia*, nux or strychnine is demanded.

Nux and strychnine are of great value in the *urinal incontinence* of children, when not due to irritation, and the same in the aged when due to a relaxed or paralyzed sphincter with feeble circulation. It is also a remedy for *paralytic retention of urine*. It is often of value in *catarrh of the bladder*. It is a remedy for *uterine inertia*, and is said to lessen the liability to *post partum hemorrhage*. Nux has long been used in *sexual atony*, as a remedy for *impotence*, *spermatorrhœa*, *sexual frigidity* in the female, etc. In *amenorrhœa* it serves well with iron if there is weakness, constipation, anemia, and torpor. When in *dysmenorrhœa*, the discharges are premature and associated with cramps and chilliness, or in *menstrual colic* with sharp, cramp-like pain and marked atony, nux vomica is the remedy to be used. Small doses benefit *leucorrhœa* with a heavy, yellow discharge, and great torpor of the system.

Nux vomica has been praised in *amblyopia* when due to excessive use of tobacco or alcoholics, in *nervous affections of the lids*, and in *muscular asthenopia*

Foltz). Where atony of the general system contributes toward the aggravation of eye and ear disorders nux should be administered. It often aids in the cure of *conjunctivitis* and *phlyctenular keratitis*. It is of some value in *choroiditis*. In *purulent otitis media* with general lack of tone, nux is the best remedy (Foltz).

Nux vomica and its alkaloids should always be given with great care, the physician closely observing its effects. The dose of powdered nux vomica is from ½ grain to 5 grains, three or four times a day, and gradually increased to 10, or until a slight influence is observed as indicated. Specific nux vomica, tincture, or alcoholic extract, are the best forms of administration. The extract may be given in doses of from $\frac{1}{12}$ to $\frac{1}{10}$ of a grain as a tonic; and in paralytic affections from ½ grain to 2 grains in the form of a pill, and, as with the powder, gradually increased. The saturated tincture may be given in doses of from 5 to 30 drops, likewise gradually increased. For specific uses, the usual prescription is: ℞ Specific nux vomica, gtt. v to xv; aqua, fl℥iv. Mix. Sig. One teaspoonful every 1 to 3 hours, as indicated. (For further consideration, see *Strychninæ Sulphas*.)

Specific Indications and Uses.—Atonic states; tongue pallid and expressionless, uncoated, or coated with a pasty-yellowish coat; yellowness of the conjunctiva; yellow or sallow countenance, and yellowish or sallow line around the mouth; fullness and dull pain in the right hypochondrium; pain in shoulder, colicky pains pointing to the umbilicus; menstrual colic; constipation; diarrhœa of atony; functional forms of paralysis.

Related Species.—*Strychnos malaccensis*, Bentham (*Strychnos Gaultheriana*, Pierre), *Hoàng-Nàn*, *Tropical bindweed*. A climber of Malacca and neighboring isles, also of China. Its bark contains *brucine* and *strychnine*, the former preponderating. The drug closely resembles the latter alkaloid in action, producing in the inferior animals violent tetanic convulsions. In doses of 3 grains of the powdered bark, it has been employed in cases in which nux vomica is applicable.

Strychnos colubrina, Linné, yields true *lignum colubrinum*, often substituted in India for nux vomica branches. It contains strychnine and brucine.

Strychnos potatorum, Linné, *Clearing nuts*, *Indian gum nuts*, *Chilbinz*.—India. The seeds of this species are subglobular, and of a brown-gray color. They are insipid in taste, and do not contain any alkaloid (*Proc. Amer. Pharm. Assoc.*, 1893, p. 865), but an abundance of an albuminous body upon the presence of which their properties most likely depend. They are used in India to clear muddy water, and as an emetic, and in *dysenteric* disorders.

Strychnos Tieute, Leschenault.—A climbing plant of Java. A decoction of the root-bark, mixed with onions, garlic, pepper, and other substances, constitutes the arrow poison *upas tieute*. Strychnine (about 1.5 per cent) and very little brucine are the toxic principles contained in it. The seeds are lighter in color, and smaller than those of nux vomica. The seeds and the leaves, according to Boorsma, also contain 1.4 per cent of strychnine.

Akazga, *Ikaja*, *M'Boundou*, *Quai*, *Ikaju*, *Icaja*, *Boundou*.—According to Pecholier and Saint-Pierre, of France, this is believed to be a shrub of the family of Apocynaceæ, which, as with some other plants of the same family (*Nerium Oleander*, *Inee*, etc.), is used in the preparation of a violent arrow poison. More recently, however, it was ascertained to be a Strychnos species, and the poison is now accepted to be derived from *Strychnos Icaja*, Baillon (1879). The root-bark is employed. It is intensely bitter, and feebly aromatic, and contains, according to Prof. T. R. Fraser, of Edinburgh, a crystallizable alkaloid which he has named *akazgine*. Heckel and Schlagdenhauffen, in 1881, established the absence of brucine and the presence of strychnine, in Icaja poison. This is confirmed by the more recent researches of Gautret and Lautier (*Jour. Pharm. Chim.*, 1896, p. 418), who also found that the active principle is chiefly contained in the bark of the root, and is also found in much smaller quantity in the leaves and the stems.

According to Pecholier and Saint-Pierre, the bark of this shrub (*Strychnos Icaja*) is employed in infusion among the Africans on the Gabon as an ordeal liquid under the name of *M'Boundou*. The bark is macerated and the infusion given to the accused to drink, followed by certain proceedings; and if the accused can successfully pass the ordeal, he is deemed innocent of the charge against him. Its effect is to determine tetanic convulsions with rapid death. Sometimes profuse urination occurs, and the person gradually returns to health and life. From experiments on frogs, a dog, and rabbits, these gentlemen have concluded that the boundou contains a poisonous principle, soluble in water and in alcohol, which exerts an action upon the sensitive nervous system analogous to that caused by nux vomica. Administered by the stomach, or used endermically, this poison increases the number of inspirations and cardiac pulsations, succeeded by a great diminution of these movements; at the same time it causes an exaggeration of sensibility, followed by tetanic convulsions, and, finally, insensibility, paralysis, and death. Its action on the motor nervous system is only secondary, and it does not affect the contractility of the muscular system. It is not a poison to the heart, which, on the contrary, continues to pulsate for a long time after death (*Montpellier Médical*).

Ipoh. At one time believed to be derived from [illegible] or *Tuba root*. The arrow-poison of the Malays and fish poison of Java. Its active constituent, an acid resin, *derrid*, is reputed intensely poisonous, gold-fish being stupefied by [illegible] part, death following in 30 minutes. Recently (1892) Ipoh has been ascertained to be identical with [illegible], from

Antiaris toxicaria (see Wray, *Pharm. Jour. Trans.*, 1892, p. 613). The pygmies of Central Africa use an arrow-poison containing both *strychnine* and *erythrophlœine* (also see *Arrow-poisons* under *Strophanthus*).

Hedwigia balsamifera.—Habitat, the Antilles. Contains a resin and an alkaloid. The extract from root and stems acts powerfully upon the nervous system. The alkaloid acts upon the spinal cord, inducing convulsions; the resin is a paralyzer.

Hyænanche globosa (*Toxicodendron capense*).—South Africa. Contains a powerfully poisonous, bitter, neutral principle *hyænanchine*, acting much like strychnine, except that it markedly affects the cerebrum, the convulsions being of centric origin (see Engelhardt, *Jahresb. der Pharm.*, 1892, p. 55).

NYMPHÆA.—WATER LILY.

The rhizome of *Nymphæa odorata* (Dryander), Aiton (*Castalia odorata*, Dryander).

Nat. Ord.—Nymphæaceæ.

Common Names: *Water lily*, *Pond-lily*, *White pond-lily*, *Sweet-scented water lily*, *Water nymph*, *Water cabbage*.

Botanical Source.—White pond-lily has a blackish, large, fleshy, perennial rhizome, growing in mud, where the water is from 3 to 10 feet in depth. It is often as thick as a man's arm, sending up leaves and flowers to the surface. The petioles are long, somewhat semi-circular, perforated throughout by long tubes or air-vessels which serve to float them. The leaves are floating, orbicular, sometimes almost kidney-shaped, peltate, cordate-cleft at the base quite to the insertion of the petiole, lobes on each side prolonged into an acute point, entire, reddish, with prominent veins beneath, dark shining-green above, 5 or 6 inches in diameter. The flowers are large, white or rose-colored, beautiful, and fragrant. Sepals 4, lanceolate, green without, white within. Petals numerous, lanceolate, 1 to 2½ inches long, of the most delicate texture, white, sometimes tinged with purple on the outside. Stamens numerous and yellow, in several rows; filaments dilated gradually from the inner to the outer series so as to pass insensibly into petals. Anthers in 2 longitudinal cells growing to the filaments, and opening inwardly. Stigma with 12 to 24 rays, very much resembling abortive anthers, at first incurved, afterward spreading. The pericarp is berry-like, many-celled, and many-seeded (L.—W.—G.).

Fig. 178.

Nymphæa odorata.

History and Chemical Composition.—This plant grows in ponds, marshes, and sluggish streams, in most parts of the United States, flowering from June to September; the flowers shut at night and open about sunrise, and the seeds ripen under water. It is one of the most beautiful of flowers, and commands a ready sale among flower-lovers. The root is the medicinal part, and becomes light, spongy, and friable on drying. It has an astringent and mucilaginous, bitter taste, and readily imparts its virtues to water. The root should be collected in the fall, freed from dirt, cut into slices and carefully dried. Nymphæa is said to contain tannic and gallic acids, with starch, mucilage, resin, sugar, tartaric acid, etc. It probably contains several non-toxic alkaloids (see *Related Species*).

Action, Medical Uses, and Dosage.—The root is astringent, demulcent, anodyne, and antiscrofulous. Used in *dysentery*, *diarrhœa*, *gonorrhœa*, *leucorrhœa*, and *scrofula*, and combined with wild cherry in *bronchial affections*. Externally, the leaves and roots have been used in form of poultice to *boils*, *tumors*, *scrofulous ulcers*, and *inflamed skin*. In infusion, used as a gargle in *ulcers of mouth* and *throat*, and as an injection in *leucorrhœa*. I recollect a lady, who, several years since, was pronounced by several physicians to have *uterine cancer*, which resisted all their treatment; she was permanently cured by a squaw, who gave her to drink freely of the decoction of a root, which proved to be that of the white pond-lily, as well as to inject it in the vagina (J. King). It should be especially experimented with for its alterative effects and its influence on mucous tissues. A tincture may be prepared from the root (℥viii), and alcohol, 76 per cent (Oj), the dose of which ranges from 1 to 10 drops. The dose of the powdered root is ½ drachm in milk or sweetened water; but one of its best forms of administration is the infusion made by macerating for 30 minutes 1 ounce of the coarsely powdered root in a pint of boiling water, of which from 2 to 4 fluid ounces may be given 3 or 4 times a day.

Related Species.—*Nuphar advena* (R. Brown), Aiton (*Nymphæa advena*, Solander). The *Yellow pond-lily*, called also *Spatterdock*, *Frog-lily*, *Cow-lily*, etc., possesses similar properties, and may be used as a substitute for the preceding. It has a large and extensively creeping rhizome, with large, erect leaves, or floating on half-cylindrical petioles, oval, rounded at apex, with rounded, diverging lobes at base, dark shining green above, and when floating, pale and slimy beneath. Flowers rather large, globular, erect, yellow, on a thick rigid stalk. Sepals 6, the 3 outer yellow inside, the 3 inner entirely yellow. Petals numerous, small, yellow, furrowed externally, inserted with the stamens on the torus. Stamens numerous, truncated, linear. Stigma sessile, discoid, with prominent rays. Fruit an ovoid, naked pericarp, many-celled, many-seeded. It is a very common plant in ponds, ditches, muddy lakes, and mostly in shallow water (W.—G.).

Nymphæa alba, Linné, *European water lily*. The flowers of this species are official in the *French Codex* as *Nénuphar blanc*. Dragendorff (1879), and W. Grüning (*Archiv der Pharm.*, 1882, p. 604) found in the rhizome an amorphous alkaloid probably closely related to, but not identical with, *nupharin*. The rhizome, according to Grüning, also contains several tannic principles, viz., ether-soluble *tanno-nymphæin* ($C_{56}H_{52}O_{36}$), *nymphæo-phlobaphene* ($C_{56}H_{48}O_{36}$), and *nymphæa-tannic acid* proper ($C_{56}H_{58}O_{38}$). (See *Amer. Jour. Pharm.*, 1883, p. 96.) This drug was formerly employed as an aphrodisiac.

Nuphar luteum, of Smith, contains a non-toxic alkaloid, *nupharine*, a white, amorphous body, soluble in alcohol, ether, chloroform, acetone, amylic alcohol, and diluted acids. The seeds contain a tannin, *nuphar-tannic acid* ($C_{56}H_{36}O_{37}$), associated with *nuphar-phlobaphene* ($C_{56}H$[illegible]O[illegible]) (Grüning, *Amer. Jour. Pharm.*, 1883, p. 96). This agent has been employed in *spermatorrhœa*, and to arrest *nocturnal emissions*, as well as to give tone and increased power to the sexual organs. Its best effects are probably obtained in *digestive disorders* with morning diarrhœa, and in *chronic diarrhœa*. Dr. Zell Baldwin praises the fluid extract of *Nuphar luteum*, employed full strength locally, as a valuable agent in many chronic forms of *uterine disease* (*Ec. Annual of Med. and Surg.*). The dose, of a strong tincture of the fresh root, is a fraction of a drop every 3 or 4 hours.

ŒNOTHERA.—EVENING PRIMROSE.

The root, bark, leaves, and twigs of *Œnothera biennis*, Linné.

Nat. Ord.—Onagraceæ.

COMMON NAMES: *Evening primrose*, *Tree primrose*.

Botanical Source.—This is an indigenous, biennial plant, with an erect, rough, hirsute, and branching stem, from 2 to 5 feet high. The leaves are ovate-lanceolate, alternate, acute, obscurely toothed, roughly pubescent, 3 to 6 inches long, ½ to 1½ inches broad, those on the stem sessile, the radicles tapering into a petiole. The flowers are numerous, pale-yellow, sessile, odorous, in a terminal, somewhat leafy spike; they are nocturnal, open but once by night, and continue only a single day. The calyx tube is 2 or 3 times longer than the ovary, deciduous, 4-lobed, and reflexed. Petals 4, equal, obcordate, or obovate, inserted into the top of the tube. Stamens 8, a little shorter than the petals. Anthers mostly linear. Capsule oblong, somewhat tapering above, 3-celled, and 4-valved. Seeds numerous, naked, and in 2 rows in each cell (G.—W.).

Fig. 179.

Œnothera biennis.

History. Tree primrose grows throughout the country in fields and waste places, flowering in July and August. There are several varieties of it, as *Œ. muricata*, *Œ. grandiflora*, *Œ. parviflora*, *Œ. cruciata*, and *Œ. canescens*. When growing in retired, isolated places, a white substance appears on the leaves, rendering them apparently very downy. By cultivating the plant, its flowers improve, growing much larger, and acquiring a darker hue. Each flower opens at the dusk of evening, and does not close till about 9 or 10 o'clock the next morning, after which they do not open again. Pursh remarks that he has "frequently observed a singularity in this plant, and it might be interesting to make further inquiry into its cause; it is that in a dark night, when no objects can be distinguished at an inconsiderable distance, this plant, when in full flower, can be seen at a great distance, having a bright white appearance, which probably may arise from some phosphoric properties of the flowers." The bark, leaves, and twigs are the parts used. Their taste is very viscid, with a subsequent slight acrimony, which last is diminished by desiccation. Water takes up the properties of the plant.

Chemical Composition.—The stem of this plant contains tannin (Braconnot). Mucilage is abundant. The *œnotherin* of Chicoisneau (1834) is composed of several substances, and has not been well studied. The alcoholic extract of *Œ. biennis* sometimes deposits crystals of potassium nitrate (*Amer. Jour. Pharm.*, 1884, p. 365).

Action, Medical Uses, and Dosage.—An ointment made by boiling the twigs, leaves, and bark, in lard or tallow—or a strong decoction of these—has been found very efficient in curing *tetter*, *milk-scall*, and other cutaneous affections of infants. Collect the material when the plant is in flower. In fomentation, or when recent, the bruised leaves form an excellent application to *ulcers*. Internally, œnothera has been used for a number of purposes, and its specific field of action seems none too well established. It has, however, been accorded a place in the treatment of *gastro-intestinal disorders* of a functional character. Dr. Scudder points out as the indications for it, a sallow, dirty skin, with full and expressionless tissues, an expressionless face, an unnatural and large tongue, having the sallow, dirty hue of the skin, and the patient's mentality is of a gloomy and despondent character. Under these conditions he has employed it with success in *dyspepsia*, *hepatic torpor*, *splenic and mesenteric glandular enlargements*, and in *female disorders*, with torpor and pelvic fullness. The dyspepsia met by it is that form associated with vomiting, distressing sensations after taking food, restlessness at night, and frequent desire to pass urine. When *cholera infantum* and *watery diarrhœas* assume a choleraic form, it has been asserted to act well, as it does in *dysentery*, with marked tenesmus and bloody stools. The intestinal irritation and consequent liability to destructive inflammation of Peyer's patches, in *enteric fever*, is said to be lessened by the timely administration of œnothera (Webster). It relieves difficult respiration and *chronic asthma*, with gastric complication. The dose of the fluid extract ranges from 5 to 30 drops; of a strong tincture of the recent plant (98 per cent alcohol), from 1 to 15 drops.

Specific Indications and Uses.—Sallow, dirty skin, tissues full and expressionless, tongue unnatural in size and color, being large and of the dirty color of the skin, face dull and apathetic; dyspepsia, with vomiting of food, and gastric distress, with desire to urinate frequently; choleraic and dysenteric discharges; nocturnal restlessness; innervation feeble; patient gloomy and despondent; atonic reproductive wrongs of the female, with pelvic fullness.

OLEA.—OILS.

The term *Oil* applies to a number of unctuous bodies not miscible with water, from both the vegetable and animal kingdoms, which are fluid at ordinary or slightly elevated temperature. When placed upon paper they render it translucent, or impart to it a greasy stain. Oils may be conveniently divided, with reference to their volatility, into two great classes: *Fixed* or *fatty oils* and *fats*, to which also belong the *waxes* (see *Cera*), and *volatile* or *essential oils*. Intermediate between the two, although chemically unlike either, stand the *mineral oils* and *mineral waxes*, or *paraffins* (see *Petrolatum*).

Olea Fixa.—FIXED OR FATTY OILS (*Olea pinguia*). Fixed oils derive their name from not being volatilized by the vapors of boiling water. The difference between fatty oils and fats is merely one of consistency, the former being liquid, the latter solid or semisolid at ordinary temperatures. In the vegetable kingdom, fixed oils are mostly derived from the seeds of dicotyledonous plants, although monocotyledonous plants, such as the palm trees, furnish several of the technically important fixed oils. The oil often constitutes a large proportion of the seeds, *e. g.*, not less than 25 per cent in linseed, 50 per cent in walnuts, about as much in almonds, as against about 2 per cent in cereals. It is obtained from the crushed oil-bearing material, either by cold or warm pressure, in hydraulic presses, or by extracting with such solvents as carbon disulphide, or by boiling the crushed material with water, whereby the oil floats on top and may be conveniently collected. The residual press-cakes, obtained in the first process (*oil cakes*), are valuable feed material for cattle, since they contain much nitrogenous and fatty matter (see table in Prof. S. P. Sadtler's *Handbook of Indust. Org. Chem.*, 2d ed., 1895, p. 70).

The oils and fats derived from the animal kingdom, are obtained from various organs of the animal; thus, bone-oil from bones, by boiling with water, or extraction with solvents; neat's-foot oil from the feet of oxen by boiling with water; cod-liver oil and shark oil, from the respective livers, by spontaneous exudation and gentle expression; tallow and lard from the internal abdominal fat of sheep and hogs (see *Sevum* and *Adeps*), etc. The crude oils and fats as obtained in the manner alluded to, are mostly of a yellow, brown or even black color, and frequently require more or less purification. This is often effected by mechanical treatment, such as filtration with or without charcoal, etc., but more frequently, by chemical processes, especially treatment with 1 or 2 per cent of strong sulphuric acid (applicable, for example, to linseed oil), or with zinc chloride, or alkalies, tanning materials and oxidizers, such as potassium bichromate, hydrogen peroxide, etc.

The fatty oils of marine animals, and those from most vegetable sources, are fluid at ordinary temperature: palm oil, cacao-butter, nutmeg butter, cocoanut oil, and others, are semisolid like butter. When exposed to cold, fixed oils solidify at temperatures varying with the oil. Fatty oils are insoluble in water, rendering that fluid milky when agitated with it, but the oil finally rises upon the surface; if a mucilaginous substance, or alkaline carbonate be added, the oil is prevented from rising, and a permanent milky mixture called an *emulsion* is formed. With the exception of castor oil and croton oil, fatty oils are nearly insoluble in cold alcohol. They dissolve readily, however, in ether, carbon disulphide, chloroform, benzol, petroleum benzin, amyl alcohol, acetone, and oil of turpentine, and freely mix with one another, as well as with resins and volatile oils. They are all lighter than water, their specific gravities ranging from 0.879 to 0.968. Fatty oils are not volatile as such, but can be heated to boiling (at about 315° C., or 600° F.) whereby decomposition takes place, acrid fumes of *acrolein* (see *Glycerin*) being evolved, together with carbonic acid gas, some volatile organic acids and inflammable hydrocarbons. Upon condensing the vapors, an empyreumatic oil is obtained. When in the state of vapor, fixed oils take fire upon the approach of an ignited body; the products of combustion are water and carbonic acid gas.

As to their chemical nature, most fatty oils are mixtures of salts of the trivalent alcohol *glycerin* ($C_3H_5[OH]_3$), with the saturated *palmitic* ($C_{16}H_{32}O_2$) and *stearic acids* ($C_{16}H_{36}O_2$), both higher homologues of acetic acid, of the general formula $C_nH_{2n}O_2$, and the unsaturated *oleic acid* ($C_{18}H_{34}O_2$), which represents the series $C_nH_{2n-2}O_2$. The salts are called *glycerin esters*, or *glycerides*, and are known respectively as *palmitin*, *stearin*, and *olein*. The former two are solid and preponderate in solid fats—*e. g.*, lard—while olein is liquid and predominates in liquid fats—*e. g.*, olive oil and almond oil. The solid and liquid constituents of a fatty oil are frequently separated by subjecting the oil to hydraulic pressure at about the temperature of melting ice. Olive oil, for example, is differentiated into a purified olive oil and solid olive oil stearin, lard into lard oil and lard stearin, sperm oil (from the head of *Physeter macrocephalus*) into purified sperm oil and solid *spermaceti* (see *Cetaceum*), etc. In some fats—*e. g.*, butter—part of the fatty acid is replaced by lower fatty acids—*e. g.*, butyric, or in porpoise oil, by valerianic acid—both occurring as glycerin esters, *butyrin*, *valerin*, respectively (see also *Glycerin* and *Adeps*). In drying oils (see below), oleic acid is in part replaced by the still more unsaturated *linoleic acid* ($C_{16}H_{28}O_2$) of the type $C_nH_{2n-4}O_2$), the chief constituent of linseed oil, which is the type of drying oils. The waxes have an analogous, yet different composition (see *Cera* and *Cetaceum*). The presence of certain albuminous matters in fatty oils, and other causes as well, often induce the liberation of free fatty acid, especially the ill-smelling lower volatile acids. Thus butyric acid is formed in old butter, causing what is known as *rancidity.* Olive oil, palm oil, etc., are also liable to become rancid with age. Oils which have a tendency to liberate free fatty acids are undesirable for lubricating purposes. Neat's-foot oil hardly possesses this tendency. Mineral oils (see *Petrolatum*) are now frequently employed as lubricants, owing to their indifferent chemical nature.

When fatty oils and fats are treated with caustic alkalies, they are decomposed (*saponified*) into glycerin and the alkali salts of the fatty acids that were combined with glycerin. These alkali salts are called *soaps*, and the process is that of *saponification*. Analogous decomposition may also be effected by means of caustic lime, or oxides of heavy metals (see *Emplastrum Plumbi*), or by superheated steam (see *Glycerinum* and *Sapo*). For analytical purposes, this reaction is likewise of great importance. Since each ester requires a definite amount of caustic potash solution for saponification, values expressing the number of grammes of the fat or oil which are saponifiable by one gramme-equivalent of the caustic alkali employed, have been obtained for all fatty oils and waxes (Koettstorfer's *Saponification Equivalent*). The values obtained present some striking differences in various classes of oils, and may serve as useful guides in the detection of adulterations by certain oils. Thus, paraffin oils, on account of being hydrocarbons, are unaffected by caustic alkali, and, if mixed with fatty oils, will raise the saponification equivalent of the latter upon saponification of the oil. Washing out the soap with water will allow of the recovery of the admixed paraffin oil (see table and comment, by A. H. Allen, *Commercial Organic Analysis*, Vol. II, Part I, 3d ed., Philadelphia, 1899, pp. 53–58, and p. 111). An additional important analytical method is based upon the absorption of bromine (Mills) or iodine (Hübl) by the different oils when they are in contact with solutions of these elements. Oils in which the glycerides of saturated acids (carbon atoms united by single bonds) dominate, as, for example, cocoanut oil, absorb much smaller quantities of halogens than those oils containing a highly unsaturated fatty acid (with two pairs of carbon atoms united by double bonds)—*e. g.*, the glyceride of linoleic acid, the chief constituent of linseed oil. (For details, see A. H. Allen, *loc. cit.*, pp. 62–66; and S. P. Sadtler, *loc. cit.*. 2d ed., 1895, pp. 78 and 79.)

Parallel with their capacity for absorbing halogens, runs the well-known quality of fatty oils to absorb oxygen by prolonged exposure to the air, and to become more or less dry and solid. Accordingly, fatty oils are differentiated into *drying oils* and *non-drying oils.* The type of drying oils is linseed oil, and of the non-drying, olive oil (see enumeration of both classes of oils in the table subjoined).

Drying oils are also characterized by not yielding solid *elaïdin* when treated with nitrous acid in form of gas or in solution, while non-drying oils by virtue of their olein contents, when treated with nitrous acid gradually become a hard mass of *elaïdin*, an isomer of olein (compare *Acidum Oleicum*). (For a special description of the more important oils, see the authorities quoted; the pharmacopœial oils are described under their respective headings.)

The following general classification of the fatty oils and waxes is adapted from A. H. Allen (*Commercial Organic Analysis*, 3d ed., Philadelphia, 1899, Vol. II, Part I, p. 88; and S. P. Sadtler, *Handbook of Indust. Org. Chem*, 2d ed., 1895, p. 51):

Classification of Fatty Oils and Waxes.—I. Olive-oil Group. *Vegetable oleins, Vegetable non-drying oils.* Lighter than Groups III, IV, and V. Specific gravity, 0.914 to 0.920. Yields solid elaidins with nitrous acid. Moderate saponification equivalents and iodine absorptions. Includes olive, almond, peach, and earthnut oils.

II. Rape-oil Group.—All oils from *Cruciferæ.* Less perfectly *non-drying oils.* Yield pasty elaïdins; have higher iodine absorptions and high saponification equivalents. Includes oils of rape-seed (colza), cabbage seed, black and white mustard.

III. Cotton-seed Oil Group.—Specific gravity, 0.920 to 0.926. Intermediate between drying and non-drying oils. Undergo more or less drying on exposure. Yield little or no elaïdin. Includes oils of cotton-seed, grape-seed, maize, sesame, sunflower, hazelnut, and beechnut.

IV. Linseed-oil Group.—*Drying oils.* Specific gravity, 0.924 to 0.937. Yield no elaïdin. Less viscous than the preceding groups. Includes oils of linseed, hemp-seed, poppy seed, tobacco seed, niger seed, Scotch fir-seed, and walnut.

V. Castor-oil Group.—*Medicinal oils.* Very viscous and of high specific gravity 0.937 to 0.985. Includes castor and croton oils, both distinguished by their solubility in alcohol and glacial acetic acid.

VI. Palm-oil Group.—Solid vegetable fats. Do not contain notable quantities of esters of lower fatty acids. Includes palm-oil, cacao butter, nutmeg butter, bayberry tallow, and shea or galam butter.

VII. Cocoanut-oil Group. Solid vegetable fats, of high specific gravity and low saponification equivalents. Members of sub-group A (cocoanut, palm-kernel, laurel, and macassar oils contain notable proportions of esters of lower fatty acids, distilling over in a current of steam. Sub-group B are wax-like and of peculiar composition. (Japan wax, myrtle wax.)

VIII. Lard-oil Group.—*Animal oleins.* Do not dry notably on exposure, and give solid elaidins with nitrous acid. Not turned brown by boiling with caustic alkalies (difference from marine animal oils). Includes neat's-foot oil, bone oil, lard oil, and tallow oil.

IX. Tallow Group.—*Solid animal fats.* Predominantly glycerides of palmitic and stearic acids, although butter contains glycerides of lower acids, notably butyric acid. Includes tallow (suet), lard, bone fat, wool fat (suint), butter fat, oleomargarine, and manufactured stearin.

X. Whale-oil Group.—*Marine animal oils.* Offensive fishy odor, especially on warming. Reddish-brown color upon warming with caustic alkali. Dries more or less upon exposure and yields but little elaïdin. Includes whale, porpoise, seal, menhaden, cod-liver, and shark-liver oils.

XI. Sperm-oil Group.—*Liquid waxes.* Are not glycerides, but are esters of higher monatomic alcohols of the methane series. Yield solid elaïdins. Includes sperm oil, bottle-nose oil (dœgling oil), and dolphin oil.

XII. Spermaceti Group.—*Waxes proper.* Are esters (organic salts) of higher monatomic alcohols with higher fatty acids in free state. Includes spermaceti, beeswax, Chinese wax, and carnauba wax.

In the early days of Eclecticism a few plant preparations in which the natural oil of the drug was intimately associated with other proximate constituents, were introduced under the name oil, and as such are still employed. Among these may be named oil of stillingia, oil of capsicum, and oil of lobelia. These preparations are made by exhausting the thoroughly dried drug (stillingia root, capsicum, and lobelia seed) with official alcohol, and then distilling the alcohol until the residue is syrupy. This product in each case is a mixture that carries the therapeutical qualities of the drug in a marked degree of concentration, but consists largely of foreign substances. The "oil of stillingia" is prone to gelatinize, but the others keep fairly well. (Compare *Oleoresinæ.*)

Olea Volatilia.—Volatile Oils (*Essential oils*). Volatile oils (essential oils) are aromatic liquids of vegetable origin, practically insoluble, or but slightly soluble in water, and capable of being distilled with more or less facility in the vapors of boiling water, even though their own boiling points lie considerably higher. Like fatty oils, they render paper translucent, but the oily stain produced gradually disappears upon exposure. With one exception (*Oil of Aspidium*) essential oils have been obtained from phanerogamous plants only, in which, as a rule, they occur ready-formed. Some oils, *e. g.*, of bitter almond, black mustard, or sweet birch, originate in definite compounds contained in the plants (*amygdalin*, *sinigrin*, *gaultherin* respectively), and are evolved therefrom in the presence of water by the action of certain ferments or enzymes (*emulsin*, *myrosin*, *betulase*) that are likewise present.

All parts of a plant, leaves, flowers, fruits, stems, and roots may yield essential oils, although the oil is in most cases derived only from one or two of these organs. In a few cases, such as Chinese cinnamon (Cassia cinnamon), oil of uniform quality may be obtained in fair quantities from various parts of the plant, while reversedly, in Ceylon cinnamon (*Cinnamomum zeylanicum*) the oils yielded by the bark, the leaves, and the root differ materially in their chemical composition.

Some essential oils, *e. g.*, of bitter orange, oil of lemon, etc. (which see), are prepared by expressing the rind of the fruit containing the oil. Certain oils used in perfumery, which are sensitive to heat, *e. g.*, the odoriferous principles of hyacinth, jasmine, etc., are obtained by maceration, especially by abstracting the aroma by means of liquid fats or semisolid paraffins (*enfleurage*). Again, synthetic oils, such as artificial methyl salicylate, are obtained by laboratory processes which are briefly described under their respective headings. All other oils are obtained by distillation with the vapors of boiling water. Directions for the pharmaceutical preparation of essential oils were given by the older pharmacopœias, for example, the *Edinburgh* and the *Dublin Pharmacopœias* (see this *Dispensatory*, preceding editions).

The technical preparation of essential oils in the different countries producing them is carried out by distilling the oil from the oil-bearing material, mixed with water, by means of steam, which either runs into the material direct, or is applied to the vessel externally by means of a steam-jacket. In some cases (*e. g.*, eucalyptus oils) the oil-bearing material is deprived of its oil by direct steam without previous maceration. Rectification of the crude oils thus obtained is effected by fractional distillation either at atmospheric pressure, or, if decomposition is to be feared, at reduced pressure, whereby the boiling point is lowered.

The advances made within comparatively recent years in the theoretical study of essential oils has been the cause of a simultaneous development of this branch of chemical industry. By operating upon the basis of exact physical and chemical investigation, the manufacture of essential oils has been carried to a degree of refinement well illustrated by the classical work now before us, *Die Ætherischen Oele*, by E. Gildemeister and Frederick Hoffmann, published within recent months by Messrs. Schimmel & Co., of Leipzig. We are greatly indebted to this invaluable work, which we freely consulted in the preparation of this paper, but which, in its complete form, should be in the hands of every pharmacist.

Most essential oils are colorless or yellowish, although some are greenish or bluish-green, while others, like oil of thyme, soon acquire a dark red-brown color. Some oils deposit a crystalline body upon standing, often called a *stearopten* or *camphor;* the fluid portion being termed an *elæopten*. Such deposits are formed, for example, in the oils of neroli, chamomile, matico leaves (Flückiger's *matico camphor*), elecampane (*alant camphor*), etc. Other oils produce crystalline deposits at low temperatures, *e. g.*, anise oil deposits *anethol*, American peppermint oil *menthol;* Japanese peppermint oil is a semisolid mixture of menthol and liquid oil.

The specific gravities of essential oils vary more than those of fatty oils. While all of the latter class are lighter than water, a number of essential oils, such as those of bitter almond, cassia, cinnamon, cloves, sassafras, mustard, and wintergreen, are heavier than water. The specific gravities vary from 0.800 for oil of heracleum and 0.833 for oil of rue, to 1.187 for oil of wintergreen. All essential oils are soluble in absolute alcohol, ether, chloroform, benzene, benzol, carbon disulphide, etc.; most of them also form clear solutions with weaker alcohol, of even as low strength as 70 per cent by volume. This property assists us in recognizing many adulterations, *e. g.*, mineral oils and most fatty oils. An important agency in the identification of an essential oil consists in its behavior toward a ray of polarized light, which is determined by means of *polarimeters* (*polariscopes*). (See article on "The Polarimeter and Its Use in Pharmacy," by Dr. Charles Symes, in *Amer. Jour. Pharm.*, 1880, p. 44, where there is also appended a list of specific gravities and optical rotations for a number of essential oils.)

Most essential oils readily undergo a change in color, consistency, and composition if exposed to air and light, and gradually change in odor; hence the necessity of keeping them in well-stoppered bottles, preferably of amber color, protected from air and light. The constituents of essential oils are of a far greater variety than those of fatty oils, and may be conveniently classed as follows (adapted from the work above quoted):

I. HYDROCARBONS.—*Paraffins* (C_nH_{2n+2}), and *olefines* (unsaturated paraffins C_nH_{2n-4}) are sometimes found in essential oils, such as arnica flowers, matricaria (*matricaria-camphor*), oil of bay (*myrcen*, $C_{10}H_{16}$), etc. Other hydrocarbons of occasional occurrence are *para cymol* ($C_{10}H_{14}$) in oil of thyme, etc., and *styrol* ($C_6H_5.CH:CH_2$) in oil of storax. By far the most important essential oil hydrocarbons are those known as the TERPENES. They are isomers of the formula $C_{10}H_{16}$, unsaturated, boiling between 150° and 180° C. (302° and 356° F.). They are optically dextro- or lævo-rotatory, or inactive, and comprise the following: (1) *Pinene;* (2) *camphene*, solid, melting at 50° C. (122° F.); (3) *fenchene;* (4) *limonene;* (5) [illegible]; (6) *sylvestrene;* (7) *terpinene;* (8) *phellandrene.*

SESQUITERPENES are hydrocarbons of the formula $C_{15}H_{24}$; they boil between 250° and 280° C. (482° and 536° F.); their specific gravity is above 0.90; they comprise: (1) *cadinene;* (2) *caryophyllene;* (3) *humulene;* (4) *cedrene*, etc.

POLYTERPENES.—Diterpenes and triterpenes, boiling above 300° C. (572° F.). They have been little investigated.

The following classes comprise substances which constitute the characteristic odoriferous principles of the oils in which they occur:

II. ALCOHOLS.—(1) *hexyl-* ($C_6H_{13}OH$) and *octyl-alcohol* ($C_8H_{17}OH$) in heracleum oils; (2) *linalool* (*coriandrol*) ($C_{10}H_{18}O$) in oils of bergamot, coriander, etc.; (3) *geraniol* (*rhodinol*, $C_{10}H_{18}O$) in oils of rose and lemon grass; (4) *citronellol* ($C_{10}H_{20}O$), in oils of geranium and rose; (5) *terpineol* ($C_{10}H_{18}O$), in oils of cajeput and camphor; (6) *borneol* ($C_{10}H_{18}O$) in Borneo camphor; (7) *menthol* ($C_{10}H_{20}O$).

III. ALDEHYDES.—(1) *Citral* (*Geranial*) ($C_{10}H_{16}O$), the aldehyde of geraniol; in lemon-grass oil; (2) *Citronellal* ($C_{10}H_{18}O$), in citronella oil; (3) *furfurol* (C_4H_4O), in oil of cloves; (4) *benzaldehyde* ($C_6H_5.CHO$), in oils of bitter almond and cherry laurel; (5) *salicylic aldehyde* ($C_6H_4OH.CHO$), in spiræa oil; (6) *anis-aldehyde* ($C_6H_4.OCH_3.CHO$), in old anise oil; (7) *cumin aldehyde* ($C_6H_4.C_3H_7.CHO$), in oil of Roman chamomile; (8) *vanillin* ($C_6H_3.OH.OCH_3.CHO$), (9) *heliotropin*, in spiræa oil; (10) *cinnamic aldehyde* ($C_6H_5CH:CH.CHO$), in cassia and cinnamon oils; (11) *ortho-cumar-aldehyde methyl-ether* ($C_6H_4.OCH_3.CH:CH.CHO$), in oil of cassia.

IV. KETONES.—(1) *Methyl-amyl-ketone* ($CH_3.CO.C_5H_{11}$), in oil of cloves; (2) *methyl-heptenone* ($C_8H_{14}O$), allied to linalool; (3) *carvone* ($C_{10}H_{14}O$), in oil of caraway; (4) *anis-ketone* ($C_6H_4.OCH_3.CH_2.CO.CH_3$); (5) *Japan camphor* ($C_{10}H_{16}O$) (see *Camphora*); (6) *fenchone* ($C_{10}H_{16}O$), liquid, in oil of fennel; (7) *thujone* (*tanacetone*) ($C_{10}H_{16}O$), in oil of thuja; (8) *pulegone* ($C_{10}H_{16}O$), in oil of pennyroyal; (9) *menthone* ($C_{10}H_{18}O$), in oil of peppermint; (10) *irone* ($C_{13}H_{20}O$), in oil of orris root.

V. ACIDS.—*Acetic, propionic, butyric, valerianic, tiglinic acids*, seldom free, mostly as esters, combined with higher alcohols. Furthermore, *benzoic, salicylic*, and *cinnamic acids*. LACTONES.—*coumarin* and *hydrocoumarin*, *alanto-lactone* (*helenin*) in oil of elecampane; OXIDES.—*Cineol* (*eucalyptol* $C_{10}H_{18}O$), occuring in many oils, especially from *Artemisia cina*, cajeput and eucalyptus.

VI. PHENOLS and PHENOL-ETHERS.—(1) *Vanillin*; (2) *anethol*; (3) *para-cresol methyl-ether* ($C_6H_4.CH_3.OCH_3$), in ylang-ylang oil; (4) *carvacrol* (*iso-propyl ortho-cresol*), in oil of *Monarda fistulosa*, etc.; (5) *thymol* (*iso-propyl meta-cresol*), in oil of thyme, etc.; (6) *chavicol* (*para-allyl-phenol*), in Java betel-leaf oil, and oil of bay; (7) *methyl-chavicol*, in anise oil; (8) *eugenol* (*allyl-guaiacol*) ($C_6H_3.C_3H_5.OCH_3OH$), in oil of cloves; (9) *safrol* ($C_{10}H_{10}O_2$), in sassafras and camphor oils; (10) *asarone* ($C_{12}H_{16}O_3$), in oil of *Asarum europæum*; (11) *apiol* ($C_{12}H_{14}O_4$), from oil of parsley.

VII. MUSTARD OILS.—Contain sulphur compounds.

The more important of these constituents will be briefly described under the oils wherein they chiefly occur. Since the chemical nature of essential oils is in many cases well-defined, it often permits of a more or less exact quantitative determination of their characteristic constituents. Thus, *esters, e. g.*, linaloyl acetate in oil of bergamot, may be determined by their saponification value (compare *Fatty Oils;* also see *Cera*); certain *aldehydes, e. g.*, cinnamic aldehyde in oil of cassia, by means of the crystalline compounds they form with sodium bisulphite; *phenols, e. g.*, eugenol in Ceylon cinnamon oil, by the loss of volume which the oil incurs by being shaken with solution of caustic potash. An interesting analytical method, applicable to oils containing an *alkyl-oxy-group* (*e. g., methoxy*, OCH_3) as anethol in anise oil (which see), consists in determining the *methyl-number, i. e.*, the number of milligrammes of methyl that is split off when 1 gramme of oil is boiled with hydriodic acid (measured by the amount of silver iodide that is precipitated when the vapors of the methyl iodide formed are conducted into an alcoholic solution of silver nitrate). Since alcohol also gives a methyl-number when subjected to this reaction, the latter may serve as a good test for alcohol in such oils as do not contain a methoxy-group, and consequently do not yield a methyl number, as bitter almond, bergamot, caraway, lemon, cubeb, eucalyptus, lavender, peppermint oils, etc.

Owing to their high price, essential oils are frequently subject to adulteration. If a few drops of the oil in question be placed on filtering paper, the odor will sometimes indicate impurities. An addition of *alcohol* reduces the specific gravity of the oil. Larger quantities may be recognized by shaking out with water, distilling the aqueous liquid and testing the distillate for alcohol by the iodoform test, viz., by warming with sodium carbonate and iodine, whereby iodoform is precipitated. Or, shaking the oil with dry chloride of calcium (Borsarelli), or acetate of potassium (J. J. Bernoulli), will separate the alcohol from the essential oil. *Oil of turpentine* is the adulterant most frequently used. It may often be recognized by its odor. Its presence affects the specific gravity and the solubility of the oil in 70 per cent alcohol. Its chief constituent being *pinene*, the presence of this body in oils not naturally containing it, proves the presence of turpentine. Addition of *fatty oils* to essential oils may be recognized by a permanent greasy stain they leave on paper, upon prolonged exposure. Their presence may also be detected by distilling the essential oil with the vapors of boiling water, and heating a portion of the residue on platinum foil, or in a dry test-tube with acid potassium sulphate, whereby the irritant vapors of acrolein are evolved. Treatment with 70 per cent alcohol, in which all fatty oils, including castor oil, are insoluble, will also reveal their presence in many oils. *Mineral oils* (petroleum) are easily separated and recognized by reason of their insolubility in alcohol, their low specific gravity, and their inability to saponify with alkalies.

Some essential oils as stated above, contain small quantities of paraffins as regular constituents. *Oils of cedar*, *copaiba*, and *gurjun balsam*, are also used as adulterants of essential oils, and are detected with difficulty. They dissolve with difficulty in alcohol of 70 to 90 per cent, are strongly lævo-rotatory, and boil at temperatures above 250° C. (482° F.).

OLEA INFUSA (N. F.)—INFUSED OILS.

Preparation.—"The dry herb, in moderately coarse (No. 40) powder, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; alcohol, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; water of ammonia (*U. S. P.*), four grammes (4 Gm.) [62 grs.]; lard oil, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; cotton seed oil, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]. Moisten the powdered herb with a sufficient quantity of the alcohol and water of ammonia previously mixed, then pack it tightly into a stone or enamelled iron vessel of suitable capacity, pour on the remainder of the ammoniated alcohol, cover it well, and allow the mixture to macerate for 24 hours. Then add one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.] of the mixed oils, digest, under frequent agitation, during 12 hours, at a temperature between 50° and 60° C. (122° and 140° F.), transfer the mixture to a strainer, and express strongly. To the residue, returned to the vessel, add the remainder of the oils, digest and express in the same manner, and unite the expressed portions. *Note.*—This process is a modification of that prescribed by the *German Pharmacopœia*. The alcohol and free ammonia are dissipated during the digestion. Infused oils are usually prepared only from so-called narcotic plants, but it is known that only a portion of their active constituents is taken up by the oil. The above process is to be used for the preparation of *Oleum Hyoscyami* of the *German Pharmacopœia*, and similar infused oils"—(*Nat. Form.*).

The uses of the infused oils will be those of the ingredients which enter into their composition.

OLEANDER.—OLEANDER.

The leaves of *Nerium Oleander*, Linné.

Nat. Ord.—Apocynaceæ.

COMMON NAMES: *Oleander*, *Laurier rose.*

Botanical Source.—The oleander bush is an arborescent shrub, having branches ternately divided, and coated with an almost smooth bark of a grayish or greenish-gray color. The smooth, coriaceous, deep-green, almost sessile leaves, are in whorls of three; above, they are glossy; beneath, grayish or pale-green. They are linear-lanceolate, acuminate, entire, marked with delicate, feather veins, and about 4 to 6 inches long. The flowers are beautiful, and of a rose or white color, and waxy appearance.

Fig. 180.

Nerium Oleander.

History and Chemical Composition.—The leaves of this ornamental shrub, grow wild in northern Africa, western Asia, and the south of Europe. They have been used in the treatment of epilepsy, but without apparent benefit. All parts of the shrub are cardiac poisons. The acrid and bitter leaves of Nerium Oleander contain, according to Schmiedeberg (1882), three glucosids, namely: non-basic, amorphous, poisonous *oleandrin*, discovered by Leukowsky (1864), who believed it to be an alkaloid; *nerein* (*neriin*), considered by Schmiedeberg to be identical with *digitalein* (see *Digitalis*), and crystallizable *nerianthin*, free from nitrogen. (For details regarding the study of Oleander, see Husemann and Hilger, *Pflanzenstoffe*, 1884, p. 1331.)

From the bark of Nerium Oleander, E. Pieszczek (*Archiv der Pharm.*, 1890, p. 352) isolated a new, poisonous, nitrogen-free glucosid, *rosaginin*, in the form of warty crystals, melting at 171° C. (339.8° F.), soluble in strong alcohol with neutral reaction, nearly insoluble in water, petroleum ether, chloroform and ether if free from alcohol. In addition were obtained, bitter, amorphous *neriin*, of

Schmiedeberg, nitrogen-free, lemon-yellow, soluble in water and absolute alcohol with neutral reaction, insoluble in ether and petroleum ether, and producing a purple-violet coloration when dissolved in concentrated sulphuric acid and brought into contact with bromine vapor; a *volatile oil* of an unpleasant odor, and a crystallizable, fluorescent body occurring more pronouncedly in older bark, probably identical with *umbelliferon*. The oleander of Algeria, upon incision of the twigs, yields a poisonous exudate which is said to contain *strophanthin* (*Amer. Jour. Pharm.*, 1899, p. 281). The flowers of the oleander are reputed to yield a poisonous honey. The exhalation of the flowers of oleander in bedrooms is said to have caused death (see Pieszczek, *loc. cit.*).

Action, Medical Uses, and Dosage.—According to Orfila, Kurzak, and others, all parts of the oleander plant are poisonous. From experiments upon birds and the lower animals, it was determined that both the voluntary and involuntary muscles were paralyzed by it, and the voluntary muscles were somewhat convulsed. When death ensues, respiration is first arrested and then the heart's action stops. The action of the active constituents has been compared to that of digitalis. Water in which oleander leaves have lain, is said to have caused the death of animals, and the flesh of fowls has been rendered sufficiently toxic to be fatal to man. Rats are said to be poisoned by the bark, and *pediculi* destroyed by a decoction of the leaves. In fatal cases, the heart has been found flaccid, and the larger venous trunks filled with a dark-colored blood. The chief therapeutic use that has been made of oleander, is in *epilepsy*, and it has been abandoned in that malady as useless. From its decidedly toxic power over the heart, it seems worthy of an investigation as a cardiac remedy. In fact it has been found to act well in *valvular affections*, rapidly slowing the heart's action, reducing the œdema, and relieving the dyspnœa. Some have preferred it to digitalis in *atheromatous states*. It is actively diuretic, and occasionally purges. The dose, in infusion or tincture, represents from 1 to 3 grains of fresh bark or dried fruit.

Related Species.—*Nerium odorum*, Aiton (*Nerium odoratum*, Lamarck). India. Wild and cultivated. Closely resembles the preceding plant, but its flowers are fragrant, its leaves longer, and has a paracorolla which is fringed. Greenish, in 1881, isolated two toxic, bitter glucosids, and a fixed oil. *Nerodorin* is a yellow, tenacious, transparent varnish, soluble in chloroform, somewhat less in alcohol, and little soluble in water. According to Schmiedeberg, it is analogous to oleandrin, while *neriodoriin* is a lemon-yellow powder, insoluble in chloroform, but soluble in water and alcohol, and resembling neriin. Neither are dissolved by carbon disulphide, benzin or benzol.

Geissospermum læve, Baillon.—A Brazilian tree known in its habitat as *pao pereira*. The bark is very bitter, and contains three alkaloids. *Geissospermine* ($C_{19}H_{24}N_2O_2 + H_2O$, O. Hesse, 1877), crystallizable, melting at 160° C. (320° F.), is insoluble in water and ether, not easily soluble in cold, but readily soluble in warm alcohol; soluble in concentrated sulphuric acid to a colorless liquid which soon turns blue; it is poisonous, and causes death by paralysis. *Pereirine* ($C_{19}H_{24}N_2O$, O. Hesse), an amorphous alkaloid, soluble in alcohol, ether, chloroform, nearly insoluble in water. Nitric acid dissolves it with blood-red color which does not turn violet with stannous chloride (difference from *brucine*, see *Nux Vomica*). Large doses cause paralysis, fever, and death. *Villosine* ($C_{23}H_{26}N_2O_4$, M. Freund and Fauvet, *Jahresb. der Pharm.*, 1893, p. 513, and 1895, p. 449) is a well-crystallizable alkaloid, insoluble in water, soluble in chloroform, alcohol, warm benzol and petroleum benzin, partly soluble in ether. According to analysis by T. Peckolt (*ibid.*, 1896, p. 40), the air-dried bark contains *pereirine*, 2.72 per cent; *geissospermine*, 0.125 per cent; wax, starch, resin, etc. The leaves, but not the bark, contained tannic acid. The bark is an antiperiodic also.

Parameria vulneraria, Radlkofer.—Philippine Islands. A climbing plant, the bark and leaves of which, when boiled in cocoanut oil, yield a peculiarly odorous, yellow substance known as *Cebu balsam* (*Balsamo de Tagulaway*). An aromatic resin, 3 per cent, and caoutchouc, 8.5 per cent, are yielded by the bark of the root (Zipperer, *Archiv der Pharm.*, 1885, p. 81). The oily, yellow-white liquid is applied to *wounds* and *cutaneous affections*.

Thevetia yccotli, De Candolle (*Cerbera thevetioides*, Kunth). The tree known in the Mexican Cordilleras as the *joyote*. It inhabits the damp, hot sections of the mountains. The fruit is applied to *hemorrhoids*. The seeds, which are known as joyote seeds are very acrid and poisonous. A. Herrera (*Amer. Jour. Pharm.*, 1877, p. 145) obtained, by pressure, 40 per cent, of a fixed oil, and a crystallizable, acrid glucosid which he called *thevetosin*. Merck (1894) isolated another glucosid which he named *cerberid*. It is a cardiac poison.

Thevetia neriifolia, De Candolle (*Cerbera Thevetia*, Linné). West Indies. Bark of this shrub used as an antiperiodic. It yields the crystallizable glucosid *thevetin*, discovered by De Vrij. By treatment with diluted acids, it splits into sugar and a resinoid body, *the* [illegible]. *Thevetin* ($C_{54}H_{84}O_{24}$) is bitter, odorless, soluble to some extent in cold water, more soluble in alcohol and acetic acid. *Thereresin* ($C_{48}H_{70}O_{17}$) is a white powder, and is but slightly dissolved by hot water. Both principles are toxic. Thevetin is a cardiac, and to some extent a respiratory paralyzer. Its effects are practically identical with those of digitalin. Its identity with *cerberin* and *tanghine* has been questioned. The latter is the active constituent of the "Madagascar ordeal bean," from the *Tanghinia venenifera*; the former, the active constituent of *Cerbera odallum*. Gaertner. *Thevetia ovata*, De Candolle, and *Thevetia cuneifolia*, De Candolle, have properties similar to *yccotli*, and are known as *narcisos amarillos* and also as *joyote*. This bark is a drastic cathartic, and the fruit causes emesis.

OLEATA.—OLEATES.

M. L'hermite (1854) proposed solutions of alkaloids in *oleic acid* as substitutes for the oleaginous and glycerinic solutions of these bases. He objected to the oils from their incapability of dissolving the alkaloids, and to the glycerin from its not possessing unctuous properties. His suggestions passed largely unnoticed until the matter was revived, in 1872, by Prof. John Marshall. Oleic acid triturated with the alkaloids dissolves these and their salts perfectly, and the solutions, if desired, may be perfumed. When either alkaloids or metallic oxides are treated with oleic acid, a salt known as an *oleate*, is produced. The *oleates*, as employed medicinally, are solutions of these normal salts (true oleates) in an excess of oleic acid. Heat should be avoided where possible, though in many instances a moderate degree of heat is permissible.

Oleates, especially of the metallic oxides, are also prepared by double decomposition between a salt of the base selected and a sodium or potassium oleate or castile soap (sodium oleo-palmitate), with the last-named soap yielding an impure oleate. Prof. J. M. Good (*Proc. Mo. Pharm. Assoc.*, 1891) suggests dissolving the alkaloids in just sufficient oleic acid to effect solution, and then diluting with almond oil or other bland oil.

The oleates possess the properties of their bases, and are employed like the ointments of the same bodies, being, however, more cleanly and finer in appearance, and, on the other hand, more irritating, unless diluted with some bland oil. They should not be applied with friction, but should be gently applied with the finger or brush. (For a short treatise on the oleates, see G. M. Beringer, *Amer. Jour Pharm.*, 1889, pp. 593–600; also see John V. Shoemaker, *The Oleates*, Phila., 1885.)

OLEATUM VERATRINÆ (U. S. P.)—OLEATE OF VERATRINE.

Preparation.—"Veratrine, two grammes (2 Gm.) [31 grs.]; oleic acid, ninety-eight grammes (98 Gm.) [3 ozs. av., 200 grs.]. To make one hundred grammes (100 Gm.) [3 ozs., 231 grs.]. Rub the veratrine with a small quantity of oleic acid, in a warm mortar, to a smooth paste. Then add the remainder of the oleic acid, previously warmed, and stir frequently until the veratrine is dissolved"—(*U.S.P.*).

This preparation contains 2 per cent of veratrine. The other alkaloidal oleates may be made after this formula, when a 2 per cent strength is desired; should a 5 per cent preparation be wanted, as is usually the case with cocaine and morphine, use 5 parts of the alkaloid and 95 parts of oleic acid. Quinine oleate is usually 25 per cent in strength; for making this use 25 parts of the alkaloid and 75 parts of oleic acid.

Action and Medical Uses.—This oleate is just half the strength of *veratrine ointment*. It is employed in localized *neuralgia*, and well adapted for inunction purposes. Where it is desired that the alkaloid shall not be absorbed the ointment is preferable.

Other Oleates.—Oleatum Aconitinæ (N. F.), *Oleate of aconitine*. "Aconitine, alkaloid, two grammes (2 Gm.) [31 grs.]; oleic acid, ninety-eight grammes (98 Gm.) [3 ozs. av., 200 grs.]. Triturate the aconitine with a small portion of the oleic acid in a mortar, then incorporate the remainder of the oleic acid, and stir the mixture frequently until the alkaloid is dissolved. *Note.*—The market affords a variety of aconitines made by different processes, by different manufacturers, and of greatly different potency. Only the pure crystallized or crystallizable alkaloid, prepared by Duquesnel's method, or at least one equal to it in strength, should be used for this preparation"—(*Nat. Form.*). This agent, in very small amounts, is employed as a topical application for *local neuralgias* (see article by E. R. Squibb, in *Amer. Jour. Pharm.*, 1882, p. 572). This preparation is a dangerous remedy, and is seldom employed by Eclectic physicians.

Oleatum Bismuthi, *Oleate of bismuth*.—Rub to a fine powder, 480 grains (1 troy ounce) of bismuth oxide, dried at 100° C. (212° F.) until it no longer loses weight, and mix thoroughly with 175 grains of purified oleic acid. Add water, 2 parts, and boil until complete saponification takes place, adding water to replace that lost by evaporation. When the process has so far proceeded that a portion of the oleate, when dropped into water, assumes an ointment-like consistence, without separating any free oleic acid, the operation may be considered finished. This method was proposed by G. M. Beringer (*Amer. Jour. Pharm.*, 1889, p. 599). The uses of the oleate are those of bismuth oxide.

Oleatum Hydrargyri (*U. S. P.*), *Oleate of mercury, Mercuric oleate.*—"Yellow mercuric oxide, thoroughly dried, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; oleic acid, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.], to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Introduce the oleic acid into a capacious mortar, and gradually add to it the yellow mercuric oxide by sifting it upon the surface of the acid, and incorporate it by continuous stirring. Then set the mixture aside in a warm place, at a temperature not exceeding 40° C. (104° F.), and stir frequently, until the oxide is dissolved"—(*U. S. P.*). Contact with metals must be avoided in its preparation. The above oleate is of a yellow color, and firm, butyraceous consistence. It contains 20 per cent of the yellow oxide, and is rather an unstable compound. It is employed like mercurial ointment. The *British Pharmacopœia* (1898) prepares it by the interaction of mercuric chloride with oleic acid and hard soap.

Oleatum Plumbi (N. F.), *Lead oleate.*—"Lead acetate, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; solution of sodium oleate (N. F. 246), two thousand cubic centimeters (2000 Cc.) [67 fl℥, 301 ♏]; acetic acid (*U. S. P.*), water, each, a sufficient quantity. Dissolve the lead acetate in four thousand cubic centimeters (4000 Cc.) [135 fl℥, 122 ♏] of water. Should the solution be turbid or opalescent, add to it acetic acid, in drops, until it has become clear. Then filter, if necessary, through a pellet of absorbent cotton placed in the neck of a funnel, and mix it slowly, and under constant stirring, with the solution of sodium oleate. Heat the mixture to boiling, transfer it to a strainer, and when the liquid has drained off, wash the residue with four thousand cubic centimenters (4000 Cc.) [135 fl℥, 122 ♏] of boiling water. Lastly, take the mass from the strainer, remove any occluded water by pressure, and transfer it, while warm and soft, to suitable vessels. This product contains an amount of lead corresponding to about 28 per cent of lead oxide. *Note.*—The theoretical yield of lead oleate obtainable from 75 grammes of lead acetate is 143 grammes; in practice, about 125 grammes will be obtained. Lead oleate prepared by the above process is of about the consistence of lead plaster, and may be converted into an ointment by mixing with it such a proportion of oleic acid as may be required"—(*Nat. Form.*). Its uses are practically those of lead acetate, locally applied.

Oleatum Quininæ (N. F.), *Oleate of quinine.*—"Quinine (*U. S. P.*), dried at 100° C. (212° F.), until it ceases to lose weight, twenty-five grammes (25 Gm.) [386 grs.]; oleic acid, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]. Triturate the quinine with the oleic acid, gradually added, then apply a gentle heat, and stir frequently, until the quinine is dissolved. The product contains 25 per cent of dry quinine. *Note.*—When the official quinine ($C_{20}H_{24}N_2O_2.3H_2O$) is not available, the quantity corresponding to 25 grammes of dry quinine may be prepared as follows: Take 34 grammes of official quinine sulphate, dissolve it in 200 grammes of water with the aid of a sufficient quantity of diluted sulphuric acid, then precipitate the quinine by means of water of ammonia, added, under constant stirring, until it is in slight excess. Transfer the magma to a close muslin strainer, previously wetted, allow the liquid to drain off, and wash the precipitate with ice-cold water, until the washings are practically tasteless, but using not more than about 200 grammes of water. Lastly, dry the precipitate. The theoretical quantity of dry quinine obtainable from 34 grammes of the sulphate is 25.27 grammes. In practice, approximately 25 grammes will be obtained"—(*Nat. Form.*). Its uses are those of quinine by inunction.

OLEATUM ZINCI (U. S. P.)—OLEATE OF ZINC.

Preparation.—"Zinc oxide, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; oleic acid, nine hundred and fifty grammes (950 Gm.) [2 lbs. av., 1 oz., 223 grs.]. To make one thousand grammes (1000 Gm.) [2 lbs., 3 ozs., 120 grs.]. Introduce the oleic acid into a capacious capsule, and gradually add to it the zinc oxide by sifting it upon the surface of the acid, and incorporate it by continuous stirring. Set the mixture aside for a few hours, and then heat it on a water-bath, frequently stirring, until the oxide is dissolved"—(*U. S. P.*).

This oleate is of soft, ointment consistence, and contains 5 per cent of zinc oxide. That of the *British Pharmacopœia* (1885) contains 10 per cent of oxide of zinc, and is a much firmer preparation. Uses, those of zinc oxide, locally applied.

Oleatum Zinci (N. F.), *Zinc oleate.*—"Zinc acetate, crystallized, one hundred and fifteen grammes (115 Gm.) [4 ozs. av., 25 grs.]; solution of sodium oleate, five thousand cubic centimeters (5000 Cc.) [169 fl℥, 33 ♏]; water, a sufficient quantity. Dissolve the zinc acetate in ten thousand cubic centimeters (10,000 Cc.) [338 fl℥, 66 ♏] of cold water, filter the solution, if necessary, through a pellet of absorbent cotton placed in the neck of a funnel, and then mix it slowly, and under constant stirring, with the solution of sodium oleate. Transfer the mixture to a wetted muslin strainer, and when the liquid has drained off, wash the precipitate with water, until the washings are practically tasteless. Lastly dry the precipitate, spread on paper, by exposure to dust-free air, without heat. The product contains an amount of zinc corresponding to about 13 per cent of zinc oxide. *Note.*—The theoretical yield of zinc oleate obtainable from 115 grammes of zinc acetate is 287.5 grammes; in practice, about 265 grammes will be obtained. Zinc oleate, prepared by the above process is in the form of a soft, white powder, and may be converted into a plaster or ointment by mixing it with such a proportion of oleic acid as may be required"—(*Nat. Form.*).

Powdered Zinc Oleate.—Dissolve castile soap, 1 ounce, in water, 2 pints; also dissolve zinc acetate, 360 grains, in water, 4 pints. Both solutions being cold, add the soap solution slowly to the zinc solution, with constant stirring. The precipitate should now be collected, washed well with cold water, and dried without heat. This is the method of Parsons.

OLEORESINÆ.—OLEORESINS.

Oleoresins are those substances obtained from vegetable medicines by means of ether (sometimes alcohol, etc.), which consist principally of a fixed or volatile oil and a resin. In some cases the resin will be held in solution in the oil, while in others it will be deposited upon standing, and will require agitation to again diffuse and suspend it in the oil. A third case occurs in which the oil and resin form a more or less permanent mixture, having the consistence of a very soft extract. The resins in these preparations, like the essential oils, are generally mixtures of two or more resins, but which on account of their unequal solubility in different menstrua, may frequently be isolated from each other. Often the resins are formed by the oxidation of the essential oils contained in the plants, or of a certain portion of these oils. In many instances, especially with the oleoresins obtained from alcoholic tinctures, it will be better not to distill off the remaining third of the alcohol from the water, until the oleoresin has spontaneously precipitated and been separated from the liquid, because an elevated or too prolonged heat will injure the preparation. All these oleoresins should be kept in well-stopped vessels.

Mr. N. H. Rittenhouse, in the process for obtaining oleoresins, recommends the use of 1½ ounces of ether for each ounce of drug treated, followed by sufficient benzin to make the amount of percolate equal to the amount of ether employed, as both economical and satisfactory (*Proc. Amer. Pharm. Assoc.*, 1866, p. 208). The expense may be considerably reduced by recovering a part of the ether distilled for employment in future operations. The suggestion of Mr. George M. Beringer (*Amer. Jour. Pharm.*, 1892, p. 145), to use acetone in place of ether can not but be regarded favorably. It is equally as efficient, has a higher boiling point than ether, and is much less expensive.

OLEORESINA ASPIDII (U. S. P.)—OLEORESIN OF ASPIDIUM.

Synonyms: *Oleoresin of male fern*, *Liquid extract of male fern*, *Oleum filicis maris*, *Oleoresina filicis*, *Extractum filicis liquidum*, *Oleoresin of fern*, *Ethereal extract of fern.*

Preparation.—"Aspidium, recently reduced to No. 60 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; ether, a sufficient quantity. Put the aspidium into a cylindrical glass percolator, provided with a stop-cock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with ether, added in successive portions until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining ether to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle. *Note.*—Oleoresin of aspidium usually deposits on standing, a granular-crystalline substance. This should be thoroughly mixed with the liquid portion before use"—(*U. S. P.*).

Or, by percolation, exhaust coarsely powdered root of male fern, any quantity, with ether, a sufficient quantity. Distill off three-fourths of the ether, and, having placed the remainder of the solution in an evaporating dish, allow it to evaporate spontaneously.

Description.—A thick, deep-green or brownish-green liquid, having a bitterish, nauseous, subacrid taste, and the odor of male fern. On standing it deposits *filicic acid* in granules, hence the above pharmacopœial direction to shake the oleoresin before use. Only such parts of the rhizomes as are greenish in color should be employed in making this oleoresin; the rhizome with the stipes gives a brown product.

Action, Medical Uses, and Dosage.—This may be used in all cases where male fern is indicated, for which see *Aspidium*. Six grains in capsule, with or without a like quantity of ether, may be given every quarter hour until 1½ or 2 drachms have been taken.

OLEORESINA CAPSICI (U. S. P.)—OLEORESIN OF CAPSICUM.

SYNONYM: *Ethereal extract of capsicum.*

Preparation.—"Capsicum, in No. 60 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; ether, a sufficient quantity. Put the capsicum into a cylindrical glass percolator, provided with a stop-cock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining ether to evaporate spontaneously. Then pour off the liquid portion, transfer the remainder to a strainer, and, when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the oleoresin in a well-stoppered bottle"—(*U. S. P.*).

Or, exhaust finely powdered capsicum, any quantity, in a percolating apparatus, by ether, a sufficient quantity. Distill off three-fourths of the ether, and, having placed the remainder of the solution in an evaporating dish, allow it evaporate spontaneously.

Description.—This oleoresin consists of a thick oily liquid holding the active principle *capsaicin* (see *Capsicum*), and a fatty substance which gradually separates when the fluid is allowed to rest, and which may be separated by decantation or straining. The oleoresin forms a thick, dark-brownish fluid possessing in a high degree the acrid, burning taste of the capsicum, which is slightly soluble in water or vinegar, but very soluble in alcohol, ether, oil of turpentine, and the caustic alkalies, forming reddish-brown solutions. Benzin is an excellent solvent of capsicum, and may be employed in the above process instead of ether.

Action, Medical Uses, and Dosage.—As this oleoresin is a very powerful stimulant, it may be added to liniments, poultices, etc., whenever excessive stimulation or rubefaction is desired. It is entirely too active to employ as an internal remedy, except in very small doses, not exceeding 1 drop, which should be greatly diluted with syrup, glycerin, mucilage, or olive oil. Thus used it may prove useful in *delirium tremens*, and *torpid conditions of the stomach.*

OLEORESINA CUBEBÆ (U. S. P.)—OLEORESIN OF CUBEB.

Preparation.—"Take of cubeb, in No. 30 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; ether, a sufficient quantity. Put the cubeb into a cylindrical glass percolator, provided with a stop-cock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining ether to evaporate spontaneously. Keep the product in a well-stoppered bottle. *Note.*—Oleoresin of cubeb deposits after standing for some time, a waxy and crystalline matter, which should be rejected, only the liquid portion being used"—(*U. S. P.*).

Description.—This oleoresin is of a deep brownish-green, or bright green color, according to the amount of chlorophyll present in the cubebs. It contains active resins (*cubeb resin* and *cubebic acid;* see *Cubeba*) and volatile and fixed oils, its relative fluidity depending on the quantity of the oil present. *Cubebin* and waxy matter are also present, and will deposit on standing. These should be separated by decantation, as their presence adds nothing of special value to the preparation.

Action, Medical Uses, and Dosage.—(See *Cubeba.*) Dose, 1 to 30 minims, in capsule or on sugar.

OLEORESINA CYPRIPEDII.—OLEORESIN OF CYPRIPEDIUM.

Synonym: *Cypripedin.*

Preparation.—By percolation, exhaust coarsely powdered root of yellow ladies' slipper any quantity, with alcohol a sufficient quantity. Distill off about two-thirds of the alcohol, and add the residue to two or three times its volume of water; by distilling off the remaining alcohol, or by allowing the mixture to stand, the oleoresin precipitates. Collect it, wash it in clear water, allow it to subside, and then separate it from the water by decantation and filtration. The result is a dark substance of the consistence of a soft extract.

Action, Medical Uses, and Dosage.—This oleoresin may be used in all cases where cypripedium is indicated, in doses of from 1 to 5 grains, 2 or 3 times a day; it is best given in pill form with some inert or active (as may be desired) excipient. A dry *Cypripedin* has been presented to the profession, consisting of the oleoresin and a sufficient quantity of magnesia or other absorbent powder; in other instances, it has been simply a dried aqueous extract. Either of these dried preparations are nearly worthless.

OLEORESINA IRIDIS.—OLEORESIN OF IRIS.

Synonyms: *Oleoresin of blue flag, Iridin.*

Preparation.—By percolation, exhaust moderately fine powder of the root of blue flag any quantity, with alcohol a sufficient quantity. Distill off about two-thirds of the alcohol, and add the residue to two or three times its volume of water. By distilling off the remaining alcohol, or by allowing the mixture to stand, the oleoresin precipitates, collect it, wash it in clear water, allow it to subside, and then separate it from the water by decantation and filtration.

History.—I had the pleasure of calling the attention of the profession to this article in 1844, about the same time I introduced podophyllin (to remarks on which I refer the reader), and again in 1846. I have used it extensively and find it to be an invaluable medicine. It is soluble in alcohol, but insoluble in water (J. King). *Iridin*, or *Irisin*, in powder, is prepared by adding to the oleoresin about 10 per cent of magnesia or other absorbent; sometimes the extract of the root deprived of its oleoresin, has been dried, powdered, and sold under one of the above names.

Action, Medical Uses, and Dosage.—This oleoresin is cathartic, alterative, sialagogue, diuretic and anthelmintic. I have used it more or less extensively for several years in combination with the resin of podophyllum, and in the form of pill, for *dropsy*, *primary* and *secondary syphilis*, *chronic visceral affections*, *rheumatism*, *gonorrhœa*, and many *female affections*. It is not as nauseating, when given alone, as the resin of podophyllum, and requires rather larger doses. One grain, triturated with 10 grains of sugar, may be given in 3-grain doses, every hour or two, until a cathartic effect is produced. I have long used the following as a sialagogue in those cases of *glandular diseases* which seemed to resist the action of other means, viz.: equal parts of oleoresins of iris, podophyllum, and xanthoxylum, given in grain doses every hour or two until ptyalism was produced. By trituration with sugar or lactin, this combination becomes more active. Oleoresin of iris is not as prompt in its effects as resin of podophyllum, although it may be substituted for this in all instances; and its alterative influence, though slowly developed and without any immediate appreciable effect, is yet positive and certain. For several years I used it in preference to the resin of podophyllum, conjoined with resin of cimicifuga, in *uterine diseases*. The usual dose of oleoresin of iris ranges from $\frac{1}{2}$ grain to 5 grains. Physicians will occasionally meet with patients upon whom resin of podophyllum, even in small doses, exerts a powerful and long-continued influence, sometimes not readily obviated; in such cases, oleoresin of iris seems to me to be more especially indicated. The addition of capsicum or resin of caulophyllum to oleoresin of iris, mitigates any harshness of action it may produce. A combination of oleoresins of iris and xanthoxylum, with resin of podophyllum, or extract of corydalis, is a most powerful and certain remedy for *syphilis*, either primary or secondary, and will be found very useful in *scrofula*. Oleoresin of iris, 3 grains, extract of leptandra, 6 grains, and bitartrate of potassium, 20 grains, made into one powder, forms a hydragogue cathartic of much value in some forms of *dropsy*. Oleoresin of iris may be used in all cases where iris is indicated (J. King).

OLEORESINA LUPULINI (U. S. P.)—OLEORESIN OF LUPULIN.

SYNONYMS: *Oleoresina lupulinæ* (*U. S. P.*, 1870), *Extractum lupulini æthereum*, *Ethereal extract of lupulin.*

Preparation.—"Lupulin, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; ether, a sufficient quantity. Put the lupulin into a cylindrical glass percolator, provided with a stop-cock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug very lightly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining ether to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle"—(*U. S. P.*).

Description.—This forms a thick, dark red-brown oleoresin, of the consistence of a very soft extract, and possessing the taste and smell peculiar to lupulin. It is soluble in ether, alcohol, and water of ammonia.

Action, Medical Uses, and Dosage.—Similar to those of lupulin (see *Lupulinum*). The dose of this oleoresin is from 1 to 6 grains, 2, 3, or 4 times a day, given in pill form with some inert, or active if desired, excipient. It may also be rubbed up with syrup, glycerin, mucilage, etc., by the aid of a little ether or other solvent.

OLEORESINA PIPERIS (U. S. P.)—OLEORESIN OF PEPPER.

SYNONYMS: *Oleoresin of black pepper*, *Ethereal extract* (or *Oil*) *of black pepper.*

Preparation.—"Pepper, in No. 60 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; ether, a sufficient quantity. Put the pepper into a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and receptacle for volatile liquids. Press the drug firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, set this aside until the remaining ether has evaporated, and the deposition of crystals of piperin has ceased. Lastly, separate the oleoresin from the piperin by expression through a muslin strainer. Keep the oleoresin in a well-stoppered bottle"—(*U. S. P.*).

Description.—Oleoresin of pepper forms a dark, greenish, rather thick liquid, containing volatile and fixed oil, and the pepper-resin, and possessing all the active properties of the pepper. About one-sixteenth part of the oleoresin is thus obtained, mixed with *piperin*, which is removed by the expression. This is not so dark in color, and contains more of the volatile oil than *oil of black pepper*, once employed and for which this oleoresin is a substitute. Oil of black pepper is a dark, almost black-green body, and is obtained as a by-product in the preparation of piperin.

Action, Medical Uses, and Dosage.—Oleoresin of black pepper may be used in cases where the fruit itself is indicated, in doses of from 1 to 3 or 4 drops, rubbed up with mucilage, glycerin, syrup, or with pill mass.

OLEORESINA PTELEÆ.—OLEORESIN OF PTELEA.

SYNONYMS: *Oleoresin of wafer ash*, *Ptelein.*

Preparation.—By percolation exhaust moderately fine powder of the bark of wafer ash, any quantity, with alcohol, a sufficient quantity. Distill off two-thirds of the alcohol, and add the residue to two or three times its volume of water. By distilling off the remaining alcohol, or by allowing the mixture to stand, the oleoresin precipitates. Collect it, wash it in clear water, allow it to subside, and then separate it from the water by decantation and filtration.

History and Description.—The oleoresin of ptelea, improperly named *ptelein*, was, I believe, first prepared by Mr. Wm. S. Merrell, and is obtained from the tincture of the bark by precipitation with water, in the same manner by which the oleoresins of Eupatorium purpureum, iris, xanthoxylum, etc., are obtained. It is of the consistence of thick syrup or molasses, dark-brown in mass, much lighter when in thin layers, and has a peculiar odor, somewhat similar to that ot the extract of liquorice, and an oily, bitterish, acrid, persistent taste, peculiar and rather disagreeable, and acting powerfully on the fauces. It is soluble in alcohol, ether, oil of turpentine, and rather imperfectly in alkaline solutions; insoluble in acids and water. It imparts a slight milky color to water, and separates into two portions, one of which floats on the water while the other sinks. Acetic acid added to its alcoholic or ethereal solution does not disturb them, unless added in excess. Water added to the alcoholic solution produces a milky color, precipitating the resin; added to the ethereal solution it separates the oil which floats on the surface. The same remarks apply to "*ptelein*" in powder, as are given concerning "*irisin*" in powder (J. King).

Action, Medical Uses, and Dosage.—Oleoresin of ptelea is a tonic, and possesses other properties, not yet satisfactorily understood. It is a valuable medicinal agent. I have used it extensively and successfully, combined with equal parts of oleoresin of xanthoxylum, and given in doses of 1 or 2 grains, repeated 3 times a day, in cases of *dyspepsia;* if *constipation* be present, I have found the following an admirable combination: Take of oleoresin of ptelea, 19 grains; alcoholic extract of nux vomica, 1 grain; white sugar, or lactin, 2 drachms. Mix thoroughly together. The dose is 6 grains, to be repeated 3 or 4 times a day. I have found the following a valuable pill in *chronic erysipelas*, *hepatic torpor*, *enlarged spleen*, *habitual constipation*, *chronic dysentery*, and some forms of *dyspepsia:* Take of resin of podophyllum and extract of leptandra, each, 1 grain; sulphate of quinine, 4 grains; oleoresin of ptelea, 8 grains; mix these together, and divide into 8 pills. The dose is 1 pill, to be repeated 2 or 3 times a day, and the alkaline bath to be used daily (J. King).

OLEORESINA SENECII.—OLEORESIN OF SENECIO.

SYNONYMS: *Oleoresin of life root*, *Senecin*.

Preparation.—By percolation, exhaust moderately fine powder of the root and herb of life root, any quantity, with alcohol, a sufficient quantity. Distill off about two-thirds of the alcohol, and add the residue to two or three times its volume of water. By distilling off the remaining alcohol, or by allowing the mixture to stand, the oleoresin precipitates. Collect it, wash it in clear water, allow it to subside, and then separate it from the water by decantation and filtration. Any other of the Senecios referred to in this work may be used in the preparation of this oleoresin.

Description.—Oleoresin of senecio thus prepared, is of thick consistence, a very dark green color, appearing quite black in mass, having a peculiar, herbaceous odor, and a bitter, slightly pungent, persistent, and rather unpleasant taste. A portion of it, probably the oil, is soluble in alcohol, imparting a green color to the solution; on the addition of liquor potassæ to the alcoholic solution, the oleoresin is rendered wholly soluble, and if hydrochloric acid be added in small quantity, it changes the green solution to greenish-white, without precipitation. It is entirely soluble in ether, forming a greenish solution, which is not precipitated by water nor acetic acid. It is insoluble in water, but becomes soluble on the addition of strong alkaline solutions.

Action, Medical Uses, and Dosage.—Oleoresin of senecio possesses the virtues of the plant from which it is obtained in a high degree. It is, however, more especially employed in the treatment of female diseases, as *amenorrhœa*, *dysmenorrhœa*, and other *uterine derangements*. Combined with alcoholic extract of aletris, resin of caulophyllum, or resin of cimicifuga, it will be found especially useful in these complaints. In *menorrhagia* it may be combined with extract of geranium advantageously; or its ethereal tincture may be administered in some astringent infusion. A pill of oleoresin of senecio, alcoholic extract of aletris, and sulphate of iron, will be found of benefit in *chlorosis* accompanied with *amenorrhœa*. In *dysmenorrhœa* it may be combined with extract of belladonna and sulphate of quinine. It is one of those agents which exert a tonic influence upon the uterus, thereby restoring its various functional derangements to a normal condition. Dose of the oleoresin, from 3 to 5 grains, 3 times a day (J. King).

Related Preparation.—SENECIONINE is the incorrect name given to a concentrated powdered preparation formerly made by our manufacturers. Dr. H. H. Hill prepared it as follows: Make a tincture of the coarsely powdered leaves and roots of *Senecio*, with alcohol of 76 per cent. Distill off the alcohol until the liquid is of the consistence of a fluid extract, add to it several times its weight of water, and precipitate with a solution of alum. Wash the precipitate to free it from the alum, and dry it in the open air without heat. It forms a dark-green powder, having a peculiar, herbaceous, strong, unpleasant, somewhat resinous and senna-like taste and odor, is soluble in water, partially soluble in alcohol, and more so in ether. It is said to possess the virtues of the plant, and may be given in doses of from 1 to 5 grains, 3 or 4 times a day (J. King).

OLEORESINA XANTHOXYLI.—OLEORESIN OF XANTHOXYLUM.

SYNONYMS: *Oleoresin of prickly ash*, *Xanthoxylin*.

Preparation.—By percolation exhaust finely powdered prickly ash bark, any quantity, with alcohol, a sufficient quantity. Distill off two-thirds of the alcohol, and add the residue to two or three times its volume of water. By distilling off the remaining alcohol, or by allowing the mixture to stand, the oleoresin precipitates. Collect it, wash it in clear water, allow it to subside, and then separate it from the water by decantation and filtration.

History and Description.—The profession is indebted to Mr. Wm. S. Merrell for the preparation of this valuable agent, which appears to possess all the medicinal properties of the bark in a concentrated form. When in mass it is blackish, but of a reddish-brown color in thin layers; it has a peculiar odor, somewhat similar to that of most oleoresins, and a peculiar bitterish taste, quickly succeeded by a persistent pungency in the mouth and fauces. It is insoluble in water, partially soluble in aqua ammoniæ and liquor potassæ, forming a solution with a soapy feeling; soluble in ether, from which aqua ammoniæ removes a portion without much change of color; soluble in oil of turpentine, and to a greater or less extent in oil of savin, and some other essential oils; soluble in alcohol, from which water precipitates it, forming a dirty-white solution. Acetic, nitric, sulphuric, and hydrochloric acids, when added to the alcoholic solution, occasion no precipitate.

"*Xanthoxylin*" in powder is prepared somewhat similar to the process named for "*irisin*" in powder; as a rule all these so-called dry oleoresins (?) are nearly inert, and not as active as the powdered crude article from which they are made.

Action, Medical Uses, and Dosage.—Oleoresin of prickly ash bark is stimulant, tonic, alterative, and sialagogue, and may be used in all cases where it is desired to stimulate and strengthen mucous tissues. It forms an excellent remedy for *rheumatism* unaccompanied with inflammation, or where there is an asthenic condition of the system, and I have often used it for this purpose with resin of black cohosh, in doses of 1 grain of each, every 1, 2, or 3 hours, with much advantage. Combined with quinine, it will be found very beneficial in cases where quinine alone appears to exert no influence, and will prove a valuable agent in *dyspepsia*, accompanied with loss of appetite, flatulence, and distress after eating, given in conjunction with oleoresin of ptelea. In *low typhoid fever*, oleoresin of prickly ash bark will be found a valuable and permanent stimulating tonic, and may, when necessary, be added to laxatives in that disease, to prevent too much prostration —it must, however, be employed only during the stage of prostration. It may be used alone as a stimulating tonic and alterative. When a stimulating tonic is required for children after *diarrhœa*, *dysentery*, or other *debilitating diseases*, a combination of hydrochlorate of berberine with oleoresin of prickly ash bark will admirably fulfil the indication. In *chronic rheumatism* I have found the following preparation highly beneficial: Take of resin of cimicifuga, oleoresin of prickly ash bark, and extract of apocynum, each, 1 drachm; proof-spirits or whiskey, 1 pint. Mix. Of this, the dose is a tablespoonful 3 times a day, or sufficient to slightly affect the head, at the same time attending to the surface and the excretory functions. Sometimes I add 2 drachms of guaiacum to the above. The dose of the oleoresin of prickly ash bark is from 1 to 3 grains, 3 or 4 times a day (J. King).

OLEORESINA ZINGIBERIS (U. S. P.)—OLEORESIN OF GINGER.

SYNONYMS: *Extractum zingiberis æthereum*, *Ethereal extract of ginger.*

Preparation.—"Ginger, in No. 60 powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; ether, a sufficient quantity. Put the ginger into a cylindrical glass percolator, provided with a stop-cock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly and percolate slowly with ether, added in successive portions until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining ether to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle"—(*U. S. P.*).

Description and History.—This substance is the *piperoid of ginger* of Beral. It is a clear, thickish, deep-brown liquid, having the sharp pungency and the flavor of ginger root. Less oleoresin is obtained from the uncoated Jamaica ginger, but it has a more pleasant flavor, a lighter color, and greater fluidity when obtained from the latter. Acetone extracts the full amount of it.

Action, Medical Uses, and Dosage.—Same as for ginger. Dose, 1 minim, well diluted.

OLEOSACCHARA (N. F.)—OIL-SUGARS.

SYNONYM: *Elæosacchara (Ger. Pharm.).*

Preparation.—"Any volatile oil, one drop (1 drop); sugar, two grammes (2 Gm.) [31 grs.]. Triturate the sugar with the volatile oil to a fine powder. This preparation should be freshly made when wanted for use. *Note.*—When *Elæosaccharum Anisi*, *E. Fœniculi*, *E. Menthæ piperitæ*, etc., are prescribed, these are to be prepared from the corresponding essential oils, according to the above formula"—(*Nat. Form.*).

OLEUM ADIPIS (U. S. P.)—LARD OIL.

A fixed oil expressed from lard at a low temperature.

Preparation.—If lard be enclosed in stout bags and exposed to a very low temperature, about that of freezing, and then subjected to a gradually increased, yet powerful pressure, the olein separates from the stearin and yields a little over 60 per cent of lard oil. The residual stearin is utilized in the manufacture of soap. Lard oil chiefly contains olein, with some palmitin and stearin. Its composition is similar to that of olive oil.

Description and Tests.—Lard oil, according to the *U. S. P.*, is "a colorless or pale-yellow, oily liquid, having a peculiar odor, and a bland taste. Specific gravity, 0.910 to 0.920 at 15° C. (59° F.). At a temperature a little below 10° C. (50° F.) it usually commences to deposit a white, granular fat, and at or near 0° C. (32° F.) it forms a semisolid, white mass. When it is brought in contact with concentrated sulphuric acid, a dark reddish-brown color is instantly produced. If 5 Cc. of the oil be thoroughly shaken in a test-tube, with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol, and adding 2 drops of nitric acid), and the mixture heated for about five minutes in a water-bath, the oil should remain nearly or quite colorless, not acquiring a reddish or brown color, nor should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent of cotton-seed oil). If 5 Cc. of the oil, contained in a small flask, be mixed with a solution of 2 Gm. of potassium hydrate in 2 Cc. of water, then 5 Cc. of alcohol added, and the mixture heated for about 5 minutes on a water-bath, with occasional agitation, a perfectly clear and complete solution should be formed, which, on dilution with water to the volume of 50 Cc., should form a transparent, light-yellow liquid, without the separation of an oily layer (absence of appreciable quantities of paraffin oils)"—(*U. S. P.*).

Medical Uses.—Lard oil is used chiefly in pharmacy. In the absence of other fats it might be employed in *poisoning by the caustic alkalies.*

OLEUM ÆTHEREUM (U. S. P.)—ETHEREAL OIL.

"A volatile liquid consisting of equal volumes of heavy oil of wine and ether"—(*U. S. P.*).

Preparation.—"Alcohol, one thousand cubic centimeters (1000 Cc. [33 fl℥, 391 ♏]; sulphuric acid, one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏], distilled water, twenty-five cubic centimeter (25 Cc. [406 ♏]; ether, a sufficient quantity. Add the acid slowly to the alcohol, mix them thoroughly, and allow the mixture to stand, in a closed flask, for 24 hours, or until the liquid is clear; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure, so that the bulb shall be deeply immersed in the liquid, and, having connected the retort with a well-cooled condenser, and also having connected with the receiver a bent glass tube for conducting the uncondensed gases into water, distill, by means of a sand-bath, at a temperature between 150° and 160° C. (302° and 320° F.), until oily drops cease to come over, or until a black froth, which forms on the surface, begins to rise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it to the air for 24 hours, in a shallow capsule. Then transfer it to a wet filter, and when the watery portion has drained off, wash the oil which is left on the filter with the distilled water, which should be as cold as possible. When this also has drained off, transfer the oil to a graduated measure, and add to it an equal volume of ether. Keep the product in small, glass-stoppered vials, in a cool place"—(*U. S. P.*).

Description and Chemical Composition.—Ethereal oil is officially described as "a transparent, nearly colorless, volatile liquid, of a peculiar, aromatic, ethereal odor, a pungent, refreshing, bitterish taste, and neutral to dry litmus paper. Specific gravity, 0.910 at 15° C. (59° F.)"—(*U. S. P.*).

The chemical composition of this oil is tersely stated by Bruno Hirsch (*Universal Pharmacopœia*, 1890, No. 2109) as follows: "The heavy oil of wine which constitutes one-half of the finished product, is to be considered a solution of solid *ætherin* and liquid *ætherol*, both of the empirical formula C_2H_4, in *diethyl-sulphurous acid* ($[C_2H_5]_2SO_3$) and *diethyl-sulphuric acid* ($[C_2H_5]_2SO_4$) in variable quantities, the proportions of which are not yet determined." (Also see Prof. J. M. Maisch, *Amer. Jour. Pharm.*, 1865, p. 100; and Charles L. Diehl, *ibid.*, p. 126.)

Uses.—This oil is used only for pharmaceutical purposes. It is a constituent of compound spirit of ether. In moderate doses ethereal oil stimulates the vasomotor centers, and if the dose be sufficiently large, this is followed by paralysis of the tunics of the blood vessels.

OLEUM AMYGDALÆ AMARÆ (U. S. P.)—OIL OF BITTER ALMOND.

"A volatile oil obtained from bitter almond by maceration with water, and subsequent distillation. It should be kept in small, well-stoppered bottles, protected from light"—(*U. S. P.*).

SYNONYM: *Oleum amygdalarum (amararum) æthereum.*

Preparation and Chemical Composition.—The greater quantity of commercial oil of bitter almond is prepared from the seeds of apricots, which yield an oil identical with that from bitter almond (Gildemeister and Hoffmann, *Die Ætherischen Oele*, Leipzig, 1899, p. 572). The seeds are first deprived of their fixed oil by subjecting them, ground, to a hydraulic pressure of 350 atmospheres. Bitter almonds yield 50 per cent, apricots 35 to 38 per cent of fatty oil. The powdered press-cake is then mixed with about 6 parts, by weight, of water, the mixture allowed to digest at about 50° C. (122° F.) for some 12 hours; the oil is then distilled off with steam. Oil of bitter almond does not preexist in the kernels, but is produced in the presence of water by the action of the ferment *emulsin* upon the glucosid *amygdalin*, whereby dextrose, oil of bitter almond, and hydrocyanic acid are formed, thus: $C_{20}H_{27}NO_{11}$ (*amygdalin*) + $2H_2O$ (*water*) = $2C_6H_{12}O_6$ (*glucose*) + C_7H_6O (*oil of bitter almond*) + HCN (*hydrocyanic acid*). Time must be allowed this chemical decomposition to take place, and the temperature must not be too high, or else the fermentative power of emulsin will be destroyed (compare *Amygdala Amara* and *Laurocerasus*).

The yield of the oil from bitter almonds is 0.5 to 0.7 per cent; from apricots, 0.6 to 1 per cent. It consists of *benzaldehyde* (C_6H_5CHO) and *hydrocyanic acid*, the former being easily convertible by oxidation into benzoic acid. This change is favored by removal of hydrocyanic acid. The quantity of the latter may normally vary from 1.5 to 4 per cent (F. B. Power, *Essential Oils*, published by Fritzsche Brothers, 1894). A third body may occur in the oil, namely the *nitril of mandelic acid* ($C_6H_5.CHOH.CN$), which is merely an addition product of equal molecules of benzaldehyde and hydrocyanic acid. It forms when both substances are in prolonged contact with each other, and is decomposed into its constituents by steam heat. It is therefore not present in the fresh oil. It has the specific gravity 1.124, while the normal oil has the specific gravity of 1.045 to 1.060. Thus a high specific gravity of the oil (exceeding 1.070) indicates the presence of dangerous proportions of hydrocyanic acid. As to the method of valuation of hydrocyanic acid in bitter almond oil, see paper by Prof. Edward Kremers and O. Schreiner, in *Pharm. Review*, 1896, p. 196. The oil may be completely deprived of its hydrocyanic acid by shaking with milk of lime and ferrous sulphate, whereby insoluble calcium ferrocyanide is formed (Gildemeister and Hoffmann, *loc. cit.*). The crude oil may also contain *benzoin* ($C_{14}H_{12}O_2$), a solid, crystallizable substance formed by polymerization of benzaldehyde.

Description.—Oil of bitter almond is officially described as "a clear, colorless or yellowish, thin, and strongly refractive liquid, having a peculiar, aromatic odor, and a bitter and burning taste. Specific gravity, 1.060 to 1.070 at 15° C. (59° F.). Boiling point, about 180° C. (356° F.). Optically inactive. Soluble in 300 parts of water at 15° C. (59° F.), and in alcohol or ether in all proportions; also soluble in nitric acid at ordinary temperatures without the evolution of nitrous vapors. In the fresh state the oil is neutral to litmus, but when kept for some time it assumes an acid reaction, due to the formation of benzoic acid"—(*U. S. P.*). *Warm* nitric, or fuming nitric acid converts it into nitrobenzaldehyde and benzoic acid.
