Tests.—The *U. S. P.* gives the following tests: "If 10 drops of the oil, dissolved in a little alcohol, be shaken with a few drops of a strong solution of sodium hydrate, then with a little ferrous sulphate T.S., and finally mixed with a slight excess of hydrochloric acid, a blue precipitate will be produced (presence of hydrocyanic acid). The presence of artificial oil containing chlorinated products may be detected in the following manner. Fold a small strip of filter paper in the form of a taper, saturate it with the oil, and lay it in a small porcelain capsule. Set this capsule into a larger one, and provide a large beaker to be inverted over the capsule containing the taper. Then, having moistened the inner surface of the beaker with distilled water, ignite the taper, immediately invert the beaker over the capsule, and allow the products of combustion to be absorbed by the water in the beaker. If the beaker be now rinsed with a little distilled water, and the liquid filtered, the filtrate should yield no turbidity with silver nitrate T.S. If 5 Cc. of the oil be vigorously shaken, in a flask, with 50 Cc. of a cold, saturated solution of sodium bisulphite, and the mixture heated for a few minutes on a water-bath, the odor of the oil should disappear, and a nearly clear solution be formed, without the separation of any oily drops on the surface of the liquid (absence of most other volatile oils and of nitrobenzol)"—(*U. S. P.*). The latter test depends on the property of aldehydes to enter into crystallizable, inodorous addition-compounds with sodium bisulphite. Thus: $C_6H_5.CHO + NaHSO_3 = C_6H_5.CHOH.SO_3Na$ (also see test under *Nitrobenzenum*). Another rapid and simple test for artificial oil containing chlorine compounds depends upon the distinct, but evanescent, green-flame coloration imparted to the flame of a Bunsen burner by a clean, copper wire when moistened with the oil in question, the coloration being due to the vapors of copper chloride (F. B. Power, *loc. cit.*).

Artificial Oil of Bitter Almond, or *pure benzaldehyde* (*benzoic aldehyde*) C_7H_6O. or $C_6H_5.COH$, is now extensively prepared, in Europe, from certain chlorine substitution products, *e. g.*, *benzalchloride* ($C_6H_5.CHCl_2$), of the fluid coal-tar hydrocarbon *toluene* ($C_6H_5.CH_3$). This artificial product is now frequently used; it is naturally free from hydrocyanic acid, but has a slightly peculiar smell owing to the presence of traces of chlorine compounds, which are difficult to remove (see *Tests*).

Action, Medical Uses, and Dosage.—The medicinal uses of this agent are those named under diluted hydrocyanic acid, which see. It is used in the arts to give flavor and odor to candies, and in pharmacy to flavor castor and cod-liver oils. It is extremely poisonous, 1 drop having proved fatal to small animals, and 15 drops to an adult. Locally (oil, 1 drop, to water, 1 fl℥) it allays itching. The maximum dose internally should not exceed one-half minim, given in emulsion with sugar, water, and acacia.

OLEUM AMYGDALÆ EXPRESSUM (U. S. P.)—EXPRESSED OIL OF ALMOND.

"A fixed oil expressed from the bitter or sweet almond. It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Synonyms: *Oleum amygdalæ* (*Br.*), *Oleum amygdalæ dulcis*, *Oleum amygdalarum*, *Expressed oil of almond*, *Sweet oil of almond*.

Preparation.—Both bitter and sweet almonds deprived of the adherent brownish dust by means of rubbing or sifting, and freed from inferior pieces, are bruised or ground, put into a bag, and strongly pressed between perfectly smooth and slightly warmed steel plates. The heat should not be greater than 30° C. (86° F.). The margins of the press-cake, if again powdered and expressed, yield an additional quantity of oil. At first the oil is turbid. It is allowed to stand, and the clear oil is then decanted. The yield is from 40 to 55 per cent for sweet almonds; about 30 to 50 per cent for bitter almonds. The highest yields are obtained only by strong hydraulic pressure. If almonds be immersed in hot water, deprived of their cuticular covering, oven-dried and then expressed, a colorless oil is obtained, but it is more liable to become rancid than if prepared as above directed, and to develop a prussic acid odor.

Description and Chemical Composition.—"A clear, pale straw-colored or colorless, oily liquid, almost inodorous, and having a mild, nutty taste. Specific gravity, 0.915 to 0.920 at 15° C. (59° F.). Only slightly soluble in alcohol, soluble in ether and in chloroform in all proportions. It remains clear at —10° C. (14° F.), and does not congeal until cooled to near —20° C. (—4° F.)"—(*U. S. P.*). Almond oil is non-drying and when exposed to the atmosphere is liable to become rancid and acrid. Benzin and the fixed oils readily dissolve it in all proportions. The coloring matter, together with a small portion only of the oil, is dissolved by alcohol. According to G. M. Beringer (*Amer. Jour. Pharm.*, 1889, p. 232), 1 part of oil of almond is completely dissolved in 4 parts of boiling absolute alcohol, and in 34 parts of the same solvent at ordinary temperature, while 42 parts of boiling alcohol of the specific gravity 0.820, are required for complete solution. Expressed oil of almond consists principally of the glyceride of oleic acid with appreciable amounts of the glyceride of linoleic acid (see A. Hazura, in *Amer. Jour. Pharm.*, 1889, p. 471).

Tests.—"If 2 Cc. of the oil be vigorously shaken with 1 Cc. of fuming nitric acid and 1 Cc. of water, a whitish, not red or brownish, mixture, should be formed, which, after standing for some hours at about 10° C. (50° F.), should separate into a solid, white mass, and a scarcely colored liquid (distinction from the fixed oils of apricot and peach kernels, and from sesamum, cotton-seed and poppy-seed oils). If 10 Cc. of the oil be mixed with 15 Cc. of a 15 per cent solution of sodium hydrate and 10 Cc. of alcohol, and the mixture allowed to stand at a temperature of 35° to 40° C. (95° to 104° F.), with occasional agitation, until it becomes clear, and then diluted with 100 Cc. of water, the clear solution thus obtained, upon the subsequent addition of an excess of hydrochloric acid, will set free a layer of oleic acid. This, when separated from the aqueous liquid, washed with warm water, and clarified in a water-bath, will remain liquid at 15° C. (59° F.), although sometimes depositing particles of solid matter and becoming turbid. One part of this oleic acid, when mixed with 1 volume of alcohol, should give a clear solution, which, at 15° C. (59° F.) should not deposit any fatty acids, nor become turbid on the further addition of 1 volume of alcohol (distinction from olive, arachis, cottonseed, sesamum, and other fixed oils)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—A non-poisonous, bland oil of agreeable taste, which may be given like olive oil, in dose of 1 to 8 drachms in mucilage or egg emulsion for the relief of *chronic coughs.*

OLEUM ANETHI.—OIL OF DILL.

The volatile oil distilled from the fruit of *Anethum graveolens*, Linné.

Nat. Ord.—Umbelliferæ.

Preparation and Description.—The yield of the oil, obtained by distillation with water, is from 2.5 per cent (East Indian) to 4 per cent (Russian) (Schimmel & Co.). The residual herb is rich in nitrogenous and fatty matter, and in dried form is used as feed for cattle. The oil is pale yellow, having a sweetish, sharp, burning taste, and a penetrating odor resembling that of the fruit. It gradually becomes darker in color. The odor of East Indian dill oil differs markedly from that of the German product. The density is 0.905 to 0.915 (as high as 0.970 for East Indian) (Schimmel & Co.). Optical rotation, +70° to +80°; East Indian, +41° 30′.

Chemical Composition.—Oil of dill contains from 40 to 60 per cent of *carvone* (*carvol*), identical in optical rotation and other physical and chemical properties with that from oil of caraway (see A. Beyer, *Amer. Jour. Pharm.*, 1884, p. 324). Furthermore, the terpene hydrocarbons, *dextro-limonene*, and sometimes *phellandrene* are present. The East Indian dill oil contains a peculiar heavy constituent, ascertained by Ciamician and Silber (1896) to be an isomer of apiol from parsley oil and named by these chemists *dill-apiol* ($C_{12}H_{14}O_4$) (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899).

Action, Medical Uses, and Dosage.—Carminative and local anodyne. Useful in *flatulent colic*. Dose, 5 to 10 drops in sweetened hot water.

OLEUM ANIMALE ÆTHEREUM.—ANIMAL OIL.

SYNONYMS: *Oleum animale Dippelii, Dippel's animal oil, Oleum cornu cervi rectificatum.*

History and Preparation.—J. C. Dippel, in 1711, first obtained this oil by the destructive distillation of dried blood. It is now produced by the rectification of *Crude* (or *fetid*) *animal oil* (*Oleum Cornu Cervi*, or *Bone oil*). When animal substances, such as bones (previously freed from fat), hoofs, horns, blood, hide, etc., are subjected to dry distillation, the following substances are chiefly produced: Carbonic acid gas and combustible gaseous products, a sublimate of carbonate of ammonium (*salt of hartshorn, sal cornu cervi*); an aqueous liquid (*Spiritus Cornu Cervi*), containing ammonium salts of carbonic and hydrocyanic acids, ammonium sulphide, and empyreumatic oils; furthermore, a black-brown, fetid tar (*Oleum Cornu Cervi*), and a residue of charcoal containing nitrogen. The tar chiefly consists of pyridine bases, such as *pyridine* (C_5H_5N), *picoline* (C_6H_7N), *lutidine* (C_7H_9N), *collidine* ($C_8H_{11}N$), etc., and yields upon repeated rectification Dippel's ethereal oil. According to Hager (*Handbuch der Pharm. Praxis*, Vol. II, 1886, p. 568), the crude oil is first distilled from a glass retort by the heat of a sand-bath, as long as a thin oil passes over. The distillate is mixed with four times its bulk of distilled water, and this mixture distilled from a metallic retort. The distillate separates into an aqueous and an oily layer; the latter is drawn off and run into small bottles, securely sealed and put into a dark and cool place. The yield is about 15 to 20 per cent.

Description.—Medicinal, or rectified animal oil is a thin, colorless, or but faintly yellow, oily body, the average specific gravity of which is 0.80. Its odor is ethereal, not fetid, and powerfully penetrating; its taste acrid and sharp, with a cooling, bitter after-taste. Water (80 parts), volatile and fixed oils, alcohol, and ether, dissolve it. When exposed to the atmosphere and light its color deepens rapidly, and the oil assumes a denser consistence. Its reaction is feebly alkaline.

Chemical Composition.—This oil is a mixture of many substances which are but partly known. Besides several hydrocarbons, methyl-, propyl- and butylamine, aniline, *pyrrol* (C_4H_5N), *pyridine* (C_5H_5N), *lutidine* (C_7H_9N), *picoline* (C_5H_7O), and *collidine* ($C_8H_{11}N$), etc., are present (Anderson).

Action, Medical Uses, and Dosage.—Animal oil is not now employed to any extent in therapy. Formerly it was employed, alone or combined, by friction, for the same purposes as liniments. From 5 to 30 drops were formerly used internally, combined with sugar, ether, and Hoffmann's anodyne, for the expulsion of *tapeworms*, and in *chorea, epilepsy, paralysis, hysteria, sciatic neuralgia, chronic rheumatism*, and in *typhoid states*. It has much to condemn it and nothing to commend it. It is extremely poisonous, 3 drachms having quickly killed an adult.

Derivatives of Crude Animal Oil.—PYRIDINE (not *pyrodine*) (C_5H_5N) is a colorless fluid base obtained from Dippel's animal oil, and is found also in tobacco smoke, coal-naphtha, shale-oil, peat-tar, etc. It is obtained by treating the oil with sulphuric acid, afterward with caustic soda, subjecting the decomposed mixture to fractional distillation, treating with oxidizers to remove aniline, and fractionating a second time. It is also synthetically prepared. Its specific gravity is 0.980; its boiling point, 116° C. (240.8° F.); it has a sharp, peculiar, empyreumatic, and persistent taste. With acids it unites to form salts. Water dissolves it, but caustic potash or soda in excess precipitates it. Fixed oils, ether, alcohol, benzol, and chloroform mix with it in all proportions. Large doses of it act as a powerful poison, inducing cyanosis, general muscular paralysis, and death from respiratory failure. Small doses are reputed stimulant, and are said to have been employed successfully in *angina pectoris*. Dose, 6 to 12 drops, once a day; or better, 2 to 4 drops, 3 times a day. It has been more generally recommended as a palliative inhalant in *asthmatic affections*. An aqueous solution (1 in 300) has been employed locally in *gonorrhœa*.

PYRIDINE TRICARBOXYLIC ACID ($C_5H_2[COOH]_3N$).—A derivative of pyridine, and also obtained from certain of the cinchona alkaloids. It forms prismatic crystals which fuse at 244° C. (471.2° F.). Reputed antipyretic, antiasthmatic, and antiseptic. Ten-grain doses are said to have been more effective than quinine in *malarial fever*, given after the paroxysm. Asserted useful in *typhoid fever, asthma* (1 to 2-grain doses), and to have a specific effect on *gonorrhœa* (locally applied).

PYRODINE.—(See *Related Compounds and Derivatives of Phenacetinum.*)

OLEUM ANISI (U. S. P.)—OIL OF ANISE.

"A volatile oil distilled from anise. It should be kept in well-stoppered bottles protected from light, and, if it has separated into a liquid and a solid portion, it should be completely liquefied by warming before being dispensed"—(*U. S. P.*).

Source and Chemical Composition.—This oil is prepared by distilling anise seed, from *Pimpinella anisum*, Linné, with water. The Russian seeds are now mostly used; they yield, according to Schimmel & Co. (*Reports*, April, 1897), from 2.4 to 3.2 per cent of oil; Italian fruit (Bolognese) yielded as high as 3.5 per cent. Over 90 per cent of the oil consists of *anethol* (*para-methoxy-propenyl-benzol*, $C_{10}H_{12}O$, or $C_6H_4[OCH_3].CH:CH.CH_3$), which is the essential aromatic constituent of the oil. It was obtained synthetically, in 1877, by Perkin. It is a snow-white, crystallizable body, of sweet taste, melts at 21.5° C. (69.8° F.), and is optically inactive. The liquid constituent of anise oil is *methyl-chavicol*, an isomer of anethol. Both anethol and methyl-chavicol also occur in the oil of star-anise (*Illicium verum*) (Schimmel's *Report*, Oct., 1895); anethol is also found in fennel oil (Cahours, 1841). In oil of star-anise, *dextro-pinene* and *lævo-phellandrene* were also found.

Description and Tests.—The *U. S. P.* describes the oil as follows: "A colorless or pale-yellow, thin, and strongly refractive liquid, having the characteristic odor of anise, and a sweetish, mildly aromatic taste. Specific gravity, about 0.980 to 0.990 at 17° C. (62.6° F.), increasing with age. At a low temperature, usually between 10° and 15° C. (50° and 59° F.), it solidifies to a white, crystalline mass. Soluble in an equal volume of alcohol to a clear solution (absence of most fixed oils and oil of turpentine). This solution is neutral to litmus paper, and should not assume a blue or brownish color on the addition of a drop of ferric chloride T.S. (absence of some volatile oils containing phenols). When the oil is dropped into water, without agitation, it should not produce a milky turbidity (absence of alcohol)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Both oil of anise and oil of star-anise, are carminative and antispasmodic, and especially adapted to *flatulency* and *colic of infants.* They likewise, in connection with aqua ammoniæ, ammonium chloride, or ammonium carbonate, afford relief in *spasmodic cough.* The dose is from 5 to 10 drops. Ruschenberger states that the offensive odor of the tersulphides in solutions or ointments is removed or completely covered by the presence of oil of anise. Oil of anise is an ingredient of paregoric and other well-known preparations.

Related Oil.—OIL OF ANISE BARK. From Madagascar; botanical source unknown, but the bark closely resembles the Massoi bark, and yields 3.5 per cent of essential oil. The oil is pale-yellow, spicy and feebly sweet to the taste, and has an odor suggestive of *safrol.* Density, 0.969. It contains chiefly Eykman's *methyl-chavicol* ($CH_3O.C_6H_4.CH_2.CH.CH_2$), the fluid anethol isomeric with ordinary anethol, of which it also contains a small proportion (Schimmel & Co.'s *Report*, April, 1892, p. 53).

OLEUM ANTHEMIDIS.—OIL OF CHAMOMILE.

The essential oil distilled from the flowers of *Anthemis nobilis*, Linné.

Nat. Ord.—Compositæ.

SYNONYMS: *Oleum chamomillæ Romanæ, Oil of Roman chamomile.*

Source and Description.—Oil of chamomile is obtained by distillation of chamomile flowers (*Anthemis nobilis*) with water, the yield being 0.8 to 1 per cent (Schimmel & Co.'s *Report*, April, 1897). When first obtained it is bluish, afterward greenish, but finally becomes yellowish-brown; its specific gravity is about 0.9083 (0.905 to 0.915). It has the odor of chamomile flowers, and an aromatic, somewhat pungent taste. It dissolves in 6 parts of 70 per cent alcohol.

Chemical Composition.—The constituents of this oil, according to Schimmel & Co., are chiefly the *isobutylester* of *isobutyric* and *angelic acids*, the *amyl-* and *hexyl-ester* of *angelic* and *tiglic acids.* The highest boiling fractions yield upon saponification and distillation, principally two alcohols, viz., *methyl-ethyl-propyl alcohol* ($C_2H_5.CH_3:CH.CH_2.CH_2OH$), and *anthemol* ($C_{10}H_{16}O$) an isomer of camphor. A paraffin-like body, *anthemen* ($C_{18}H_{36}$) (Naudin, 1884) is probably also present in the highest fractions. (For interesting details regarding the chemistry of this oil, see Gildemeister and Hoffmann, *loc. cit.*) Angelic and tiglic acids are isomers, their composition being $C_5H_8O_2$. Heat converts the former into the latter acid.

Action, Medical Uses, and Dosage.—Oil of chamomile is tonic and antispasmodic; and has been found very serviceable in *spasm of the stomach, painful dysmenorrhœa, hiccough, pertussis,* to allay *nausea* and *vomiting,* and to prevent or lessen the griping influence of some cathartics. The dose is from 5 to 10 drops. The *Matricaria Chamomilla* furnishes a thick, deep-blue oil, becoming brown by age, and which is frequently substituted for the oil of chamomile. It is less antispasmodic than the true chamomile oil. It is an ingredient of some liniments for *painful affections.*

OLEUM AURANTII CORTICIS (U. S. P.)—OIL OF ORANGE PEEL.

"A volatile oil obtained by expression from the fresh peel of either the bitter orange, *Citrus vulgaris*, Risso, or the sweet orange, *Citrus Aurantium*, Linné (*Nat. Ord.*—Rutaceæ). It should be kept in well-stoppered bottles, in a cool place" (*U. S. P.*).

SYNONYM: *Essential oil of orange peel.*

Source and Preparation.—There are in commerce two oils of orange peel, viz.: OLEUM AURANTII DULCIS, *Oil of sweet orange peel*, and OLEUM AURANTII AMARI, *Oil of bitter orange peel.* Both are included in the official oil. They are prepared in southern Europe by at least five different methods: (1) by rupturing the superficial portion of the rind, thus liberating the oil from the glands; (2) by forcibly twisting the fresh rind and collecting the oil upon sponges, and afterward squeezing the contents of the saturated sponges into a suitable vessel; (3) by grating the exterior of the rind and expressing; (4) by putting the scrapings into hot water and skimming off the oil; (5) by distillation of the residues after expression, which yields an inferior product.

Chemical Composition.—Both oils are composed chiefly (to 90 per cent) of *dextro-limonene* (Wallach, 1884). In addition the oil of sweet orange peel contains, according to Semmler (1891), a small quantity of *geranial* (*citral*), and an aldehyde of lower boiling point (Power, *Essential Oils*). The oil of orange peel is under further chemical investigation. Ninety per cent of the oil distills between 175° and 180° C. (347° and 354° F.).

Dextro-limonene occurs chiefly in orange and lemon oils; also found in oils of caraway, dill and elsewhere; *lævo-limonene* in American oil of peppermint and a few other oils. Both modifications are identical in every respect except their optical antagonism. Combined in equi-molecular quantities, they form a terpene nearly identical with *dipentene* which is inactive. *Limonene* is a colorless liquid of a pleasant lemon odor; its specific gravity at 15° C. (59° F.) is 0.846; boiling point 175° to 176° C. (347° to 348.4° F.). Being an unsaturated terpene, 1 molecule absorbs 4 atoms of bromine, forming therewith a characteristic addition product which melts at 104.5° C. (220° F.) (Wallach, 1887).

Description and Tests.—Chemically, and in most other particulars, these two oils are similar. Their flavor differs somewhat, and that from the bitter oranges undergoes change more quickly on exposure. Oil of sweet orange peel is generally preferred in making elixir of orange. The best is the Sicilian oil, though not all is made in Sicily. That from Bigarade orange is known in France as *Essence de Bigarade*, and regarded the most valuable; that from the Portugal or Sweet orange is called *Essence de Portugal*. Oil of orange peel is officially described as "a pale yellowish liquid, having the characteristic, aromatic odor of orange, and an aromatic and, when obtained from the bitter orange, somewhat bitter taste. Specific gravity, about 0.850 at 15° C. (59° F.). Its optical rotation should not be less than 95° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Soluble in about four times its volume of alcohol, this solution being neutral to litmus paper; also soluble in all proportions, in absolute alcohol or in carbon disulphide, and in an equal volume of glacial acetic acid. When kept for some time the oil should not develop a terebinthinate odor or taste (absence of oil of turpentine or of other oils containing pinene)"—(*U. S. P.*). Both oils have the same specific gravity (0.848 to 0.854, Schimmel & Co.).

Action and Uses.—This agent is employed for perfuming or flavoring medicines. Its properties are those of an irritant, and it is somewhat narcotic. Those who prepare the oil are subject to mental confusion, muscular debility, neuralgia, headaches, disordered digestion, and erythema, papules, and vesicles upon the skin.

OLEUM AURANTII FLORUM (U. S. P.)—OIL OF ORANGE FLOWERS.

"A volatile oil distilled from the fresh flowers of the bitter orange, *Citrus vulgaris*, Risso (*Nat. Ord.*—Rutaceæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Synonyms: *Oil of neroli*, *Essence of neroli*.

Preparation and History.—This oil is obtained in the making of orange-flower water, the oil floating upon the surface of the fluid in small amounts. It is best when prepared from the petals rather than from the whole flower. As found in commerce it is usually adulterated with *oil* or *essence of petit grain*. The latter is the volatile oil of the leaves, shoots, and the young fruits of the Bigarade orange. The term *oil* or *essence of petit grain*, was at one time applied to the oil obtained by distillation from small, immature oranges, but is now referred to the oil produced as above stated.

Description.—"A yellowish or brownish, thin liquid, having a very fragrant odor of orange flowers, and an aromatic, somewhat bitter taste. Specific gravity, 0.875 to 0.890 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper. If a little alcohol be poured on the surface of the oil, and the mixture gently undulated, a bright, violet fluorescence will usually be observed. In contact with a saturated solution of sodium bisulphite it assumes a handsome and permanent purplish-red color"—(*U. S. P.*). The oil has a slight right-handed optical rotation.

Chemical Composition.—Orange-flower oil contains an odorless stearoptene formerly called *neroli camphor;* it is a paraffin, melting at 55° (131° F., *Pharmacographia*). Tiemann and Semmler, in 1893, obtained by fractional distillation of the oil *limonene*, *lævo-linalool*, *linaloyl acetate*, and *geraniol.* Schimmel & Co., in 1894, discovered in the oil small quantities of *anthranilic acid methyl-ester* ($NH_2.C_6H_4.COOCH_3$), melting at 25° C. (77° F.), to the presence of which the fragrance and the fluorescence of the oil are due (see *Report*, April, 1899, p. 32). An artificial body, many times stronger than oil of neroli, and used quite extensively by soap-makers and perfumers, is on the market under the name *nerolin.* It is a white powder, soluble in fixed oil and alcohol, but not in water.

Uses.—Oil of orange flowers is used chiefly in manufacturing perfumes, and has been suggested for perfuming local applications.

OLEUM BERGAMOTTÆ (U. S. P.)—OIL OF BERGAMOT.

"A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Bergamia*, Risso et Poiteau (*Nat. Ord.*—Rutaceæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYM: *Oleum bergamii* (*Pharm.*, 1880).

Botanical Source, Preparation, and History.—Oil of bergamot exists in the rind of the ripe fruit of *Citrus Bergamia*, from which it may be obtained by expression in the same manner as for procuring the oil of lemon. It may also be obtained by distillation, but the product is not so agreeable as by expression. According to Wight and Arnott, the leaves of the bergamot tree are oblong, more or less elongated, acute, or obtuse, underside somewhat pale; the petiole more or less winged or margined; the flowers usually small and white; the fruit pale-yellow, pyriform or depressed; the rind with concave receptacles of oil; the pulp more or less acid. About 2½ ounces of oil may be obtained by expression from 100 bergamots. The plant is cultivated in the south of Europe from whence the oil is imported.

Description and Tests.—Bergamot oil is sometimes erroneously called *essence of bergamot.* The *U. S. P.* describes it as "a greenish or greenish-yellow, thin liquid, having a peculiar, very fragrant odor, and an aromatic, bitter taste. Specific gravity, 0.880 to 0.885 at 15° C. (59° F.). Its optical rotation should not be more than 20° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Two volumes of the oil, when mixed with 1 volume of alcohol, should give a clear solution of a slightly acid reaction, and this solution should not become turbid on the further addition of alcohol (distinction from oil of orange or oil of lemon). The oil should also be soluble at 20° C. (68° F.), without the separation of oily drops, in 1.5 to 2 volumes of alcohol of 80° per cent by volume. It is soluble, in all proportions, in glacial acetic acid. If about 2 Gm. of the oil be evaporated in a small, tared capsule, on a water-bath, until the odor has completely disappeared, a soft, green, homogeneous residue should be left, amounting to not more than about 6 per cent of the oil (absence of fatty oils)"—(*U.S.P.*).

Chemical Composition.—The fragrance of oil of bergamot is due to the *acetic ester* of *lævo-linalool*, its quantity varying in the oil from 36 to sometimes 40 per cent. The fully matured fruits yield most of this ester. Furthermore, free *linalool*, *dextro-limonene*, perhaps *dipentene*, and 5 per cent of inodorous *bergamot camphor* or *bergapten* ($C_{12}H_8O_4$) are present. According to Pomeranz (1891), it is the *mono-methyl-ether* of *dioxy-coumarin*, derived from *phloroglucin* (Gildemeister and Hoffmann, *loc. cit.*).

Action and Medical Uses.—Gently excitant, but is used almost wholly in perfumery, soaps, and for scenting toilet preparations and ointments.

Related Oils.—OIL OF LEMON GRASS, *Oleum andropogon citrati*. An essential oil, sometimes called *oil of verbena*, derived from several species of *Andropogon*, particularly *Andropogon citratus*, cultivated in India, Ceylon, Malayan peninsula, and near Singapore. It is yellowish-brown with a sharp taste and peculiar odor, used only in perfumes in this country, but as a stimulant and carminative in the East. When treated with a saturated solution of sodium bisulphite, it yields a crystalline compound. The known constituents of this oil are the aldehyde *citral* ($C_{10}H_{16}O$), an unsaturated ketone *methyl-heptenone* ($C_8H_{14}O$), and in the highest boiling fractions the alcohol *geraniol* ($C_{10}H_{18}O$).

Oil of Citronella, *Oleum andropogon nardi.*—The volatile oil distilled from a plant in cultivation in Ceylon, in the Straits Settlement, and coast of Malabar. The natives of Ceylon are engaged in the treatment of the plant, which is distilled by steam in suitable apparatus. It is a yellowish-green oil, slightly lævo-rotatory, of the specific gravity 0.886 to 0.900, has a sharp taste and characteristic odor. With alcohol, it mixes in all proportions. Two or two and one-half volumes of alcohol (80 per cent) should mix perfectly transparent with 1 volume of the oil, at a temperature not lower than 20° C. (68° F.). If the mixture be cloudy it indicates the presence of fixed oils. If oily drops form upon standing, when 5 to 10 volumes of 80 per cent alcohol are added, the presence of petroleum is indicated. Citronella oil contains about 50 per cent of *geraniol*, *citronellal*, an aldehyde ($C_{10}H_{18}O$) which Semmler (1891) succeeded in converting into *citronellic acid* ($C_{10}H_{18}O_2$); furthermore *borneol* (1 to 2 per cent), *methyl-heptenone*, *acetic* and *valerianic acids* in the form of esters. The higher specific gravity observed in *Lana batu oil* is due to the presence of *methyl-eugenol* (*allyl-veratrol* $C_6H_3.C_3H_5.OCH_3.OCH_3$) (Gildemeister and Hoffmann, *loc. cit.*). The oil is employed in perfuming soaps.

Ylang-Ylang Oil, *Cananga oil*, *Oleum unonæ*, *Oleum anonæ*.—The flowers of a south Asiatic tree, growing in Java and Manila, yield this essential oil which is used only in perfumes. A reputed solution of it, in the oil of the cocoanut, is known as *Macassar Hair Oil.* Ylang-Ylang oil contains *lævo-linalool*, *geraniol*, *benzoic* and *acetic acids* (in the form of esters), *methyl-ether* of *para-kresol* ($CH_3.C_6H_4.OCH_3$), traces of a phenol, *cadinene*, etc.

OLEUM BETULÆ VOLATILE (U. S. P.)—VOLATILE OIL OF BETULA.

"A volatile oil obtained by distillation from the bark of *Betula lenta*, Linné, *Sweet birch* (*Nat. Ord.*—Betulaceæ). It is identical with *methyl salicylate* ($CH_3C_7H_5O_3$), and nearly identical with oil of gaultheria. It should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

Synonym: *Oil of sweet birch.*

History and Chemical Composition.—This oil is formed in the bark by the action of the ferment *betulase* (Schneegans, 1896) upon the glucosid *gaultherin* ($C_{14}H_{18}O_8 + H_2O$) (Procter, 1843; Schneegans and Gerock, 1894). Upon saponification, it yields salicylic acid and methyl alcohol. The oil was first distilled from sweet birch, in 1865, in Luzerne county, Pennsylvania, and although the yield is only 0.23 per cent, against 0.80 per cent from gaultheria, distillation of the former material is less expensive. (See, in this connection, two interesting papers by Mr. Geo. W. Kennedy, in *Amer. Jour. Pharm.*, 1882, p. 49, and W. H. Breisch, *ibid.*, 1891, p. 579.) The oil is frequently sold for *Natural oil of wintergreen*. Dr. F. B. Power and Dr. C. Kleber (*Pharm. Rundschau*, 1895, p. 228) summarize the differences between oil of wintergreen and oil of sweet birch as follows: (1) "*Oil of wintergreen* (*Gaultheria*) contains about 99 per cent of methyl salicylate, together with a small amount of a paraffin, which is probably *triacontan* ($C_{30}H_{62}$), an aldehyde or ketone, an apparently secondary alcohol ($C_8H_{16}O$), and an ester ($C_{14}H_{24}O_2$). A pure, fresh oil of gaultheria deviates a ray of polarized light to the left, and the extent of this rotation should not be less than —0° 25′ in a tube of 100 Mm. (2) *Oil of sweet birch* (*Betula*), in its unrectified state, contains about 99.8 per cent of methyl salicylate, together with a very small amount of the above-mentioned paraffin ($C_{30}H_{62}$), an aldehyde or ketone, and the ester ($C_{14}H_{24}O_2$), but does not contain the alcohol ($C_8H_{16}O$), which is found in gaultheria oil. The oil of sweet birch is always optically inactive. (3) Both of these oils have a specific gravity varying from 1.180 to 1.187 at 15° C. (59° F.). Both of them, as well as synthetic methyl salicylate, form a clear solution with five times their volume of 70 per cent alcohol, at 20° to 25° C. (68° to 77° F.). Neither the oil of gaultheria nor the oil of sweet birch contains any trace of benzoic acid or its esters, nor do they contain any terpene or sesquiterpene."

Volatile oil of betula "has the same properties and conforms to the same reactions and tests as methyl salicylate"—(*U. S. P.*). (See *Methyl Salicylas;* also *Oleum Gaultheriæ.*)

Action, Medical Uses, and Dosage.—Same as *Oleum Gaultheriæ* (which see).

OLEUM BUBULUM.—NEAT'S-FOOT OIL.

The oil obtained from the feet of the *Bos domesticus*.

Synonyms: *Oleum pedum tauri*, *Axungia pedum tauri*.

Preparation.—Having removed the skin and hoof from ox feet, subject them to the long-continued action of water at 100° C. (212° F.); the fatty matters which rise and float upon the surface must be skimmed off from time to time, placed into another portion of clear water, and the whole be heated to about 90.6° or 93.3° C. (195° or 200° F.). The oil again floats upon the surface, and may be taken therefrom. The oil may be still further purified, if necessary, by placing it in clean water, and subjecting it, for 20 or 25 hours, to a temperature which will be just sufficient to isolate the oil from its fat; upon the cooling of the water, and after the solidification of the fat, the thin oil which remains should be passed through a coarse charcoal filter.

Description.—Good neat's-foot oil has no smell, a mild taste, an oily feel, and is of a white or pale-yellowish color. According to Hager (*Handbuch*, 1886), it does not become rancid, even after a lapse of one year; its use for hair pomades is therefore suggested. Its specific gravity at 15° C. (59° F.) is 0.915. It does not readily solidify remaining fluid at very low temperatures, and is used for lubricating purposes, likewise by saddlers and shoemakers, to soften and preserve leather and prevent its cracking. Glycerin, oleic acid, and a small portion of stearic acid, are yielded upon saponification.

Action, Medical Uses, and Dosage.—This oil is emollient and relaxant, and may be applied with advantage to the breast and throat, in *croup* or *cough*, rubbing it on with brisk friction. It likewise enters into various extemporaneous liniments and poultices. Dr. C. R. Hall stated in the *London Journal of Medicine*, that he has used this oil in the place of cod-liver oil, in *tuberculous diseases* with much efficacy; the dose is the same as that of the cod-liver oil, and occasionally proves laxative. He found it especially useful among those patients with whom the fish oil occasioned nausea. The oil used was merely freed from foreign particles; it was of a yellowish-brown color, and thick and opaque with stearin, like honey not over clear. It does not, however, find favor at the present day, on account of its taste and odor, and its tendency to purge. It is now largely used for rendering leather soft and pliable.

OLEUM CADINUM (U. S. P.)—OIL OF CADE.

"A product of the dry distillation of the wood of *Juniperus Oxycedrus*, Linné (*Nat. Ord.*—Coniferæ)"—(*U. S. P.*).

SYNONYM: *Oleum juniperi empyreumaticum.*

Description and Chemical Composition.—"A brownish or dark-brown, clear, thick liquid, having a tarry odor, and an empyreumatic, burning, somewhat bitter taste. Specific gravity, about 0.990 at 15° C. (59° F.). It is almost insoluble in water, but imparts to it an acid reaction. It is only partially soluble in alcohol, but is completely soluble in ether, chloroform, or carbon disulphide"—(*U. S. P.*).

It is inflammable, and is prepared in France in a manner similar to that for making tar. Common juniper-wood oil is often substituted for it. Oil of cade contains phenols and large quantities of the sesquiterpene *cadinene* ($C_{15}H_{24}$) (Wallach, 1887).

Action, Medical Uses, and Dosage.—Oil of cade has been much used in France as a remedy in many *cutaneous affections*, as *prurigo*, *chronic eczema*, particularly of the moist variety, *psoriasis*, *pityriasis rubra*, and *favus*, and for the removal of *worms* (3 to 5 drops, several times a day). Probably our common tar will, as a substitute, prove fully as effectual. It is largely used upon animals. It may be used pure, or in ointment, liniments, soaps, or glycerites.

OLEUM CARBOLATUM (N. F.)—CARBOLIZED OIL.

Preparation.—"Carbolic acid, five grammes (5 Gm.) [77 grs.]; cotton-seed oil, ninety-five grammes (95 Gm.) [3 ozs. av., 154 grs.]. Melt the carbolic acid with a gentle heat, and mix it with the cotton-seed oil"—(*Nat. Form.*).

Action and Medical Uses.—(See *Acidum Carbolicum.*)

OLEUM CAJUPUTI (U. S. P.)—OIL OF CAJUPUT.

"A volatile oil distilled from the leaves of *Melaleuca Leucadendron*, Linne (*Nat. Ord.*—Myrtaceæ). It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

SYNONYMS: *Oleum cajeputi, Oil of cajeput, Oleum Wittnebianum.*

Botanical Source and History.—This oil is distilled from the leaves of *Melaleuca Leucadendron*, a tree growing in the Moluccas and adjacent islands. It is variously known as *White tea-tree, Broad-leaved tea-tree, Paper-barked tea-tree, Swamp tea-tree*, and *White-wood*. It is a small tree, with a tolerably erect but crooked trunk; a soft, thick, spongy, whitish, ash-colored bark; and scattered branches, with the slender twigs often drooping as completely as in the weeping willow (*Salix Babylonica*). The leaves are alternate, most frequently vertical, short-stalked, narrow-lanceolate, while young, sericeous, sometimes slightly falcate, entire, from 3 to 5 inches long, and from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch broad; and very aromatic when bruised. The flowers are ternate, sessile, small, white, scentless, in terminal and axillary, downy spikes; the bracts are solitary, lanceolate, silky, and caducous. Calyx urceolate. Corolla white and orbicular; filaments 30 to 40, much longer than the petals; anthers ovate-cordate, with a yellow gland on the apex. The style is somewhat longer than the stamens; the stigma obscurely 3-lobed. The capsules are 3-celled and 3-valved; the seeds numerous, and angularly wedge-shaped (L.). This tree is the *Melaleuca Cajuputi* of Roxburgh, and the *Melaleuca minor* of De Candolle. By Bentham, it is regarded as a variety of *Melaleuca Leucadendron*. Several other species of Melaleuca, as *M. latifolia*, *M. viridifolia*, and *M. hypericifolia*, yield closely related oils, while an extract prepared from the *M. paraguayensis* has been used in rheumatic and allied complaints.

Fig. 181.

Melaleuca Leucadendron.

Preparation and Description.—*Cajuput oil* is obtained by distillation of the leaves, which are collected in autumn, allowed to steep for a night in water, and then distilled in copper vessels. The yield is very small. It is imported from the East Indies in green-glass bottles. The *U. S. P.* describes it as "a light, thin, bluish-green, or, after rectification, colorless liquid, having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, bitterish taste. Specific gravity, 0.922 to 0.929 at 15° C. (59° F.). With an equal volume of alcohol it affords a clear solution, which either has a slightly acid reaction, or, in the case of the rectified oil, is neutral to litmus paper"—(*U. S. P.*). The odor of the oil has been stated to resemble the combined fragrance of camphor, rosemary, and cardamom. The green color is not essential, and may be removed by distillation; it is due chiefly to the presence of copper, and partly to the presence of some altered chlorophyll. The oil is slightly lævogyre. Sulphuric and nitric acids have but little action on cajuput oil.

Adulterations and Tests.—In consequence of its high price, oil of cajuput is subject to adulteration. Oils of rosemary or turpentine, combined with camphor and bruised cardamom seeds, and appropriately tinted with milfoil resin, have been sold as genuine oil. Oil of camphor has been used as an adulterant. Oils of lavender, origanum, and rosemary, frequently serve for adulteration, but are distinguished by the energetic action of a solution of iodine, besides, all would materially affect the nature of the residue of the iodine test subsequently described. "On shaking 5 Cc. of the oil with 5 Cc. of water containing a drop of diluted hydrochloric acid, the oil loses its green tint and becomes nearly colorless. If to this acid liquid, separated from the oil, a drop of potassium ferrocyanide T.S. be added, a reddish-brown color will usually be produced (presence of traces of copper). If 5 parts of the oil be heated to 50° C. (122° F.), and 1 part of powdered iodine gradually added, with avoidance of any further rise of temperature, the mixture, on cooling, will deposit a mass of crystals"—(*U. S. P.*).

Chemical Composition.—The chief constituent of cajuput oil is *cineol* (*cajeputene hydrate, cajeputol* $C_{10}H_{18}O$) (Blanchet, 1833; Wallach, 1884), *terpineol* ($C_{10}H_{18}O$), both free and as an ester of acetic acid, and small amounts of *terpenes*, such as *lævo-pinene.* The lowest fraction of the crude oil contained *valeric aldehyde* and *benzoic aldehyde* (Voiry, 1888). (For interesting details regarding this oil, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899.)

CINEOL (*Eucalyptol*, $C_{10}H_{16}O$) is a constituent of many essential oils. It is a colorless liquid, of a characteristic camphoraceous odor, optically inactive, boils at 177° C. (350.6° F.), congeals at a temperature slightly below the freezing point of water, and forms a characteristic addition product with hydrobromic acid which is decomposable by water into its constituents.

Action, Medical Uses, and Dosage.—Cajuput oil is a powerful diffusive stimulant, diaphoretic and antispasmodic. When swallowed, it occasions a warmth in the stomach, with an increased action of the pulse, and occasionally diaphoresis. It is very much valued in the islands of the Indian Ocean, the inhabitants of which employ it extensively in *rheumatism, palsy, epilepsy*, and many other diseases; using it both internally and as a local application. It may be advantageously employed internally in *chronic rheumatism, hysteria, colic, spasms* or *cramps of the stomach* or *bowels, cholera morbus, Asiatic cholera, congestive dysmenorrhœa, hiccough, nervous dysphagia*, in the *typhoid stage of fevers*, in *nervous vomiting*, and wherever a powerful stimulant is required. It also appears to be useful in removing *worms*, and in *chronic affections of mucous tissues*, being especially useful in *chronic laryngitis* and *chronic bronchitis*, as well as *catarrh of the bladder.* It should never be given internally when inflammation is present. Externally, it is very beneficial as an application to *rheumatic, neuralgic* and other *pains, nervous headache*, and may be used alone, or in combination with other oils. It has likewise been found efficient as a local application in *gutta rosea, parasitic* and other *cutaneous maladies.* Applied to the cavity of a carious tooth, it alleviates *toothache* The dose is from 1 to 10 drops, on sugar, in emulsion, or in sweetened brandy and water. Externally, it may be applied 3 or 4 times a day.

OLEUM CARI (U. S. P.)—OIL OF CARAWAY.

A volatile oil distilled from *Carum Carvi*, Linné.

Nat. Ord.—Umbelliferæ.

"It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYMS: *Oleum carui, Oleum carvi.*

Preparation and Description.—This oil is easily separated by distillation of the fresh fruit (caraway) with water, which yields from 3.2 to 3.6 per cent (Russian, wild), or 6 to 7 per cent (Hessian, wild). The Dutch fruit, cultivated, yields from 4 to 6.5 per cent (Schimmel & Co.'s *Report*, April, 1897). The residue from the distillation of caraway seeds is used as feed for cattle. When fresh-prepared the oil is colorless, but by keeping it becomes yellow, and ultimately brown. It produces right-handed rotation on a ray of polarized light (+75° to +85°). The official oil is described as "a colorless, or pale yellow, thin liquid, having the characteristic, aromatic odor of caraway, and a mild, spicy taste. Specific gravity. 0.910 to 0.920 at 15° C. (59° F.). Soluble in an equal volume of alcohol, this solution being neutral to litmus paper"—(*U. S. P.*). Oil of caraway is little soluble in 70 per cent alcohol, but dissolves clear in 3 to 10 volumes of 80 per cent alcohol. Its boiling point is between 175° and 230° C. (347° and 446° F.).

Chemical Composition.—Oil of caraway is chiefly composed of two constituents, the hydrocarbon *dextro-limonene* (Schweizer's *carvene*, 1841), and the ketone *dextro-carvone* ($C_{10}H_{14}O$, Völckel, 1840; Wallach, 1893), formerly called *carvol.* The latter is the peculiar odoriferous principle of oil of caraway, and occurs therein to the extent of 50 to 60 per cent. *Carvone* is official in the *German Pharmacopœia* under the name of *Oleum Carvi* or *Carvol*, specific gravity 0.96, boiling point 224° C. (435.2° F.); according to Schimmel & Co., 229° to 230° C. (444.2° to 446° F.) if mercurial column is surrounded by the vapors. *Carvone* is soluble in 20 parts of 50 per cent alcohol to a clear liquid; the presence of 2 per cent of *carvene* is indicated by turbidity (Schimmel & Co.). *Carvone*, if exposed to air, turns yellow, and then produces a red-violet coloration with a *diluted* solution of ferric chloride. *Carvone* is an unsaturated ketone, forms a crystallizable compound with hydrogen sulphide ($C_{10}H_{14}O.H_2S$), by means of which it can be isolated and purified; with *hydroxylamine* (NH_2OH) it forms a crystallizable, not very volatile *oxime* ($C_{10}H_{14}$:NOH), melting at 72° C. (161.6° F.). E. Kremers and O. Schreiner (*Pharm. Review*, 1896, p. 76) estimate the quantity of carvone in oil of caraway by converting it into the *oxime* and separating the latter from the volatile carvene by distillation with steam.

Carvone, when heated with sulphuric acid, phosphoric acid, chloride of zinc, or alkalies, etc., is converted into its isomer *carvacrol* (*isopropyl-ortho cresol*) which is also an isomer of *thymol*, the principal constituent of oil of thyme. Carvacrol occurs chiefly in *Oleum Origani* (which see), and occasionally in the oil of *Monarda punctata* (see *Monarda*).

Action, Medical Uses, and Dosage.—Oil of caraway is a warm diffusible stimulant and carminative. It is frequently used to allay the griping and sickening effects of medicines, also to increase their flavor. Like oil of anise it allays *flatulent colic*, and is a local anodyne. The dose is from 1 to 5 or 10 drops. *Carvacrol*, placed on cotton and introduced into the cavity of a *carious tooth*, is said to give prompt relief.

OLEUM CARYOPHYLLI (U. S. P.)—OIL OF CLOVES.

A volatile oil distilled from the immature flower-buds of *Eugenia aromatica* (Linné), O. Kuntze (*Eugenia caryophyllata*, Thunberg).

Nat. Ord.—Myrtaceæ.

"It should be kept in well-stoppered bottles, in a cool place, protected from the light"—(*U. S. P.*).

Preparation.—Oil of cloves is procured by submitting cloves, with water, to repeated distillation; to extract the whole of the oil from cloves, they must be subjected to repeated cohobations. The addition of common salt is often resorted to to raise the point of ebullition. On an average they yield from 17 to 22 per cent of volatile oil. At the present time nearly all the oil is produced by means of superheated steam. The bulk of the oil used in this country is distilled here from South American cloves. In Europe *clove-stalks* are said to furnish a portion of the oil. The yield from this source is 5.5 to 6 per cent, and the specific gravity 1.055 to 1.065 (Schimmel & Co.).

Description.—The official oil is described as "a pale-yellow, thin liquid, becoming darker and thicker by age and exposure to the air, having a strongly aromatic odor of cloves, and a pungent and spicy taste. Specific gravity, 1.060 to 1.067 at 15° C. (59°F.). Soluble in an equal volume of alcohol, this solution being slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid"—(*U. S. P.*). It is also dissolved by ether and the fixed oils. Nitric acid reddens it, and when the mixture is heated, oxalic acid is formed. It is one of the least volatile and most difficult to distill of all the volatile oils. It boils between 250° and 260° C. (482° and 500° F.). It sinks in water, and is sparingly soluble in it. Its optical rotation is slightly left-handed.

Chemical Composition.—The principal constituents of oil of cloves are *eugenol* (70 to 85 per cent), *aceto-eugenol* (2 to 3 per cent, Erdmann, 1897), the sesquiterpene *caryophyllene* constituting the remainder. *Eugenol* (*allyl-guaiacol*, $C_6H_3.C_3H_5.OCH_3.OH$) is a faintly yellowish liquid possessing a strong clove odor and a burning taste. It is heavier than water, its specific gravity being 1.072 at 14.5° C. (58.1° F.). By oxidation it yields *vanillin*, which is also a constituent of the oil. Like the typical phenol (carbolic acid), eugenol dissolves in solution of caustic alkalies, forming phenolates, whereby its odor is lost; the eugenol may be liberated again by the addition of acid. On account of its being an ortho-diphenol-derivative, it turns blue in alcoholic solution with ferric chloride (compare *Guaiacolum*). *Caryophyllene* ($C_{15}H_{24}$, Church, 1875; Wallach, 1892) is a colorless liquid of a faint odor; it forms a crystallizable compound with 1 molecule of water (*caryophyllene hydrate*, $C_{15}H_{26}O$), melting at 96° C. (204.8° F.). Caryophyllene also occurs in oil of copaiba. Minor constituents of oil of cloves are *salicylic acid* (Scheuch, 1863; Erdmann, 1897), *methyl alcohol, furfurol* (*furfur-aldehyde*, $C_4H_3O.CHO$), to the presence of which is probably due the turning brown of oil of cloves upon exposure, and *methyl-amyl-ketone*, having an ethereal fruit odor (see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899).

Tests.—The *U. S. P.* directs the following tests for oil of cloves: "When shaken with an equal volume of a concentrated solution of potassium hydrate, or of stronger ammonia water, it forms a semisolid, yellowish mass. If 2 drops of the oil be dissolved in 4 Cc. of alcohol, and a drop of ferric chloride T.S. added. a bright green color will be produced; and if the same test be made with a drop of dilute ferric chloride T.S., prepared by diluting the test-solution with four times its volume of water, a blue color will be produced which soon changes to yellow. If 1 Cc. of the oil be mixed with 2 Cc. of a mixture of 2 volumes of alcohol and 1 volume of water, it should form a clear and perfect solution (absence of petroleum, most fatty oils, oil of turpentine, and similar oils). If 1 Cc. of the oil be shaken with 20 Cc. of hot water, the water should show a scarcely perceptible acid reaction to litmus paper. If, after cooling, the aqueous layer be passed through a wet filter, the clear filtrate should yield, with a drop of ferric chloride T.S., only a transient grayish-green, but not a blue or violet color (absence of carbolic acid)"—(*U. S. P.*). A markedly lower specific gravity than that given above, points to the addition of lighter oils, as oil of turpentine, etc. Oil from clove-stalks is difficult to identify chemically; according to Gildemeister and Hoffmann (*loc. cit.*), it differs from oil of cloves in being devoid of *aceto-eugenol*.

The *eugenol* contents of oil of cloves may be determined quantitatively, according to H. Thoms (1891), by converting it into its benzoyl compound and weighing the latter; or, according to Umney (*Pharm. Jour. Trans.*, Vol. XXV. 1895, p. 950), by adding a 10 per cent (better a 4 to 5 per cent) solution of caustic potash to a definite quantity of the oil, and measuring the volume of the oil above the eugenol-potassium layer.

Action, Medical Uses, and Dosage.—Oil of cloves is stimulant and irritant, and is much used as a corrector of other medicines, and as an external counter-irritant. It is frequently inserted on cotton into the cavity of a carious tooth to alleviate *toothache*, and in the external auditory meatus to relieve *earache*. Its dose is from 2 to 5 drops on sugar, or in emulsion. One part of oil of cloves mixed with 3 parts of linseed oil, and given in doses of 6 or 8 drops in milk, 2 or 3 times a day, has been found useful in allaying pain, palpitation, and other annoying symptoms common to some forms of *heart disease*. It preserves mucilage of tragacanth prepared for adhesive purposes.

Derivatives of Eugenol.—EUGENOL-ACETAMIDE $C_6H_3.C_3H_3.OCH_3.OCH_2CONH_2$. This body is said to be obtained by the interaction of concentrated solution of ammonia and eugenol-acetic-ethyl-ether. It forms shining, crystalline needles or scales, which melt at 110° C. (230° F.). Water and alcohol dissolve it. It is reputed antiseptic and a local anæsthetic, acting somewhat like cocaine. It is a patented preparation (see *Pharm. Centralhalle*, 1892, p. 441).

BENZOYL-EUGENOL ($C_6H_3.C_3H_5[OCH_3]O.COC_6H_5$).—This compound forms colorless, odorless, slightly bitter needles, of a neutral reaction. It fuses at 70.5° C. (158.9° F.). Water scarcely dissolves it, but it is readily dissolved by hot alcohol, acetone, ether, and chloroform. It is recommended for the treatment of *tuberculous disorders*. It is patented.

CINNAMYL-EUGENOL ($C_6H_3.C_3H_5[OCH_3]O.CO[CH]_2C_6H_5$).—Tasteless, odorless, colorless, shining needles, fusing at 90° to 91° C. (194° to 195.8° F.). Hot alcohol, ether, acetone, and chloroform dissolve it. Its uses are the same as those of the preceding drug (see *Pharm. Centralhalle*, 1891, p. 366).

OLEUM CHENOPODII (U. S. P.)—OIL OF CHENOPODIUM.

"A volatile oil distilled from chenopodium. It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

SYNONYM: *Oil of American wormseed.*

Preparation, History, and Description.—Oil of wormseed is prepared in this country; that produced near the city of Baltimore is the most esteemed. It is obtained by distillation of the bruised seed or ripe tops of the plant with water, and when first obtained is of a light-yellow color, but becomes darker by age. It possesses the odor and taste of the plant, and has a varying specific gravity which may become higher by age. An oil of less strength is prepared in the western states from the leaves, stalks, and seeds of the matured plant, and probably possesses similar properties when given in larger doses. That from the seeds always commands the highest price. Thirteen ounces of the seeds gave 3½ drachms of volatile oil, according to Engelhardt, which corresponds to a yield of about 3.4 per cent. Gildemeister and Hoffmann (*loc. cit.*), however, report a much smaller yield from the seeds, namely, 0.6 to 1 per cent. The herb of *C. ambrosioides* yields 0.25 per cent of oil, of specific gravity 0.901 (Schimmel & Co.'s *Report*, April, 1897). The oil is soluble in alcohol and ether. The *U. S. P.* describes it as "a thin, colorless or yellowish liquid, having a peculiar, penetrating, somewhat camphoraceous odor, and a pungent and bitterish taste. Specific gravity, about 0.970 at 15° C. (59° F.). One Cc. of the oil should form a perfectly clear solution with 10 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water"—(*U. S. P.*). The oil is slightly lævo-rotatory.

Chemical Composition.—This oil has not been recently investigated. According to Garrigues (*Amer. Jour. Pharm.*, 1854, p. 404), it contains a hydrocarbon ($C_{10}H_{16}$), boiling at 176° C. (348.8° F.), probably *limonene*, and a body ($C_{10}H_{16}O$).

Action, Medical Uses, and Dosage.—This oil is used only as an anthelmintic. Its dose is from 3 to 6 drops for a child, repeated twice a day for 4 or 5 days, and then followed by an active cathartic. It forms the basis of several popular nostrums for *worms*. Poisonous effects have been observed, from its immoderate use. It has also been used in *dyspepsia of stomach and bowels*, and in certain *spasmodic nervous disorders*.

OLEUM CINNAMOMI (U. S. P.)—OIL OF CINNAMON.

"A volatile oil distilled from cassia cinnamon. It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Synonyms: *Oil of cassia, Oleum cinnamomi cassiæ, Oleum cassiæ, Chinese oil of cinnamon.*

Source, Preparation, and Description.—There are several oils of cinnamon the chief commercial varieties of which are the *Oil of Chinese Cinnamon*, and the *Oil of Ceylon Cinnamon;* the former alone is recognized by the present edition of the *U. S. P.*

I. Oleum Cinnamomi Zeylanici, *Oil of Ceylon cinnamon.*—Oil of cinnamon is obtained in Ceylon, by macerating refuse bark and chips, reduced to a coarse powder, in sea-water for two days, adding chloride of sodium, and then distilling off the water. Part of the oil floats, and the other part sinks in the water which comes over; the whole amounting on an average to 8 ounces from 80 pounds, avoirdupois, of recently prepared cinnamon (0.5 to 1 per cent, Schimmel & Co.). The color of oil of cinnamon is pale-yellow, or wine-yellow, which slowly passes to cherry-red. Its taste is at first sweetish, afterward burning and aromatic. It is readily soluble in alcohol, also clearly soluble in 3 parts of 70 per cent alcohol. Its specific gravity varies from 1.024 to 1.040 (about 1.040, *U. S. P.*, 1880). This oil has the finest aroma of all cinnamon oils; the chemical nature of the aromatic principle, however, is not known. The oil contains 65 to 75 per cent of *cinnamic aldehyde*, and about 4 to 8 per cent of *eugenol*, both of which form the heavy distillate; the lighter distillate contains the hydrocarbon *phellandrene*. This oil is often adulterated with the oil from the leaves, which are frequently distilled along with the bark; the oil of the leaves (1.8 per cent) is characterized by a much higher percentage of its *eugenol* contents (70 to 90 per cent), and consequently by a higher specific gravity (1.044 to 1.065).

II. Oleum Cinnamomi Cassiæ.—*Oil of cassia*, or *Chinese oil of cinnamon*, resembles the Ceylon oil in color, odor, and taste, but it is much inferior. Its chemical reactions are similar to those of the oil of cinnamon, as well as are its medicinal virtues. The Chinese oil is optically inactive, while the Ceylon oil is slightly lævo- or dextro-gyrate. According to Schimmel & Co. (*Report*, Oct., 1892), this oil is obtained mainly from cassia leaves mixed with stem, twigs, and refuse portions of the trees. Schimmel & Co. (*Semi-Annual Report*, Oct., 1892 and Oct., 1893) obtained by separate distillations of various parts of cassia, the following percentages of cinnamic aldehyde:

Part.	Per cent.	Yield of oil. Per cent.	Specific gravity.
Cassia bark.	88.9	1.5	1.035 at 20° C.
Cassia buds	80.4	1.55	1.026 at 20° C.
Cassia bud-sticks	92	1.64	1.046 at 15° C.
Cassia branch tops	90	0.2	1.045 at 15° C.
Cassia leaves	93	0.54	1.056 at 15° C.
Cassia leaves, leaf-stalks, and young twigs, mixed.	93	0.77	1.055

The *U. S. P.* describes the official oil as follows: "A yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor of cinnamon, and a sweetish, spicy, and burning taste. Specific gravity, 1.055 to 1.065 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid. When shaken with a saturated solution of sodium bisulphite, it solidifies to a crystalline mass. If 4 drops of the oil, contained in a test-tube, be cooled to 0° C. (32° F.), and then shaken with 4 drops of fuming nitric acid, crystalline needles or plates will be formed"—(*U. S. P.*). In the latter reaction, the cinnamic aldehyde of the oil and the nitric acid unite to form a decomposition product, decomposable by water.

Chemical Composition and Tests.—The chief constituent of cassia (*Chinese*) oil is *cinnamic aldehyde* ($C_6H_5CH{:}CHCHO$), discovered, in 1834, by Dumas and Péligot. It is a light-yellow liquid, of specific gravity 1.064 at 15° C. (59° F.), forming a crystallizable compound, as stated above, with nitric acid, also with sodium bisulphite. Upon the formation of this compound is based a method for the valuation of cinnamic aldehyde in oil of cassia, devised by Messrs. Schimmel & Co. (For a description of this process, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899.) Other constituents of oil of cassia are *cinnamyl-acetate* ($C_9H_9.C_2H_3O_2$) (Schimmel & Co., 1889), and 1 per cent of free *cinnamic acid*, formed by oxidation of cinnamic aldehyde. The presence of this acid causes corrosion of the leaden containers in which the oil is shipped. Oil of cassia was at one time much adulterated with colophony and petroleum. The *U. S. P.* directs the following tests: "If a portion of the oil be shaken with water, and the liquid passed through a wet filter, the clear filtrate should give, with a few drops of basic lead acetate T.S., a white turbidity, without a yellow color (absence of oil of cloves). If 4 drops of the oil be dissolved in 10 Cc. of alcohol, the subsequent addition of a drop of ferric chloride T.S. should produce a brown, but not a green or blue, color (absence of oil of cloves or of carbolic acid). If 1 Cc. of the oil be mixed with 3 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water, a clear solution should result; and if to this solution there be gradually added 2 Cc. of a saturated solution of lead acetate in a mixture of 3 volumes of alcohol and 1 volume of water, no precipitate should be produced (absence of petroleum, or of colophony)"—(*U. S. P.*). The latter test is that of Hirschsohn (1890).

Action, Medical Uses, and Dosage.—Oil of cinnamon is stimulant, aromatic, antispasmodic, and carminative. It is frequently used to modify the taste of medicines, and is given as a stimulant in *flatulent colic, cramps of the stomach, paralysis of the tongue*, etc. It exerts an influence upon the uterus, and is one of the most valuable of agents, in the form of alcoholic tincture, in *uterine hemorrhage*. The tincture of the bark is frequently administered for this purpose, but we know from experience, that although destitute of astringency, yet the tincture or essence of the oil has the same, if not a better action, in such cases; again it is an unsafe remedy to exhibit during pregnancy, as it is very apt to produce miscarriage. The essence, or even cordial of cinnamon, stimulates the generative organs, and produces an aphrodisiac influence. Tincture of oil of cinnamon combined with ergot, ipecac, erigeron, or lycopus, as indicated, is an excellent remedy for *hemoptysis*. The dose of oil of cinnamon is 1 or 2 drops, given in emulsion; of the essence from ½ to 1 fluid drachm, given in a wine-glass of sweetened water. Ten drops of oil of cinnamon added to a fluid drachm of olive oil, gently heated and rubbed upon the spine, will frequently quiet a restless, fretful child suffering with *flatulence* or *colic*, and cause it to sleep; if the rubefacient power requires to be increased, 10 drops of aqua ammoniæ may be added.

Related Oils.—OLEUM CINNAMOMI RADICIS, *Oil of cinnamon root.* Distilled from the root-bark of *Cinnamomum Zeylanicum*, Breyn. This oil is nearly colorless, has a cinnamon-like and camphoraceous odor, and a camphor-like taste. It is not so heavy as water, and at ordinary temperature separates common camphor. It also contains *cinnamic aldehyde*.

OLEUM CINNAMOMI FOLIORUM, *Oil of cinnamon leaves.* Distilled from the leaves of *Cinnamomum Zeylanicum.* This is a bright, limpid, pale-yellow oil, with a combined cinnamon-clove odor. Its constituents are *eugenol*, *safrol*, and *cinnamic aldehyde*, sometimes replaced by *benzaldehyde* (also see *Oleum Cinnamomi Zeylanici*).

OIL OF CINNAMON from the bark of a north Indian tree, the *Cinnamomum Wightii*, of Meissner, is highly aromatic, has a specific gravity of 1.01, and boils between 130° and 170° C. (266° and 338° F.). The yield is 0.3 per cent (Schimmel & Co.).

OLEUM COCOS.—COCOANUT OIL.

The fixed oil obtained from *Cocos nucifera*, Linné.

Nat. Ord.—Palmæ.

SYNONYMS: *Oleum cocois, Cocoanut butter.*

Botanical Source and History.—The cocoanut tree (*Cocoanut palm*) yields the cocoanut (properly coconut), much used in this country for culinary purposes, and in the confectioner's art. The tree is met with in most tropical climes, growing from 50 to 100 feet high. The narrow, long, rigid leaflets compose the leaves, which are of great length (12 feet or more), and borne in a cluster at the apex of the tall trees. The flowers are yellowish-white and the fruits, borne in clusters of from 10 to 20, are the well-known cocoanuts. When unripe they are filled with a sweetish liquid. As many as 120 of these large nuts are sometimes to be found on the tree. The uses of the cocoanut palm, and its products, are probably more extensive than those of any other plant. (For an account of its varied uses, see *Practical Flora*, by O. R. Willis; *Useful Native Plants of Australia*, by Maiden; *Treasury of Botany;* and *Materia Medica of Western India*, by Dymock.) The oil is obtained by boiling in water, or preferably by hot expression.

Description.—*Cocoanut oil* must not be confused with *palm oil*, or with *cacao butter*. It is white, butyraceous, of a mild, bland taste, and a peculiar odor. It is capable of forming a hard, white soap, which is not precipitated by salt, and therefore may be used with sea-water. On exposure to the atmosphere, it becomes rancid. Its melting point ranges from 20° to 28° C. (68° to 82.4° F.), the cold expressed oil having the lowest melting point. When fused it is thin, yellowish, and transparent, congealing again between 14° and 23° C. (57.2° and 73.4° F.). It may retain its fluidity for many days after having been subjected to a heat of 240° C. (469° F.). The soap combines with much water when mixed with it near the congealing point.

Chemical Composition.—This oil contains a small amount of oleic acid, as glyceride (*olein*). The bulk of the oil consists of a glyceride sometimes called *coconin* (*cocinate of glycerin*), which is a mixture of several glycerides (Oudemans), chiefly *laurin*, the glycerin ester of lauric acid. *Myristin*, *palmitin*, and *stearin* are likewise present, as well as the glycerides of caproic, caprinic, and caprylic acids. The oil is separable by hydraulic pressure into a solid portion utilized in candle-making, and an oily portion used for salad dressings, illuminating purposes, the manufacture of soaps, etc.

Action, Medical Uses, and Dosage.—Besides the commercial uses above referred to, cocoanut oil has been employed, but without success, as a substitute for cod-liver oil. The dose is about ½ ounce.

OLEUM COPAIBÆ (U. S. P.)—OIL OF COPAIBA.

"A volatile oil distilled from copaiba. It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Preparation.—The oil is obtained by distilling copaiba balsam with water. "Take of copaiba, 12 ounces; water, 2 gallons. Distill, preserving the water;

when most of the water has passed over, heat, return it into the still, and resume the distillation; repeat this process so long as a sensible quantity of the oil passes over with the water" (*Ed.*).

Description and Chemical Composition.—The more recent the copaiba balsam, the greater the amount of volatile oil obtained. Usually about 33 to 50 per cent of oil may be distilled from copaiba, and it is stated that one specimen yielded 80 per cent (*Amer. Jour. Pharm.*, Vol. XXII, p. 289). It is inflammable, soluble in ether and sulphide of carbon; its boiling point is 243.3° C. (470° F.); it dissolves caoutchouc; absorbs hydrochloric acid gas, artificial camphor being deposited in crystals. The *U. S. P.* describes the oil as "a colorless or pale yellowish liquid, having the characteristic odor of copaiba, and an aromatic, bitterish, and pungent taste. Specific gravity, 0.890 to 0.910 at 15° C. (59° F.), increasing with age. Soluble in about ten times its volume of alcohol, forming a slightly turbid liquid, which is neutral to litmus paper"—(*U. S. P.*). Potassium may be preserved in the oil unchanged. When dropped on iodine, hydriodic acid is produced with sudden development of heat. It dissolves sulphur, iodine, and phosphorus, and is converted into a resinous substance by nitric and sulphuric acids. It has a left-handed optical rotation. It is composed mainly of the hydrocarbon *caryophyllene* ($C_{15}H_{24}$). (Compare *Oil of Cloves;* also see *Copaiba.*)

Action, Medical Uses, and Dosage.—The oil of copaiba exerts an influence upon the system similar to that of copaiba, to which it is preferred on account of the smaller dose required, and its non-tendency to cause nausea. It enters into many of the nostrums of the day for the cure of *gonorrhœa.* It is also reputed useful in *bronchial catarrh.* The dose is 10 or 20 drops, which should be given in syrup, peppermint, or cinnamon water, mucilage, or emulsion.

OLEUM CORIANDRI (U. S. P.)—OIL OF CORIANDER.

A volatile oil distilled from the fruit of *Coriandrum sativum*, Linné.

Nat. Ord.—Umbelliferæ.

"It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Preparation.—This is obtained by distilling ground coriander fruit with water or by steam. The yield ranges from 0.2 per cent (East Indian) to 0.8 to 1 per cent (Russian) (Schimmel & Co.).

Description and Chemical Composition.—"A colorless or slightly yellowish liquid, having the characteristic, aromatic odor of coriander, and a warm, spicy taste. Specific gravity 0.870 to 0.885 at 15° C. (59° F.). One Cc. of the oil forms a perfectly clear solution with 3 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water, the solution being neutral to litmus paper. The oil is also soluble in an equal volume of glacial acetic acid"—(*U. S. P.*). The oil is dextrogyrate (+4° to +13°) and contains about 5 per cent of *dextro-pinene;* the bulk consists of the dextro-rotatory modification of *linalool* ($C_{10}H_{18}O$), formerly called *coriandrol.* Neither of these constituents nor their mixture exhibits the peculiar odor of coriander. The flowering herb distilled yields an oil of a repulsive bedbug odor, which disappears, however, upon standing.

Action, Medical Uses, and Dosage.—This oil is carminative, aromatic, and anodyne. It may be used locally for *neuralgic* and *rheumatic pains*, and internally for *flatulent colic, cramps*, etc. It gives an agreeable flavor to many medicines, senna in particular. Dose, from 1 to 5 drops.

OLEUM CUBEBÆ (U. S. P.)—OIL OF CUBEBS.

A volatile oil distilled from the fruit of *Piper Cubeba*, Linne filius.

Nat. Ord.—Piperaceæ.

"It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

Preparation, Description, and Chemical Composition.—Cubebs ground and distilled with water, furnish from 10 to 18 per cent of this oil. The bulk of the oil boils between 250° and 280° C. (482° and 536° F.). It is lighter than water, of specific gravity 0.910 to 0.930 (Schimmel & Co.), and thickens on exposure to the air without losing its odor; occasionally it deposits crystals which are called cubeb camphor ($C_{15}H_{24}H_2O$). This camphor is deposited in old oil, or in that distilled from old fruit. Oil of cubeb is officially described as "a colorless, pale greenish, or yellowish liquid, having the characteristic odor of cubeb, and a warm, camphoraceous, aromatic taste. Specific gravity, about 0.920 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper"—(*U. S. P.*). It contains some *dipentene* ($C_{10}H_{16}$), but is composed mainly of *cadinene* ($C_{15}H_{24}$).

Action, Medical Uses, and Dosage.—Oil of cubebs may be substituted for the powdered berries, in many instances with benefit. It is less pungent than the oleoresin or fluid extract, and is probably only one of the active principles of cubebs. The dose is 10 or 12 drops, 3 times a day, gradually increased, as the stomach will permit, or until it produces some decided results. It may be given in syrup, emulsion, or in the form of capsules, like copaiba.

OLEUM ERECHTITIS.—OIL OF FIREWEED.

Botanical Source and Description.—This oil is obtained by distilling the plant *Erechtites hieracifolia* with water. Thus obtained, it is quite fluid, transparent, yellowish, of a strong, peculiar, fetid, and slightly aromatic odor, and a fetid, bitterish, burning taste. In its odor and taste it somewhat resembles the oil of fleabane. It is soluble in ether, alcohol, and partially in acetic acid; its specific gravity, according to Prof. Power (*Pharm. Rundschau*, Vol. V, 1887, p. 201), is 0.838 at 18.5° C. (65.3° F.). According to Beilstein and Wiegand (1882), its chief constituent is a terpene ($C_{10}H_{16}$), boiling at 175° C. (347° F.). The oil of commerce is liable to be mixed with oil of fleabane (see *Oleum Erigerontis;* also see A. M. Todd, *Amer. Jour. Pharm.*, 1887, p. 302, and *Drugs and Med. of N. A.*, Vol. II, pp. 126–140).

Action, Medical Uses, and Dosage.—The therapeutical action of oil of fireweed is not well understood. It seems to resemble the oil of fleabane in its influence upon various *hemorrhages*, and for which agent it is frequently substituted, and is considered by many to be the most efficient in such cases, of the two oils. It also exerts a beneficial effect on mucous surfaces, and has been successfully used in *diarrhœa*, *dysentery*, *hemorrhoids*, etc. As an antispasmodic it has been found of value in *spasms of the stomach and bowels*, *colic*, *hiccough*, *hysteria*, and *pertussis*, though it is apt to disagree with the stomach, causing nausea, etc. It is chiefly employed for the same purposes as the oil of fleabane. The dose is from 5 to 20 drops on sugar, or in emulsion. When triturated with the extract of stramonium, oil of fireweed is said to form a valuable preparation for *piles*.

OLEUM ERIGERONTIS (U. S. P.)—OIL OF ERIGERON.

"A volatile oil distilled from the fresh flowering herb of *Erigeron canadense*, Linné (*Nat. Ord.*—Compositæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYMS: *Oil of fleabane, Oleum erigerontis canadensis* (*U. S. P.*, 1870), *Oil of Canada fleabane.*

Preparation, History, and Description.—This oil is obtained by distillation of the leaves and flowers of fleabane (*Erigeron canadense*) with water. When freshly obtained it is colorless, or of a light-yellow color, and transparent; both the odor and taste recall to mind those of oil of spearmint, combined with oil of amber. The oil is inflammable, burning with an abundant, sooty flame. The *U. S. P.* describes this oil as "a pale-yellow, limpid liquid, becoming darker and thicker by age and exposure to the air, having a peculiar, aromatic, persistent odor and an aromatic, slightly pungent taste. Specific gravity, about 0.850 at 15° C. (59° F.), increasing with age. Soluble in an equal volume of alcohol (distinction from oil of fireweed [derived from *Erechtites hieracifolia*, Rafinesque, *Nat. Ord.*—Compositæ] and from oil of turpentine), this solution being neutral or slightly acid to litmus; also soluble in an equal volume of glacial acetic acid. It distills for the most part between 175° and 180° C. (347° and 356° F.)"—(*U. S. P.*). Oil of erigeron was introduced into practice by Eclectic physicians.

Chemical Composition.—This oil is mainly composed of *dextro-limonene* (see Fritz W. Meissner, *Amer. Jour. Pharm.*, 1893, p. 420), and *terpineol* (Kremers and Hunkel, *Pharm. Rundschau*, Vol. XIII, 1895, p. 137).

Action, Medical Uses, and Dosage.—Oil of fleabane is hæmostatic, stimulant, and carminative, with scarcely any perceptible astringency. It appears, notwithstanding, to exert a very remarkable influence on the system in *hemorrhages*, to check which it is chiefly used. It is of superior value in all hemorrhages, but more especially when from the uterus. Further investigations with this remedy are required in order to know its proper therapeutic action. The dose is from 2 to 10 drops, dissolved in alcohol, and administered in mucilage or sweetened water. It should be repeated, according to circumstances, every 15 or 30 minutes, or every 1, 2, or 4 hours. Combined with 5 or 6 parts of castor oil, or of stramonium ointment, it forms a valuable application to *piles.* (For further uses, see *Erigeron.*)

OLEUM EUCALYPTI (U. S. P.)—OIL OF EUCALYPTUS.

"A volatile oil distilled from the fresh leaves of *Eucalyptus globulus*, Labillardière; *Eucalyptus oleosa*, F. von Mueller, and some other species of *Eucalyptus* (*Nat. Ord.*—Myrtaceæ). 'It should be kept in well-stoppered bottles, in a cool place, protected from the light"—(*U. S. P.*).

History and Description.—When the leaves are distilled with steam, and the distillate purified by treatment with caustic soda solution and again rectified, a fragrant, yellowish oil is obtained, which becomes brown and resinous from oxidation, when exposed to the atmosphere. *Eucalyptus tar* is the soap-like, brown residue from the purification of the crude oil with caustic soda. It is sometimes used as a cheap disinfectant. The flower buds yield eucalyptus oil in great quantity, and even when dry are found to contain numbers of large oil glands filled with oil. As described by the *U. S. P.*, it is "a colorless or faintly yellowish liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity, 0.915 to 0.925 at 15° C. (59° F.). Soluble, in all proportions, in alcohol, carbon disulphide, or glacial acetic acid. Its alcoholic solution is neutral, or slightly acid, to litmus paper. If 1 Cc. of the oil be mixed with 2 Cc. of glacial acetic acid, and 1 or 2 Cc. of a saturated, aqueous solution of sodium nitrite be gradually added, the mixture, when gently stirred, should not form a crystalline mass (distinction from oils of eucalyptus containing a considerable portion of phellandrene)"—(*U. S. P.*). The oil, if rich in cineol, solidifies when surrounded by a freezing mixture; it dissolves resins readily, but does not dissolve gutta-percha. The oils of various species of Eucalyptus differ in many respects. Since 1854, the manufacture of eucalyptus oil has been established in Australia by Joseph Bosisto, and it is now an article of considerable commerce. (In this connection, see an interesting article by Mr. E. M. Holmes, on the manufacture, etc., of eucalyptus oil, in *Pharm. Jour. Trans.*, Vol. XXV, 1894, p. 501.) Large quantities of the oil are now also produced in Algeria.

Chemical Composition.—The oil of *Eucalyptus globulus* contains *cineol* ($C_{10}H_{18}O$, Jahns, 1884), formerly called *eucalyptol* (Cloëz, 1870). It is the chief constituent of this oil, as well as oil of cajuput (which see), and occurs in smaller quantities in a number of other oils (see enumeration, in Gildemeister and Hoffmann, *loc. cit.*). It is a colorless fluid of a characteristic camphoraceous odor, and crystallizing slightly below the freezing point of water. It boils at 177° C. (350.6° F.), and is optically inactive. It forms crystallizable addition compounds, chiefly with hydrobromic acid gas and with concentrated phosphoric acid, which serve in the isolation, and perhaps the quantitative determination of cineol.

The oil of Eucalyptus globulus also contains the hydrocarbon *dextro-pinene* (Wallach and Gildemeister, 1884), formerly called *eucalyptene*, and other hydrocarbons. The crude oil contains *valeric*, *butyric*, and *caproic aldehydes*, to which the acrid odor of the oil is due. The oil of the Australian *E. amygdalina*, Labillardière, or *White* and *Brown peppermint tree*, contains chiefly *phellandrene*, with little cineol. The aldehyde *citronellal* ($C_{10}H_{18}O$) is the principal constituent (80 to 90 per cent) of the oil of *E. citriodora*, Hooker, and other species; and *citral* ($C_{10}H_{16}O$) is found in large quantity in the oils from *Eucalyptus Staigeriana*, F. von Mueller, and *Backhousia citriodora*, F. von Mueller. *E. oleosa*, F. von Mueller, contains *cineol* and *cumin-aldehyde*. (For abundant information regarding eucalyptus oils, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899.)

Action, Medical Uses, and Dosage.—(For uses, see *Eucalyptus*.) Dose, 2 to 10 drops.

OLEUM FŒNICULI (U. S. P.)—OIL OF FENNEL.

"A volatile oil distilled from *Fœniculum capillaceum*, Gilibert (*Fœniculum vulgare*, Gaertner) (*Nat. Ord.*—Umbelliferæ). It should be kept in well-stoppered bottles, in a cool place, and, if it has partly or wholly solidified, it should be completely liquefied by warming before being dispensed"—(*U. S. P.*).

Description.—Oil of fennel is prepared from bruised fennel seeds, by distillation with water. The yield from different sources (Saxon, Galician, Moravian, Roumanian) varies from 4 to 6 per cent. As officially described, the oil is "a colorless or pale-yellowish liquid, having the characteristic, aromatic odor of fennel, and a sweetish, mild, and spicy taste. Specific gravity, not less than 0.960 at 15° C. (59° F.). Between 5° and 10° C. (41° and 50° F.) it usually solidifies to a crystalline mass, but occasionally it remains liquid at a considerably lower temperature. Soluble in an equal volume of alcohol, the solution being neutral to litmus paper; also soluble in an equal volume of glacial acetic acid"—(*U. S. P.*).

Chemical Composition and Tests.—Oil of fennel contains from 50 to 60 per cent of *anethol* (see *Oleum Anisi*) which crystallizes out upon cooling, and *dextro-fenchone* ($C_{10}H_{16}O$, Wallach and Hartmann, 1890), an oily, camphoraceous ketone of bitter taste, solidifying above the temperature of melting ice, boiling at 192° to 193° C. (377.6° to 379.4° F.) and forming with hydroxylamine a crystallizable *oxime* ($C_{10}H_{16}$:N.OH), characterized by its melting point, 164° to 165° C. (327.2° to 329° F.). Furthermore, *dextro-pinene* and *dipentene* are present. Tardy (1897) found in a specimen of French fennel oil, in addition, *methyl-chavicol* (see *Oleum Anisi*), and perhaps *anise-ketone* ($C_6H_4.OCH_3.CH_2COCH_3$). The relative amounts of these constituents vary according to the geographical sources of the oil; thus, fenchone is entirely absent in sweet or Roman fennel from southern France and Macedonia, while Sicilian fennel (*Fœniculum piperitum*, De Candolle) contains but traces of anethol. Oil of bitter fennel, growing wild in France, Spain, and Algeria, contains principally *dextro-phellandrene*, and traces of fenchone and anethol. According to Gildemeister and Hoffmann (*Die Ætherischen Oele*, p. 740), oil of fennel from which part of its anethol is removed by refrigeration, does not solidify at or above 3° C. (37.4° F.). An addition of alcohol or oil of turpentine reduces the specific gravity of the oil. The specific gravities, according to Schimmel & Co. (*Report*, April, 1897), range from 0.920 (Spanish fruit) to 0.987 (Asia Minor or Aleppo fruit). The *U. S. P.* gives the following tests for the purity of oil of fennel: "The oil is not colored by the addition of a drop of ferric chloride T.S. (absence of some foreign oils containing phenols, and of carbolic acid). If the oil be dropped into water, without agitation, it should not produce a milky turbidity (absence of alcohol)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Oil of fennel is principally used as a carminative, and for the purpose of correcting or concealing the unpleasantness of other medicines. It is emmenagogue, and increases the lacteal secretions. The dose is from 5 to 20 drops.

OLEUM GAULTHERIÆ (U. S. P.)—OIL OF GAULTHERIA.

"A volatile oil distilled from the leaves of *Gaultheria procumbens*, Linné (*Wintergreen*, *Nat. Ord.*—Ericaceæ), consisting almost entirely of methyl salicylate ($CH_3C_7H_5O_3$ = 151.64), and nearly identical with volatile oil of betula. It should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

SYNONYMS: *Oil of wintergreen*, *Oil of teaberry*, *Oil of partridgeberry*.

History.—This volatile oil is not peculiar to gaultheria alone, but has been derived also from the bark of *Betula lenta*, the root of *Polygala paucifolia*, and the stems and roots of *Spiræa Ulmaria*, *Spiræa lobata*, the leaves of *Gaultheria hispidula*, *Gaultheria leucocarpa*, *Gaultheria punctata*, and from *Monotropa Hypopitys*. Gaultheria procumbens is a small, herbaceous plant, growing in the United States along the Atlantic coast as far south as Georgia and Alabama, and westward as far as Minnesota. The oil was first distilled early in this century, in the states of Pennsylvania, New Jersey, and New York, but its production has gradually been superseded, to a great extent, by the distillation of the oil from *Betula lenta*, and later by the manufacture of artificial methyl salicylate, which is the chief constituent of both oils, a fact discovered almost simultaneously by Wm. Procter, Jr. (1842), and Cahours, in France (1844). Oil of gaultheria was first mentioned in American literature by Jacob Bigelow, in 1818 (see historical notes in *Pharm. Review*, 1898, p. 176; and especially Dr. Frederick Hoffmann, in *Die Ætherischen Oele*, 1899, p. 765).

Description.—"A colorless or yellow, or occasionally reddish, liquid, having a characteristic, strongly aromatic odor, and a sweetish, warm, and aromatic taste. Specific gravity, 1.175 to 1.185 at 15° C. (59° F.). Boiling point, 218° to 221° C. (424.4° to 429.8° F.). It deviates polarized light slightly to the left. In other respects it has the same properties and conforms to the same reactions and tests as methyl salicylate (see *Methyl Salicylas;* also *Oleum Betulæ Volatile*)"—(*U. S. P.*). Oil of gaultheria is the heaviest essential oil known. It dissolves in 6 parts of 70 per cent alcohol, which is not the case if the oil is adulterated with petroleum oil. An addition of the latter also reduces the specific gravity of the oil. Its odor distinctly differs from that of synthetic methyl salicylate. The only physical difference between the oils of gaultheria and sweet birch, consists in the optical inactivity of the latter.

Chemical Composition.—According to Power and Kleber (*Pharm. Rundschau*, 1895, p. 228), 98.05 per cent of the oil consists of methyl salicylate, and may be removed by shaking the oil with solution of caustic potash (7.5 per cent); this converts the salicylate into the water-soluble potassium-methyl-salicylate ($C_6H_4.OK.COOCH_3$). The remainder, a semisolid, insoluble mass, was differentiated into the paraffin *triacontan* ($C_{30}H_{62}$); an aldehyde or ketone, possessing the odor of œnanth-aldehyde; its corrresponding alcohol ($C_8H_{16}O$); and an ester ($C_{14}H_{24}O_2$), saponifiable into the same alcohol ($C_8H_{16}O$), and an acid ($C_6H_{10}O_2$). Both alcohol and ester possess the characteristic odor of wintergreen not to be found in the artificial oil (Gildemeister and Hoffmann, *loc. cit.*). The terpene *gaultherilene*, observed by Cahours (1844) in the quantity of 10 per cent, must have been due to an adulteration of his specimen with oil of turpentine. Oil of gaultheria, according to recent investigations (see *Oleum Betulæ Volatile*), is formed in the plant by decomposition of the glucosid *gaultherin*, under the influence of a peculiar ferment; but some oil, at least, must exist ready-formed, judging from the odor it emits when rubbed between the fingers.

Action, Medical Uses, and Dosage.—This oil is stimulant and aromatic, and is largely employed to correct or disguise the taste of other medicines. The essence, or the oil dissolved in alcohol, is stated to have been found effectual in curing *intermittent fever*. Oil of wintergreen possesses decidedly active properties, and in ½ ounce doses has produced death. It acts much like salicylic acid, but death is preceded by coma. Congestion of the kidneys, stomach, and duodenum, and black fluid blood, are revealed upon autopsy. The symptoms produced are drowsiness, cerebral congestion with throbbing of the arteries, delirium, visual impairment with contracted or dilated pupils, tinnitus, paresis, somnolence and coma. Oil of wintergreen has been more recently largely employed in *gonorrhœa*, and in *gonorrhœal* and other forms of *rheumatism*, in *trigeminal neuralgia, tic douloureux*, and in *subacute* and *chronic cystitis*. As large doses as can be borne should be given in rheumatic disorders, but like salicylic acid and the salicylates its action upon the heart must be closely watched. Locally used, it relieves pain. The dose of the oil is from 5 to 10 to 30 drops on sugar, in capsules, or in emulsion.

OLEUM GOSSYPII SEMINIS (U. S. P.)—COTTON-SEED OIL.

"A fixed oil expressed from the seed of *Gossypium herbaceum*, Linne, and of other species of *Gossypium* (*Nat. Ord.*—Malvaceæ), and subsequently purified. It should be kept in well-closed vessels"—(*U. S. P.*).

SYNONYMS: *Oleum gossypii, Oil of cotton, Cotton oil.*

Source and Preparation.—Cleaned cotton seeds are about ⅓ inch long and ⅙ inch wide, irregularly ovoid, covered with a hard, somewhat fragile, brown testa marked with a conspicuous raphè. Internally, the cotyledons are folded, and, imbedded throughout their substance are a number of resin-glands of a blackish color. The embryo is whitish. To obtain the oil, of which 2 gallons are yielded by 1 bushel of the seeds, the testa is crushed by machines especially designed for this purpose, the fragments winnowed out, the kernel ground, placed in bags, and expressed by powerful hydraulic pressure.

Purification.—Cotton-seed oil, when freshly expressed, is thick, turbid, of a ruby-red to dark-brown color, and contains much albuminous matter. Upon standing it deposits a considerable quantity of its impurities, leaving the oil as a clear orange-yellow liquid. This is known as *clarified oil.* The albuminous constituents may be coagulated by heating the oil by means of boiling water. Another method of purifying the crude oil consists in agitating the oil in the cold with a weak solution of caustic soda, which removes the characteristic coloring matter of the oil (see *Chemical Composition*), and forms with part of the oil a soap which settles upon standing, in the form of a black deposit. Thus the oil becomes of a much lighter color and constitutes *refined oil.* The loss by this process is about 4 to 7 per cent, sometimes considerably more. Bleaching agents are also frequently employed in the refining of cotton-seed oil.

Description and Tests.—This oil is officially described as "a pale yellow, oily liquid, without odor, and having a bland, nut-like taste. Specific gravity, 0.920 to 0.930 at 15° C. (59° F.). Very sparingly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide. On cooling the oil to a temperature below 12° C. (53.6° F.), particles of solid fat will separate. At about 0° to —5 C. (32° to 23° F.), the oil solidifies"—(*U. S. P.*).

This oil stands intermediate between the non-drying and drying oils; it thickens upon exposure, but does not become solid. Strong solutions of alkalies readily saponify cotton-seed oil. Purified cotton-seed oil is largely employed for culinary purposes, *e. g.*, as salad oil, as a butter substitute, one of its chief uses being to adulterate other oils, especially olive oil. It also serves in the manufacture of soap, in the preparation of woolen and Morocco leather goods, and has taken a prominent place in pharmaceutical preparations, displacing, in a measure, olive and almond oils. The crude oil may be easily recognized by the beautiful purple or violet coloration (*cotton-seed blue*) which the soap prepared from it assumes upon exposure to the air. For the purified cotton-seed oil there are several color tests, in addition to the requirements of specific gravity and other physical constants. A red color is observed upon treating the oil with strong solution of lead acetate and allowing it to stand; S. S. Bradford (*Amer. Jour. Pharm.*, 1882, p. 481) regards it an easy test for the detection of this oil as an adulterant of olive oil. The *U. S. P.* tests are as follows: "When the oil is brought in contact with concentrated sulphuric acid, a dark reddish-brown color is instantly produced. If 6 Gm. of the oil be thoroughly shaken, in a test-tube, for about 2 minutes, with a mixture of 1.5 Gm. of nitric acid and 0.5 Gm. of water, then heated in a bath of boiling water for not more than 15 minutes, the oil will assume an orange or reddish-brown color, and, after standing for 12 hours at the ordinary temperature, will form a semisolid mass. If 5 Cc. of the oil be thoroughly shaken, in a test-tube, with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol and adding 2 drops of nitric acid), and the mixture heated for about 5 minutes in a water-bath, the oil will assume a red or reddish-brown color."—(*U. S. P.*). The second of these includes the elaïdin test; the third is Becchi's test. Halphen's test, introduced in 1897, seems to be very delicate. According to A. H. Allen (*Commercial Organic Analysis*, Vol. II, Part I, 3d ed., 1889, p. 143), it is executed as follows: Carbon disulphide, containing about 1 per cent of sulphur in solution, is mixed with an equal volume of pentyl (amyl) alcohol. Equal volumes of this reagent and the sample—about 3 Cc. of each—are mixed and heated in a bath of boiling brine for 15 minutes. A red or orange tint is produced when cotton-seed oil is present. If the color is not produced, 1 Cc. more of the reagent is added, and heating continued for 5 or 10 minutes longer; in the absence of color, the addition is repeated once more.

Chemical Composition.—This oil is composed mainly of *palmitin* and *olein*. *Cotton-seed blue* ($C_{17}H_{24}O_4$), an amorphous body, has been obtained by Kuhlmann (1861) as an oxidation product of a chromogene contained in the oil. Exposure to light and air bleaches the blue substance, while oxidizers wholly destroy it. It dissolves in strong sulphuric acid with a purple color, is also soluble in ether and alcohol, while chloroform and carbon disulphide sparingly dissolve it. It is insoluble in water, diluted acids, and alkalies. The chromogene body, according to J. Longmore, is a pungent, golden-yellow substance insoluble in water, soluble in alcohol and alkalies. insoluble in acids. It is a fast dye for wool and silk (see A. H. Allen, *loc. cit.*).

Action, Medical Uses, and Dosage.—This oil is a wholesome and digestible food, and is employed in pharmacy, medicine, and surgery, for many of the purposes for which olive oil is employed. Dose, 1 fluid drachm to 2 fluid ounces.

Related Oils.—OIL OF BRAZIL NUTS. The tree, whose seed yields this oil, is the handsome South American *Bertholletia excelsa*, of Humboldt and Bonpland (*Nat. Ord.*—Lecythidaceæ). It is known to the Brazilians as *castanhiero de Para*, and the seeds are edible and an article of commerce under the names of *Brazil* or *Para nuts*. These nuts are the seeds of a large globular fruit nearly a foot in diameter, from 16 to 20 seeds being contained in 1 fruit. Brazil nuts are long (1½ to 2 inches), triangular, convex on back, and have a rough, hard, brownish-gray testa, inclosing a kernel of a creamy white hue, and tasting somewhat like almonds. It is considerably used in making a cream-syrup for soda fountain uses. The kernels yield over 60 per cent of a fixed oil used by the natives as a burning fluid, as an adulterant of copaiba, and in unguents. It is a bland oil of a light-yellow color, readily becoming rancid. At —1° C. (30° F.) it congeals. It is composed chiefly of olein, palmitin, and stearin.

OIL OF SAPUCAYA NUTS.—An oil similar to Brazil-nut oil is obtained from the nuts (*Sapucay nuts*) of *Lecythis Zabucajo*, Aublet, a Brazilian tree.

OLEUM FAGI, *Beech oil*, *Beech-nut oil*.—The fruit of the beech tree of Europe (*Fagus sylvatica*, Linné (*Nat. Ord.*—Cupuliferæ), yields a yellow oil, mild if prepared by cold expression, and acrid if heat be employed; in this case it becomes mild after a time. It is obtained from the kernels deprived of the integuments, the yield being about 22 per cent. Its specific gravity is 0.921 to 0.923; its congealing point near —17.5 C. (+.5° F.). A soft soap may be obtained from it by saponification. It does not readily become rancid. The oil contains stearin and palmitin, but is composed chiefly of olein. The press-cake, while eaten with impunity by fowls and swine, is said to produce untoward effects in horses or cattle. (See also interesting data on beech-nut oil by Charles H. La Wall, *Amer. Jour. Pharm.*, 1896, p. 11.)

OIL OF MAIZE.—The germ alone of our *Indian corn*, or *American maize*, contains about 22 per cent of a rich golden-yellow oil of a characteristic, not unpleasant odor and taste. It is obtained largely as a by-product in preparing starch, glucose and alcohol. It is thickish and has a specific gravity of 0.916 at 15° C. (59° F.). At —10° C. (14° F.) it congeals. It is composed of olein, stearin, and palmitin, and easily becomes rancid.

OLEUM HEDEOMÆ (U. S. P.)—OIL OF HEDEOMA.

A volatile oil distilled from the leaves and tops of *Hedeoma pulegioides* (Linné), Persoon. "It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYMS: *Oil of pennyroyal*, *Oil of American pennyroyal*.

Preparation.—The oil of pennyroyal is distilled from the wild herb mainly in North Carolina, and eastern and southern Ohio, by means of rather crude apparatus, in the same manner as oil of sassafras (see T. C. Harris, *Pharm. Jour. Trans.*, Vol. XVII, 1887, p. 672; and J. F. Patton, *Proc. Amer. Pharm. Assoc.*, 1891, p. 548). The yield from the fresh herb in the districts named, is 10 to 25 pounds of oil from 1 ton of herb, gathered while in bloom and partially dried; Schimmel & Co. (*Report*, Oct., 1893) obtained 3 per cent from dried leaves, and 1.3 per cent from dried leaves and herb.

Description.—"A pale-yellowish, limpid liquid, having a characteristic, pungent, mint-like odor and taste. Specific gravity, 0.930 to 0.940 at 15° C. (59° F.). The oil should form a perfectly clear solution with twice its volume of a mixture of 3 volumes of alcohol and 1 volume of water, this solution being neutral or slightly acid to litmus paper. It is also readily soluble in carbon disulphide, or in glacial acetic acid"—(*U.S.P.*). By means of this test, adulteration with petroleum, oil of turpentine, etc., may be recognized. The oil is optically dextrogyrate (+18° to +22°

Chemical Composition.—The principal constituent of oil of pennyroyal is *pulegone*, identified by Habhegger (*Amer. Jour. Pharm.*, 1893, p. 417). Besides there are present two ketones ($C_{10}H_{16}O$), one *hedeomol*, the other probably *menthone*; furthermore, small quantities of formic, acetic, and isoheptylic acids ($C_7H_{14}O_2$) (E. Kremers, *Proc. Amer. Pharm. Assoc.*, 1887, pp. 546–561; and *Pharm. Rundschau*, 1891, p. 130).

Action, Medical Uses, and Dosage.—Oil of pennyroyal is a stimulant, carminative, antispasmodic, and emmenagogue. It has been used with benefit in *cramp of the stomach, flatulent colic, nausea, amenorrhœa*, and to diminish the harshness of griping, as well as nauseating, medicines. It is frequently employed for the purpose of occasioning abortion, but as with all agents of this sort, it is very dangerous. It is sometimes applied externally as a mild rubefacient. The dose is from 2 to 10 drops on sugar, or in emulsion. (For further uses, see *Hedeoma*.)

Related Oils. Oil of European Pennyroyal. Distilled from *Mentha Pulegium*, Linné (*Pulegium vulgare*, Miller). A strongly aromatic, mint-like, yellowish or greenish-yellow oil, whose purity is to be tested for in the same manner as the American oil; it appears to possess like therapeutic properties. Specific gravity, 0.935 to 0.955. Contains about 80 per cent of the ketone *pulegone* ($C_{10}H_{16}O$), a colorless fluid having an agreeable, peppermint-like odor. Optical rotation of the oil +18° to +23°; of pulegone, +21° 16′. The boiling point of the latter, at reduced pressure (60 Mm.), is 130° to 131° C. (266° to 267.8° F.). The major portion of the oil distills at 212° to 216° C. (413.6° to 420.8° F.), pure pulegone at 221° to 222° C. (430.8° to 431.6° F.) (see Power, *Essential Oils*).

Oil of Pulegium micranthum, Claus, resembles the preceding, but its boiling point is higher, and its specific gravity greater. This plant grows in southern Russia.

OLEUM JUNIPERI (U. S. P.)—OIL OF JUNIPER.

"A volatile oil distilled from the fruit of *Juniperus communis*, Linné (*Nat. Ord.*—Coniferæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Synonyms: *Oleum fructus juniperi*, *Oleum baccæ juniperi*, *Oil of juniper-berries*.

Preparation and Description.—Oil of juniper is procured from the bruised berries by distillation with water. The full-grown, green fruit yields more oil than the ripe, as in the process of ripening the oil becomes converted into resin. Schimmel & Co. (*Report*, April, 1897) obtained a yield varying from 0.6 per cent in east Prussian to 1.5 per cent in Italian berries. Oil of juniper is "a colorless or faintly greenish-yellow liquid, becoming darker and thicker by age and exposure to air, having the characteristic odor of juniper, and a warm, aromatic, somewhat terebinthinate and bitterish taste. Specific gravity, 0.850 to 0.890 at 15° C. (59° F.). Soluble in about four times its volume of alcohol, forming a somewhat turbid liquid, which is neutral or slightly acid to litmus paper. Also soluble in an equal volume of carbon disulphide"—(*U. S. P.*). The optical rotation of oil of juniper is mostly left-handed (to —18°), sometimes right-handed, rarely inactive. As a rule, the oil is soluble in about 8 to 10 parts of alcohol of 90 per cent by volume; age diminishes its solubility in alcohol.

Chemical Composition.—*Pinene* is contained in the fraction of the oil boiling from 155° to 162° C. (311° to 323.6° F.); *cadinene* in the fraction 260° to 275° C. (500° to 527° F.); the intermediary fractions, containing esters, have not been fully analyzed, but contain the characteristic aroma of the oil. The aroma can not be due to an ester, because it outlasts saponification. *Juniper-camphor*, frequently observed by older chemists, forms crystalline deposits in the higher fractions of the oil when exposed to cold. One such deposit of needles, upon purification, melted at 165° to 166° C. (329° to 330.8° F.) (Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 350).

Action, Medical Uses, and Dosage.—Oil of juniper is a stimulant diuretic, and is employed to arrest *chronic mucous discharges*, especially from the urethra. It may also be used as a diuretic with other agents in cases of *dropsy*. Locally, it reddens the skin, and may vesicate. The dose is from 5 to 15 or 20 drops. The peculiar taste and diuretic property of Holland gin is owing to the presence of this oil.

OLEUM JUNIPERI VIRGINIANÆ.—OIL OF CEDAR.

An essential oil distilled from the leaves of *Juniperus virginiana*, Linné (*Nat. Ord.*—Coniferæ). *Red cedar.*

Synonym: *Oil of cedar leaves* (American).

Preparation, History, and Description.—This oil is prepared by distillation of the tops and leaves of red cedar with water. Messrs. Schimmel & Co. (*Report*, April, 1898) state that commercial cedar oil is liable to be found admixed with oil from the leaves of *Thuja occidentalis*, because this is also called cedar in the United States, though distinguished as *White cedar;* also the leaves of other coniferæ are said to be used by distillers of cedar oil. A number of commercial oils examined, varied in specific gravities from 0.863 to 0.920, in optical rotation from—3° 40′ to —24° 10′; some were soluble in 4 or 5 volumes of 70 per cent alcohol, others were not. A genuine oil, distilled by the same authorities (yield 0.2 per cent), had the following properties: Specific gravity 0.887, optical rotation +59° 25′. Not soluble in 10 parts of 80 per cent alcohol. The fraction below 180° C. (356° F.) constituting the larger portion, consisted chiefly of *dextro-limonene:* the higher fractions yielded *cadinene*, some *borneol*, and small quanities of *bornyl esters* (Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 358).

Action, Medical Uses, and Dosage.—Internally this oil is stimulant and emmenagogue, possessing properties similar to those of the oil of savin; however, it is very seldom administered internally. It is chiefly used as a rubefacient, and forms an excellent application in *inflammatory rheumatism* and other *painful affections*, either alone or combined with other articles to form a liniment. The dose, internally, is from 2 to 10 drops on sugar.

Related Oil.—OIL OF CEDAR WOOD. Florida. Distilled from the wood of *Juniperus virginiana*, Linné. Light or greenish-yellow, thickish, having an agreeable and characteristic odor, and a specific gravity of 0.940 to 0.960. Its optical rotation is from —20° to —40°. It is largely employed in perfuming soaps, and is also employed as an adulterant of oil of sandal. Its constituents are *cedar camphor* (*cedrol*, $C_{15}H_{26}O$), melting at 84° C. (183.2° F. Rousset, 1897), and *cedrene* ($C_{15}H_{24}$).

OLEUM LAVANDULÆ FLORUM (U. S. P.)—OIL OF LAVENDER FLOWERS.

"A volatile oil distilled from the fresh flowers of *Lavandula officinalis*, Chaix (*Nat. Ord.*—Labiateæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Preparation.—Oil of lavender is distilled in France, from wild-growing, in England, from cultivated flowers. Distillation in France is effected by means of portable copper stills, in which the flowers are heated with water by direct fire, wood being used as fuel. The stills are carried to the fields where the flowers grow, because it is believed that the flowers deteriorate upon transportation. (In this connection, see an excellent illustration of such a *distillerie ambulante* in Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 785.) In stationary distilleries, the oil is obtained by distillation with steam. The yield is 1 pound of oil from 200 pounds of fresh flowers. Schimmel & Co. obtained from dried French flowers a yield of 1.2 per cent, from dried German flowers, 2.8 per cent. All lavender oils were indiscriminately termed *oil of spike* in former centuries (see *Related Oils*).

Description.—The official oil is described as "a colorless or yellowish liquid, having the fragrant odor of lavender flowers, and a pungent and bitterish taste. Specific gravity, 0.885 to 0.897 at 15° C. (59° F.). It is soluble in all proportions in alcohol (distinction from oil of turpentine), and in three times its volume of a mixture of 3 volumes of alcohol and 1 volume of water (distinction from, and absence of, oil of turpentine); it is also soluble in glacial acetic acid. With an equal volume of carbon disulphide it forms a turbid mixture. The alcoholic solution of the oil is neutral or slightly acid to litmus paper. When heated on a water-bath, in a flask provided with a well-cooled condenser, the oil should yield no distillate having the characters of alcohol"—(*U. S. P.*). The oil is optically lævo-rotatory (—3° to —10°). Upon exposure to the air it has been observed to absorb oxygen to the amount of about 120 volumes in 4½ months.

Oil of lavender is distinguished from all other oils of the natural order Labiateæ by the quick and violent fulmination which takes place with iodine when about 0.1 Gm. of dry iodine is placed on a watch-glass and about 4 to 6 drops of the oil are brought in contact with it. Oil of lavender shares this property with oils of turpentine, lemon, orange peel, bergamot, spike, etc. A number of other oils, *e. g.*, peppermint, cajuput, rue, etc., does not react in this manner, and this difference in behavior toward iodine, may sometimes be useful in detecting adulterations. (See classification of oils along this line in Hager's *Handbuch der Pharm. Praxis*, Vol. II, 1886, p. 565.)

Chemical Composition.—French lavender oil, according to Bertram and Walbaum (1892), and Schimmel & Co. (1893 and 1898), consists of large quantities of *linalool* ($C_{10}H_{18}O$, or $CH_3.C[CH_3]:CH.CH_2.CH_2.C[CH_3]OH.CH:CH_2$), *l-linaloyl-acetate* (30 to 45 per cent), *butyrate*, and probably *propionate* and *valerianate;* traces of *pinene* and *cineol*, and *geraniol*. Contrary to the statements of older observers, no camphor is present in true oil of lavender. The esters are the carriers of the aroma. English lavender oil, according to Semmler and Tiemann (1892), and Schimmel & Co. (1894), contains *limonene*, *l-linalool*, *l-linaloyl acetate* (7 to 10 per cent), a sesquiterpene, and appreciable quantities of *cineol*. (For method of determining the quantity of *linaloyl acetate* in lavender oils, see Power, *Essential Oils*, p. 20.) Large amounts of cineol in lavender oil indicate adulteration by oil of spike; pinene, by oil of turpentine.

Action, Medical Uses, and Dosage.—Oil of lavender possesses stimulant and carminative properties, and is sometimes administered in *hysteria*, *nervous debility*, and *headache*. Its fragrance renders it an important article in perfumery, in which it is principally used. Its dose is from 1 to 6 drops.

Related Oils.—Oil of Spike. The broad-leaved variety of lavender (*Lavandula spica*, De Candolle) furnishes the *Oil of spike;* it is not so fragrant as the preceding oil, and has a camphoraceous odor. Its specific gravity is 0.905 to 0.920; optical rotation, +3° (Schimmel & Co.). It is chiefly used in the manufacture of varnishes for artists, in painting on porcelain, and in veterinary practice. With 3 volumes of 70 per cent alcohol at 20° C. (68° F.), according to Power (*Essential Oils*), it should produce a clear solution (absence of turpentine). It contains *camphor* (Kane, 1838), *cineol* (10 per cent), *pinene* (?), *camphene*, *linalool*, *borneol*, and possibly *geraniol* and *terpineol*.

Oil of Lavandula stœchas, Linné.—Distills between 180° and 245° C. (356° and 473° F.); specific gravity, 0.942; odor, rosemary-camphor; known constituent, cineol.

Oil of Lavandula dentata, Linné.—Distills almost entirely between 170° and 200° C. (338° and 392° F.); specific gravity, 0.926; known constituent, cineol.

OLEUM LIMONIS (U. S. P.)—OIL OF LEMON.

"A volatile oil obtained by expression from fresh lemon peel. It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Preparation.—Oil of lemon is obtained by lightly grating the fresh rind of the lemon, placing it in a fine cloth bag, and then subjecting it to pressure; the sediment is allowed to settle, and the clear oil is poured off (C.). It may also be obtained by distillation, but this mode is not advisable, because the distilled oil readily decomposes. Other methods, such as the process of rupturing the oil glands and gathering the product upon sponges, etc., are likewise followed (see *Oleum Aurantii Corticis*). The oil is imported from the southern parts of Europe, as Italy, Portugal, etc.

Description and Tests.—Oil of lemon as officially described, is "a pale yellow, limpid liquid, having the fragrant odor of lemon, and an aromatic, somewhat bitterish taste. Specific gravity, 0.858 to 0.859 at 15° C. (59° F.). Its optical rotation should not be less than 60° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Soluble in three times its volume of alcohol, the solution being neutral or slightly acid to litmus paper; also soluble, in all proportions, in absolute alcohol, carbon disulphide, or glacial acetic acid. When kept for some time, the oil should not develop a terebinthinate odor or taste (absence of oil of turpentine, or other oils consisting chiefly of pinene)"—(*U. S. P.*). When exposed to light and air, oil of lemon readily decomposes, becoming thicker, and forming a brown, sticky sediment.

Oil of lemon is frequently adulterated by alcohol, the fixed oils, or more frequently oil of turpentine. Alcohol may be detected by the milky fluid which forms upon agitating the oil with water. The fixed oils may be known by leaving a residue of more than 5 per cent upon evaporation of the oil. Well rectified coal oil has its odor entirely covered when added to oil of lemon, but the adulteration may be detected by the difference in specific gravity, and by the almost complete insolubility of the coal oil in alcohol. Oil of turpentine may be detected by the turpentine odor evolved when the impure oil is evaporated from heated paper. Its presence can be more accurately established by its diminishing influence upon the optical rotation of the oil. Oil of lemon contains no pinene (Schimmel & Co., 1897).

Chemical Composition.—Ninety per cent of oil of lemon consists of terpenes, the chief constituent of which is *dextro-limonene* (Wallach, 1885; Tilden's *citrene*, 1877), with a small quantity of *phellandrene* (Schimmel & Co., 1897). The highest fractions contain a *sesquiterpene* (Olivieri, 1891). The agreeable fragrance of lemon oil is due to oxygen compounds, especially *citral* ($C_{10}H_{16}O$, or $CH_3.C[CH_3]:CH.CH_2.CH_2.C[CH_3]:CH.CHO$), a doubly unsaturated aldehyde, present in the quantity of about 7 to 10 per cent (J. Bertram, 1888). Its chief occurrence is in lemon-grass oil (70 to 80 per cent). It is a golden-yellow fluid, optically inactive, boiling with slight decomposition at 228° to 229° C. (442.4° to 444.2° F.), under atmospheric pressure. It is the aldehyde of *geraniol* (see *Oleum Rosæ*), and forms a crystallizable compound with sodium bisulphite. It is convertible into *ionone*, an isomer of *irone*, both possessing the essential odor of orris root (see Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 215). Oil of lemon furthermore contains the fragrant aldehyde *citronellal* ($C_{10}H_{18}O$), and small amounts of the esters *geranyl-acetate* (in Messina and Palermo oils), and *linaloyl-acetate* in the latter oil alone (Umney and Swinton, *Pharm. Jour. Trans.*, Vol. VII, 1898, pp. 196 and 370). The non-volatile *lemon camphor* is not a uniform substance.

Action, Medical Uses, and Dosage.—Stimulant and aromatic. Its chief use is in perfumery, and to impart an agreeable flavor to medicines. It has been recommended in certain *affections of the eye*, as a local application. A very agreeable drink for the summer and for febrile patients may be made of white sugar, 4 ounces; oil of lemon, 10 drops; triturate together, and add citric acid, 2 drachms; a teaspoonful of this to a tumbler of water forms a pleasant, refreshing draught. Tartaric acid may be substituted for the citric, if desired.

OLEUM LINI (U. S. P.)—LINSEED OIL.

"A fixed oil expressed from linseed without the use of heat. It should be kept in well-stoppered bottles"—(*U. S. P.*).

SYNONYM: *Oil of flaxseed.*

Preparation.—When prepared by cold expression the yield varies from 15 to 20 per cent. Prepared by the aid of heat, the gummy substance in the tegument of the seeds is often removed by roasting or steaming them previous to expression, and after expression, the oil in the expressed fluid separates and floats above the mucilaginous water. The yield by hot expression varies from 24 to 28 per cent. For medicinal purpose only that prepared without heating is admissible, because otherwise it has a darker color and an acrid taste. The press-cake remaining in the expression of the oil is known as *oil cake* (see *Linum*). The oil as first obtained is called *raw oil*, and is mostly purified by agitation with about 1 per cent of strong sulphuric acid, the latter being removed by boiling water. The oil thus obtained is called *refined oil*.

Description.—The *U. S. P.* describes linseed oil as a "yellowish, or yellow, oily liquid, having a slight, peculiar odor, and a bland taste. When exposed to the air, it gradually thickens, and acquires a strong odor and taste; and if spread, in a thin layer, on a glass plate, and allowed to stand in a warm place, it is gradually converted into a hard, transparent, resin-like mass (absence of non-drying oils). Specific gravity 0.930 to 0.940 at 15° C. (59° F.). It does not congeal above —20 C. (—4° F.). Soluble in about 10 parts of absolute alcohol, and, in all proportions, in ether, chloroform, benzin, carbon disulphide, or oil of turpentine" (*U. S. P.*). When cooled to —27° C. (—16.6° F.) linseed oil congeals to a yellowish mass. Upon exposure to the air, old oil is liable to become rancid. On account of its drying properties, facilitated by warmth, linseed oil is a most important article, being used in the making of paints and varnishes, of printer's ink, oilcloth, etc. Its affinity for the oxygen of the air is so great that it is liable to inflame cotton waste and other fibrous material soaked with it.

Boiled Linseed Oil.—For technical purposes, the raw oil absorbs oxygen and hardens too slowly. This process is promoted by heating the oil to a temperature of 130° C. (266° F.) while a current of air is made to pass through it; its temperature is then raised until bubbles arise, due to decomposition of the oil. Then it is called *boiled oil*, as contrasted with the *raw* or *unboiled oil*. Boiled oil is thicker, darker, has a somewhat higher specific gravity (0.939 to 0.950) and dries more rapidly than raw oil, hence is preferred by painters for outside work when it is desired that the paint dry rapidly. The drying properties are materially increased by incorporating during the process certain metallic oxides, as litharge, ferric oxide, red lead, manganese dioxide, especially lead acetate, manganous borate, etc., whose function seems to be partly to facilitate the transmission of oxygen, and partly to form more readily oxidizable metallic salts of the fatty acids. The nature of these substances, as well as the mode of manipulation, is usually kept secret. Of late, oil-soluble "driers" or "siccatives" have come into use—namely resinates of certain metals, as lead and manganese. (Concerning these, see A. H. Allen, *Commercial Organic Analysis*, Vol. II, Part I, 3d ed., Philadelphia, 1899, p. 150.)

Chemical Composition and Tests.—Linseed oil consists of 10 to 15 per cent of *stearin*, *palmitin*, and *myristin;* the remainder is chiefly *isolinolenin* (the glyceride of *isolinolenic acid*, $C_{18}H_{30}O_2$, of the type $C_nH_{2n}—_6O_2$), and smaller amounts of *linolein* (the glyceride of *linoleic acid*, $C_{18}H_{32}O_2$, type $C_nH_{2n}—_4O_2$), and *olein* (the glyceride of *oleic acid*, $C_{18}H_{34}O_2$, type $C_nH_{2n}—_2O_2$). Unsaponifiable constituents amount to about 1 per cent (also see *Linum*). The drying qualities of linseed oil depend on the presence of the highly unsaturated linolein, linolenin, and isolinolenin. Upon drying, linseed oil becomes gradually converted into a hardened varnish, which is insoluble in ether. Chemically, it is an ester, called *hydroxy-linolin* (Mulder's *linoxyn*). Linseed oil is subject to many sorts of adulteration. Flaxseed itself is often found mixed with oil-bearing weed seeds, adulterated with hemp-seeds, and the oil may be adulterated with cotton-seed, niger-seed, and fish oils, mineral oils, and turpentine. These additions influence the specific gravity, congealing point, iodine absorption, and other physical and chemical constants of pure linseed oil. (For details regarding the analysis of linseed oil, see A. H. Allen, *loc. cit.*, pp. 152–155.)

The *U. S. P.* gives the following tests for linseed oil: "It should not more than slightly redden blue litmus paper previously moistened with alcohol (limit of free acid). If 2 Cc. of the oil be shaken with 1 Cc. of fuming nitric acid and 1 Cc. of water, it should neither completely nor partially solidify, even after standing for 1 or 2 days (absence of non-drying oils). If 10 Cc. of the oil, contained in a small flask, be mixed with a solution of 3 Gm. of potassium hydrate in 5 Cc. of water, then 5 Cc. of alcohol added, and the mixture heated for about 5 minutes on a water-bath, with occasional agitation, a dark-colored, but clear and complete solution should be obtained. If this liquid be diluted with water to the measure of 50 Cc., then cooled, and shaken with 50 Cc. of ether, the clear, ethereal layer, after having separated, should not show a bluish fluorescence, and, when carefully decanted, and allowed to evaporate spontaneously, should leave not more than a slight, and not oily, residue (absence of paraffin oils)"—(*U. S. P.*).

Rancid linseed oil may be again made sweet by shaking it with warm water, allowing it to stand a while, and finally decanting.

Action, Medical Uses, and Dosage.—(See *Linum.*)

Related Oils.—The following are drying oils:

Candle-nut Oil.—This oil is obtained by boiling in water the crushed seeds of *Aleurites triloba*, Forster (*Aleurites moluccana*, Willdenow), found in tropical regions, in the isles of the Indian and Pacific Oceans, India, and the West Indies. The oil is known by several names, as *Kekune oil*, in Ceylon; *Bankul oil*, in India; *Spanish-walnut oil*, in Jamaica, *Kukui oil*, in the Sandwich Isles, where it is used as a mordant for vegetable colors. The tree yielding the fruit is known as the *Candleberry tree*, from the fact that the seeds, strung upon palm-fibers, are used for lighting purposes by the Polynesians. The nuts taste like walnuts, and are used as food by the natives of New Georgia. The tree is called *Indian akrot* (walnut) in India. On account of the oil being much used by painters, it is sometimes known as *country-walnut oil* or *artist's oil* (see *Treasury of Botany*). The oil is limpid, transparent, syrupy, amber-yellow, odorless, and rapidly drying. The yield is about 60 per cent. It consists of *palmitin*, *stearin*, *myristin*, and *olein*, the latter being somewhat like *linolein* from linseed oil. The oil is laxative (see *Wood Oil of China*).

Grape-seed Oil.—From 10 to 20 per cent of a slowly drying, odorless, pale-yellow or brownish oil is obtained from the seeds of grapes (*Vitis vinifera*, Linné). It has a feebly bitter taste. At near —16° C. (3.2° F.) it congeals. Its chief constituent is the *glyceride of erucic acid* ($C_{22}H_{42}O_2$). At 34° C. (93.2° F.) this acid fuses, and, if melted with caustic potash, yields *arachic* and *acetic acids*. The lesser constituents are *stearin* and *palmitin*.

Niger-seed Oil.—A yellow oil, intermediate between the drying and non-drying oils, obtained to the extent of about 40 per cent from the black akenes of *Guizotia oleifera*, De Candolle (*Verbesina sativa*, Roxburgh), a composite plant of India and East Africa. It has a nut-like flavor, and congeals at —10° C. (14° F.). It is composed of two kinds of olein, one closely analogous to *linolein*, and *myristin* and *palmitin*.

Madia Oil.—The akenes of *Madia sativa*, Molina, a composite annual found native in Chili and cultivated in the Old World, yields a bland, yellow, fixed oil (about 40 per cent), having a distinctive odor, a specific gravity of 0.930, and congeals at about —20° C. (—4° F.). It readily turns rancid on exposure, and gradually assumes a semisolid state.

Walnut Oil.—(See *Juglans*.)

OLEUM MENTHÆ PIPERITÆ (U. S. P.)—OIL OF PEPPERMINT.

A volatile oil distilled from *Mentha piperita*, Smith (*Nat. Ord.*—Labiateæ).

"It should be kept in well-stoppered bottles in a cool place"—(*U. S. P.*).

History and Preparation.—The three most important peppermint-growing countries are the United States, Japan, and England, the Japanese oil being derived from the species *Mentha arvensis*, Linné, var. *piperascens*, Holmes. Distillation in the United States began in 1816, in Wayne county, in the State of New York; since 1835, peppermint has been grown and oil distilled therefrom in Michigan. Until 1846 distillation was carried out by means of simple copper stills heated by direct fire; since that date distillation by steam has become the rule. Indiana also distills large quantities of oil. Much care is now taken to exclude from the peppermint fields such weeds as *Erechtites* (fireweed), *Erigeron*, and *Hedeoma* (pennyroyal), to prevent undesirable contamination with the oils from these plants. The total production of oil of peppermint has reached enormous proportions, the United States alone, in 1897, producing 251,000 pounds. Minor quantities of oil of peppermint are produced in Russia, Germany, Italy, Norway, etc. (For much interesting detail regarding the history and statistics of this oil, see Dr. Frederick Hoffmann, in *Die Ætherischen Oele*, pp. 825–836.) The yield from German herb (fresh) is reported by Schimmel & Co. to be 0.1 to 0.25 per cent; from dried herb, 0.7 per cent.

Description.—The *U. S. P.* describes oil of peppermint as "a colorless, or yellowish, or greenish-yellow liquid, becoming darker and thicker by age and exposure to the air, having the characteristic, strong odor of peppermint, and a strongly aromatic, pungent taste, followed by a sensation of cold when air is drawn into the mouth. Specific gravity, 0.900 to 0.920 at 15° C. (59° F.). The oil does not fulminate with iodine. It form a clear solution with an equal volume of alcohol, becoming turbid when somewhat further diluted, and is soluble in all proportions, in carbon disulphide and in glacial acetic acid. The alcoholic solution of the oil is neutral to litmus paper"—(*U. S. P.*). The oil is optically lævo-rotatory varying in American oil from —25° to —33°. The better grades of oil from Wayne county, New York, do not form a clear solution with 3 to 5 volumes of 70 per alcohol, while the Michigan (western oils), the English and the Japanese oils do. Schimmel & Co. suggest that this difference may be due to the practice of previously drying the herb, which yields an oil not soluble in diluted alcohol, while that from fresh herb is soluble (Gildemeister and Hoffmann, *loc. cit.*, p. 838). When American oil of peppermint is subjected to cold, crystals of *menthol* fall out (see *Tests* below). The Japanese oil is semisolid at ordinary temperature, owing to the large quantity of menthol it contains.

Tests.—Adulterations of the oil with alcohol and oil of turpentine are not infrequent; the latter may be known by the turpentine odor, by the imperfect solution it forms with alcohol, and by its fulmination when iodine is added to it; the former may be known by the formation of a dirty-white liquid when an equal volume of water is added to it. Sometimes adulteration is practiced by removing part of the menthol by freezing. The following are the official tests, which include the characteristic color reactions of the oil of peppermint: "If 5 drops of the oil be added to 1 Cc. of glacial acetic acid, and the mixture gently warmed, the liquid will assume a blue color, with a red fluorescence. If 2 Cc. of the oil be mixed with 1 Cc. of glacial acetic acid, and 1 drop of nitric acid added, the liquid will soon acquire a green, greenish-blue, blue, or violet tint with a copper-red fluorescence. If 1 Cc. of the oil be dissolved in 5 Cc. of alcohol, 0.5 Gm. of sugar, and 1 Cc. of hydrochloric acid added and the mixture gently heated, a deep-blue or violet color will gradually be produced. If to 5 Cc. of nitric acid 1 drop of the oil be added, and the mixture gently agitated, and allowed to stand for about 3 hours, it should have a yellowish, but not a bright red color (absence of oil of camphor and of oil of sassafras). If a portion of the oil, contained in a test-tube, be placed in a freezing mixture of snow (or pounded ice) and salt for 15 minutes, it should become cloudy and thick, and after the addition of a few crystals of menthol, being still exposed to cold, it should soon form a crystalline mass (distinction from dementholized oil). When heated on a water-bath, in a flask provided with a well-cooled condenser, the oil should not yield a distillate having the characters of alcohol"—(*U. S. P.*).

Chemical Composition.—The chief constituent of peppermint oil is *menthol*, known also as *mint stearopten*, or *mint camphor* (see *Menthol*). New York oil contains 50 to 60 per cent total menthol, of which 40 to 45 per cent are free, and the rest combined in the form of ester. It also contains 12 per cent of *menthone*. Michigan oil contains about 48 to 58 per cent total menthol, of which 43 to 50 per cent are free menthol. By distilling menthol with phosphoric anhydride, a colorless liquid of an agreeable odor, *menthene* ($C_{10}H_{18}$) results. This hydrocarbon has been said to occur in Russian oil of peppermint; the American oil does not contain it. According to a detailed research on American peppermint oil by F. B. Power and C. Kleber (*Pharm. Rundschau*, 1894, p. 157), this oil contains the following substances: (1) *Acetaldehyde;* (2) *isovaleric aldehyde;* (3) *amyl alcohol;* (4) free *acetic*, and (5) *isovalerianic acids;* (6) *pinene;* (7) *phellandrene;* (8) *l-limonene;* (9) *cadinene;* (10) *cineol;* (11) a *lactone* ($C_{10}H_{16}O_2$); (12) *menthone;* (13) *menthol;* (14) *menthyl-acetate;* (15) *menthyl-isovalerianate;* (16) *menthylester* of an *acid*, $C_8H_{12}O_2$; (17) *dimethyl sulphide* ($S[CH_3]_2$). Substances 3 and 17 were additionally found in the laboratory of Schimmel & Co., in 1894 and 1896.

English oil of peppermint, according to Umney (*Pharm. Jour. Trans.*, 1896, Vol. II, p. 123, and Vol. III, p. 103), contained of total menthol, 63 to 66 per cent; menthol in the form of ester, 3 to 14 per cent; *menthone*, 9 to 11 per cent. Gildemeister and Hoffmann (*loc. cit.*, p. 844) believe that the other constituents of the English oil will prove the same as those of the American oil above enumerated. The Japanese oil contains of total menthol, 70 to 91 per cent; of free menthol, 65 to 85 per cent. It does not give the above-described color reactions, or but very faintly, with glacial acetic acid.

Action, Medical Uses, and Dosage.—Oil of peppermint is a powerful diffusible stimulant, with carminative, antispasmodic, and antiemetic properties. It is much employed to relieve flatulence, gastrodynia, nausea, spasms of the stomach, and to cover the taste of other drugs. Externally, it is occasionally employed as a rubefacient and anodyne. It relieves the pain of *burns, scalds*, and *toothache* from carious teeth. In spray, it is useful to alleviate *painful and inflamed fauces and tonsils*, and by inhalation relieves many of the unpleasant symptoms of *asthma* and *chronic bronchitis* in old persons. It enters into a liniment, which at one time was a popular remedy for various painful local affections; it is composed as follows: Take of oil of olives, oil of peppermint, oil of turpentine, tincture of opium, alcohol, aqua ammoniæ, each, 1 fluid ounce. Mix. To be applied 3 or 4 times a day. Peppermint oil is commonly used under the name of essence of peppermint, which is a tincture of it. The dose of the oil is 2 to 10 drops on sugar.

OLEUM MENTHÆ VIRIDIS (U. S. P.)—OIL OF SPEARMINT.

"A volatile oil distilled from *Mentha viridis*, Linné (*Nat. Ord.*—Labiatæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Preparation and Description.—The oil is obtained by distillation of spearmint herb with water; the yield from American fresh herb, gathered at the beginning of flowering, was 0.3 per cent (Schimmel & Co.). It is extensively distilled in this country, and in smaller quantities in Germany and Russia. The *U. S. P.* describes it as "a colorless, yellowish, or greenish-yellow liquid, becoming darker and thicker by age and exposure to the air, having the characteristic, strong odor of spearmint, and a hot, aromatic taste. Specific gravity. 0.930 to 0.940 at 15° C. (59° F.). With an equal volume of alcohol it forms a clear solution, which is neutral or slightly acid to litmus paper. When somewhat further diluted with alcohol, it becomes turbid. It also yields a clear solution with an equal volume of glacial acetic acid, and with half its volume of carbon disulphide; but with an equal volume of the latter it forms a turbid mixture"—(*U. S. P.*). The oil is optically lævo-rotatory (as high as —43°). An exceptionally high specific gravity (0.980) is reported by Schimmel & Co. for the oil above mentioned.

Chemical Composition.—This oil consists of two, and probably three, lævogyrate bodies. One is *lævo-carvone* ($C_{10}H_{14}O$), a ketone of a pure caraway odor, found also in the oils of caraway and dill (in the latter two as *dextro-carvone*). The quantity of carvone in spearmint oil was found by Kremers and Schreiner (*Pharm. Review*, 1896, p. 244) to be 56 per cent. The second body is *lævo-limonene*, once known as *carvene* ($C_{10}H_{16}$). The third constituent is probably *pinene*.

Action, Medical Uses, and Dosage.—Oil of spearmint is carminative, antispasmodic, and diuretic. It is used very frequently as a substitute for the oil of peppermint, and is more often prescribed on account of its diuretic properties. The tincture of the oil combined with potassium acetate renders the latter more efficient as a diuretic, besides imparting a pleasant flavor to it. The dose of the oil is 5 or 10 drops on sugar.

OLEUM MONARDÆ.—OIL OF HORSEMINT.

A volatile oil distilled from the fresh herb of *Monarda punctata*, Linne (*Nat. Ord.*—Labiatæ).

Preparation and Description.—Oil of horsemint is obtained in this country from the fresh herb, by distillation with water. The yield is about 3 per cent. The oil is of a yellowish or brownish-amber color, having a penetrating, aromatic, thyme-like odor, like that of the plant, and a strong, pungent, somewhat acrid taste; and is soluble in alcohol. Its specific gravity is 0.930 to 0.940.

Chemical Composition.—Oil of horsemint contains *thymol* (*monardin*) and *cymol*, sometimes *carvacrol*, and traces of *dextro-limonene*. (For details, see *Monarda*.)

Action, Medical Uses, and Dosage.—Oil of horsemint is stimulant, antispasmodic, and antiemetic, and in the form of the essence, has been much used to allay *nausea* and *vomiting* in *Asiatic cholera*, *cholera morbus*, etc.; it relieves the *diarrhœa of debility*, its action in these cases being prompt and permanent. It stimulates the nervous system and increases cardiac force. It gives sleep and quiet when there is exhaustion with nervous excitation. It restores *suppressed menses* when due to colds, and given with turpentine or wintergreen it renders good service in the *tympanites of enteric fever*. Oil of horsemint serves well in the *vomiting of inebriates*, and in *nausea* accompanying a flatulent distension of the stomach. Externally, it is rubefacient and even vesicant, and has been advantageously used in *low forms of fever*, *cholera infantum*, *paralysis*, *rheumatic* and *neuralgic pains*, etc. It soon causes rubefaction when locally applied, affording in many instances almost immediate relief. The dose of the oil is from 2 to 5 drops on sugar; of the essence, from 10 to 30 drops in sweetened water.

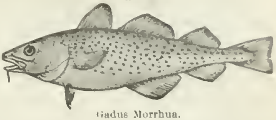
OLEUM MORRHUÆ (U. S. P.)—COD-LIVER OIL.

"A fixed oil obtained from the fresh livers of *Gadus Morrhua*, Linné, and of other species of *Gadus* (Class, *Pisces;* Order, *Teleostia;* Family, *Gadidæ*). It should be kept in well-stoppered and perfectly dry bottles"—(*U. S. P.*).

SYNONYMS: *Oleum jecoris aselli*, *Cod oil*, *Oleum hepatis morrhuæ*.

Source and History.—The common codfish is the *Gadus Morrhua* of Linnæus, or *Morrhua vulgaris* and *Asellus major* of other naturalists. It is a fish 2 or 3 feet in length, having a gray back with yellowish spots, and a white abdomen. The body is somewhat flattened, and symmetrical; the ventral fins are pointed and placed under the throat. There are 3 dorsal and 2 anal fins, and a cirrus or beard at the end of the snout. The teeth are pointed and unequal, and are disposed in several rows. The large gills are 7-rayed. On the external surface of the body are scales, rather soft, and not of large size. It is an inhabitant of cold or temperate seas, and is found, at certain seasons of the year, in abundance on the coast of Norway, in the neighborhood of Iceland, in the Russian Arctic Sea, and on the New England and Newfoundland coasts. The Norwegian oil, from the Lofoten Archipelago, is the most famous, and much of it is consumed in this country; but in recent years, the oil from the Newfoundland coast is gradually gaining in favor, owing to improvements in its manufacture. Other species of Gadus from which cod-liver oil is sometimes obtained, are coal-fish (*G. carbonarius*, Linné, or *Merlangus carbonarius*, Cuvier), dorsch, or dorse (*G. callarius*, Linne), turbot (*Rhombus maximus*, Cuvier), and occasionally from the pollack (*Gadus pollachius*, Linne, or *Merlangus pollachius*, Cuvier), hake (*Gadus Merluccius*, Linné, or *Merluccius communis*, Cuvier), whiting (*Gadus Merlangus*, Linné, or *Merlangus vulgaris*, Cuvier), ling (*Gadus Molva*, Linné, or *Lota Molva*, Cuvier), and haddock (*Gadus æglifinus*, Linné). In the Lofoten Islands, the codfish come in innumerable quantities in the month of January to deposit their spawn, all other fishes disappearing as if by enchantment. The codfishing commences about the early part of January and terminates about the middle of April; there being no less than 25,000 persons engaged in the business, and the quantity of the fish is prodigious, incalculable. The annual production in the Lofoten Archipelago alone is on an average about 400,000 gallons. Three barrels of liver yield 1 barrel of first quality oil, and ½ barrel of brown oil obtained by heat and expression. (For details regarding the Norwegian codfisheries, we refer those interested to an exceedingly readable monograph entitled *Cod-liver Oil and Chemistry*, published quite recently, by Dr. F. Peckel Möller, London and Christiania, 1895.) Among many other items of interest, it is demonstrated how the peculiar formation of the Norway seaboard together with the habits of the codfish serves to make the Lofoten Islands the natural center of the Norwegian fisheries. (Also see résumé of the commerce in cod-liver oil and its chemistry, by J. H. Stallmann and E. H. Gane, in *Amer. Drug.*, Jan., 1899, pp. 37–40.)

Fig. 182.



Gadus Morrhua.

Preparation.—The principal process by which the oil is now prepared is to remove blood and impurities from the carefully sorted livers by repeated washings; then the gall-bladder is removed and the livers, as soon as practicable, are put into iron kettles and subjected to steam heat with constant stirring. The oil separates from the liver tissue, and, after decantation and filtration through a funnel, is drawn off into barrels. In the Newfoundland fisheries, the oil obtained by steam heat is exposed to intense cold until it is partly solidified; the mass is then put into bags and subjected to strong pressure. In this manner the American *shore oil* is obtained. The residual stearin is sold to soap-makers.

Description.—Three kinds of cod-liver oil are usually met with in commerce: The white or pale-yellow, which is obtained from fresh and perfectly healthy livers (*shore oil*). It is the official oil and is described by the *U. S. P.* as "a pale-yellow, thin, oily liquid, having a peculiar, slightly fishy, but not rancid odor, and a bland, slightly fishy taste. Specific gravity, 0.920 to 0.925 at 15° C. (59° F.). Scarcely soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide; also in 2.5 parts of acetic ether"—(*U. S. P.*). The second form is pale-brown, or brownish-yellow (*straits oil*); less care is exercised in the selection of the livers and the preparation of the oil. The third kind is dark-brown (*banks oil*), and is an inferior grade, being derived from putrefied livers; its odor is disagreeable, its taste acrid and bitter; and it has an acid reaction. The best grade is universally preferred in the United States.

Adulterations and Tests.—Cod-liver oil is subjected to adulterations in several ways. One method is to bleach an inferior, dark oil, it is stated, by exposure to the rays of the sun. The addition of mineral oils can be recognized by saponification which leaves the adulterant unaffected. An oil that has undergone partial putrefaction may be judged by the quantity of free volatile acids in the oil. Such oils also absorb much less iodine than fresh cod-liver oil. Refined seal oil and seed oils are also used as adulterants of cod-liver oil. (For a more detailed consideration of this phase of the subject, see special works on analysis, *e. g.*, A. H. Allen, *Commercial Organic Analysis*, Vol. II, Part I, 3d ed., 1899, p. 197.) The *U. S. P.* gives the following tests for the purity of cod-liver oil: "If 1 drop of the oil be dissolved in 20 drops of chloroform, and the solution shaken with 1 drop of sulphuric acid, the solution will acquire a violet-red tint, rapidly changing to rose-red and brownish-yellow. If a glass rod, moistened with sulphuric acid, be drawn through a few drops of the oil, on a porcelain plate, a violet color will be produced. Cod-liver oil should be only very slightly acid to litmus paper previously moistened with alcohol (limit of free fatty acids). When the oil is allowed to stand for some time at 0° C. (32° F.), very little or no solid fat should separate (absence of other fish oils, and of many vegetable oils). If 2 or 3 drops of fuming nitric acid be allowed to flow alongside of 10 or 15 drops of the oil, contained in a watch-glass, a red color will be produced at the point of contact. On stirring the mixture with a glass rod, this color becomes bright rose-red, soon changing to lemon-yellow (distinction from seal oil, which shows at first no change of color, and from other fish oils, which become at first blue, and afterward brown and yellow"—(*U. S. P.*). The presence of seal oil may also be detected by means of Amagat and Jean's oleo refractometer (see *Proc. Amer. Pharm. Assoc.*, 1898, p. 888).

Chemical Composition.—For a chronological history of the chemical study of cod-liver oil, see M. P. Heyerdahl in F. Peckel Möller's monograph above mentioned. According to older analyses, especially by De Jongh (1843), cod-liver oil was accepted to consist of about 19 to 26 per cent of palmitin and stearin, 72 to 76 per cent of olein, and from 2 to 5 per cent of non-fatty matters. The following substances have been observed in cod-liver oil in minor quantities, although the presence of many are no doubt due to putrefactive changes in the liver:

(1) *Volatile acids* (valerianic, Spaarmann, 1828, acetic and butyric acids, De Jongh); (2) *iodine* (De l'Orme, 1836; on an average only 0.000322 per cent, Stanford, 1884); (3) *bromine* (Herberger, 1839); (4) *phosphorus* (De Vrij, 1838); (5) *biliary constituents* (De Jongh, 1843; this is not confirmed by subsequent researches; if the gall-bladders are excluded from the process, no bile reaction can be obtained in cod-liver oil; Buchheim, 1884, Salkowsky, 1887); (6) *cholesterin* (Allen and Thompson, 1885; 0.46 to 1.32 per cent); (7) *lipochrom* (of W. Kühne, to which, in part, the color reaction with sulphuric acid is due; Salkowsky, 1887); (8) volatile bases: *butyl-amine, amyl-amine, hexyl-amine, dihydro-lutidine;* (9) non-volatile alkaloids—*asellin* ($C_{25}H_{32}N_4$) and *morrhuine* ($C_{19}H_{27}N_3$), both occurring only in the darker oils; (10) crystallizable *morrhuic acid* ($C_9H_{13}NO_3$), a pyridine derivative, existing in the oil to the extent of 0.1 per cent. Numbers 8, 9 and 10 were observed by Gautier and Mourgues, 1888; the existence of alkaloids in light-brown Norwegian oil, as well as in Newfoundland and Maine oils, was also confirmed by J. O. Schlotterbeck, *Pharm. Jour. Trans.*, Vol. XXV, 1895, p. 585, from *Pharm. Era.* A solid, fatty acid, *gadinic acid*, melting at 63° to 64° C. (145.4° to 147.2° F.), was obtained by Luck, in 1856, from a deposit in cod-liver oil. *Morrhuol* is an alcoholic extract of cod-liver oil obtained by Chapoteaut (*Amer. Jour. Pharm.*, 1886, p. 19).

According to M. P. Heyerdahl's researches, published in the monograph aforementioned, pure cod-liver oil contains no stearin, no olein, and only about 4 per cent of *palmitic acid* as *tri-palmitin*. Two new glycerides, however, were discovered, namely, 20 per cent of *tri-therapin*, the glyceride of *therapic acid* ($C\ .H_{26}O_{.}$), a hitherto unobserved, unsaturated fatty acid containing four double bonds, and forming an octo-bromine addition product ($C_{17}H_{26}Br_8O_2$); and over 20 per cent of *tri-jecoleïn*, the glyceride of *jecoleïc acid* ($C_{19}H_{36}O_2$) which contains only one double bond, and is isomeric with *dœglic acid*. The remainder of the oil contains glycerides with one or more unsaturated acids belonging to the same series as jecoleïc acid, but as yet entirely unknown. The solid fat removed in the manufacture of cod-liver oil by cooling and subsequent pressure, and believed to be stearin, probably contains chiefly these undetermined acids. *Therapic* and *jecoleïc* acids, both free and as glycerides, become rapidly oxidized when exposed to air, especially if heated at the same time. They are converted into hydroxyacids which the author demonstrates to be the cause of rancidity in the oil, hitherto ascribed to the presence of free fatty acids. These hydroxyacids are thus shown to be physiologically undesirable, hence the necessity of absolutely excluding the air in the preparation of the oil; this is done by a patented process, in which an inert gas (carbonic acid) remains in contact with the oil during its manufacture.

Action, Medical Uses, and Dosage.—Cod-liver oil is nutritive and alterative. It has long been used as a domestic remedy in *chronic rheumatic* and *strumous diseases*, especially in the northern parts of Europe, and has been in general medicinal use only since the treatise upon it by Prof. Bennett, of Edinburgh, in 1841, although employed occasionally in the profession as early as 1766. Cod-liver oil is a remedy for defective nutrition, and when tolerated can be relied upon to give good results; but if it provokes persistent nausea, vomiting, disgust, and diarrhœa, it can not be expected to be other than harmful. Cod-liver oil is a fat-producing agent, excelling other fats which have been proposed as substitutes for it, in digestibility. When cod-liver oil "is kindly received by the stomach it increases the quantity of red corpuscles, improves the appetite and general strength, and the pulse becomes full and strong, flesh increases, and nutrition is improved" (Locke's *Syllabus of Mat. Med.*, p. 346). Though used for many conditions, it has been shown to do the most good in the poorly nourished, suffering from *phthisis pulmonalis, tabes, rickets, chronic bronchitis*, and *chronic rheumatism* in the scrofulous. It is not necessarily a curative agent, but in many conditions it tides the patient over while other agents exert their curative effects. In *tubercular arthritis*, and so-called *scrofulous inflammations of the joints*, its influence is often marked. Where there is necrosis, however, its effects are less evident. It may be given in *tabes mesenterica* when there is emaciation, a hard abdomen, offensive breath, and cough. When *epilepsy* depends upon a scrofulous and debilitated condition, cod-liver oil often proves a good remedy (Locke). In *rickets*, given internally and applied locally to the spine, it is one of our best remedies. *Fistula in ano, scrofulous enlargements*, and *scrofulous ulcerations* call for it. It undoubtedly prolongs the consumptive's life, but it should not be forced if the stomach persistently refuses to tolerate it. In some cases it does not seem to derange the stomach, but nauseates by its unpleasant taste. In these cases the difficulty is sometimes overcome by persisting in the use of the remedy or by changing from one to another preparation of the oil. In all cases where it can be tolerated, the pure oil should be preferred over the emulsions.

The diseases, besides those enumerated, in which it is said to be most efficient, are *strumous diseases, strumous ophthalmia, pseudo-syphilis*, in *scrofulous constitutions*, and various *chronic cutaneous diseases*, as in *eczema, impetigo, prurigo, lichen, squamous affections, pityriasis, ichthyosis*, etc. *Gout*, and occasionally *caries*, it is said, have yielded to its influence. It is also asserted to have been found useful in *diseases of the joints and spine, lupus, obstinate constipation, worms*, and *incontinence of urine;* and may be advantageously employed in all chronic cases, in which the disease appears to consist mainly in impaired digestion, assimilation, and nutrition. Externally used in *opacities of the cornea*, a drop or two placed on the cornea with a camel's-hair pencil; also in various *chronic cutaneous diseases, rhagades, chaps, eczema, excoriations*, and *fissures*. Its use is contraindicated in plethora, or where there is a strong tendency to it, lest hemorrhage be provoked. When long used, it is said to frequently occasion an eruption on the surface of an eczematous character. But little advantage will be apparent from the administration of cod-liver oil, until its use has been persevered in for 5 or 6 weeks, though it often commences earlier. The light-colored oil is the best. Some prefer the darker colored oils. The dose of cod-liver oil is ½ fluid ounce, twice a day, or more; but it is best to begin with small doses at first, say 1 drachm only, in order to lessen the risk of nausea and vomiting. Patients soon accustom themselves to its use without repugnance. It is best given alone, followed by some claret, or a little sugar and cinnamon powder, or prepared with aromatic oils, the same as castor oil (which see). It may be given in coffee, milk, or brandy, and for consumptives in Bourbon. A pinch of salt sometimes renders it palatable, while others advise the chewing of a small portion of smoked herring. Tomato catsup, and particularly the froth of malted beverages appears to mask the unpleasantness of the oil. (For various methods of rendering the oil palatable, see *Emulsio Olei Morrhuæ*.)

Dr. Alexander Wallace recommends a mixture of equal parts of lime-water and cod-liver oil, well shaken together, as a tonic, sedative, antacid, and nutrient; it forms a thick, milky emulsion, palatable, especially when taken with a little sherry wine, and may be used in all the forms of disease in which cod-liver oil is recommended.

In Germany a ferruginous cod-liver oil is much employed; it is prepared by first making a soda soap, from which its glycerin is removed by concentrated solution of sea salt, giving as the result an iron soap by double decomposition—this last soap is dissolved in sixteen times its weight of cod-liver oil. The oil thus prepared is brown and holds in solution $\frac{1}{500}$ of iron, the taste of which is hardly discernible.

Related Oils.—OLEUM RAJÆ, *Ray*, or *Skate oil*. From the *livers* of *Raja Batis*, Linné. Specific gravity, 0.928. Odor and taste, fishy; color, bright or pale-yellow; reaction, neutral. Said to contain a greater quantity of iodine than cod-liver oil. It is used by the Belgians and French as a substitute for cod-liver oil.

OLEUM BALÆNÆ, *Whale oil*, *Train oil*.—Obtained from the blubber of *Balæna mysticetus*, Linné, *Greenland whale;* and *Balæna australis*, Desmoulins, *Cape whale*. Specific gravity, 0.926. Odor, fishy; taste, disagreeable. At 10° C. (50° F.) it deposits a solid material, palmitin. Some whale oils contain notable quantities of *valerin*.

MENHADEN OIL.—Obtained on the New England coast from the *Alosa Menhaden*, Cuvier. It constitutes one of the oils known as the *fish oils* or *whale oils*, and is used in the manufacture of leather. The term *train oils* now includes all oils from the fleshy parts of the seal, shark, cod, and like fishes or marine mammals.

OLEUM SQUALI, *Shark oil*.—Specific gravity varies from 0.911 to 0.928. Taste, acrid; color, pale-yellow. At —6° C. (21.2° F.) it is still a limpid fluid. It is obtained from the liver of *Squalus Carcharias*, Linné, or *Shark*, besides some other related species. The livers of *Pastinaca hastata*, De Kay, or *American stingray*, also yield an oil by expression. From 0.7 to 17.3 per cent of *cholesterol* (*cholesterin*) have been obtained from six specimens of shark oil by A. H. Allen (*Org. Chem. Anal.*, Vol. II, Part I, 3d ed., p. 200).

OLEUM CETI, *Sperm oil*.—Found in the cranial cavity of the *Physeter macrocephalus*, Linné, or *Sperm whale*, and obtained by expression. Specific gravity, about 0.879. Color, yellow or brownish-yellow. It is distinguished from the oils of the *Whale-oil group* by its lower specific gravity and its composition. Upon cooling, spermaceti is deposited. Sperm oil proper yields, upon saponification, chiefly *oleic acid* and *dodecatyl alcohol* ($C_{12}H_{25}OH$). It is a valuable lubricant.

OULACHON OIL, or EULACHON OIL.—A proposed substitute for cod-liver oil, yielded abundantly by the *Candle-fish* (*Thalicthys pacificus*) of the north Pacific coast. Congelation of this oil begins at—7° C. (19.4° F.), though according to some statements it is of the consistence of lard at common temperatures. Specific gravity, 0.907 at 15.5° (60° F.). It contains *oleic acid* (60 per cent), *stearic*, and *palmitic acids* (20 per cent), and non-saponifiable matter (about 13 per cent).

DUGONG OIL.—The Dugong (*Halicore Dugong*, Cuvier) is an herbivorous mammal found in shallow waters throughout the Indian seas. There are two species of them—the Malay or Indian Dugong (*Halicore indicus*), and the Australian (*Halicore australis*). They are from 6 to 16 feet in length, and weigh from 400 to 600 pounds upon an average; occasionally, however, they are found of larger size. They frequent the neighborhood of ocean inlets where sea-grass, algæ, and fuci abound, and the water is shallow. They are called Sea-hogs, and their flesh (intermediate in flavor between beef and pork), is esteemed a great delicacy by the natives of the islands and countries near which the animal abounds. Underneath the skin (which is about ½ inch in thickness, and is often made into gelatin) is found a layer of adipose tissue, which yields from 4 to 16 gallons of oil, according to the size of the dugong. This oil is very palatable, and is acceptable to the most sensitive stomach, and has obtained somewhat of a reputation as a substitute for cod-liver oil. The oil is fully as nutritious as cod-liver oil, and may be administered in all forms of *tuberculous* and *wasting diseases*, and with equal advantage in cases where there is a decided repugnance to the cod-liver oil (J. King).

TURTLE OIL.—This oil is said to be fully as efficacious as cod-liver oil in malnutrition, especially in strumous individuals. Large quantities of it are consumed in South America, where it is prepared from turtle-eggs; in Jamaica and the Seychelle Island it is prepared from turtle-fat.

OLEUM MYRCIÆ (U. S. P.)—OIL OF MYRCIA.

"A volatile oil distilled from the leaves of *Myrcia acris*, De Candolle (*Nat. Ord.*—Myrtaceæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYM: *Oil of bay*.

Botanical Source and History.—The tree producing the leaves which yield *oil of bay*, is indigenous to Venezuela and the West Indies, where it is known as the *Wild cinnamon*, *Bayberry*, and *Wild clove tree*. Its branches are 4-angled, and support broad-ovate, almost obtuse, short-petiolate, strongly-veined, entire, leathery leaves. These are dotted with pellucid oil-glands, and when bruised give off a pleasant, clove-like aroma. The flowers are small and reddish, and the fruit is a smooth, subglobular berry. *Oil of bay* and *Spirit of bay*, or *Bay rum*, are distilled from this plant.

Preparation.—This oil is obtained partly in the islands from the fresh leaves, but mostly in the United States, from the dried leaves, by distilling them with water, or by means of steam. An oil lighter than water first distills over, followed by another heavier than water. The commercial oil consists of a combination of these two fractions.

Description and Tests.—"A yellow or brownish-yellow liquid, having an aromatic and somewhat clove-like odor, and a pungent, spicy taste. Specific gravity, 0.975 to 0.990 at 15° C. (59° F.). With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions. The alcoholic solution is slightly acid to litmus paper. When mixed with an equal volume of a concentrated solution of sodium hydrate, it forms a semisolid mass. If 2 drops of the oil be dissolved in 4 Cc. of alcohol, and a drop of ferric chloride T.S. be added, a light-green color will be produced; and if the same test be made with a drop of diluted ferric chloride T.S., prepared by diluting the test-solution with four times its volume of water, a light-bluish coloration will be produced, which soon disappears. If to 3 drops of the oil, contained in a small test-tube, 3 drops of concentrated sulphuric acid be added, and, after the tube has been corked, the mixture be allowed to stand for ½ hour, a resinous mass will be obtained. On adding to this mass 4 Cc. of diluted alcohol, vigorously shaking the mixture, and gradually heating to the boiling point, the liquid should remain nearly colorless, and should not acquire a red or purplish-red color (distinction from oil of pimenta and oil of cloves). If 1 Cc. of the oil be shaken with 20 Cc. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper. If, after cooling, the liquid be passed through a wet filter, the clear filtrate should produce, with a drop of ferric chloride T.S., only a transient grayish-green, but not a blue or violet color (absence of carbolic acid)"—(*U. S. P.*). The test for distinguishing between this oil and oil of pimenta, above given, is regarded by Schimmel & Co. (Prof. F. B. Power, *Essential Oils*, 1894) as unreliable.

Chemical Composition.—The following substances, arranged in the order of their relative proportions, have been ascertained to occur in oil of bay: (1) *Eugenol*, first observed in this oil by Prof. Markoe (1877); (2) *myrcen* ($C_{10}H_{16}$), a liquid, unsaturated, open-chain hydrocarbon (*olefine*) of a characteristic odor, specific gravity 0.802, and convertible by hydration into *linalool;* (3) *chavicol* ($C_9H_{10}O$); (4) *methyl-eugenol;* (5) *methyl-chavicol;* (6) *l-phellandrene;* (7) *citral.* No pinene is present, hence oil of turpentine may easily be recognized if present as an adulterant (Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 669).

Action, Medical Uses, and Dosage.—This oil is chiefly employed in perfumes, and is a constituent of *Spiritus Myrciæ*, or *Bay rum.*

OLEUM MYRISTICÆ (U. S. P.)—OIL OF NUTMEG.

"A volatile oil distilled from *Nutmeg*. It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Synonyms: *Oleum nucistæ æthereum*, *Volatile oil of nutmeg.*

Preparation.—This oil is obtained by distilling ground nutmegs by means of steam. It may be prepared as suggested by Cloëz (1864), by exhausting the nuts with carbon disulphide or ether, and finally distilling the extract thus obtained with the aid of steam. Nutmegs yield from 8 to 15 per cent (Schimmel & Co.) of oil.

Description and Chemical Composition.—The *U. S. P.* describes oil of nutmeg as "a thin, colorless or pale yellowish liquid, having the characteristic odor of nutmeg, and a warm, spicy taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 0.870 to 0.900 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper; also soluble in an equal volume of glacial acetic acid, and in carbon disulphide in all proportions"—(*U. S. P.*).

The specific gravity at 15° C. (59° F.), according to Schimmel & Co., may be as high as 0.920. It is dextrogyre (+14° to +30°), fulminates with iodine, and forms a clear solution with 3 parts of 90 per cent alcohol. Oil of nutmeg consists of (1) *pinene* (Wallach, 1884; Schacht's *macene*, 1862); (2) *dipentene*; (3) Gladstone's *myristicol* ($C_{10}H_{14}O$; Wright, $C_{10}H_{16}O$) boiling at 224° C. (435.2° F.); specific gravity, 0.9466; convertible into cymol; (4) *myristicin (isomyristicin)* (C H O) in the highest fractions, melts at 30° C. (86° F); its specific gravity is 1.150 at 25° C. (77° F.), and it has a strong odor of mace; (5) *myristic acid* ($C_{14}H_{28}O_2$), formerly called *myristicin*, often forms a sediment (stearopten) in old oils. Oil of nutmeg contains more terpenes than oil of mace, otherwise their composition and properties are alike (Gildemeister and Hoffmann, *Die Ætherischen Oele*).

Action, Medical Uses, and Dosage.—Rarely used in medicine. In 2 or 3-drop doses it may be used for the same purposes as nutmeg.

OLEUM MYRISTICÆ EXPRESSUM.—EXPRESSED OIL OF NUTMEG.

The fixed oil obtained from nutmegs.

SYNONYMS: *Adeps myristicæ, Adeps nucistæ, Balsamum nucistæ, Butyrum nucistæ, Nutmeg butter, Oleum nucistæ expressum, Concrete oil of nutmeg.*

Preparation, Description, and Chemical Composition.—The powder of nutmegs, beaten to a pulp with a little water, and pressed between heated plates, yields from 20 to 30 per cent of a fragrant, orange-colored, concrete oil, mottled with white, sometimes, but incorrectly, called *oil of mace*. It may also be obtained by extracting the bruised nutmegs with disulphide of carbon. This oil is imported from the East Indies (Penang and Singapore) in the form of rectangular cakes about 2½ inches wide and thick, and 10 inches long, enveloped in bast-fibers or pisang leaves. The best grade is the Java article. Much oil is also obtained in Europe from unsalable nutmegs. The fat has the consistence of suet, and possesses the odor and taste of the nutmeg. It is inflammable, burns with a bright, nearly smokeless flame, and, when free from tallow, etc., does not emit a tallow odor when the flame is extinguished. Nutmeg butter is soluble in boiling alcohol and ether, depositing *myristin* upon cooling; its specific gravity is about 0.995; its melting point is given by the *German Pharmacopœia* as 45° to 51° C. (113° to 123.8° F.). The crude article, when melted, leaves a sediment of foreign matters, and must therefore be purified by melting and sedimentation. Nutmeg butter consists chiefly (to 40 or 50 per cent) of *myristin* (Playfair, 1841), the glyceride of *myristic acid* ($C_{14}H_{28}O_2$). It melts at 55° C. (131° F.), and is insoluble in cold alcohol or ether. The fat also contains free *myristic acid*, some *palmitin*, and *olein*, about 6 per cent of volatile oil, and a red-brown coloring matter. Factitious nutmeg butter has been made by melting together tallow, spermaceti, etc., flavoring this with essential oil of nutmeg, and coloring it with saffron. Adulteration with fat is recognized by its being left in the residue when treated with hot alcohol; smaller quantities of fat which go into solution, fall out with the *myristicin* upon cooling, and reduce its melting point.

Action and Medical Uses.—This oil is bland, and does not readily become rancid; hence it furnishes a good vehicle for topical applications. It has been employed alone by friction for the relief of *rheumatism*.

Related Fats.—BECUIBA TALLOW (*Bicuhiba fat*, or *B. balsam*). This fat is obtained from the seeds of a Brazilian species *Myristica Becuhyba*, Schott, by expression. It resembles expressed oil of nutmeg, except in its taste, which is sharp and acidulous. Fusing point, 47° C. (116.6° F.). Alcohol but partially dissolves it.

OCUBA WAX, or VIROLA TALLOW.—A subcrystalline, yellowish fat, melting at 45° to 50° C. (113° to 122° F.), dissolving wholly in alcohol, obtained from the fruit of a Para shrub, the *Virola sebifera*, Aublet (*Myristica sebifera*, Swartz).

OTOBA BUTTER.—Obtained from the fruit of *Myristica Otoba*, Humboldt and Boupland. A nearly colorless or yellowish fat, the odor resembling that of nutmegs when fresh, but becoming brownish in color and disagreeable in odor with age. It fuses at 38° C. (100.4° F.). It contains *myristin*, *olein*, and *otobit*. The latter forms colorless, odorless, tasteless, prismatic crystals, which fuse at 133° C. (271.4° F.). Cold alcohol sparingly dissolves them.

UCUHUBA FAT.—A yellow solid fat obtained from *Ucuhuba nuts*, the fruit of *Myristica surinamensis*. (Compare *Myristica, Related Species.*)

OLEUM OLIVÆ.—OLIVE OIL.

"A fixed oil expressed from the ripe fruit of *Olea europæa*, Linné (*Nat. Ord.*—Oleaceæ). It should be kept in well-stoppered bottles, in a cool place"—(*U. S. P.*).

SYNONYM: *Sweet oil.*

ILLUSTRATION: (Tree) Bentley and Trimen, *Med. Plants*, 172.

Botanical Source.—The olive-tree is an evergreen, from 12 to 20 feet high, with hoary, rigid branches, and a grayish bark. The leaves are opposite, lanceolate, or ovate-lanceolate, mucronate, short-petioled, green above, and hoary on the underside. The flowers are small, in short, axillary, erect racemes, very much shorter than the leaves. The corolla is short, white, with 4 broad, ovate segments; the calyx short and 4-toothed. Stamens 2, rather projecting; style very short; stigma bifid, with emarginate segments. The fruit is a drupe about the size of a damson, smooth, purple, 2-celled, with a nauseous, bitter flesh, inclosing a sharp-pointed stone (L.).

Fig. 183.

Olea europæa.

History.—The native country of the olive-tree is unknown; it is supposed to have been originally from Asia, since it is mentioned in the Bible. At present it is extensively cultivated in the south of Europe, especially in Spain, France, Sicily, Italy, Calabria, and Apulia. It has been introduced into South America, California, and our southern states; in the latter section it does not thrive successfully, but in California it promises to have a commercial future. The tree commences yielding fruit in its third year; in its sixth year it is very productive, and remains so for an indefinite length of time. Varieties of the tree are based on the size, color and taste of fruit, and character of the foliage. The bark of the tree was formerly used in medicine, as well as the leaves, which have a bitter and acrid taste. In the warmer provinces of Europe a substance exudes from the bark, which has been called *Gomme d'Olivier*, and which, according to Pelletier, consists of a peculiar resin containing a small quantity of benzoic acid, and a peculiar crystalline principle, which he called *olivin* or *olivile.* This was at one time used as a remedial agent. The fruit, gathered when not quite ripe, is very solid, bitter, and acrimonious; but when steeped for several days in a lye of wood ashes, and then pickled in brine, it constitutes the olive of commerce, much valued by many as a food. According to Flückiger, the bitterish seeds yield a bland, non-drying oil, which, when obtained together with that of the pulp, amounts to $\frac{1}{10}$ of the whole quantity. The leaves and fruit of this tree, before maturing, contain mannit, but when the fruit has ripened this substance has wholly disappeared.

Preparation.—The oil is obtained by expression from the fleshy pericarp of the fruit. The fruit is carefully collected immediately previous to its ripening, or when it assumes a reddish hue, one day usually completing the gathering; if the olives be collected when fully ripe, the tree will bear only every other year. Without delay, the drupes are passed through a mill, having its stones so arranged as not to break the olive nuts; the pulpy mass thus obtained undergoes cold expression, from which the finest oil, termed *virgin oil*, is procured. The residual press cake is crushed, dampened with boiling water, and again exposed to pressure, thus yielding a second-rate oil, which is made use of as a *salad oil* and for preparing fine soaps; it is the ordinary olive oil of commerce. Upon again breaking up the press-cake, steeping it in water, allowing it to remain for 10 or 12 days, until it begins to ferment, and then expressing it, an inferior oil is obtained, which is used in lamps, and for making plasters, inferior soaps, etc. Carbon disulphide is sometimes used to extract residual oil in marc that has already been treated with pressure and water. Such an oil is very inferior. The process here described is followed in more or less modified form in the different olive-growing countries.

Description.—The best grade of olive oil comes from the south of France (*Provence oil*), and from Italy (*Lucca oil*, *Gallipoli oil*, etc.). Spain and, recently, California yield good grades of olive oil. Olive oil that is dark in color, cloudy, having a pronounced acrid after-taste, easily becomes rancid, and congeals at a point lower than that given below, is inferior in quality and should have no place in medicine. The *U. S. P.* describes the best oil as follows: "A pale-yellow, or light greenish-yellow, oily liquid, having a slight, peculiar odor, and a nutty, oleaginous taste, with a faintly acrid after-taste. Specific gravity, 0.915 to 0.918 at 15° C. (59° F.). Very sparingly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide. When cooled to about 10° C. (50° F.), the oil begins to become somewhat cloudy from the separation of crystalline particles, and at 0° C. (32° F.) it forms a whitish, granular mass"—(*U. S. P.*). Olive oil is little soluble in alcohol if free from uncombined oleic acid. It is soluble in petroleum benzin and benzol, and in 5 parts of acetic ether. If exposed to light and air, olive oil becomes rancid and liberates oleic acid. Olive oil is the type of non-drying oils, and is therefore much used as a lubricant, although its tendency to become rancid prevents its unrestricted application for this purpose. Pure olive oil is also characterized by giving the *elaïdin* reaction (see *Tests* below).

Chemical Composition.—Olive oil may be differentiated by cold and pressure into about 30 per cent of a solid fat, chiefly consisting of *palmitin*, *stearin*, and a small amount of *arachin*, the glyceride of *arachic acid* ([$C_{20}H_{40}O_2$], a constituent of earthnut oil), and about 70 per cent of a fluid oil composed of *olein* with about 7 per cent of *linolein* (the glyceride of *linoleic acid;* see *Oleum Lini*). Rancid olive oil may contain from 2 to 24 per cent of free *oleic acid*. Chlorophyll and small amounts of the alcohol *cholesterin* ($C_{26}H_{43}.OH$) likewise occur in olive oil. Olive oil is frequently adulterated, being substituted, wholly or in part, by cotton-seed oil, earthnut oil, poppy, rape-seed, sesame, and lard oil. Its physical and chemical characteristics, such as specific gravity, point of congelation, saponification equivalent, its non-drying quality, the elaïdin test, its low iodine number, resulting from its limited power to absorb iodine, and other tests, assist in detecting adulterations.

Tests.—The *U. S. P.* gives the following tests for the purity of olive oil: "If 10 Cc. of the oil be shaken frequently, during 2 hours, with a freshly prepared solution of 1 Gm. of mercury in 3 Cc. of nitric acid, a perfectly solid mass of a pale straw-color will be obtained. If 6 Gm. of the oil be thoroughly shaken, in a test-tube, for about 2 minutes, with a mixture of 1.5 Gm. of nitric acid and 0.5 Gm. of water, then heated in a bath of boiling water for not more than 15 minutes, the oil should retain a light-yellow color, not becoming orange or reddish-brown, and, after standing at the ordinary temperature for about 12 hours, it should form a perfectly solid, light-yellowish mass (absence of appreciable quantities of cotton-seed oil, and most other seed oils). If 5 Cc. of the oil be thoroughly shaken, in a test-tube, with 5 Cc. of an alcoholic solution of silver nitrate (prepared by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol, and adding 2 drops of nitric acid), and the mixture be heated for about 5 minutes in a water-bath, the oil should retain its original, pale-yellow color, not becoming reddish or brown, nor should any dark color be produced, at the line of contact of the two liquids (absence of more than about 5 per cent of cotton-seed oil, and of many other foreign oils). If 30 Cc. of the oil be saponified by heating with 20 Cc. of alcohol and 5 Gm. of potassa, the liquid then diluted with 200 Cc. of water, and freed from alcohol by boiling, on supersaturating the solution with diluted sulphuric acid, the fatty acids will form a layer on the surface. If these be separated as far as possible, free from water, and filtered, 5 Cc. of the filtrate, when shaken in a test-tube with 5 Cc. of concentrated hydrochloric acid, should not color the latter green; and, on the subsequent addition of about 0.5 Gm. of sugar, and again shaking the mixture, no violet or crimson tint should be produced in the acid layer within 15 minutes (absence of sesamum oil)"—(*U. S. P.*). (For the detection of oil of sesame in olive oil, by a new color test, see J. F. Tocher, *Amer. Jour. Pharm.*, 1891, p. 140. For details of analysis, we must refer the reader to special works, such as A. H. Allen's *Commercial Organic Analysis*, Vol. II, Part I, 3d ed., 1899, p. 126.)

Action, Medical Uses, and Dosage.—According to Mr. Sidney H. Maltass, a strong decoction of the leaves of the olive-tree, given in doses of a wineglassful every 3 hours, has cured the most obstinate and severe forms of *intermittent fever*. He considers it more effectual than quinine. Olive, or sweet oil, as it is often called, is emollient, nutritive, and aperient. A fluid ounce or two purges, but is uncertain and often ineffective; yet is very useful in teaspoonful doses for newly-born infants, where the mother's milk does not prove sufficiently laxative. As a demulcent, it is very useful in *irritation of the mucous surfaces of the air passages*, and of the *alimentary tube*. It may be given as a gentle aperient in cases where other agents would cause too much intestinal irritation; and is of service as an *antidote to the strong alkalies*, in which it acts by combining with them to form soap. It has been used in cases of *poisoning by cantharides*, but owing to its readily dissolving their active principle, it increases the peril of the patient. As an article of diet it is generally harmful to dyspeptics. Olive oil is largely used by workers in lead to prevent *constipation* and *lead poisoning*. Large doses, prepared in emulsion with egg and mint, have been successful in removing *biliary concretions*. It is said to be effectual in *phthisis*, particularly to control *excessive sweating*. Externally (with lime-water), it is a valued agent for anointing *bruises, excoriations, superficial wounds, burns* and *scalds*. It is a good application to the body outlets to prevent excoriation from acrid discharges. Olive oil is frequently used as a vehicle for anodynes and local anæsthetics, such as morphine, menthol, camphor, etc. An olive oil solution of camphor, applied warm, is very effective in *mastitis*. Olive oil relieves the various forms of *earache*. It removes *rectal worms*, and has a soothing effect upon the rectum in *dysentery*. Live *insects in the ear* may be destroyed and removed by filling the canal with the oil. Applied warm it gives relief to the *bites and stings of insects*. Rubbed over the whole surface of the body, it has been considered beneficial in the treatment of *plague, scarlatina*, and some other *exanthematous affections*. Finally, it is largely used as a lubricant for the operator's hands, and for specula, bougies, and other instruments to be introduced into the orifices of the body. To facilitate the passage of catheters, first introduce into the urethra a quantity of warm olive oil. Olive oil enters largely into the formation of liniments, cerates, ointments and plasters. The dose of olive oil ranges from 2 fluid drachms to 2 fluid ounces. In the countries where the olive grows the oil is used as a food.

OLEUM ORIGANI.—OIL OF ORIGANUM.

SYNONYM: *Oil of wild marjoram.*

Preparation and Description.—This oil is produced from the *Origanum vulgare*, by distillation of the plant with water. The yield referred to dried herb is 0.15 to 0.4 per cent (Schimmel & Co.). It is of a yellowish or reddish-yellow color, of a peculiar, agreeable, balsamic odor, and a warm, very pungent taste. Its specific gravity ranges from 0.87 to 0.91. It is imported from Europe, and frequently contains oil of turpentine. Very little true oil of origanum is met with in this country; that generally sold for it is imported from France.

Chemical Composition.—A camphor-like stearopten has been observed in this oil by Kane (1839). Two phenols, one being *carvacrol*, were found in the oil by Jahns (1880) in small quantity, not exceeding 0.1 per cent. The bulk of the oil is probably composed of *terpenes* ($C_{10}H_{16}$). Its chemical examination is incomplete.

Action, Medical Uses, and Dosage.—Oil of origanum is stimulant and rubefacient, and is chiefly employed in the form of liniment as an application to various parts suffering from *painful affections*. As with many other essential oils, it affords relief in *toothache* upon being applied to the decayed tooth by means of lint or cotton. It is very seldom administered internally.

Related Oils.—OLEUM MAJORANÆ. The *Oil of sweet marjoram*, obtained by distillation of the *Origanum majorana*, Linné, is a pale yellow or greenish-yellow oil with the strong odor and taste of sweet marjoram, and on standing deposits a camphor. Its specific gravity is 0.890 to 0.91. Optical rotation +17° 10′ (Schimmel & Co.). According to W. Biltz (1898), this oil contains 40 per cent of terpenes, chiefly *terpinene*, and in addition, *dextro-terpineol*, partly in the form of ester. It is employed as a medicine and as a perfume for soaps. It is seldom used in the United States.

OLEUM ORIGANI CRETICI, *Cretian oil of origanum.*—This herb is distilled from several species of *Origanum*, as *O. creticum*, Linné; *O. hirsutum*, Link; *O. macrostachyum*, Link, and *O. megastachyum*, Link. A golden-yellow oil when fresh, becoming yellowish or brownish with age. It has an aromatic, penetrating, thyme-like odor. Specific gravity, 0.960 to 0.980 (Power). The Trieste commercial variety, probably derived from *O. hirsutum*, Link, contains, according to

Jahns (1879), *carvacrol* (*isopropyl ortho-cresol*, $C_6H_3.CH_3.OH.C_3H_7$), a colorless, thick, liquid phenol, solidifying in the cold. Good origanum oil should contain from 60 to 85 per cent. Jahns furthermore found 0.2 per cent of a second phenol and a large amount of *cymol*. Smyrna origanum oil (from the herb of *Origanum smyrnæum*, Linné) also contains cymol, but less *carvacrol* (25 to 60 per cent), and contains in addition *l-linalool* (Gildemeister, *Archiv der Pharm.*, 1895, p. 182). Origanum oil forms a clear solution with 3 parts of 70 per cent alcohol. For microscopical purposes the oil should be pale-yellowish and kept in well-filled and closely-stopped bottles, placed in a dark situation (Power, *Essential Oils*).

OLEUM PALMÆ.—PALM OIL.

The fixed oil from the fruit of *Elæis guineensis*, Jacquin.

Nat. Ord.—Palmæ.

SYNONYMS: *Palmöl*, *Palm butter*.

Botanical Source.—The oil palm is a native of western Africa, and is found growing in other tropical sections. It is a very handsome, graceful tree, growing to a great height, and supports on its spine-armed petioles, large, pinnately-divided leaves, the leaflets of which are narrow, long, and linear. The fruit is a drupe, yellow, mottled, and about an inch in length. Its leathery sarcocarp contains much oil; the seed kernel is likewise oily.

Preparation and History.—Palm oil, or fat is obtained either by pressure of the oily sarcocarp, or by boiling it in water. It is produced in western Africa, West Indies, Brazil, and Cayenne. The best varieties are those known as *Lagos prima* and *Lagos secunda*, the bulk of the oil being shipped from that port and from Palmas.

Description.—Palm oil is of a butyraceous consistence, of a reddish-yellow or orange-yellow color, and a pleasant odor. It melts at 27° C. (80.6° F.). By exposure and age the fat becomes whitish and rancid, a large portion of it being decomposed into glycerin and fatty acids; this change is not objectionable to its use in soap-making. Such changes are accompanied by rise of melting point, which reaches occasionally as high as 42° C. (107.6° F.). When fresh it will melt by the heat of the hand. Its specific gravity is 0.945. Ether completely dissolves it, while it is but partially soluble in alcohol.

The kernels also yield an oil (*palm-kernel oil*, or *palm-nut oil*), which has a white or pink color and an agreeable, orris-like, or violaceous odor. Palm oil is largely employed in the making of soaps, which retain the agreeable odor of the fat. To prepare a white soap, the oil is first bleached by means of potassium dichromate solution. It is the most easily saponified of the fixed oils.

Chemical Composition.—Palm oil consists of *palmitin*, *olein*, and free *palmitic acid*. Palm-kernel oil differs from palm oil in containing a considerable quantity of glycerin esters of lower fatty acids. According to Oudemans (see A. H. Allen, *Com. Org. Anal.*, Vol. II, Part I, 3d ed., 1899, p. 164), one sample of palm-kernel oil consisted of *olein* (26.6 per cent); *stearin*, *palmitin*, and *myristin* (33 per cent), and *laurin*, *caprin*, *caprylin*, and *caproin* (40.4 per cent). All fatty acids here represented contain an even number of carbon atoms.

Action, Medical Uses, and Dosage.—This is an agreeable emollient, useful as an application to *bruises*, *sprains*, and like *injuries*. It is less drying than most of the vegetable oils used for this purpose.

Related Oils.—(Compare *Oleum Cocos.*) TUCUM OIL. A bright-red, pleasantly fragrant oil obtained from the fruit of the South American *Astrocaryum vulgare* of Martius.

MACAJA BUTTER. A yellowish, butyraceous oil, having an agreeable, violaceous odor, prepared from the seeds of the *Cocos aculeata*, Jacquin, of the American tropical belt.

OLEUM PHOSPHORATUM (U. S. P.)—PHOSPHORATED OIL.

Preparation.—"Phosphorus, one gramme (1 Gm.) [15.5 grs.]; expressed oil of almond, ether, each, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Introduce a sufficient quantity of expressed oil of almonds into a flask, heat it on a sand-bath to 250° C. (482° F.), and keep it at that temperature for 15 minutes. Then allow it to cool, and filter it. Put ninety grammes (90 Gm.) [3 ozs. av., 76 grs.] of the filtered oil together with the phosphorus, previously well dried by filtering paper, into a dry, tared bottle capable of holding about one hundred and twenty cubic centimeters (120 Cc.) [4 fl℥, 28♏]; insert the stopper, and heat the bottle in a water-bath until the phosphorus melts. Then agitate it until the phosphorus is dissolved, allow it to cool, add enough ether to make the mixture weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.], and agitate again. Lastly, transfer the solution to small glass-stoppered vials, which should be completely filled and kept in a cool and dark place"—(*U. S. P.*).

To prevent the oxidation of the phosphorus the oil is heated to expel any moisture or air that may be present. Dr. Squibb advises that the phosphorus be dissolved in the oily fluid only in the presence of carbon dioxide. In this way he prepares a solution of 1 part of thoroughly dried phosphorus in 99 parts of cod-liver oil. The ether is present to preserve the preparation by preventing oxidation, and to impart a more agreeable taste. In the *British Pharmacopœia* formula ether is omitted, hence the strong phosphorescence of the British official product, which fumes in the air through combination of the phosphorus with atmospheric oxygen. The *U. S. P.* oil contains 1 per cent of phosphorus, that of the *British Pharmacopœia*, 0.99 per cent.

Description.—The *U. S. P.* describes phosphorated oil as "a clear, yellowish liquid, having the odor of phosphorus and of ether, but not phosphorescent in the dark. It should be perfectly free from any particles of undissolved phosphorus"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This is a convenient form for the administration of *Phosphorus* (which see).

OLEUM PICIS LIQUIDÆ (U. S. P.)—OIL OF TAR.

"A volatile oil distilled from tar"—(*U. S. P.*).

Preparation.—When common wood-tar is distilled, that portion of less density than water passing over, is called *oil of tar;* a residue known as *pitch* is left in the retort.

Description and Chemical Composition.—"An almost colorless liquid when freshly distilled, but soon acquiring a dark reddish-brown color, and having a strong, tarry odor and taste. Specific gravity, about 0.970 at 15° C. (59° F.). It is readily soluble in alcohol, the solution being acid to litmus paper"—(*U. S. P.*).

The density of oil of tar is apt to vary according to the amounts of its various constituents present. If prepared from coniferous tars turpentine is likely to form a large portion of the oil. Oil of tar contains empyreumatic substances, several acids, among them acetic acid, and a number of hydrocarbons.

Action and Medical Uses.—This oil has the uses of *Tar* (which see). It is applied locally in scaly and other forms of *skin diseases.* It has been used for the relief of *chronic coughs.* The dose is 1 to 5 drops in emulsion or capsule.

OLEUM PIMENTÆ (U. S. P.)—OIL OF PIMENTA.

A volatile oil distilled from *Pimenta officinalis*, Lindley. "It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

SYNONYMS: *Oil of allspice, Oil of pimento.*

Preparation, Description, and Tests.—When unripe and sun-dried allspice or pimento berries are bruised and distilled with water, they yield a volatile oil to the extent of from about 3 to 4.5 per cent. The ripe fruits are nearly odorless. The oil is heavier than water, its lowest density being given as 1.024 (Schimmel & Co.'s *Report*, April, 1899). The official oil is "a colorless, or pale-yellow liquid, having a strong, aromatic, clove-like odor, and a pungent, spicy taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 1.045 to 1.055 at 15° C. (59° F.). With an equal volume of alcohol it forms a clear solution which is slightly acid to litmus paper. It also forms a clear solution with an equal volume of glacial acetic acid, and a nearly clear solution with an equal volume of carbon disulphide. When mixed with an equal volume of a concentrated solution of sodium hydrate, it forms a semisolid mass. If 2 drops of the oil be dissolved in 4 Cc. of alcohol, and a drop of ferric chloride T.S. be added, a bright green color will be produced; and if the same tests be made with a drop of diluted ferric chloride T.S., prepared by diluting the test-solution with four times its volume of water, a blue color will be produced changing to green, and soon becoming yellow. If 1 Cc. of the oil be shaken with 20 Cc. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper. If, after cooling, the liquid be passed through a wet filter, the clear filtrate should produce, with a drop of ferric chloride T.S., only a transient grayish-green, but not a blue or violet color (absence of carbolic acid)"—(*U. S. P.*).

Chemical Composition.—This oil contains over 60 per cent of the heavy *eugenol* ($C_6H_3.C_3H_5[OH][OCH_3]$), the chief constituent of oil of cloves (which see). and a sesquiterpene of the composition $C_{15}H_{24}$, boiling at 255° C. (491° F.).

Action, Medical Uses, and Dosage.—Oil of pimenta is stimulant and aromatic, and may be used for similar purposes as the other oils of like character, in doses of from 2 to 10 drops.

OLEUM PINI SYLVESTRIS.—FIR-LEAF OIL.

The volatile oil distilled from the *Pinus sylvestris* (*silvestris*), Linné.

Nat. Ord.—Coniferæ.

SYNONYM: *Oleum folii pini sylvestris*, *Fir-wool oil*, *Pine-needle oil*, *Oleum pini foliorum.*

Preparation and History.—This oil is in use in various parts of Europe, and is distilled in Scotland, Sweden, and Germany, from the leaves of *Pinus sylvestris*, or "*Scotch pine*," which is found in the highlands of Scotland, where it occurs, as tree or shrub, according to the locality of its growth. The oil was admitted into the *Pharmacopœia of the Throat Hospital*, London (1872). It must not be confounded with *oil of turpentine*, which is abundantly produced from the trunk of same tree. This oil is, like that from the other species of pine, also known as pine-needle oil, and is prepared by distilling with water the leaves pounded into a fibrous condition, and then known as *fir-wool*. The yield is about 0.5 per cent. Scotch leaves yielded in winter 0.13 per cent.

Description and Chemical Composition.—Fir-leaf oil is a limpid, greenish-yellow fluid, soluble in about 10 volumes of 90 per cent alcohol. It has a strong, but agreeable, coniferous odor, combined somewhat with that of lavender. The German and Swedish oils are dextro-rotatory (about +10°), but the Scotch oil is lævo-rotatory (about —8° to —19°). The specific gravities of the German and Scotch oils vary from 0.884 to 0.889; that of the Swedish is 0.872. The German oil contains *dextro-pinene*, *d-sylvestrene*, *cadinene*, and probably *bornyl-* or *terpinyl-acetate* (about 3.5 per cent). The Swedish and English oils are similarly constituted, except that the hydrocarbons occur in the left-handed modification, in the English oils. (For other *pine-needle oils*, see table of oils in Schimmel & Co.'s *Report*, April, 1897, and especially Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899.)

Action, Medical Uses, and Dosage.—It is said that fir-leaf oil is largely sold in England and on the continent, as a patent liniment for the cure of *rheumatism*. In *maladies of the throat* it may be administered internally in the dose of a few drops, diluted, and likewise locally applied to the throat and chest.

OLEUM RICINI (U. S. P.)—CASTOR OIL.

"A fixed oil expressed from the seed of *Ricinus communis*, Linné (*Nat. Ord.*—Euphorbiaceæ). It should be kept in well-stoppered bottles"—(*U. S. P.*).

Botanical Source.—*Ricinus communis*, the *Castor-oil bush*, in the United States, is a herbaceous annual, with a white, frosted, or glaucous, hollow, smooth stem, of a purplish-red color upward. The root is long, thick, and fibrous. The leaves are large, alternate, deeply divided into 7 or 9 lanceolate segments, peltate, palmate, serrate, 4 to 12 lines in diameter, and on long, tapering, purplish petioles The flowers are borne in long, green, and glaucous spikes, springing from the divisions of the branches; males from the lower part of the spike, females from the upper. The capsule is prickly, 3-celled, and 3-seeded; the seeds ovate, shining, and black dotted with gray (L.—W.)

History.—Ricinus communis, or *Palma Christi*, is an East Indian plant, in which country it attains the size of a tree. In the United States, where it has become naturalized, it seldom grows higher than 8 or 10 feet, flowers in July and August, and matures its seeds in August and September. The plant is much grown in California for its oil, also in Italy. The fixed oil of the seeds is the castor oil of commerce, and was known to the ancient Egyptians. The seeds are poisonous, about 4 lines in length, 3 lines in width, and about 1½ lines in thickness, and consist of a smooth external coat, covering a thick, hard, and dark-brown shell, composed of two layers which inclose the white nucleus or oleaginous kernel, which has within it a large, dicotyledonous, leafy embryo. A non-griping cathartic oil, *Tambor oil*, is obtained from a Central American euphorbiacea, *Omphalea oleifera*, Hemsley. (For a detailed historical account of the castor-oil plant, see H. Stillmark's dissertation on *Ricin*, 1889.)

Fig. 184.

Ricinus communis.

Preparation.—Castor oil may be obtained by several methods, mostly by warm or cold pressure after the seeds are deprived of their husks. The *cold-drawn* oil is the most esteemed, although the *U. S. P.* does not expressly demand it. In order to remove the acridity of the fresh oil, and to coagulate albuminous matter, the oil is purified by repeatedly boiling it with water. By cold expression the seeds yield 40 to 45 per cent of oil, and a smaller quantity upon subsequent warm expression. The latter oil, however, is not used medicinally. The poisonous principle contained in the seed remains in the press-cake, and is destroyed by boiling with water.

Description and Tests.—Castor oil, as demanded by the *U. S. P.*, is "a pale-yellowish or almost colorless, transparent, viscid liquid, having a faint, mild odor, and a bland, afterward slightly acrid, and generally offensive taste. Specific gravity, 0.950 to 0.970 at 15° C. (59° F.). Soluble in an equal volume of alcohol, and in all proportions in absolute alcohol, or in glacial acetic acid; also soluble at 15° C. (59° F.), in three times its volume of a mixture of 19 volumes of alcohol and 1 volume of water (absence of more than about 5 per cent of most other fixed oils). With an equal volume of benzin, it forms, at 15° C. (59° F.), a turbid mixture, but at 17° C. (62.6° F.), it yields a clear solution. When exposed to the air in a thin layer, it slowly dries to a varnish-like film. When cooled to 0° C. (32° F.), it becomes turbid, with the separation of crystalline flakes, and at about —18° C. (—0.4° F.) it congeals to a yellowish mass. If 3 Cc. of the oil be shaken for a few minutes with 3 Cc. of carbon disulphide and 1 Cc. of sulphuric acid, the mixture should not acquire a blackish-brown color (absence of many foreign oils)"—(*U. S. P.*).

This oil is one of the heaviest and most viscid of the fixed oils, and is distinguished from all other oils except croton oil, by its ready solubility in alcohol and acetic acid in the cold. Its remarkable insolubility in an excess of benzin (see above) may be overcome by the admixture of a third fatty oil, *e. g.*, lard oil. When exposed to the air in bulk, its viscidity increases, and the oil becomes rancid; in thin layers it slowly dries, it also yields with nitrous acid (according to *Pharmacographia*, 6 parts of castor oil warmed with 1 part of starch and 5 parts of nitric acid of specific gravity 1.25) solid *ricin-elaidin*. Thus castor oil shares the conspicuous properties of both drying and non-drying oils. Unlike most other fixed oils, some specimens of castor oil, *e. g.*, East Indian oils, show a right-handed optical rotation. When heated to temperatures above 100° C. (212° F.), castor oil becomes altered, the characteristic *œnanthol* being among the products of decomposition (see below).

It is stated that rancid, acrid castor oil may be deprived of its disagreeable odor and taste, as well as of acrimony, by boiling it for 15 minutes with water and a little calcined magnesia. Castor oil, in addition to its medicinal uses, is much employed in the preparation of lubricants and cheap soaps, and in the making of turkey-red oil, which is used as a mordant in dyeing cotton with alizarin dyes.

Chemical Composition.—I. Seeds. According to Geiger, the seeds consist to about one-fourth of the husks, and three-fourths of nucleus. The *seed-coats* contain tasteless resin and extractive, 1.91; brown gum, 1.91; ligneous fiber, 20.00. The *nucleus of the seeds* contains fatty oil, 46.19; gum, 2.40; casein (albumen), 0.50; ligneous fiber, with starch, 20.00; loss or moisture, 7.09 (P.). They also contain a peculiar and acrid principle which does not enter the oil, for the seeds are powerfully active after the oil has been expressed. The active poisonous principle, according to Stillmark (*loc. cit.*, 1889), is an unorganized albuminous ferment, called *ricin*. In air-dry seeds it is present in the quantity of about 3 per cent. It is obtained in largest amount by extracting the press-cake cold, with a 10 per cent solution of sodium chloride, and precipitating the filtrate with magnesium sulphate. The poison is destroyed by boiling with water, although not by dry heat. It is not a glucosid.

II. Oil.—According to Alfred H. Allen (*Com. Org. Anal.*, Vol. II, Part I, 3d ed., 1889, p. 156), castor oil is free from *palmitin* or *olein*, but contains small amounts of *stearin*. Its chief constituents are *ricinolein* ($C_3H_5[C_{18}H_{33}O_3]_3$), *isoricinolein*, and *dihydroxystearin*. Ricinoleic acid ($C_{18}H_{34}O_3$) is the principal acid of the oil; it forms a thick oily liquid, solidifying below 0° C. (32° F.), soluble in alcohol and ether. It does not absorb oxygen from the air, although as an unsaturated acid it absorbs 2 atoms of bromine. By the action of nitrous acid it is slowly converted into its stereo-isomer, *ricinelaïdic acid*, which crystallizes in needles melting at 50° C. (122° F.). By distillation under diminished pressure, ricinoleic acid yields among other products *œnanthol* (*œnanthic* or *heptoic aldehyde* $C_7H_{14}O$ or $C_6H_{13}.CHO$), a highly refractive liquid of a characteristic odor, boiling at 154° C. (309.2° F.). Castor oil also yields *œnanthol* when rapidly distilled. In addition, *œnanthic acid* ($C_6H_{13}.COOH$), *acrolein*, and other substances are formed. In this connection we may refer to *œnanthic ether* ($C_6H_{13}.COOC_2H_5$), a constituent of the bouquet of wines, which is prepared by conducting dry hydrochloric acid gas into a solution of *œnanthic acid* in absolute alcohol. It boils at 188° C. (370.4° F.).

Action, Medical Uses, and Dosage.—The castor-oil seed or bean is a powerful cathartic and gastric irritant, and has proved fatal to man when taken to the extent of 20 seeds at once. Yet the oil expressed from it is only a mild cathartic, operating promptly, producing thin, feculent, but not watery stools, and causing but little griping or nausea. From its mildness of action, it is especially adapted to young children, pregnant or puerperal females, likewise in *hemorrhoidal affections*, *colic*, *diarrhœa*, *dysentery*, *enteritis*, after the *reduction of hernia*, *obstinate constipation*, *collections of indurated feces*, *accumulation of acrid secretions*, and in *worms*. It is frequently used to remove constipation, and also in diarrhœa when due to undigested material. When throat and skin disorders depend upon intestinal accumulations, castor oil is an efficient purgative. One part of oil of turpentine mixed with 3 or 4 parts of castor oil increases its purgative and anthelmintic effect. The greatest objections to this cathartic are its nauseous taste and its tendency to cause sickness or unconquerable disgust. This may be overcome by adding to 1 pint of the oil ½ fluid ounce each of oils of origanum and wintergreen, or 1 ounce of sassafras oil; the dose of this may be given in sweetened water. Any other aromatic oils will answer equally as well. When not contraindicated it may be taken in wine, spirituous liquors, or the froth of beer, likewise in cinnamon or peppermint water. I find it a very pleasant mode of administration to boil the dose of oil with about a gill of good sweet milk for a few minutes, sweeten with loaf-sugar, and flavor with essence of cinnamon or other favorite aromatic; it somewhat resembles custard in its taste and appearance, and is readily taken by even the most delicate stomach (J. King).

Stuncke states that castor oil saponifies readily with alkalies, and gives with soda a white solid soap, which, in the form of pills, is a certain and agreeable purgative. M. Parola proposes an ethero-alcoholic extract and the ethereal and alcoholic tinctures of the seeds as a substitute for the oil; he states that the above tinctures have a purgative action four times as strong as the oil, are less irritating, and remain unalterable in all climates. As an enema, castor oil may be used in the quantity of 2 or 3 fluid ounces mixed with some mucilaginous liquid. Externally, it has been recommended in *itch*, *ringworm*, and other *cutaneous diseases*. Daily applications of castor oil to *warts* is said to remove them in a few weeks. Dose for an adult, 1 or 1½ fluid ounces; for an infant, 1, 2, or 3 fluid drachms, according to its age. Equal parts of castor oil and copal varnish form an excellent local application for *hemorrhoidal affections*. A hairwash for keeping the hair from falling, and cleansing it of *dandruff*, is sold by the perfumers, and is made as follows: Take castor oil, ½ pound; strongest alcohol, ½ pint; powdered cantharides, 48 grains; oil of bergamot, ½ ounce; otto of roses, 4 drops. Mix, let them stand for 7 days, frequently shaking, and then filter, and keep in well-closed bottles.

CASTOR-OIL LEAVES.—According to Dr. J. O. McWilliam, the natives of the Cape Verde Islands use the leaves of the castor-oil plant, which they term "*Bofareira*," for accelerating and increasing the flow of milk, in cases where it is tardy in appearing or deficient in quantity, and also in cases of emergency, where the females are not child-bearing, or have not suckled a child for many years. The *white* plant, known by the light-green color of the leaf-stem, is used instead of the *red*, having a purplish-red leaf-stem. The breasts are frequently fomented, and the boiled leaves placed upon the breasts in the form of a poultice. This operation is frequently repeated, and in obstinate cases the thighs and generative organs are exposed to the vapor from the decoction. One, two, or three days are required before the child can procure a supply of milk from the breasts of persons thus treated—according to circumstances.

Women with well-developed breasts are most easily affected by it, while those with small and shriveled breasts have the uterine system acted upon, bringing on the menses, if their period be distant, or causing their immoderate flow if their advent be near. Exposure to cold is carefully avoided by women brought under its influence; they scrupulously abstain from wetting the hands or feet with cold water. It is said to affect virgins of adult age, similar to child-bearing women. It sometimes produces swelling and pain in the breasts and axillary glands, pain in the back, and an increase of a leucorrhœal discharge.

This remedy, and the Red bofareira, both of which are common to this country, have been tried by physicians, as an emmenagogue, and the results have been sufficiently favorable to render further investigation very desirable.

OLEUM ROSÆ (U. S. P.)—OIL OF ROSE.

"A volatile oil distilled from the fresh flowers of *Rosa damascena*, Miller (*Nat. Ord.*—Rosaceæ). It should be kept in well-stoppered vials, in a cool place, protected from light. When dispensed, it should be completely liquefied by warming, if necessary, and well mixed by agitation"—(*U. S. P.*).

SYNONYMS: *Otto of roses, Attar of roses, Essence of rose.*

History and Source.—The earliest nations gave attention to the rose aroma, and employed oil of rose in many of their religious ceremonies. This oil consisted for centuries merely of some fatty oil saturated with the aroma of the flower. Arab writers mention the distillation of the oil of rose in the eighth and ninth centuries. In the middle ages Persia was the principal country of its production. It gradually extended to India and westward, and gained a foothold in Bulgaria early in the seventeenth century. Since about 1850 the French, and in more recent years the German rose industries, have become important. Adulteration with santal-wood oil was practiced in Persia (E. Kämpfer, 1682–1684), and with East Indian geranium (Palma rosa) oil in Kashmir (Polier, 1788). (See Dr. Hoffmann in *Die Ætherischen Oele*, p. 556.) Rose oil is distilled in Bulgaria as well as in Germany, from the fresh leaves of *Rosa damascena*, Miller; in southern France from *Rosa centifolia*, Linné. The yield of German oil is 1 pound from 5,000 to 6,000 pounds of flowers, or about 0.02 per cent.

Description.—The official oil of rose is thus described: "A pale-yellowish, transparent liquid, having the strong, fragrant odor of rose, and a mild, slightly sweetish taste. Specific gravity, 0.865 to 0.880 at 20° C. (68° F.). It is but slightly soluble in alcohol, and neutral to litmus paper moistened with alcohol. The congealing and melting points of the oil are subject to some variation, depending upon the amount of stearopten, but, when slowly cooled to a temperature, usually between 16° and 21° C. (60.8° and 69.8° F.) it becomes a transparent solid, interspersed with numerous slender, shining, iridescent, scale-like crystals. Upon the application of the heat of the hand, the crystals should float in the upper portion of the liquefied oil"—(*U. S. P.*). It is combustible, and its vapor is said to form an explosive mixture with oxygen. The pharmacopœial description is that of the Bulgarian oil. The German oil is stated to have a much stronger rose odor than the Bulgarian, and to be of absolute purity (see Power, *Essential Oils*, p. 30). At ordinary temperatures, it is a semisolid, soft mass, congealing between 27° and 37° C. (80.6° and 98.6° F.), and containing from 26 to 34 per cent of stearopten, while Bulgarian oil contains from 10 to 15 per cent.

Chemical Composition.—*Rose-stearopten*, or *rose camphor*, is odorless, and was recognized by Flückiger (1869) to be a paraffin hydrocarbon. It may be differentiated, by distillation in vacuo, into two paraffins, one melting at 22° C. (71.6° F.), the other at 40° and 41° C. (104° and 105.8° F.). The presence of this paraffin renders the oil partly insoluble in alcohol. The liquid portion of oil of rose contains as its chief constituent the alcohol *geraniol* (Bertram and Gildemeister, 1894; U. Eckart's *rhodinol*, 1891).

GERANIOL is a colorless liquid, boiling at 230° C. (446° F.), of a rose-like odor, having the formula $C_{10}H_{18}O$ or $(CH_3.C[CH_3]:CH.CH_2.CH_2.C[CH_3]:CH.CH_2OH)$. It is a primary alcohol, and yields, upon oxidation, the aldehyde *citral* ($C_{10}H_{16}O$). It is likewise the principal constituent of East Indian geranium, rose geranium, citronella, and lemon-grass oils. It forms a characteristic, crystallizable addition compound with dry calcium chloride insoluble in the usual organic solvents, but decomposable by water; this regenerates therefrom geraniol, which may be obtained chemically pure by this method. Oil of rose furthermore contains about 20 per cent of *l-citronellol* (Tiemann and Schmidt, 1896). Both geraniol and citronellol are, for the smaller part, combined in the form of ester (about 3 per cent). The exact honey-like odor of rose oil has not yet been obtained by a combination of the constituents enumerated.

Adulterations and Tests.—Owing to its high price, oil of rose is subject to adulteration; the additions to it are mostly the oils of palma rosa (East Indian geranium from *Andropogon*) and of rose geranium (from *Pelargonium*). A deficiency in rose camphor, resulting from the addition of these oils, is sometimes made up by adding spermaceti. The addition of these oils, if carried out intelligently, is very difficult to detect. Crude adulterations may be recognized by determining the following constants: Specific gravity, optical rotation, congealing point, amount and chemical nature of stearopten, saponification, and acetylation (see details of these determinations in Gildemeister and Hoffmann, *Die Ætherischen Oele*, pp. 566–570). The *U. S. P.* gives the following color tests for the purity of oil of rose: "If to 5 drops of the oil, contained in a test-tube, 5 drops of concentrated sulphuric acid be added, a reddish-brown, thick mixture will be produced, but no white fumes or tarry odor should be developed, and the fragrant odor of the oil should not be destroyed. If this mixture be then shaken with 2 Cc. of alcohol, the resulting liquid may be turbid, but should be nearly colorless, and should not at once assume a red or reddish-brown color (absence of oil of ginger-grass or Turkish oil of geranium, from *Andropogon Schœnanthus*, Linné [*Nat. Ord.*—Gramineæ], and from oil of rose geranium, from *Pelargonium Radula* [Cavanilles], Aiton, *Pelargonium capitatum* [Linné], Aiton, and *Pelargonium odoratissimum* [Linné], Aiton [*Nat. Ord.*—Geraniaceæ])"—(*U. S. P.*). Power (*loc. cit.*) suggests that the foregoing test is rather reliable if 5 Cc. of alcohol is employed instead of 2 Cc., and if the adulterant is present in considerable quantity. The oils mentioned in the above test all have an acid reaction, as well as the *oil of rhodium* (from roots of *Convolvulus* [*Rhodorrhiza*, Webb] *Scoparius*, Linne, and *Convolvulus floridus*, Linné, of Canary Isles), which is occasionally an adulterant. The latter has the combined odor of rose, copaiba, and cubeb, and is bitter.

Uses.—Oil of rose is used altogether as a perfume, and is frequently added to cerates, ointments, liquors, etc., for the purpose of rendering them fragrant.

OLEUM ROSMARINI (U. S. P.)—OIL OF ROSEMARY.

"A volatile oil distilled from the leaves of *Rosmarinus officinalis*, Linne (*Nat. Ord.*—Labiatæ). It should be kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Source and Description.—*Rosmarinus officinalis*, Linné, is a shrub growing in the European Mediterranean countries from Greece to Spain. There are two kinds of oil in commerce, the Italian and the French oil. The former is obtained from the Dalmatian Islands in the Adriatic Sea. The French oil has the finer aroma. The yield from Dalmatian leaves is 1.4 to 1.7 per cent, from dry French leaves 2 per cent, from the flowers 1.4 per cent (Schimmel & Co., *Reports*, October, 1893 and 1897). The commercial oils are often adulterated with oil of turpentine. The *U. S. P.* gives the following description of oil of rosemary: "A colorless or pale yellow, limpid liquid, having the characteristic, pungent odor of rosemary, and a warm, somewhat camphoraceous taste. Specific gravity, 0.895 to 0.915 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral or very slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid" (*U. S. P.*). Oil of rosemary is optically dextro-rotatory, but is *never* lævo-rotatory, unless adulterated with oil of French turpentine. The oil requires from 2 to 10 volumes of alcohol of 80 per cent (by volume) for complete solution.

Chemical Composition and Tests.—Pure oil of rosemary contains *camphor* (Lallemand, 1860); *borneol* (Bruylants, 1879), about 18 per cent (Gildemeister and Stephan, 1897); *cineol* (E. Weber, 1887); *d*-and *l-pinene* and *camphene* (Gildemeister and Stephan, 1897). In order to test the oil for adulterations, its optical rotation, especially that of the lowest fraction, which is always dextro-rotatory in pure oil, and its specific gravity and solubility in alcohol render useful aid.

Action, Medical Uses, and Dosage.—Oil of rosemary is stimulant and rubefacient; it is principally employed, however, in perfumery. It may be used in *colic*, *nervous disorders*, *debility*, *painful* or *tardy menstruation*, etc., and locally to *painful parts*. The dose of oil of rosemary is from 2 to 10 drops.

A very pleasant *cologne* may be made as follows: Take of oil of rosemary, oil of lemon, each, 2 fluid drachms; oil of lavender, oil of bergamot, of each, 1 fluid drachm; oil of cinnamon, oil of cloves, oil of rose, of each, 8 minims; alcohol, 1 pint. Mix, agitate well, and after allowing the mixture to stand for a few days, with frequent agitation, filter. The following formula has been published by Farina, one of the originators of Cologne: Take of purified benzoin, oil of rosemary, each, by weight, ¼ ounce; oil of lavender, ½ ounce, by weight; strong alcohol, 9 pints. Mix, and agitate thoroughly together, and then add, successively, oil of neroli (*petit grains*), oil of lemon, each, 1 ounce and 144 minims; oil of sweet orange (*Aurantii dulcis*), oil of limmetta (lime), oil of bergamot, each, 2 ounces and 228 minims; tincture of rose geranium flowers, a sufficient quantity to impart the desired fragrance. Macerate for several weeks, and then fill into flasks (*Amer. Drug. Cir.*, Vol. VIII, p. 85; *Amer. Jour. Pharm.*, 1864, p. 375). I have reduced the weights and measures in the above (J. King).

OLEUM RUTÆ.—OIL OF RUE.

The essential oil distilled from *Ruta graveolens*, Linné.

Nat. Ord.—Rutaceæ.

Preparation and Description.—The fresh leaves and tops of *Ruta graveolens*, Linne, an herbaceous plant indigenous to the Mediterranean countries, yield, when distilled with water, about 0.06 per cent of volatile oil (Gildemeister and Hoffmann, *loc. cit.*). It is a colorless to yellow liquid, of a strong, penetrating, persistent odor. Its specific gravity is 0.833 to 0.840, this being nearly the lowest of all essential oils. It is slightly dextro-rotatory (+0° 30′ to +2° 10′), and congeals between 8° and 10° C. (46.4° and 50° F.). The bulk of the oil distills between 215° and 232° C. (419° and 449.6° F.); 5 per cent distills below 200° C. (392° F.) (Umney, 1895 and 1897). The oil forms a clear solution with 2 to 3 volumes of 70 per cent alcohol.

Chemical Composition and Tests.—About 90 per cent of oil of rue consists of *methyl-nonyl-ketone* ($CH_3CO.C_9H_{19}$, Giesecke, 1870; Gorup-Besanez and Grimm, 1874). Below 15° C. (59° F.) it is solid, boils at 224° C. (435.2° F.), and has a specific gravity of 0.8295 at 17.5° C. (63.5° F.). The oil is also said to contain *lauric aldehyde* ($C_{12}H_{24}O$) (C. G. Williams, 1858). No terpene is present in oil of rue. Adulterations with other essential oils increase the specific gravity and decrease the congealing point of oil of rue. Petroleum and oil of turpentine may be recognized by being insoluble in alcohol of 70 per cent by volume.

Action, Medical Uses, and Dosage.—Oil of rue is stimulant, antispasmodic, and emmenagogue. It has decidedly active properties. Locally it is irritant, and internally, even in small doses, it has produced severe gastro-intestinal and nervous disturbances. Oil of rue, in the dose of from 1 to 5 drops, 3 times a day, has been used with advantage in *hysteria*, *convulsions*, *pertussis*, *amenorrhœa*, and *dysmenorrhœa*. It is sometimes criminally used for the purpose of producing abortion, in which it is highly dangerous, having been followed by fatal consequences.

OLEUM SABINÆ (U. S. P.)—OIL OF SAVINE.

A volatile oil distilled from the tops of *Juniperus Sabina*, Linné.

Nat. Ord.—Coniferæ.

"It should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

SYNONYM: *Oil of savin.*

Preparation and Description.—The tops and leaves of savine, when submitted to distillation with water, yield this oil in the quantity of from 4 to 5 per cent (Schimmel & Co., *Report*, April, 1897). The official oil is described as "a colorless or yellowish liquid, having a peculiar, terebinthinate odor, and a pungent, bitterish, and camphoraceous taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 0.910 to 0.940 at 15° C. (59° F.). Soluble in an equal volume of alcohol (distinction from oil of juniper and oil of turpentine), the solution being neutral to litmus paper; also soluble in an equal volume of glacial acetic acid"—(*U. S. P.*). The oil is dextro-rotatory.

Chemical Composition.—The chief constituent of oil of savine is the alcohol *sabinol* (Schimmel & Co., *Report*, 1895), of the formula $C_{10}H_{16}O$, and boiling at 208° to 209° C. (406.4° to 408.2° F.) (E. Fromm, 1898). It exists partly free (10 per cent), partly in the form of acetate (40 to 44 per cent) The highest fractions of oil of savine contain *cadinene* (Wallach, 1877). The lowest fractions contain *terpenes*, probably *pinene*. According to Umney (*Pharm. Jour. Trans.*, 1895), not more than 25 per cent of the oil distills below 200° C. (392° F.). If the quantity of distillate exceeds this figure, adulterations with oil of turpentine may be looked for. French oil of savine is stated to be frequently adulterated with oil of turpentine. An addition of the latter (if of French origin) also reduces the optical rotation of the oil (see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 352).

Action, Medical Uses, and Dosage.—Oil of savine is a powerful irritant to the mucous tissues, and powerfully deranges the nervous system. It may induce gastro-intestinal inflammation, vesical tenesmus and strangury, congestion of the pelvic organs, fever, mental excitation and intoxication, coma, and death. Oil of savine is an emmenagogue, and is seldom used for any other purpose, save as a liniment to the lumbar and sacral regions, and internally in *amenorrhœa* from torpor of the reproductive organs, in which it is sometimes very efficient. It also acts as a stimulant and abortivant. Ten drops of the oil on sugar, repeated 3 times a day, will, it is stated, positively produce abortion in from 1 to 3 weeks; but, as with all other agents of this kind, is apt to be followed by very serious consequences. It has been used for the relief of *uterine leucorrhœa*, *uterine hemorrhage*, *dysmenorrhœa*, and *sterility*. It is reputed to cure *condylomata*. The dose of oil, ordinarily, is from 2 to 10 drops.

OLEUM SANTALI (U. S. P.)—OIL OF SANTAL.

"A volatile oil distilled from the wood of *Santalum album*, Linné (*Nat. Ord.*—Santalaceæ). Oil of santal should be kept in well-stoppered bottles, in a cool place, protected from the light"—(*U. S. P.*).

SYNONYMS: *Oil of sandal-wood*, *Oleum ligni santali*, *Oleum santali flavi*, *East Indian oil of santal.*

Botanical Source and History.—The White santal is indigenous to the Indian Peninsula, and to some of the islands of the Indian Archipelago, notably Sumba

(Sandal-wood Island) and Timul. It grows in the mountainous districts in dry open places, and not in woods, a strip of country 250 miles long, north and northwest of the Nilgherry Hills, lying mainly in Mysore and Coimbatore, yielding the most valuable wood. By the provisions of a treaty made in 1770, with Hyder Ali, the cutting of the trees in Mysore is entirely under the control of the East India Company, whose officers see to the felling of the trees. In other places these restrictions have been removed (see *Pharmacographia*).

The Santalum album is a small tree growing to a height of 20 or 30 feet, the trunk measuring in girth from 18 to 35 inches. The leaves are opposite, smooth, glaucous on under surface, oval or lanceolate in shape, or rather varying between these two forms. Its numerous small flowers are without odor and of varying hues, and borne in a panicled cyme. The tree attains about a foot in diameter when from 20 to 30 years old, when they are in their prime. The tree is parasitic, and will attach itself to other plants by tuberous processes on its roots. In regard to the manner of collecting the wood, the authors of *Pharmacographia* give the following account: "A tree having been felled, the branches are lopped off, and the trunk allowed to lie on the ground for several months, during which time the white ants eat away the greater part of the inodorous sapwood. The trunk is then roughly trimmed, sawn into billets 2 to 2½ feet long, and taken to the forest depots. There the wood is weighed, subjected to a second and more careful trimming, and classified according to quality. In some parts it is customary not to fell, but to dig the tree up; in others the root is dug up after the trunk has been cut down, the root affording valuable wood, which, with the chips and sawdust, are preserved for distillation, or for burning in the native temples. The sapwood and branches are worthless"—(*Pharmacographia*, p. 601).

SANTAL-WOOD (*Lignum santali album*, *Santalum album*, *Lignum santali citrinum*), *Yellow* or *White sanders wood*.—Whitish or brownish-yellow billets, from 3 to 9 inches thick, and 3 or 4 feet long, hard, heavy, of a bitterish, subacrid, aromatic taste, and an agreeable, rose-like odor (when rubbed or rasped). On transverse section the wood has a lustrous, waxy appearance, showing alternate light and dark, irregularly-concentric circles, which are, however, sometimes not well marked. The medullary rays are delicate and the vessels very fine. The darker-colored wood is most highly valued (that from the root being the best quality), and the taste and odor vary according to the source of the wood. In the Chinese markets three grades are known: *South Sea Island*, *Timor*, and *Malabar*, the last far exceeding the others in price.

Preparation.—Santal oil is procured by distilling the wood with water or by means of steam. The most and best oil is obtained from the root-wood. According to Flückiger, 2.5 per cent are obtained in India, notwithstanding imperfect apparatus. The yield, according to Schimmel & Co., is 1.6 to 3 per cent for *Macassar* (Dutch Indian), and 3 to 5 per cent for *East Indian*. Speaking of its uses, Prof. Flückiger says: "It is employed as a perfume and for the fabrication of small articles of ornament. Among the natives of India it is largely consumed in the celebration of sepulchral rites, wealthy Hindus showing their respect for a departed relative by adding sticks of sandal-wood to the funereal pile. The powder of the wood, made into a paste with water, is used for making the caste mark, and also for medicinal purposes. The consumption of sandal-wood in China appears to be principally for the incense used in the temples"—(*Pharmacographia*, p. 603).

Description and Tests.—Oil of sandal-wood is described officially as "a pale yellowish or yellow, somewhat thickish liquid, having a peculiar, strongly aromatic odor, and a pungent, spicy taste. Specific gravity, 0.970 to 0.978 at 15° C. (59° F.). It deviates polarized light to the left, distinction from *Australian* (specific gravity, 0.953) and *West Indian* (specific gravity, 0.965) *sandal-wood oils*, which deviate polarized light to the right. Readily soluble in alcohol, the solution being slightly acid to litmus paper. If to 1 Cc. of the oil, at 20° C. (68° F.), there be added 10 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water, a perfectly clear solution should be obtained (test for cedar-wood oil, castor oil, and other fatty oils, etc.)"—(*U. S. P.*). According to Schimmel & Co., the optical rotation remains rather constantly between the limits —17° to —20°. Oil of copaiba, as an adulterant, has the effect of diminishing the optical rotation to some extent. West Indian sandal wood oil may also be recognized by being very little soluble in alcohol. True sandal-wood oil, however, when exposed to air and light, or by age, becomes less soluble in diluted alcohol than when fresh, which must be considered in applying the above pharmacopœial test.

Chemical Composition.—The official oil is the *East Indian Oil of Santal*, and according to Chapoteaut (1882), and Chapman and Burgess (1896), contains some *santalal* ($C_{15}H_{24}O$), presumed to be an aldehyde boiling at 300° C. (572° F.), and from 93 to 98 per cent of *santalol* ($C_{15}H_{26}O$), an alcohol boiling at 310° C. (590° F.). Phosphoric anhydride converts the latter into the hydrocarbon *santalene* ($C_{15}H_{24}$), which boils at 260° C. (500° F.). When oil of sandal-wood is heated to 150° C. (302° F.) with acetic anhydride, the acetic ester of santalol ($C_{15}H_{25}O.COCH_3$) is formed. Upon this reaction is based a method of valuation for oil of sandal-wood (see Gildemeister and Hoffmann, *Die Ätherischen Oele*, 1899, p. 446).

Action, Medical Uses, and Dosage.—Oil of santal is an active substance of agreeable odor employed in the treatment of *subacute* and *chronic affections of mucous tissues*, particularly *gonorrhœa* after the active symptoms have been mitigated. *Chronic bronchitis*, with fetid expectoration, *chronic mucous diarrhœa*, *chronic inflammation of the bladder* and *pyelitis* are also said to be benefited by it. It occasionally disturbs the gastro-intestinal tract, and, like copaiba, which it was introduced to supersede, it will occasion cutaneous eruptions. The dose ranges from 5 to 20 drops, in capsules or emulsion.

Related Products.—I. OTHER SANTAL-WOODS. The following species furnish varieties of santal-wood. (For *Pterocarpus santalinus*, see *Santalum Rubrum*.)

Santalum freycinetianum, Gaudin.—Sandwich or Hawaiian Isles.

Santalum pyrularium, A. Gray.—Sandwich or Hawaiian Isles.

Santalum Gasi, Seeman.—Fiji Islands.

Santalum austro-caledonicum, Veiell.—New Caledonia.

Fusanus spicatus, R. Brown (*Santalum spicatum*, A. De Candolle; *S. cygnorum*, Miquel), *Fragrant sandal-wood.*—Australia. Not very fragrant, and shipped to China and India for the production of oil.

Fusanus acuminatus, R. Brown (*Santalum Preissianum*, Miquel; *Santalum acuminatum*, A. De Candolle), *Native peach.*—Australia. Edible fruit and seed. The nuts yield a fatty oil which is used as an illuminant. The wood is pleasantly fragrant, takes a very fine polish, and is much used in cabinet work.

Fusanus persicarius, F. von Mueller (*Santalum persicarium*, F. von Mueller), *Native sandal-wood.*—Australia. Yields a grade of sandal-wood.

Santalum lanceolatum, R. Brown (*S. oblongatum*, R. Brown).—Australia. *Sandal-wood* of the colonists. Yields an agreeable purple fruit. Wood firm, yellow, and close-grained. Useful in cabinet work.

Santalum obtusifolium, R. Brown (*Santalum ovatum*, R. Brown), *Sandal-wood.*—Australia. Yields a portion of Australian sandal-wood.

The source of JAPANESE SANDAL-WOOD is unknown. WEST INDIAN SANDAL-WOOD is derived from *Amyris balsamifera*, Linné, not belonging to *Santalaceæ* (Schimmel & Co., 1899).

The wood furnishing the last-named oil is called *Venezuela sandal-wood*.

The *Eremophila mitchelli*, Bentham (*Nat. Ord.*—Myropinæ), is known in Queensland as *Sandal-wood*, *Bastard sandal-wood*, and *Rosewood*. It is very fragrant, beautifully grained, brown, and used for veneers. It is not a true sandal-wood. The so-called *sandal-wood bark* bears no relation to the sandal-woods, and is thought to be derived from a species of *Myrospermum*, or *Myroxylon*. A fluid resembling Peru balsam may be obtained from it. The bark is used as an altar incense.

II. OTHER SANTAL OILS. (See Schimmel & Co., *Report*, Oct., 1893; also Power's *Essential Oils*.) OIL OF SANTAL (*South Australian*).—From *Santalum Preissianum*, Miquel (*Fusanus acuminatus*, R. Brown). Color, cherry-red; congeals at ordinary temperature; specific gravity, 1.022; constituent, a crystallizable alcohol, melting at 101° to 103° C. (213.8° to 217.4° F.); yield 1.5 per cent.

OIL OF SANTAL (*African*).—Botanical source unknown. From Madagascar. Color, ruby-red; specific gravity, 0.969; consistence, like the official santal oil; yield, 3 per cent.

OIL OF SANTAL (*West Indian*).—(For botanical source, see *Related Woods*.) Specific gravity, 0.963 to 0.967; optical rotation, about +26°; yield, 1.5 to 3.5 per cent.

OIL OF SANTAL (*West Australian* from Swan River). From *Santalum cygnorum*, Miquel (*Fusanus spicatus*, R. Brown). Specific gravity, 0.953; optical rotation, −5° 20′; odor, resinous, empyreumatic, and sharp; yield, 2 per cent; seems to contain 75 per cent santalol (E. J. Parry, 1898).

OLEUM SASSAFRAS (U. S. P.)—OIL OF SASSAFRAS.

A volatile oil distilled from the bark of the root of *Sassafras variifolium* (Salisbury), O. Kuntz (*Sassafras officinale*, Nees). "It should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

Nat. Ord.—Laurineæ.

History and Preparation.—The sassafras tree grows in North America from Canada to Florida and Alabama, and westward as far as Kansas, and early attracted the attention of the American Indians on account of its peculiar and pleasant aroma, and its supposed power to purify the blood. Until about 1860, oil of sassafras was distilled from the root-bark in the states of Pennsylvania, Maryland, and Virginia, often in a rather primitive manner; since then, the oil has been manufactured on a large scale in other states, as New Jersey, New York, Tennessee, and the New England states. In large plants, one charge consists of 20,000 pounds of wood, which is exhausted of its oil in about 48 to 50 hours. The yield is from 6 to 9 per cent, the wood of the root yields only about 0.9 per cent. (For interesting details regarding the history of sassafras and the preparation of its oil, see Dr. Frederick Hoffmann, in *Die Ätherischen Oele*, 1899, p. 514; also see J. U. Lloyd, "An Historical Study of Sassafras," in *American Druggist*, 1898, p. 258.)

Description.—According to Prof. W. Procter, Jr. (*Amer. Jour. Pharm.*, 1866, p. 481), a reddish colored oil is yielded from the bark of old stump roots, while young roots are said to yield a colorless oil. The *U. S. P.* describes the oil as "a yellowish or reddish-yellow liquid, having the characteristic odor of sassafras without the odor of camphor, and a warm, aromatic taste. It becomes darker and thicker by age and exposure to air. Specific gravity, 1.070 to 1.090 at 15° C. (59° F.). Soluble, in all proportions, in alcohol, the solution being neutral to litmus paper; also soluble, in all proportions, in glacial acetic acid, and in carbon disulphide. If to 5 drops of the oil 5 drops of nitric acid be added, a violent reaction will take place, producing at first a red color, and finally converting the oil into a red resin. If to a few drops of the oil a drop of sulphuric acid be added, a deep-red color will be produced at first, which soon becomes blackish"—(*U. S. P.*). The oil is slightly dextro-rotatory (+3° to +4°). The above reaction with nitric acid, first observed by Bonastre (1828), is attended with emission of flame.

Chemical Composition.—Oil of sassafras, according to Gildemeister and Hoffmann (*loc. cit.*, p. 522), has the following percentage composition, ascertained by Power and Kleber (*Pharm. Review*, 1896, p. 101): *safrol* ($C_{10}H_{10}O_2$), 80 per cent; *pinene* (*safrene* of Grimaux and Ruotte, 1869) and *phellandrene*, together 10 per cent; *dextro-camphor* (ordinary *Japan camphor*), 6.8 per cent; *eugenol* (Pomeranz, 1890), 0.5 per cent; *sesquiterpene* in the highest fractions, and residue, 3 per cent.

SAFROL is a colorless or yellowish liquid, possessing the pure sassafras odor, and becomes solid upon moderate cooling; it melts again at 11° C. (51.8° F.). It was first observed by Binder, in 1821, as a deposit from the oil. Its specific gravity is 1.108, its boiling point 233° C. (451.4°). Chemically, it is the *methylene ether* of an *allyl-pyrocatechin* ($C_6H_3.C_3H_5.OOCH_2$), and also occurs in large quantity in camphor oil, and in oils of star anise and cinnamon leaves.

Adulteration.—The substitution of sassafras oil by camphor oil is very difficult to detect, since the constituents of both are the same; sometimes deviations in specific gravity will point to substitution. *Artificial oil of sassafras* is thought to be a fraction of camphor oil having the same specific gravity as oil of sassafras (see Gildemeister and Hoffmann, *loc. cit.*, p. 522). Oil of sassafras is rarely adulterated in this country with oils of turpentine, cloves, or lavender.

Action, Medical Uses, and Dosage.—Sassafras oil is stimulant, diuretic, carminative, alterative and diaphoretic. It may be used for all the purposes for which the bark is recommended. It is said to be an efficient application to *wens*. It is much used as a local application to *rheumatic* and other *pains*, and has proved advantageous when given internally in *chronic gonorrhœa* and *cystirrhœa*. Its dose is from 3 to 12 drops on sugar, or in emulsion. It is stated by Dr. Shelby, of Huntsville, that oil of sassafras will not only prevent the injurious effects of tobacco, but speedily remove them when produced; he has verified this either by combining the tobacco with some sassafras bark, and by smoking tobacco, in a strong pipe, to which a few drops of the oil has been added (*Boston Jour. Chem.*, 1860).

OLEUM SESAMI (U. S. P.)—OIL OF SESAMUM.

"A fixed oil expressed from the seed of *Sesamum indicum*, Linné (*Nat. Ord.*—Pedaliaceæ It should be kept in well-stoppered bottles"—(*U. S. P.*)

SYNONYMS: *Sesame oil*, *Teel* or *Til oil*, *Benne oil*, *Gingili* or *Jingili oil*

Preparation.—This oil is obtained by expressing the seeds, the yield being about 50 per cent by weight. When pure, it is one of the least alterable of oils (Flückiger). *German sesame oil* is derived from *Camelina sativa*, Crantz.

Description and Tests.—Oil of sesamum stands intermediate between the drying and the non-drying oils. It shares with castor oil and croton oil the property of being optically active; it is dextro-rotatory. The *U. S. P.* describes the oil as "a yellowish or yellow, oily liquid, inodorous or nearly so, and having a bland, nut-like taste. Specific gravity, 0.919 to 0.923 at 15° C. (59° F.). When cooled to —3° C. (26.6° F.) it becomes thick, and at —5° C. (23° F.) it congeals to a yellowish-white mass. Concentrated sulphuric acid converts it into a brownish-red jelly. If 5 Cc. of the oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will usually assume a bright emerald-green color, especially if the oil has been exposed for some time to the action of air and light; and, on the subsequent addition of about 0.5 Gm. of sugar, and again shaking the mixture, a blue color, changing to violet, and finally to deep crimson, will be produced"—(*U. S. P.*). The latter test is that known as *Baudoin's Test*. It was modified by Villavecchia and Fabris (*Jahresb. der Pharm.*, 1893, p. 693) who observed that furfurol is the active principle in Baudoin's test. They proceed as follows: Mix 0.1 Cc. of a solution of 2 Gm. furfurol ($C_4H_3O.CHO$) in 100 Cc. of alcohol with 10 Cc. of the oil, and shake with 10 Cc. of hydrochloric acid (specific gravity, 1.19) in a test-tube. As little as 1 per cent of sesame oil may be recognized by the crimson coloration produced in the aqueous layer. This test is characteristic for oil of sesame (also see *Amer. Jour. Pharm.*, 1894, p. 99). Another color reaction with nitro-sulphuric acid, discovered by Behrens (1852), is mentioned in *Pharmacographia*. In this connection, see J. F. Tocher's *sesamin* (*Amer. Jour. Pharm.*, 1891, p. 142, and 1893, p. 194).

Chemical Composition and Uses.—Flückiger found the oily portion to contain 76 per cent of *olein*, and a small quantity of a peculiar resinoid substance giving the above color test of Behrens. The solid portion of oil of sesamum consisted of *palmitin*, *stearin*, and *myristin* (*Pharmacographia*). The oil also contains small quantities of *linolein*, to the presence of which its partial drying qualities are due. According to Villavecchia and Fabris (see *Jahresb. der Pharm.*, 1893, p. 693), there are present crystallizable *sesamin* ($C_{11}H_{12}O_3$), melting at 123° C. (253.4° F.); an alcohol ($C_{25}H_{44}O$), melting at 137° C. (278.6° F.); and a non-nitrogenous oil to which the color reaction (in Baudoin's test) is due. Oil of sesamum is used for cooking purposes; in Germany, an addition of 10 per cent sesamum oil to oleomargarine is required in order to facilitate the detection of adulteration of butter. Sesamum oil is also used in soap manufacture, for illuminating purposes, and as a substitute for almond and olive oils.

Action, Medical Uses, and Dosage.—(See *Sesamum*.)

Related Oils.—OLEUM ARACHIS, *Peanut oil*, *Ground-nut oil*, *Earth-nut oil*, *Arachis oil*. This non-drying oil is obtained from the nutritious oily seeds known as *peanuts*, and derived from the leguminous plant *Arachis hypogæa*, Linné. The yield is nearly 50 per cent. It is obtained by cold expression. When the seeds are first warmed an inferior oil is obtained. It is thin, almost colorless, or pale yellow, has a faint, pleasant odor, and a bland, nutty taste. The specific gravity of the best product is about 0.918 (*Pharmacographia*). At 3° C. (37.4° F.) it is turbid; at —3° to —4° C. (26.6° to 24.8° F.) it concretes, and hardens at —7° C. (19.4° F.). Exposure to air slowly causes it to thicken; even in closed containers it becomes disagreeably rancid (*Pharmacographia*). It is composed of the glycerides of four fatty acids, chiefly *oleic acid*. The other acids which are present in the form of glycerides, are *palmitic*, *stearic*, *arachic* ($C_{20}H_{40}O_2$), *hypogæic* ($C_{16}H_{30}O_2$), and *linoleic acids*. This oil is official in India where it is largely consumed as a substitute for olive oil, under the name of *Katchung oil*. It is extensively employed in soap-making, and the Chinese use it for illuminating purposes.

SOY OIL.—A yellowish, bland oil, furnished to the extent of 18 per cent by the edible seeds of *Soja hispida*, Moench (*Dolichos Soja*, Linné) (*Nat. Ord.*—Leguminosæ), of Japan and southern Asia. A sauce called *soy* is also prepared from the seeds.

GERMAN SESAME OIL.—The seeds of *Camelina sativa*, Crantz, yield a slowly drying oil, sometimes feebly pungent, sometimes bland, to which the name *German sesame oil* is occasionally applied.

KURUNG OIL.—Derived from the gray, reniform seeds of *Pongamia glabra*, Ventenat (*Dalbergia arborea*, Roxburgh) (*Nat. Ord.*—Leguminosæ). A tree of the East Indies. The oil is yellow and thickish, becomes turbid at about 7° C. (44.6° F.), and has a specific gravity of 0.945. The leaves and root of this tree have been used in medicine; the oil in *skin diseases*.

NICKER-SEED OIL.—*Bonduc-nuts*, the seeds of a tropical vine, the *Cæsalpinia Bonducella*, Roxburgh (*Guilandina Bonducella*, Linné), yield, by expression, an oil which is used in liniments by the natives of India. There the seeds, as well as the root-bark, are employed as an antiperiodic and tonic. The seed is variously known as *Semen bonducellæ*, *Semen guilandinæ*, *Grey nicker seeds* (or *Nuts*), and *Bonduc seeds*. Flückiger obtained from them a non-alkaline, very bitter powder, sparingly soluble in water, and soluble in alcohol and ether (*Pharmacographia*, p. 212).

Ben Oil, Behen Oil.—The expressed oil of *ben nuts*, the seeds of *Moringa pterygosperma*, Gaertner (*Moringa oleifera*, Lamarck, and *Guilandina Moringa*, Linné), of the *Nat. Ord.*—Moringaceæ, is a palatable product, more employed in the arts than in medicine. The tree furnishing the seeds is known as the *Horseradish-tree*, on account of the resemblance of its root-bark, both in taste and odor, to our common horseradish. Several allied species are also said to yield a portion of the oil. Oil of ben resembles olive oil, and is employed for like purposes. Its density is 0.912 to 0.917; its color, yellowish and clear; it is odorless and bland in taste. If, however, the oil be expressed by heat, it becomes acrid and bitter, and possesses cathartic powers. It does not easily become rancid. At 7° C. (44.6° F.) it begins to deposit fatty materials; at 0° C. (32° F.) it becomes solid. The liquid portion overlying the solid fats is employed in extracting from flowers their delicate odors. Ben oil is composed of the glycerides of *oleic*, *palmitic*, *myristic*, *stearic*, *moringic* ($C_{15}H_{28}O_2$), and *benic* (*behenic* [$C_{22}H_{44}O_2$]) *acids* The latter acid is crystalline; *moringic acid* is fluid. The yield of this fixed oil is about 30 per cent, and it is expressed in Europe from Egyptian seeds.

OLEUM SINAPIS VOLATILE (U. S. P.)—VOLATILE OIL OF MUSTARD.

"A volatile oil obtained from *Black mustard* by maceration with water, and subsequent distillation. It should be carefully kept in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Synonyms: *Oil of mustard*, *Oleum sinapis æthereum*.

Preparation and Description.—Volatile oil of mustard does not pre-exist in black mustard seed, but is formed in the decomposition of its glucosid *sinigrin* by a process of fermentation (see *Chemical Composition*). The fixed oil is first removed by hydraulic pressure, the press-cake is crushed, digested with water at a temperature not exceeding 70° C. (158° F.), and the volatile oil of mustard is then distilled off with steam. The yield is about 0.5 to 0.75 per cent. White mustard seed does not yield a volatile oil when thus treated (see *Sinapis*).

The volatile oil of mustard thus obtained is "a colorless or pale-yellow, limpid, and strongly refractive liquid, having a very pungent and acrid odor and taste. Specific gravity, 1.018 to 1.029 at 15° C. (59° F.). Boiling point, 148° to 150° C. (298.4° to 302° F.). Freely soluble in alcohol, ether, or carbon disulphide, the solutions being neutral to litmus paper"—(*U. S. P.*). The oil is soluble in from 160 to 300 parts of water, and in 10 parts of 70 per cent by volume of alcohol. Exposed to light, volatile oil of mustard decomposes, turning reddish-brown, and depositing a thin brown film on the walls of its containing vessel.

Chemical Composition.—The principal constituent of volatile oil of mustard is *allyl-isothiocyanide* (*allyl-mustard oil*, $S:C:N.C_3H_5$), with small amounts of *allyl cyanide* ($CN.C_3H_5$) and *carbon disulphide* (CS_2), the latter being of somewhat obscure origin. *Allyl-cyanide* is formed by decomposition of allyl-mustard oil, which takes place, for example, when the oil is in prolonged contact with the copper of the still, thus: $SCNC_3H_5+Cu$ $CuS+CNC_3H_5$. Notable quantities of this compound, which has the specific gravity 0.835, may render the volatile oil of mustard lighter than water (Will, 1863).

Allyl-isothiocyanide is formed by the decomposition of the glucosid *sinigrin* (or *potassium myronate* $C_{10}H_{16}NS_2KO_9$), under the influence of the albuminous ferment *myrosin*, both being constituents of black mustard seed. The reaction, as elucidated by J. Gadamer and his predecessors (see *Archiv der Pharm.*, 1897, p. 44), takes place as follows: $C_{10}H_{16}NS_2KO_9$ (sinigrin) + H_2O $SCNC_3H_5$ (allyl-mustard oil) + $C_6H_{12}O_6$ (dextrose) + $KHSO_4$ (acid potassium sulphate). It may also be prepared synthetically by the interaction of potassium sulphocyanide (NCSK), and allyl iodide (C_3H_5I) in alcoholic solution, whereby a molecular rearrangement from $N:C.S.C_3H_5$ (*allyl-thio-cyanide*) to $S:C:N.C_3H_5$ (*allyl-isothiocyanide*) takes place

Tests and Assay.—The *U. S. P.* directs the following tests for the volatile oil of mustard: "If to 3 Gm. of the oil 6 Gm. of sulphuric acid be gradually added, the liquid being kept cool, the mixture, upon subsequent addition, will evolve sulphur dioxide, but will remain of a light-yellow color, and at first perfectly clear, becoming afterward thick, and occasionally crystalline, while the pungent odor of the oil will disappear"—(*U. S. P.*). The final product in this reaction is *sulphate of allylamine* ($C_3H_5NH_2$).

"If a portion of the oil be heated in a flask connected with a well-cooled condenser, it should distill completely between 148° and 150° C. (298.4° and 302° F.), and both the first and the last portion of the distillate should have the same specific gravity as the original oil (absence of alcohol, chloroform, carbon disulphide, petroleum, or fatty oils). If a small portion of the oil be diluted with 5 times its volume of alcohol, and a drop of ferric chloride T.S. be added, no blue or violet color should be produced (absence of phenols). If a mixture of 3 Gm. of the oil and 3 Gm. of alcohol be shaken, in a small flask, with 6 Gm. of ammonia water, it will become clear after standing for some hours, or rapidly when warmed to 50° C. (122° F.), and usually deposit, without becoming colored, crystals of *thiosinamine* (*allyl-thio urea*, $CS.N_2H_3[C_3H_5]$). To determine the proportion of thiosinamine obtainable from the oil, decant the mother water from the crystals, and evaporate it gradually in a tared capsule, on a water-bath, adding fresh portions only after the ammoniacal odor of each preceding portion has disappeared. Then add the crystals from the flask to those in the capsule, rinsing them out of the flask with a little alcohol, and heat the capsule on a water-bath until its weight remains constant. The amount of thiosinamine thus obtained from 3 Gm. of the oil should be not less than 3.25 Gm., nor more than 3.5 Gm. After cooling, thiosinamine forms a brownish, crystalline mass, fusing at 70° C. (158° F.), and having a leek-like, but no pungent odor. The mass should be soluble in 2 parts of warm water, forming a solution which should not redden blue litmus paper, and which possesses a somewhat bitter, not persistent taste"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Sinapis.*)

OLEUM SUCCINI.—OIL OF AMBER.

The volatile oil obtained by dry distillation of amber and purified by rectification.

Preparation.—The *crude oil of amber* (*Oleum Succini Crudum*) is obtained by destructive distillation of amber as a by-product in the preparation of succinic acid from this source (see *Amber*, below). It is of a syrupy consistence, dark-brown, and of an unpleasant, empyreumatic, persistent odor. In order to make *rectified oil of amber* (*Oleum Succini Rectificatum*), the *U. S. P.* (1870) directs to mix in a glass retort, oil of amber, 1 pint; water, 6 pints, and to distill until 4 pints of water have passed with the oil into the receiver; then separate the oil from the water, and keep it in a well-stopped bottle. According to Hager, the yield is from 65 to 70 per cent of the crude oil.

Description.—The oil thus obtained is thin, colorless or pale-yellow, but turns brown and viscid if not carefully kept. It has an empyreumatic, balsamic, yet disagreeable odor, and a bitter and acrid taste. Its specific gravity varies from 0.88 to 0.93; Power (*Essential Oils*) records 0.975 for crude, and 0.915 for the rectified oil. The latter is readily dissolved in absolute alcohol, chloroform, ether, disulphide of carbon, or the fixed oils; alcohol of 90 per cent by volume dissolves only about one-fifth of it. It is not soluble in water, though this fluid acquires its taste and odor in a slight degree. It is a solvent for caoutchouc. It is principally a mixture of hydrocarbons containing some phenols (Power), and has no constant boiling point. It does not fulminate with iodine. Fuming nitric acid added gradually forms with it a balsamic resin, called *artificial musk*. *Eau de Luc* is formed by dissolving 1 part of rectified oil of amber in 24 parts of alcohol, specific gravity 0.830, and 96 parts of caustic ammonia, specific gravity 0.916.

Adulterations.—Oil of amber is sometimes adulterated with oil of turpentine. Dr. Bolley suggests the following method of detecting it: In a cylindrical glass vessel about a foot high, place the suspected oil, and pass a current of hydrochloric acid gas into it by a tube dipping to near the bottom. The gas must be previously dried by passing it through two bottles containing coarsely-broken chloride of calcium, before entering the oil. The current is to be continued an hour, and if oil of turpentine is present to the extent of even 5 per cent, the mixture gives crystalline evidence of it after standing 12 hours. Of course, where the adulteration is large, the artificial camphor is apparent much sooner (*Amer. Jour. Pharm.*, 1854, p. 119). According to Mr. A. E. Ebert, rectified oil of amber is liable to adulteration with kerosene, rendering the oil insoluble in absolute alcohol, imparting an opalescence to it by exposure to direct sunlight, and forming no resin or artificial musk when treated with nitric acid. He believes that there is but a small amount of the true rectified oil of amber to be had in our markets, that which is sold for it consisting principally either of turpentine agitated with the crude oil of amber until it has the desired color, and which may be detected by its odor, and violent fulminating action with iodine; or kerosene may be substituted for the turpentine on account of the cost of the latter (*Proc. Amer. Pharm. Assoc.*, 1865, p. 149). It may be owing to this adulteration that piles are cured by a local application of it to them, as named by Prof. Procter in *Amer. Jour. Pharm.*, 1866, p. 217, as I have known numerous instances where persons have cured or relieved themselves of piles by the application of ordinary coal-oil (J. King).

Action, Medical Uses, and Dosage.—Rectified oil of amber is the only form in which oil of amber should be employed for internal use. It is stimulant, diuretic, and antispasmodic; and has been employed with benefit in *amenorrhœa, hysteria, dysmenorrhœa, tetanus, epilepsy, pertussis, infantile convulsions*, and various other *spasmodic affections*. The dose is from 5 to 30 drops on sugar, repeated as often as required. Applied externally it is a rubefacient, and has been efficaciously used as a liniment in *palsy, chronic rheumatism, pertussis*, and *infantile convulsions;* in the latter affection it should be rubbed along the spine, either alone or combined with an equal part of laudanum and 3 or 4 parts of olive oil. ROCHE'S EMBROCATION, for *pertussis* and other *spasmodic affections*, is composed of oil of olive, oil of cloves, each, 1 fluid ounce; oil of amber, ½ fluid ounce. Mix.

Related Products.—SUCCINUM, or AMBER, *Ambra flava, Electrum*. The origin of amber is somewhat uncertain; it is believed to be a fossil resin, produced by the hardening of the resinous exudates of certain extinct coniferæ. That it was at one time liquid, is obvious from the insects which are occasionally found buried in it. No living insect is known exactly similar to those found in amber; showing that a very long period must have elapsed since the trees producing it vegetated (T.). The greatest part of the amber of commerce is found in Prussia, on the south shore of the Baltic, being thrown up from the sea between Königsberg and Memel. It is supposed to be derived from beds of wood-coal from *Pinites succinifer*, Goeppert (*Pityoxylon succiniferum*, Kraus), in the basin of the Baltic. It is also met with on the Sicily coast, in Poland, in France near Paris, in China, and in several parts of the United States. Amber is a brittle, light, hard substance, usually nearly transparent; sometimes almost colorless, but commonly yellow, deep-brown, or red. It usually occurs in irregularly shaped pieces, tasteless, and without smell, except when pounded or heated, when it emits a fragrant odor. Amber is capable of acquiring a fine polish, on account of which it is used for small articles of ornament. It yields readily to the knife, has a conchoidal vitreous or resinous fracture, becomes negatively electrical by rubbing, and has a specific gravity of 1.065. Water has no action on it, but alcohol, by long digestion, dissolves about one-eighth of the amber, and forms a colored solution which, when concentrated, becomes milky when mixed with water; the precipitate possesses the properties of a resin. Volatile oils and ether but partially dissolve it. A boiling solution of fixed alkali almost wholly dissolves amber, forming a kind of soap, soluble in alcohol or water. Diluted acids have no action on amber; sulphuric acid converts it into a black resinous mass; nitric acid acts upon it, dissolving it completely.

Heated in the air, amber softens at about 215° C. (419° F.), and fuses at about 290° C. (554° F.), evolving an agreeable aromatic odor, and burning with a clear yellow flame. It can not be fused without undergoing some chemical change. By destructive distillation in a retort, amber yields first an acid liquor, which contains succinic and acetic acids; then some succinic acid is deposited in the neck of the retort, and an empyreumatic oil (oil of amber) comes over, at first thin and yellowish, afterward brown and thick; toward the end of the operation, a yellowish light sublimate is observed in the neck of the retort; this is called by Gmelin, *amber-camphor*. An inflammable gas is evolved during the whole time of the operation. The residue in the retort consists of a brown resin (*colophonium succini*). The proximate principles of amber are a volatile oil, with a strong but agreeable odor; a resin soluble in cold alcohol, a resin soluble in boiling alcohol, succinic acid as high as 6 per cent, and a bituminous matter on which alcohol, ether, fixed and volatile oils, and alkaline solutions exert no solvent action. Baudrimont found 0.48 per cent of sulphur in 100 parts of amber. *Roumanian amber* yielded to O. Helm (*Amer. Jour. Pharm.*, 188[illegible], p. 442) [illegible]15 per cent of sulphur, and 5.2 per cent of succinic acid. *Sicilian amber* yielded only 0.4 per cent of the latter acid, and a dark variety of amber, called *glessite*, had a specific gravity of only 1.015 to 1.027, and yielded no succinic acid upon dry distillation.

Amber is not used as a medicine; its principal employment is in the preparation of its oil, succinic acid, and varnish. Amber varnish is made by roasting 2 pounds of amber, and then dissolving it in 3 pounds of linseed oil, and a sufficient quantity of oil of turpentine. Adulteration with colophony may be recognized by alcohol, which dissolves out the adulterant.

Acidum Succinicum, *Succinic acid*, *Sal succini volatile* ($H_2C_4H_4O_4$). Molecular weight: 117.72. Succinic acid was observed by Agricola in 1550, and was long believed to be a volatile salt of amber, until its acid character was demonstrated in 1675, by Lemery. It exists in nature, also in fossilized wood, and in many vegetable and animal fluids. It may be obtained by the action of nitric acid upon the higher fatty acids, wax, or spermaceti. Pasteur discovered its formation in the vinous fermentation of sugar. It has also been obtained synthetically. The medicinal acid is obtained by the distillation of amber, although another and more convenient method consists in the fermentation of calcium malate or of tartaric acid (see details in Roscoe and Schorlemmer's *Chemistry*, Vol. III, Part II, New York, 1884, p. 185). The acid, when pure, forms white or transparent and odorless crystals; when prepared from amber the crystals are yellow or brown, with a smoky, acid taste, and have the odor of amber oil. They may be purified by boiling with nitric acid, of specific gravity 1.32. Succinic acid is soluble in 20 parts of cold, 2 parts of hot water, less soluble in alcohol, and nearly insoluble in ether. The pure acid melts at 180° C. (356° F.). Its salts are called succinates. It was formerly used to considerable extent in medicine, but it is now seldom employed. It has but little action except to accelerate the pulse and promote cutaneous and bronchial excretion. The dose of succinic acid is from 5 to 15 grains.

Succinate of Ammonium has been employed in *spasmodic conditions* and as a remedy for *delirium tremens*, *hysteria*, *rheumatism*, and *bronchitis*. A liquor of succinate of ammonium, known also as *Liquor Cornu Cervi Succinici*, has been considerably employed in Germany for similar purposes.

OLEUM TANACETI.—OIL OF TANSY.

The very poisonous, oxygenated volatile oil distilled from *Tanacetum vulgare*, Linné (*Nat. Ord.*—Compositæ).

Description and Chemical Composition.—Oil of tansy is prepared by distilling the flowering herb with water. It is usually yellow, sometimes of a green color, turning brown on exposure to air and light, a warm, extremely bitter taste, and an odor like that of tansy, but more intense. An oil distilled from English cultivated tansy (Schimmel & Co., *Report*, Oct., 1895) had a camphoraceous odor resembling rosemary, and upon cooling to 0° C. (32° F.) deposited part of its camphor. It also differed from American and German oils by being lævo-rotatory (—27°), the former exerting a right-handed optical rotation (+30° to +45°). Oil of tansy is soluble in alcohol; the American oil, when pure, forms a clear solution also with 70 per cent alcohol. The specific gravity of oil of tansy (fresh plant) varies from 0.925 to 0.940; dry herb 0.955. The yield of oil ranges from 0.10 to 0.20 per cent for fresh, and 0.20 to 0.30 per cent for dry herb (Schimmel & Co.). The characteristic odor of oil of tansy is due to its chief constituent *thujone* or *tanacetone* (Bruylants, 1878; Semmler, 1892). It is a ketone ($C_{10}H_{16}O$) boiling at 203° C. (397.4° F.), and combines with sodium bisulphite, and forms an oxime with hydroxylamine. The oil also contains preformed (Schimmel & Co.) the *lævo-rotatory* modification of camphor ($C_{10}H_{16}O$) with small quantities of *borneol*; a *terpene* boiling at 160° C. (320° F.) is likewise present (Bruylants).

Action, Medical Uses, and Dosage.—Oil of tansy possesses the properties of the plant (see *Tanacetum*), but is seldom employed internally on account of its bitterness. It has been employed to produce abortion, but almost always with fatal results. Dose of the oil from 2 to 5 drops. According to Peyraud (1887), the oil produces in animals a disease similar to hydrophobia, called "rage tanacetique" (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 890).

OLEUM TEREBINTHINÆ (U. S. P.)—OIL OF TURPENTINE.

"A volatile oil distilled from turpentine"—(*U. S. P.*). (See *Terebinthina*.)

"Oil of turpentine should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

Synonyms: *Spirits of turpentine*, *Essence of turpentine*.

Preparation and History.—Oil of turpentine is the volatile constituent of the oleoresinous exudate obtained from coniferous trees and known as turpentine (see *Terebinthina*). The oil is separated by distillation with water or steam; the residue in the still is known as *rosin* or *colophony* (see *Resina*). By subjecting turpentine to a dry heat, an empyreumatic oil is produced, to which the term *resin* *oil* is more properly applied. By distilling the leaves or fruit-cones of various species of the natural order Coniferæ with water or steam, the so-called *pine-needle oils* are obtained which have a somewhat different composition (see *Oleum Pini Sylvestris*).

In former centuries, the large pine forests extending through central Europe westward to the Atlantic, supplied the oils of commerce. In the eighteenth century, American turpentine made its appearance and was first distilled in North Carolina and Virginia. Up to the present time the American oil ranks first in the world's market, the French oil, which is esteemed for its finer odor, ranking second. The center of the manufacture of oil of turpentine in the United States is slowly marching southward, on account of the gradual depletion of the pine forests where the industry is carried out. The leading place of export not long ago was Charleston, South Carolina; now its position is taken by Savannah, Georgia. (For a full account of the manufacture of the oil, on the so-called "turpentine farms," see Dr. Frederick Hoffmann, in *Die Ætherischen Oele*, p. 310; also see Bastin & Trimble's "North American Coniferæ," in *Amer. Jour. Pharm.*, 1896, p. 242.)

Description.—Official oil of turpentine is "a thin, colorless liquid, having a characteristic odor and taste, both of which become stronger and less pleasant by age and exposure to the air. Specific gravity, 0.855 to 0.870 at 15° C. (59° F.). It boils at 155° to 170° C. (311° to 338° F.). Soluble in three times its volume of alcohol, the solution being neutral or slightly acid to litmus paper; also soluble in an equal volume of glacial acetic acid"—(*U. S. P.*). It is scarcely soluble in water, but is easily dissolved by chloroform, benzol, ether, etc. Of 90 per cent alcohol, 5 to 12 parts are required for complete solution. Old oil dissolves more easily than fresh oil. It dissolves resins, fixed oils, fats, sulphur, phosphorus, many alkaloids and neutral vegetable principles, and is also a solvent for caoutchouc. Unless purified, oil of turpentine has a slightly acid reaction, owing to the presence of acetic and formic acids. "Bromine or powdered iodine acts violently upon it. When brought in contact with a mixture of nitric and sulphuric acids, it takes fire"—(*U. S. P.*). It also takes fire when brought into contact with chlorine gas. The oil is inflammable, burning with a fierce, red flame and much black smoke. The various oils of turpentine are optically active; the French oil is markedly *lævo*-rotatory (—20° to —40°) while the American oil is, as a rule, *dextro*-rotatory (to +10°), and in rare cases slightly lævo-rotatory (to —2° 5′) (Gildemeister and Hoffmann, *loc. cit.*, p. 320). Oil of turpentine is quite volatile at ordinary temperatures. When exposed to the atmosphere, especially in the presence of moisture, it becomes "ozonized" by absorption of oxygen; it thickens, resinifies, and acquires an acid reaction. In this condition it is a strongly oxidizing agent, due to its containing oxygen in some active form, which is not, however, that of ozone; this has been pointed out by Kingzett (1874) and others. Hydrogen peroxide is one of the active products formed. C. Engler and J. Weissberg have more recently shown (*Berichte d. Deutsch. Chem. Ges.*, 1898, p. 3046) that absolutely dry oil of turpentine absorbs a maximum volume of active oxygen at 100° C. (212° F.), no ozone, nor hydrogen peroxide being formed. The oil thus charged with oxygen retains its active properties for years if it is kept in a dark place. Above this temperature oxidation of the oil takes place. Among the products of oxidation of "ozonized" oil are formic and acetic acids, and *camphoric acid* ($C_{10}H_{16}O_4$), and small quantities of an *aldehyde* ($C_{10}H_{16}O_3$) (Schiff, *Chem. Zeitung*, 1896, p. 361), to which the penetrating odor of old, rancid oil is probably due. For further details on this subject, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 300.)

Tests.—Oil of turpentine may be adulterated with petroleum, paraffin oils, or resin. For their detection, the *U. S. P.* directs that "if a little of the oil be evaporated in a small capsule on a water-bath, it should leave not more than a very slight residue (absence of petroleum, paraffin oils, or resin)"—(*U. S. P.*). The lighter petroleum oils reduce the specific gravity of oil of turpentine. The heavier paraffin oils may be recognized by not being volatile with steam, and may be identified in the residue by their indifference toward strong sulphuric or nitric acid. A quantitative separation of mineral oils from oil of turpentine, may be effected (Burton, 1890; Allen, 1890) by means of fuming nitric acid which destroys the latter oil only.

Chemical Composition.—Oil of turpentine consists chiefly of hydrocarbons (*terpenes*), of the formula $C_{10}H_{16}$ (Houton-Labillardière, 1817). Among these, *pinene*, boiling point 155° to 156° C. (311° to 312.8° F.), is the most prominent. *Camphene*, melting point 50° C. (122° F.), boiling point 159° to 160° C. (318.2° to 320° F.), and probably *fenchene*, boiling point 154° to 156° C. (309.2° to 312.8° F.), are also regular constituents of oil of turpentine, as well as *dipentene*, boiling point 175° to 176° C. (347° to 348.8° F.), and *sesquiterpenes*, boiling at higher temperatures. Certain pine-needle oils also contain the hydrocarbons *l-limonene*, *dipentene*, *d-sylvestrene*, *l-phellandrene* and *cadinene*, and the fragrant ester *bornyl* (*borneol*) *acetate*.

Pinene occurs in two modifications which are chemically identical. *Lævo-pinene* (Wallach, 1885; Berthelot's *terebentene*) is the principal constituent of the French oil of turpentine, while *dextro-pinene* (Berthelot's *australene*) occurs, as a rule, in the American oil. It is a colorless, mobile liquid, which, to some extent, resinifies and absorbs oxygen when exposed to the air. It is an unsaturated hydrocarbon with one double bond. Accordingly, it combines, when surrounded by ice, with dry hydrochloric or hydrobromic acid gas, the former yielding the solid compound $C_{10}H_{16}.HCl$, which has the odor of camphor, hence is called *artificial camphor*. It melts at 125° C. (257° F.), the bromine compound at 90° C. (194° F.). *Pinene* is best identified by the melting point of its nitroso-chloride ($C_{10}H_{16}.NOCl$) which lies at 103° C. (217.4° F.). When heated to 250° to 270° C. (482° to 518° F.), pinene is changed into *dipentene*, the inactive (racemic) modification of *d*-and *l-limonene*, boiling at 176° C. (348.8° F.). Alcoholic sulphuric acid converts pinene into *terpinolene* and *terpinene*. Pinene in prolonged contact with diluted mineral acids, is converted into crystallizable *terpin hydrate* ($C_{10}H_{18}[OH]_2H_2O$) (see *Terpini Hydras*). By the action of sulphuric and glacial acetic acids, pinene forms the alcohol *terpineol* ($C_{10}H_{18}O$), which has the odor of hyacinth and is much used in perfumery. By the action of diluted nitric acid, or chromic acid, pinene is oxidized with formation of the lower fatty acids, and *terephtalic* ($C_8H_6O_4$) and *terebenic* ($C_7H_{10}O_4$) *acids*. By distillation with sulphuric acid, pinene is converted into inactive *terebene* (see *Terebenum*).

Action, Medical Uses, and Dosage.—The actions of oil of turpentine are complex. It is irritant, stimulant, cathartic, diuretic, vermifuge, and, in relation to chronic mucous discharges, astringent. Given in large doses it occasions fullness of the head, or giddiness, with a feeling similar to that of intoxication, or a state resembling trance; sometimes it gives rise to pain in the stomach, nausea and vomiting, and more frequently it gives rise to violent strangury, bloody urine, and other symptoms of renal or vesical irritation. In small doses long continued, or when absorbed from its external application, or its vapor inhaled, it produces in the urine an odor resembling that of violets, and sometimes produces strangury. Its most constant effect is purgation, and when this occurs, the other effects seldom present themselves. In medicinal doses it warms the stomach, elevates the temperature of the surface, quickens the pulse, and when given at short intervals, in slight doses, it acts upon the kidneys, causing an increased urinary discharge. In the *typhoid stage of febrile diseases*, especially when *intestinal ulceration* is diagnosed from the symptoms, the tongue becoming dry and dark-colored, the skin dry and husky, and *tympanites* is present, with occasionally mental derangement, small doses given at short intervals and continued for some time, will act as a stimulant and remove all these symptoms. It is supposed, in these instances, to normally influence the ulcerated tissues. It is likewise recommended in *neuralgia*, *chronic rheumatism*, *dropsy*, *suppression of urine*, *worms*, especially *tænia*—*tympanitic distension in typhoid fever*, *peritonitis*, or other diseases—*chorea*, *hysteria*, *croup*, *colic*, *jaundice*, and in cases where gravel is habitually carried off by copious discharge of lithic acid and lithate of ammonium. It has a tendency to diminish excessive mucous discharges, and has been employed with advantage in *chronic catarrh*, *chronic bronchitis*, *fetid bronchitis*, and *pulmonary gangrene* (in lung troubles by inhalation as well as internally), *chronic dysentery*, *chronic diarrhœa*, *chronic inflammation of the bladder*, *gleet*, *chronic gonorrhœa*, and *leucorrhœa*. The dose in ordinary cases is from 6 drops to ½ fluid drachm, and even to 1 drachm, at intervals of an hour or two in acute and every 3 or 4 hours in chronic diseases. In the course of its action it is absorbed, and imparts its odor to the breath and perspiration. In doses varying from 20 minims to 1 fluid drachm, according to the urgency of the symptoms, and repeated every 3 or 4 hours, it is a most efficacious astringent, and may be used in *epistaxis, hematemesis, hemoptysis,* and other sanguineous discharges. It may be administered in water, flavored with some agreeable aromatic syrup, or in infusion of matico, in *hemoptysis;* in the decoctions of uva ursi, epigæa, or eupatorium, etc., in *hematuria;* or in the decoction or infusion of cinchona, in *purpura hemorrhagica.* Where much arterial blood has been lost, tincture of chloride of iron will form a valuable adjunct. Combined with castor oil, it is an excellent vermifuge. It probably prevents the formation of biliary calculi. Externally it is a rubefacient, and is used as a counter-irritant in the form of liniment in *rheumatism, paralysis, neuralgia, inflammation of internal organs,* in the neighborhood of *indolent tumors,* to *chilblains, indolent and erysipelatous ulcers, caries, sloughing,* especially from pressure in exhausting diseases, *gangrene, chronic inflammation of the edge of the eyelids,* and, combined with linseed oil, in *recent burns* or *scalds.*

Turpentine, locally and internally, has given signal results in *diphtheria* and *sciatica.* In the latter affection about 30 drops, 3 times a day, is the proper dose. It forms a good local application in *mammitis, pleurisy, pneumonia, bronchitis, laryngitis,* and *rhus poisoning.* It has given relief in *puerperal peritonitis.* Its vapor kills the *itch insect.* Where *deafness* is occasioned by a *scanty* or *abnormal secretion of cerumen,* the oil of turpentine rubbed up with some bland oil, may be passed into the ear, on cotton. In *amenorrhœa* arising from torpor of the uterine vessels, in *obstinate constipation,* in *tympanites,* or when the bowels are distended with *flatus,* and in *ascarides,* oil of turpentine used as an injection will frequently be found a superior remedy. From 4 to 8 fluid drachms may be rubbed up with half a pint of water and the yolk of a few eggs, or with some mucilage, and injected into the rectum, where it should be retained for some time. When given internally, it may be administered in simple or aromatized syrup, or rubbed up with sugar, or taken in gin, when not contraindicated, etc.; or it may be triturated with the yolk of egg, gradually adding syrup and essence of cinnamon, with a portion of water. One yolk is sufficient for trituration with every 2 fluid drachms of the oil. In *tapeworm,* it has been combined with gin, and given in doses of 1 or 2 fluid ounces. As an ordinary vermifuge, 3 or 4 parts of castor-oil may be added to 1 part of the oil of turpentine.

Dr. James Warren has used a preparation for a number of years in the treatment of *hemorrhages,* with uniform success. It acts both by its sedative power, in diminishing the force of the circulation, and by its astringent qualities, in contact with the bleeding vessels. He is satisfied that no known remedy exerts a more specific power and gives more speedy relief, especially in *hemoptysis, hematemesis, epistaxis,* and *menorrhagia.* Dr. Warren terms it *Styptic Balsam.* It is made as follows: Place sulphuric acid, 5 drachms by weight, in a Wedgewood mortar, and slowly add to it oil of turpentine 2 fluid drachms, stirring it constantly with the pestle; then add in the same manner alcohol 2 fluid drachms, and continue stirring until no more fumes arise, when it may be bottled, and should be stopped with a ground stopper. It should be prepared from the purest materials; and when made should exhibit a dark but clear red color, like dark blood; but if it be a pale, dirty red, it will be unfit for use. The dose is 40 drops, to be used as follows: into a common-sized teacup put a teaspoonful of brown sugar, thoroughly incorporate the 40 drops by rubbing together, and then slowly stir in water until the cup is nearly full, when the mixture should be immediately swallowed. The dose may be repeated every hour, for 3 or 4 hours, and its use should be discontinued as soon as fresh blood ceases to flow. After standing a few days, a pellicle forms upon the surface of the balsam, which should be broken, and the liquid below it used. If in well-stoppered bottles, age does not deteriorate it (*N. Y. Jour. Med.*). French oil of turpentine and old oil of turpentine are antidotes to *poisoning by phosphorus.*

Related Oil.—ABIETENE (C_7H_{16}). This highly volatile and very inflammable oil was obtained by Prof. W. T. Wenzell (*Amer. Jour. Pharm.,* 1872, p. 97) from the terebinthinous exudate of the *Nut pine* or *Digger pine* (*Pinus Sabiniana,* Douglas) of California. The nut of this species is eaten by the Digger Indians. The crude oil is colorless and boils from 101° to 115° C. (213° to 239° F.); the boiling point of the largest fraction is 101° C. (213° F.). Its specific gravity is 0.694; its odor penetrating, strong, and orange-like. According to T. E. Thorpe (*Chem. News,* 1879) it is identical with *heptane* (C_7H_{16}), one of the low-boiling petroleum hydrocarbons.

Abietene (*heptane*) dissolves both bromine and iodine without fulmination, and is soluble in 95 per cent alcohol (5 parts). According to Prof. Sadtler (*Amer. Jour. Pharm.*, 1879, pp. 176 and 293), an oil of the same composition is furnished by the Californian *Pinus ponderosa*, of Douglas.

OLEUM TEREBINTHINÆ RECTIFICATUM (U. S. P.)—RECTIFIED OIL OF TURPENTINE.

Preparation.—"Oil of turpentine, a convenient quantity; lime-water, a sufficient quantity. Shake the oil thoroughly with six (6) times its volume of lime-water, and introduce the mixture into a copper still connected with a well-cooled condenser. Then distill, until about three-fourths of the oil have passed over, and separate the clear oil from the water. Keep the product in well-stoppered bottles, in a cool place, protected from light"—(*U. S. P.*).

Description.—"A thin, colorless liquid, having the general properties mentioned under oil of turpentine (see *Oleum Terebinthinæ*). Specific gravity, 0.855 to 0.865 at 15° C. (59° F.). Boiling point, about 160° C. (320° F.). Its alcoholic solution should be neutral to litmus paper. If about 10 Cc. of the oil be evaporated in a capsule on a water-bath, no weighable residue should be left"—(*U. S. P.*). "Rectified oil of turpentine should always be dispensed when oil of turpentine is required for internal use"—(*U. S. P.*).

OLEUM THEOBROMATIS (U. S. P.)—OIL OF THEOBROMA.

"A fixed oil expressed from the seed of *Theobroma Cacao*, Linné (*Nat. Ord.*—Sterculiaceæ)"—(*U. S. P.*).

SYNONYMS: *Oleum theobromæ* (*U. S. P.*, 1880), *Butter of cacao*, *Oleum cacao*, *Butyrum cacao*.

Preparation and Description.—*Butter of cacao* must not be confounded with cocoanut oil from *Cocos nucifera;* with *palm oil* from *Elæis guineensis;* nor with *coca*, the dried leaves of *Erythroxylon Coca;* it is obtained by two or three processes, one of which is to roast the seeds, and, after removing the testa, grind the seeds, put them in canvas bags, expose them to steam, and press between hot iron plates. The butter thus expressed may be purified by melting it in hot water, by passing it through hot animal charcoal, or by the use of acids, and then running it into molds. The seeds contain about 45 per cent of this fat, 6 to 11 per cent of starch, 1 to 4 per cent of *theobromine*, nitrogenous matter, cacao-red, ash, etc. The yield of cacao butter is about 30 to 35 per cent.

Butter of cacao is officially described as "a yellowish-white, solid, having a faint, agreeable odor, and a bland, chocolate-like taste. Specific gravity, 0.970 to 0.980 at 15° (59° F.). Readily soluble in ether or chloroform, also soluble in 100 parts of cold and in 20 parts of boiling absolute alcohol, all these solutions being neutral to litmus paper. It is brittle at 15° (59° F.), and melts at 30° to 33° C. (86° to 91.4° F.), to a clear liquid"—(*U. S. P.*). The melted fat solidifies again at 20.5° C. (68.9° F.), accompanied by a sudden rise of temperature to about 27° C. (80.6° F.). It is not easily liable to become rancid.

Chemical Composition.—Butter of cacao consists of the glycerides *stearin* and *olein*, with small quantities of *laurin*, *palmitin*, and *arachin*. Kingzett's *theobromic acid* ($C_{64}H_{128}O_2$, 1877) could not be reobtained (M. C. Traub, *Archiv der Pharm.*, 1883, p. 19). P. Graf (*Archiv der Pharm.*, 1883, p. 830) also found small quantities of *formic*, *acetic*, and *butyric acids*, and *cholesterin* (*phytosterin*).

Adulterations and Tests.—Butter of cacao may be adulterated with tallow, beef suet, stearin, stearic acid, wax, spermaceti and paraffin, oils of cocoanut, almond, etc. Some of these admixtures may be recognized by determining the acid and iodine numbers and the saponification equivalent of the fat. The *U. S. P.* directs the following test: "If 1 Gm. of oil of theobroma be dissolved in 3 Cc. of ether, in a test-tube, at a temperature of 17° C. (63° F.), and the tube subsequently plunged into water at 0° C. (32° F.), the liquid should not become turbid, nor deposit a granular mass in less than 3 minutes; and if the mixture, after congealing, be exposed to a temperature of 15° C. (59° F.), it should gradually form a perfectly clear liquid (absence of paraffin, wax, stearin, tallow, etc.)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Oil of theobroma is emollient and nutrient. It forms a good dressing for *wounds* and *abraded* or *excoriated parts*, and on account of its melting at the temperature of the body, furnishes a good base for suppositories for the relief of *rectal, vaginal*, and *uterine lesions*. Internally, in 5 to 30-grain doses, it has been employed in *chronic bronchial* and *intestinal disorders*.

Related Oils.—SHEA BUTTER, also known as *Bambuk* or *Galam butter*, is a light-greenish or grayish fat, mild to the taste, and having an odor like cacao butter. It fuses near 28° C. (82.4° F.). It is expressed from the seeds of *Bassia Parkii*, De Candolle, an African tree.

MANWAH BUTTER.—From the seeds of the Indian *Bassia latifolia* of Roxburgh. The oil is yellowish or greenish. Its fusing point is near 45° C. (113° F.). The flowers of this species are fleshy and said to yield 50 per cent of sugar, and are employed by the natives in the making of a spirituous beverage, and for food. (For other species of *Bassia*, see *Monesia*.)

MAFURA BUTTER.—The seeds of the *Trichilia emetica*, Vahl (*Mafureira oleifera*, Bertero) (*Nat. Ord.*—Meliaceæ), are bitter and have the characteristic odor of cacao-beans, and yield a fat much resembling cacao-butter. It is yellow, not so soft as tallow, is mild in taste, and has the odor of cacao-butter. It fuses at 42° C. (107.6° F.). *Olein* and *palmitin* are its constituents, and when saponified it yields a large amount of *palmitic acid*. The oil is obtained in tropical Africa by boiling the seeds in water.

OLEUM THYMI (U. S. P.)—OIL OF THYME.

"A volatile oil distilled from the leaves and flowering tops of *Thymus vulgaris*, Linné (*Nat. Ord.*—Labiatæ). It should be kept in well-stoppered bottles, in a cool place, protected from the light"—(*U. S. P.*).

Preparation.—This oil is chiefly obtained in southern France, where the plant grows in immense quantity. Spain also produces oil of thyme, although this is of somewhat different physical and chemical characters. The crude product is known as *red oil of thyme*, and is usually sold under the name of *oil of origanum* (see *Oleum Origani*). The rectified oil is known as *white oil of thyme*. In southern France these two grades are known respectively as *huile rouge de thyme* and *huile blanche de thyme*. In this connection, Gildemeister and Hoffmann (*Die Ætherischen Oele*, 1899, p. 817) point out that rectified oil of thyme, unless rectified under especial precautions, soon acquires the red color of the crude oil again. The permanently pale French oil is stated to be produced by distilling the crude oil with an excess of oil of turpentine; hence such oils contain at most 5 per cent of phenols, as against 20 to 25 per cent, sometimes 42 per cent in normal oils. The yield of oil of thyme varies from 0.3 to 0.4 per cent (fresh herb, German) to 1.7 per cent (dry, German), and 0.9 per cent (fresh, French) to 2.5 and 2.6 per cent (dry, French).

Description.—"A yellowish or yellowish-red liquid, having a strong odor of thyme, and an aromatic, pungent, afterward cooling taste. It becomes darker and thicker by age and exposure to the air. Specific gravity, 0.900 to 0.930 at 15° C. (59° F.). It does not fulminate with iodine. The oil is soluble in half its volume of alcohol, forming a clear solution which is neutral or only very slightly acid to litmus paper. The oil is also soluble, in all proportions, in carbon disulphide, and in glacial acetic acid. With a drop of ferric chloride T.S. the oil yields a greenish-brown color, which changes to reddish"—(*U. S. P.*). French and German oil of thyme is soluble in 1 or 2 volumes of alcohol of 80 per cent, but 15 to 30 volumes of 70 per cent are required for complete solution, while the Spanish oil, probably from another botanical source, forms a clear solution with the latter solvent.

Chemical Composition and Tests.—The characteristic constituents of oil of thyme are the solid *thymol* and the liquid *carvacrol*, two isomeric phenols of the formula $C_{10}H_{14}O$ (see *Thymol*). As stated before, the total amount of phenols in oil of thyme (French and German oils) is 20 to 25 per cent, seldom as high as 42 per cent; *thymol* is usually the only phenol present; sometimes it is either entirely or to a small extent, replaced by *carvacrol*. The Spanish oil contains from 50 to 70 per cent of carvacrol exclusively (compare *Oleum Origani*). The correct formula for thymol was established by Lallemand (1853). He also found oil of thyme to contain the hydrocarbons *cymol* ($C_{10}H_{14}$), and a small quantity of *l-thymene*, which was identified by Schimmel & Co. (1894) as *l-pinene*. The latter also established the presence of *borneol* and *linalool* in the higher fractions of oil of thyme; these results were confirmed by Labbé (1898).

The presence of oil of turpentine in oil of thyme may be recognized by the specific gravity being lower than 0.900, or by the diminished solubility in alcohol, and the deficiency in the phenol contents of the oil. A convenient method for determining the amount of phenols in oil of thyme consists in shaking a given volume of the oil (*e. g.*, 10 Cc.) in a burette with an equal volume of a 5 per cent caustic soda solution, allowing to stand from 12 to 24 hours, and measuring the volume of the remaining non-phenols (compare *Oil of Cassia*). By drawing off the aqueous phenolate, and rendering acid with sulphuric acid, the regenerated phenols will solidify upon standing when consisting of thymol, but will remain fluid when they consist of carvacrol. An iodometric method for the estimation of phenols in oil of thyme was devised by E. Kremers and O. Schreiner (see *Pharm. Review*, 1896, p. 221). The *U. S. P.* directs the following test: "If 1 Cc. of the oil be shaken with 10 Cc. of hot water, and, after cooling, the liquid be passed through a wet filter, the filtrate should not assume, with a drop of ferric chloride T.S., a bluish or violet color (absence of carbolic acid)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Thymus* and *Thymol.*)

Related Oils.—OLEUM SERPYLLI, *Oil of wild thyme*. The essential oil distilled from *Thymus Serpyllum*, Linné. A colorless or golden-yellow, lævogyrate oil of the specific gravity 0.905 to 0.930. Odor slightly like thyme, but more like melissa. Constituents, chiefly *cymol* ($C_{10}H_{14}$), with 1 per cent of *thymol*, *carvacrol*, and probably other phenols.

OIL OF THYMUS CAPITATUS.—Has a pronounced thyme-like odor; specific gravity, 0.901; constituents, *thymol* (6 per cent), *cymol*, *pinene*, *dipentene*, *bornyl-acetate*, and possibly *carvacrol* (Schimmel & Co.'s *Report*, October, 1889). Produced in Spain.

OIL OF THYMUS CAMPHORATUS.—Specific gravity, 0.904. Constituent, *carvacrol* (Power, *Essential Oils*).

OLEUM TIGLII (U. S. P.)—CROTON OIL.

The expressed fixed oil of the seeds of *Croton Tiglium*, Linné; *Tiglium officinale*, Klotzsch.

Nat. Ord.—Euphorbiaceæ.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 239.

Botanical Source.—Croton Tiglium is a middle-sized tree, the young branches of which are terete, smooth, shining, and somewhat furrowed toward the extremities. The leaves are alternate, petiolate, oval, oblong, acute, 3 to 5-nerved at the base, acuminate at the apex, with shallow, glandular serratures; thin, membranous, with 2 glands at their base, and covered when young with very minute, scattered hairs, dark-green above, and paler below. The petioles are about one-third the length of the leaf, channeled, having stellate hairs when quite young, but soon losing them. The flowers are downy, in erect, terminal racemes; male flowers at the apex, female below. The male flowers have a 5-cleft calyx, 5 lanceolate, woolly, straw-colored petals, and 15 distinct stamens; female have a 5-cleft, permanent calyx, with long and bifid styles. The fruit is a smooth, oblong, obtusely triangular capsule, about the size of a hazel-nut, closely covered with minute, stellate hairs, with 3 cells, each of which is completely filled with a solitary seed. The skin of the seeds is of a pale, dull-brown color, and overlies a harder, dark integument (L.—Wi.).

Fig. 185.

Croton Tiglii.

History and Preparation.—This tree is a native of the East Indies, growing in Ceylon, in the Molucca Islands, in China, etc., and is cultivated in Japan and European countries. The tree was probably first known in China. Its wood (*lignum pavana*) and seeds (*pini nuclei moluccani*) were made known to the Europeans in 1578, by the Portuguese physician, Christobal Acosta. Like the various plants of this natural order, it is imbued in all its parts (root, bark, leaves, seeds) with a sharp, energetic, drastic cathartic element. The oil obtained from the seeds is the official part. The seeds are of an ovoid form, about the size of a pea, reddish-brown when recent, grayish-brown when old, sometimes brownish-black. They consist of a thin, brittle, ligneous shell; a delicate, white, membranous integument; and an oleaginous kernel composed of a pale, yellowish-white albumen, and a beautiful embryo, with large, leafy cotyledons. The oil, which constitutes about 50 to 60 per cent of the kernels, is obtained by removing the shells from the seeds, bruising these to a pulp, and subjecting the pulp to a strong pressure. By digesting the residue with sulphuric ether, filtering, and expelling the ether by a gentle heat, an additional quantity of oil is often obtained. The residual press-cakes must be burned up in order to guard against accidents that might possibly result from handling them. Or, the seeds may be extracted altogether with sulphuric ether, or with carbon disulphide, and the solvent evaporated. These methods, however, are not recognized by the *U. S. P.* A. H. Allen (*Com. Org. Anal.*, Vol. II, Part I, 1899, p. 161) reports that extraction with ether removes three times as much oil as when the oil is expressed, or extracted with alcohol. Expression yields a pale oil, ether a light-brown, and alcohol a dark-brown oil, containing twice as much free acid as the specimens obtained by the other methods. Its saponification value is also much higher.

Description and Tests.—The croton oil of commerce is partly imported from India, and partly expressed in England from the imported seeds. *English croton oil* is of a reddish-brown color, and forms a uniform, transparent mixture with equal parts of absolute alcohol, without the aid of heat. The *East Indian croton oil* is pale-yellow, like Canada balsam, and mixed with equal parts of absolute alcohol, forms an opaque, milky solution, which is rendered transparent and uniform upon the application of heat. The East Indian is the official oil, and is described as "a pale-yellow or brownish-yellow, somewhat viscid, and slightly fluorescent liquid, having a slight, fatty odor, and a mild, oily, afterward acrid and burning taste (*great caution is necessary in tasting*). When applied to the skin, it produces rubefaction or a pustular eruption. Specific gravity, 0.940 to 0.960 at 15° C. (59° F.). It reddens blue litmus paper moistened with alcohol. When fresh, it is soluble in about 60 parts of alcohol, the solubility increasing by age. It is freely soluble in ether, chloroform, carbon disulphide, and in fixed or volatile oils. When gently heated with twice its volume of absolute alcohol, it forms a clear solution from which the oil usually separates on cooling"—(*U. S. P.*). The *U. S. P.* also directs that "croton oil should be kept in small, well-stoppered bottles, and should be handled with caution"—(*U. S. P.*).

Croton oil has the highest specific gravity (see above) of all fatty oils, except castor oil. It is also soluble in glacial acetic acid, and soluble in petroleum ether, while castor oil is insoluble in the latter solvent. Croton oil is intermediate between the drying and non-drying oils, and does not give the elaïdin reaction. Accordingly the *U. S. P.* directs that "if to 2 Cc. of the oil 1 Cc. of fuming nitric acid and 1 Cc. of water be added, and the mixture vigorously shaken, it should not solidify, either completely or partially, after standing for 1 or 2 days (absence of other non-drying oils)"—(*U. S. P.*). The presence of castor oil may probably be detected by its insolubility in petroleum ether.

It is stated that an oil not quite as active as the pure croton is obtained from the *Barbadoes nuts*, or the seeds of *Curcas purgans*, Adanson (*Jatropha Curcas*, Linne (see *Curcas*); it is an active purgative in a dose of 3 to 5 drops. The seeds of the *Croton pavanæ*, Hamilton, are likewise supposed to furnish some of the commercial croton oil. An inferior oil which has been recommended as a substitute for croton oil is obtained from the Caper spurge, or Garden spurge (*Euphorbia Lathyris*, Linne) of south Europe. It is extracted with carbon disulphide, and deposits a crystalline body on standing. *Croton oblongifolius*, Roxburgh, has similar seeds, while the seeds of *Croton morifolius*, of Mexico, yield an oil, mildly cathartic in 2 or 3-drop doses.

Chemical Composition.—I. THE SEEDS. These, according to Flückiger, consist of 31.6 per cent of husks, and 68.4 per cent of kernels, the latter containing from 50 to 60 per cent of croton oil. The husks hold about 1.65 per cent of oil (Zinnel, *Amer. Jour. Pharm.*, 1890, p. 122). The seeds contain, beside the oil and the usual seed constituents, two powerfully poisonous albuminous bodies, *croton-globulin* and *croton-albumin* (Ufstrand, 1897). The poisonous principle remains to some extent in the press-cake (H. Stillmark's Dissertation, *Ueber Ricin*, 1889, p. 146).

II. THE OIL.—Croton oil was found by Schlippe (1858) to contain the *glycerides of stearic*, *palmitic*, *lauric*, *myristic*, and *oleic acids*, and a vesicating resinous principle *crotonol*. The additional *angelic acid*, of Schlippe, was found by Guenther and Fröhlich (1870) to differ from true angelic acid in melting point, and was named *tiglinic acid*. Schmitt and Berendes (1878) found this acid to be identical with Frankland and Duppa's *methylcrotonic acid* ($C_6H_8O_2$), and also established the presence of *isobutyric* and *isovaleric acids* in croton oil. *Acetic acid* was previously shown by Guenther and Fröhlich to be present.

Regarding the active principles of croton oil, it has long been known (Nimmo, 1823) that alcohol differentiates the oil into an alcohol-soluble vesicant part and an alcohol-insoluble, purgative part (Harold Senier, *Pharm., Jour. Trans.*, 1878, p. 705; and 1883, p. 446). In 1857, Buchheim and Krich, by saponification of the purgative portion, isolated therefrom a vesicant principle; hence a close relation must exist between the alcohol-soluble and insoluble portions of the oil. Kobert and von Hirschheydt, in 1890 (*Ueber die Crotonol-säure*, R. Buchheim's), came to the conclusion that the efficacy of the alcohol-soluble, vesicant part is due to the presence of free *crotonoleic acid*, a rather unstable body, while the alcohol-insoluble part contains it as a glyceride. The authors also demonstrated, by experiment, that the neutral oil (insoluble in alcohol) is decomposed by the pancreatic ferment, whereby the vesicating crotonoleic acid is liberated. More recently, Prof. W. R. Dunstan and Miss L. E. Boole (*Pharm. Jour. Trans.*, 1895, p. 5) investigated crotonoleic acid. After separating therefrom some inert oily acids, the last fraction contained a powerfully vesicating resin, *croton resin*, a hard, light-yellow, brittle substance, nearly insoluble in water, readily soluble in alcohol, ether, and chloroform. Prolonged boiling with caustic alkalies destroys its vesicating power. (Adapted from an article on Croton Tiglium, by J. U. Lloyd, in *The Western Druggist*, April, 1898.)

Action, Medical Uses, and Dosage.—Croton oil is a powerful irritant and cathartic. In large doses it is a dangerous poison, occasioning emesis, painful gripings, hypercatharsis, and other serious symptoms. Its action is prompt, frequently causing catharsis within an hour; and, from the smallness of its dose, it is especially adapted to cases where medicines requiring large doses can not be given, as in *trismus*, *coma*, *insanity*, *congestive apoplexy*, etc. In most cases, catharsis may be produced by placing a drop or two on the back part of the tongue. It is principally used as a purgative when the bowels are very torpid; in comatose conditions as a revellant; and in *dropsy* as a hydragogue. It is admissible in *obstinate constipation* when no inflammation exists, and is the most efficient purgative in *lead colic*. It is likewise asserted that, irrespective of its cathartic property, it possesses efficacious influences in *spasmodic* and *painful nervous affections*. It may be used in all cases where prompt and active purgation is indicated. It is distinguished from other powerful cathartics by occasioning much borborygmus or rumbling of wind, by its action commencing speedily and ending soon, and by the purgative effect, however exhausting at the time, being followed by little debility. In certain forms of *diarrhœa* and other *enteritic affections*, I have derived great benefit by dissolving croton oil, ½ fluid drachm, in alcohol, 2 fluid ounces, and administering it in doses of from 5 to 15 drops, according to circumstances (J. King). Externally, it produces erythematic redness, intense burning, and an eruption of minute vesicles.

A croton-oil liniment is made by mixing 1 part of croton oil with 4 or 5 parts of olive oil, or 6 parts of turpentine; it is rubbed on the skin several times a day, to cause redness and a pustular eruption; it is very beneficial in *follicular disease of the throat*, *affections of the larynx*, *bronchial vessels*, and *lungs*, *indolent tumors*, and all *painful attacks*. The dose of croton oil is from 1 to 6 drops, which is best given on sugar, or made into a pill with crumb of bread, in order to avoid the disagreeable, acrid sensation it occasions in the throat, with a constant tendency to hawk, as well as to prevent nausea or vomiting. Four drops of the oil, thoroughly rubbed around the navel, will, it is said, produce catharsis. Croton oil is now seldom used externally; it was once very popular as a counter-irritant. Soubeiran recommends the following lozenges: Take of vanilla chocolate, ½ ounce; sugar, 2 drachms; starch, 40 grains; croton oil, 10 drops; mix thoroughly together, and form into 60 lozenges.

Related Drug.—*Bocconia.* South American natives employ several species of this genus as purgative, abortifacients, and topical irritants (H. H. Rusby, *Bull. of Pharm.*, 1891).

OLEUM VALERIANÆ.—OIL OF VALERIAN.

The essential oil distilled from the root of *Valeriana officinalis*, Linné.

Nat. Ord.—Valerianaceæ.

Preparation and Description.—The root of Valeriana officinalis distilled with water yields about 1 per cent of volatile oil. When freshly prepared it is a yellowish-green, faintly acid, thin liquid, the odor of which is not unpleasant. Upon exposure to the air it becomes dark-brown, viscid, strongly acid, and of a very disagreeable odor, owing to the liberation of *valerianic acid* ($C_5H_{10}O_2$). Fresh oil of valerian has a specific gravity of 0.93 to 0.96 and is optically lævo-rotatory.

Chemical Composition.—The characteristic constituent of oil of valerian is *bornyl- (borneol-) valerianate* (Bruylants, 1878), an ester which undergoes spontaneous decomposition into borneol and valerianic acid when the oil is exposed to air. The stearopten sometimes deposited in old oil is borneol. According to Gerock (1892), about 9.5 per cent of this ester is present, with 1 per cent, each, of *bornyl-formiate, acetate*, and *butyrate*. Upon saponification of these esters with caustic alkali and fractionating the resultant oil, the hydrocarbons *l-pinene* and *l-camphene* were found in the lowest fractions, then followed *l-borneol, terpineol*, a *sesquiterpene*, and an alcohol, $C_{15}H_{26}O$ (Olivieri, 1893). From the saponification water, Olivieri isolated a crystallizable, lævo-rotatory alcohol ($C_{10}H_{20}O_2$), melting at 132° C. (269.6° F.). The highest fractions of oil of valerian, according to Prof. Flückiger (1876), contain a blue oil (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899); its taste is warm and camphoric. Caustic alkalies saponify the oil uniting with its valerianic acid to form valerianates.

Action, Medical Uses, and Dosage.—Oil of valerian possesses the properties of the root in a concentrated degree, and may be substituted for it in all cases where the root is applicable. It has been found especially useful in *hysteria, chorea, restlessness*, etc. An efficient preparation for nervous, sleepless, and hysterical cases is composed of: Tincture of lupulin, tincture of hyoscyamus, of each, 4 fluid ounces; camphor, 1 drachm; and oil of valerian, 22 minims. Mix, and give 1 or 2 fluid drachms for a dose. The dose of the oil of valerian is 2 to 6 drops in alcoholic solution, pill, or emulsion.

OLIBANUM.—FRANKINCENSE.

A dry gum-resin obtained from *Boswellia Carterii*, Birdwood, with its varieties, and several other species of *Boswellia*.

Nat. Ord.—Burseraceæ.

Synonyms: *Gummiresina olibanum, Thus.*

Illustration: (*Boswellia Carterii*) Bentley and Trimen, *Med. Plants*, 58.

Botanical Source and History.—The individual species of Boswellia yielding this product are not well known. Several trees, possibly distinct species, are classed as varieties of *B. Carterii*. The genus comprises trees having odd-pinnate leaves, with leaflets serrate, flowers small, 10-stamened, and borne in racemes, and succeeded by 3-celled, drupe-like capsules, each cell of which is 3-seeded. The trees are found in East Africa (Somali country), South Arabia, and India. (For an account of the several species consult *Pharmacographia*, 2d ed., pp. 133 and 139.) Olibanum is the frankincense of the ancients and was among the offerings of the Magi to the infant Savior. It constituted a large part of the *incense* so frequently alluded to in the Scriptures. It is collected in the Somali country by making deep incisions into the trunk of the tree from which the milky gum-resin exudes and soon concretes. The clear tears are first gathered, and the portion which has run down the side of the tree or has fallen to the ground, constitutes an inferior sort.

Description.—Olibanum is a translucent, brittle, whitish-yellow substance, in roundish, club-shaped, pear-shaped, or irregular tears, and usually covered by a whitish, farinaceous substance produced by the pieces rubbing against each other. It has a sub-acrid, terebinthinate, bitter taste, and a pleasant, resinous odor, and when burned, it produces a brilliant flame, and diffuses an agreeable aroma. It melts with difficulty, not without decomposition, becomes soft and adhesive by chewing, forms an incomplete, white emulsion when rubbed up with water, and is dissolved by alcohol to the amount of about 65 per cent. It has a specific gravity of 1.22.

Chemical Composition.—Olibanum consists chiefly of an acid *resin* (56 per cent), soluble in alcohol and having the formula $C_{20}H_{32}O_4$ (Hlasiwetz, 1867); it yields no benzene derivatives when fused with caustic potash. When burned, it emits an agreeable odor. Water removes from it a bitter, viscid substance, little soluble in ether. Olibanum also contains *gum* (30 to 36 per cent), insoluble in alcohol, and resembles ordinary gum arabic. With 3 parts of water it forms a thick mucilage (*Pharmacographia*). Finally, olibanum contains about 3 per cent of *ash*, and from 4 to 7 per cent of a *volatile oil*. According to Kurbatow (1874), it consists chiefly of a terpene *olibene* ($C_{10}H_{16}$), boiling at 158° C. (316.4° F.). Flückiger found it lævo-rotatory, and Wallach (1889) identified it as *l-pinene*, and in addition found *dipentene*. Schimmel & Co. also report the occurrence of *phellandrene* in the oil (Gildemeister and Hoffmann, *Die Ætherischen Oele*, p. 641).

Action, Medical Uses, and Dosage.—Olibanum is a stimulant, producing results similar to those from the tolu and Peru balsams; it is principally used as a fumigating article, and occasionally forms an ingredient of plasters. The dose, when used internally, is from 5 to 40 grains, in emulsion.

Related Species.—Another gum-resin is obtained from an unidentified tree inhabiting the neighborhood of the Red Sea; it grows upon the bare rocks, without any other support than the very round, thick substance, of a nature between bark and wood, which is thrown out from the base of the trunk, and which adheres very firmly to the rocks. Kempthorne (1843) alludes to this species as being the tree furnishing olibanum.

Boswellia serrata, Roxburgh, is the *Boswellia thurifera*, Colebrooke, a leafy forest tree of the Coromandel coasts and other parts of India. Though formerly thought to furnish olibanum, this tree is not the source of that drug, but yields a soft odorous resin which slowly hardens within a period of a year, and is used only by the natives as *incense*.

Boswellia papyrifera, Richard, yields a transparent resin, probably destitute of gum, though thought to contain a volatile oil. It grows in western Abyssinia.

Boswellia Frereana, Birdwood, the *Yegaar* of the Somalis, yields a fragrant resin of a lemon odor. It contains no gum, and is employed in the East as a masticatory.

Hedwigia balsamifera.—An alcoholic extract of this plant, administered hypodermatically, proved a nerve and cardiac poison. A convulsing alkaloid is contained in it, and a resin capable of lowering the body heat and inducing paralysis (*Ann. de Thérap.*, 1889). (See also p. 1318.)

ONOSMODIUM.—FALSE GROMWELL.

The root and seeds of *Onosmodium virginianum*, A. De Candolle (*Lithospermum virginianum*, Linné).

Common Names: *False gromwell, Gravel weed, Wild Job's tears.*

Botanical Source.—This plant is a perennial herb, clothed all over with harsh and rigid appressed bristles. The stems are rather slender, 1 or 2 feet in height. The leaves are oblong, or oblong-lanceolate, often oval, and even ovate-lanceolate, sessile, minutely strigose, 3 to 5-veined; lower ones narrow at base, 1 inch to 2½ inches long, ½ or ¾ of an inch broad. The flowers are yellowish-white, in terminal, leafy racemes, which are recurved at first, but finally become erect and elongated. Calyx 5-cleft, lobes lanceolate, pilose on both sides, half as long as the corolla. Corolla oblong-tubular, with a ventricose, half 5-cleft limb, with lance-subulate segments clothed externally with long hispid hairs. Stamens 5, with very short, flattened filaments supporting included, sagittate apiculate anthers. Style much exserted and smooth. Achenia ovoid, smooth and shining, fixed by a flat base (G.—W.).

History.—This plant is found growing from New York to Florida, in dry, hilly grounds, flowering from June to September. The root and seeds are the parts employed, and yield their virtues to water. There are two other species of this genus which possess similar properties (see next page).

Action, Medical Uses, and Dosage.—Diuretic and tonic. Said to dissolve *calculi*. A strong infusion of the root and seeds, taken in doses of 4 fluid ounces, every 2 hours for about a day, or until it purges, is highly extolled as a cure for *calculous affections.* It occasions excessive urination, hence care must be taken that it be not employed too long, for fear of producing too great a flow of urine. It is worthy of a full investigation. *Onosmodium carolinianum*, De Candolle, and *Onosmodium strigosum*, possess similar properties (see also *Lithospermum officinale*).

OPIUM (U. S. P.)—OPIUM.

"The concrete, milky exudation obtained by incising the unripe capsules of *Papaver somniferum*, Linné (*Nat. Ord.*—Papaveraceæ), and yielding, in its normal, moist condition, not less than *nine* (9) *per cent* of crystallized morphine, when assayed by the process given below"—(*U. S. P.*). (For *botanical description* of poppy, see *Papaveris Capsula*.)

SYNONYMS: *Meconium*, *Succus thebaicus.*

Official Forms of Opium.—I. OPIUM (as above indicated). II. OPII PULVIS, *Powdered opium*. III. OPIUM DEODORATUM, *Opium denarcotisatum*, *Deodorized opium*, *Denarcotized opium.*

History, Commercial Sources, and Description.—Opium was known to the ancient Greeks, being mentioned in the writings of Theophrastus (about 370 to 286 B.C.), and by the writers of the first century, *e. g.*, Dioscorides and Pliny. Its most probable geographical source was then Asia Minor. Egyptian (Thebaïc) opium is recorded as early as the sixth century. The knowledge of the drug was spread eastward by the Arabs. During the middle ages it was used in Europe only as a medicine, and entered into most of the narcotic preparations known as *theriac*. In eastern Asia, however, its use as a stimulant gradually increased and received a powerful impetus, since about 1770, by the exportations of opium from India into China. This trade has fallen off considerably, owing to extensive production of the drug by the Chinese themselves. The most notable event in the chemical history of the drug was the discovery of the first alkaloid known, morphine, by Sertürner, in 1811.

Fig. 186.

Papaver somniferum

The opium met with in commerce is principally that from Asia Minor, which was the kind expressly demanded by the *U. S. P.*, 1880, and the *Br. Pharm.*, 1885, and which is still required by the *Ger. Pharm.*, 1890. The present *U. S. P.* and *British Pharmacopœia* do not specify the origin of opium; still, most of the opium entering this country, comes from Asia Minor. Other opium-producing countries are Persia, India, Egypt, China, Australia, and some parts of Europe.

ASIA MINOR OPIUM, *Turkey opium*, *Smyrna opium*, *Constantinople opium.*—This is obtained from *Papaver somniferum*, Linné, var. *glabrum*, Boissier. In the northwestern provinces of Asia Minor, opium cultivation is in the hands of small holders of land, owing to the scarcity of hired labor. The poppy requires a naturally moist and rich soil, much manure, and diligent hoeing and weeding, which is done mostly by women and children, yet the opium crop is very uncertain, because the poppy may be injured or destroyed by spring frosts, drought or locusts. About the end of May the plants begin to ripen, and a few days after the petals have fallen, the head or capsule is ready for incision. This is done on hot afternoons in order that the exuding juice may dry rapidly. A transverse cut is made with a knife in the lower part of the capsule, the incision being carried round to near its starting point. Great care must be taken not to cut too deep, *i. e.*, to avoid penetrating the interior wall of the seed-vessel, because in this case the juice would flow into the inside and be lost. The following morning, the capsules are scraped off with a blunt instrument and the dried juice placed on a leaf. Night-dew promotes the flow of juice and increases the yield, but the opium is darker than when the night is dry. A high wind is also harmful, because of the dust it throws on the opium. A crop of 5 to 8¼ pounds of opium, and 200 pounds of poppy-seed, from 1 *toloom* of land (1600 square yards), is considered a good yield; in some years only a little over ½ pound has been obtained. After the opium is collected, the seeds are shaken out, expressed in hand presses, and the oil thus obtained is used for burning and for eating purposes. Part of the poppy-seeds are sold to Smyrna merchants who find a market for them in Europe. The opium, before it is marketed, is wrapped in poppy leaves, and dried in the shade, and then put into thin cotton bags which are sealed and placed into round baskets. These are sent to Smyrna, carried by mules, each animal carrying two baskets, weighing from 130 to 162 pounds each. Most of these baskets also contain about 5 per cent of inferior grades, partly adulterated with sand, pounded poppy-heads, half-dried apricots, dried grape-juice mixed with flour and sometimes turpentine, figs, or gum tragacanth. The bags are opened in Smyrna, examined by a government official, and the lowest grades (*chicantee, chikinti*) are rejected and sold at cheaper rates to manufacturers of morphine. Upon repacking, the seeds of some Rumex species are strewn between the opium cakes, in order to prevent their agglutinating together. Mr. Sidney H. Maltass, who gives the foregoing information (*Pharm. Jour. Trans.*, Vol. XIV, 1855, pp. 395–400), also states that the distinction usually made between Constantinople and Smyrna opium does not really exist, as the opium from the intermediate districts may be sent to both places. At the time of his report, preference was given to Smyrna, because the opportunities for smuggling were greater in the latter place. (For additional information on Smyrna opium, see an excellent article by E. R. Heffter, *Amer. Jour. Pharm.*, 1868, p. 362, and translation of an official Turkish bulletin on poppy-growing, *Amer. Jour. Pharm.*, 1883, p. 413, from *Pharm. Jour. Trans.*)

Good commercial opium is described by the *U. S. P.* as occurring "in irregular or subglobular cakes, with the remnants of poppy leaves and fruits of a species of Rumex adhering to the surface; plastic, or of a harder consistence; chestnut-brown or darker, and somewhat shining; internally showing some tears and fragments of vegetable tissue. It has a sharp, narcotic odor, and a peculiar, bitter taste"—(*U. S. P.*). The Smyrna opium cakes vary in weight from about 300 to 700 grammes, or about ½ to 2 pounds; in rare cases, they weigh as much as 3 kilogrammes, or over 6 pounds (Flückiger, *Pharmacognosie*, 3d ed., 1891, p. 178). The only change that good opium undergoes by keeping, is that of becoming gradually hard; too moist varieties are apt to become moldy.

Persian Opium.—This variety first appeared on the market in the later fifties. It is chiefly grown in the provinces of Kermanshah and Ispahan, from the variety *Papaver somniferum*, Linné, var. *album* (*Papaver officinale*, Gmelin), and is said to contain, when pure, from 13 to 16 per cent of morphine, while the Smyrna opium contains, at best, little over 13.5 per cent (*Amer. Jour. Pharm.*, 1885, p. 36). Persian opium, however, has greatly lost in favor, owing to its being frequently adulterated. It is mixed, for example, with evaporated grape must, or linseed oil (8 to 10 per cent), probably in order to facilitate its being rolled into small balls or cylinders. W. Stoeder (*Jahresb. der Pharm.*, 1884, p. 335) found the best variety to contain about 12 per cent of morphine. It occurs in commerce in the form of cones, weighing about 180 to 300 grammes, or in brick shape, or in circular, flat cakes of 600 grammes weight, or in the form of small cylinders wrapped in glazed paper, and weighing about 15 grammes (see Reveil, *Pharm. Jour. Trans.*, Vol. II, 1860, p. 271). It is shipped from the Persian ports Bushahr and Bender Abbas, and now and then reaches the London market, it being used chiefly in the preparation of pure morphine.

East India Opium.—About 1770 the Calcutta authorities embarked upon the cultivation of opium and its exportation into China, in order to raise revenue for the benefit of the government officials. The astonishing financial success of this measure, however, induced the East Indian Company to assume entire control of this trade, and to exercise strict supervision over the production and disposition of opium (see K. von Scherzer, *Fach. Berichte ü. d. Œst. Ung. Exp. n. Siam, China and Japan*, 1872). For the last 30 years, this trade has been gradually falling off, owing to the competition of the Chinese products (see *Pharm. Jour. Trans.*, Vol. III, 1896, p. 465).

Although East India opium is raised in greater quantity than any other kind of opium, probably, except the Chinese, it reaches the western markets only in small quantities. The principal varieties are the *Bengal* and *Malwah opium*. The *Bengal opium* is raised in the Central Ganges territory between Patna and Benares, and is fully controlled by the government. The opium growers must obtain a license, and must sell their product, which must possess a specified consistency (70 per cent of dry substance), to the government. It is produced in nearly the same manner and under the same precautions as Smyrna opium. The capsules are repeatedly cut by means of a knife with several parallel blades tied together. The opium growers bring their product to the government factories where it is roughly assayed, mixed in vats and filled into previously prepared shells of agglutinated poppy leaves. The balls thus formed weigh about 2 kilogrammes each; they are then rolled in "poppy-trash," *i.e.*, broken leaves, capsules, and stalks, then dried by exposure to the air and in drying rooms, and finally put in chests, each holding 40 balls. (See an explicit description of the Bengal opium manufacture, and the mode of its official supervision, by W. C. B. Eatwell, *Pharm. Jour. Trans.*, Vol. XI, 1851, pp. 269, 306, and 359; also J. R. Jackson, *Pharm. Jour. Trans.*, Vol. I, 1871, p. 782.) This opium is a rather inferior grade, owing to possible fermentation, during the several months which are consumed in its manufacture. It contains only from 3 to 4 per cent of morphine, and about as much narcotine. A better grade is the *Patna garden opium* (see Guibourt, *Hist. d. Drogues*, 1876), which is said to reach Smyrna opium in quality. *Malwah opium* is made in Central India; its cultivation is free, only the product has to pay a tax upon delivery at Bombay, from whence it is shipped. It is formed in balls of about 300 grammes each. Malwah opium has been most esteemed by the Chinese. The opium intended for export to China, is called in India *provision opium;* that grown for local consumption is called *excise opium* (*Benares Akbari*). In recent years the latter yielded to the Indian government an annual revenue of about £1,000,000. During 1893 the value of the total exports of opium from India was about £8,000 000 P. L. Simmonds, *Amer. Jour. Pharm.*, 1895, p. 325). The cultivation of opium in other parts of India is insignificant. In the Madras presidency it is prohibited.

CHINESE OPIUM.—Opium was hardly known in China until the importations from India began, about 1780, notwithstanding the protests of the Chinese government. The drug being admitted into China since 1858, the Chinese production has been greatly stimulated by the high import duties placed upon the foreign drug. The Chinese government, although without avail, has, from time to time, issued proclamations placing the penalty of death upon the cultivation of opium, "which covers the nourishing rice-fields with useless and harmful plants" (Scherzer, *loc. cit.*). The chief provinces where opium is now grown are Ssuchuan and Yünnan, and in recent years the import into Shanghai from the western provinces seems to correspond with the decrease in the imports of the English drug (see statistics in *Pharm. Jour. Trans.*, Vol. III, 1896, pp. 465 and 532). The Chinese opium was at one time inferior to the English opium, while also much cheaper, 20 to 50 per cent; but its quality has since improved. (For some interesting information regarding the smoking of opium by the Chinese, see editorial in the *Pharm. Jour. Trans.*, Vol. XIII, 1882, p. 225; G. Birdwood, *ibid.*, Vol. XII, 1881, p. 500; and S. Culin, *Amer. Jour. Pharm.*, 1891, p. 497.)

EGYPTIAN OPIUM.—This is now used only by the natives, and is produced at Akmim, and at Assiout, both on the river Nile. Mr. Martindale (*Amer. Jour. Pharm.*, 1889, p. 187) reports the former to contain 7.24 per cent, the latter only 0.6 per cent of morphine.

AUSTRALIAN OPIUM.—Poppy was first grown in Australia in 1871, and is sown and cultivated in the same manner as Smyrna opium, except that, on account of the antipodal seasons, sowing is done at three different times in the months of June and July, instead of from November to February, as practiced in Asia Minor. An analysis of Bacchus Marsh opium showed 10.65 per cent morphine, and 6.48 per cent narcotine (W. E. Matthews, *Amer. Jour. Pharm.*, 1888, p. 45).

EUROPEAN OPIUM.—Poppy has been planted in various parts of Germany; but while it yields a high percentage of morphine (8.7, 14.8, and 22 per cent in Würtemberg opium, E. Dieterich, 1888), the culture of opium is not promising on account of the great value of ground, and the large cost of labor. Guibourt (*Jour. Pharm. Chim.*, 1862, p. 199) reports on a number of French opiums of high percentage in morphine (from 12 to 22.8 per cent).

American Opium.—Attempts have been made to cultivate poppy in Mississippi, Louisiana, Virginia, Tennessee, Illinois, California, and other states; but while an opium rich in morphine may be obtained from the capsules, the labor it requires would make the cultivation unprofitable. Poppy grown in New Ulm, Minn., yielded 15.23 per cent of morphine, 0.325 per cent narcotine, 0.416 per cent codeine, and 3.5 per cent meconic acid (E. Weschcke, *Amer. Jour. Pharm.*, 1886, p. 407).

Pharmaceutical Preparations of Opium.—(See also other opium preparations under their respective heads.) Opii Pulvis (*U.S.P.*), *Powdered opium:* "Opium dried at a temperature not exceeding 85° C. (185° F.), and reduced to a very fine (No. 80) powder. Powdered opium, for pharmaceutical or medicinal purposes, when assayed by the process given under opium, should yield not less than 13 nor more than 15 per cent of crystallized morphine. Any powdered opium of a higher percentage may be brought within these limits by admixture with powdered opium of a lower percentage, in proper proportions"—(*U. S. P.*).

Opium Deodoratum (*U.S.P.*), *Deodorized opium*, *Opium denarcotisatum* (*U.S.P.*, 1880), *Denarcotized opium.*—"Powdered opium, containing 13 to 15 per cent of morphine, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs]; ether, fourteen hundred cubic centimeters (1400 Cc.) [47 fl℥, 163 ♏]; sugar of milk, recently dried and in fine powder, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Macerate the powdered opium with seven hundred cubic centimeters (700 Cc.) [23 fl℥, 321 ♏] of ether, in a well-closed flask, during 24 hours, agitating from time to time. Pour off the clear, ethereal solution as far as possible, and repeat the maceration with two further portions of ether, each of three hundred and fifty cubic centimeters (350 Cc.) [11 fl℥, 401 ♏], first for 12 hours, and the last time for 2 hours. Collect the residue in a weighed dish, dry it, first by a very gentle heat, and finally at a temperature not exceeding 85° C. (185° F.), and mix it thoroughly, by trituration, with enough sugar of milk to make the product weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]"—(*U. S. P.*). The purpose of this process is to remove narcotine from opium by means of ether, in which it is soluble, while morphine is nearly insoluble (see *Morphina*).

Adulterations and Tests.—In addition to the adulterants before enumerated, opium may be falsified with stones, sand, clay, gypsum, litharge, starch, gum Arabic, ashes, fragments of poppy capsules, resins, wax, licorice juice, etc. Some of these additions may be recognized by closer ocular or microscopic examination; others may be more difficult to detect. Inorganic matter will be indicated by the increase in ash, of which good opium yields not more than 5 or 6 per cent. Gum would be indicated by a gelatinous consistency of a hot aqueous infusion of opium; starch by the iodine test; licorice extract by a dark coloration of the moderately diluted aqueous infusion.

The presence of morphine alone in a vegetable extract does not suffice to prove the extract to contain opium; it must also give the tests for *meconic acid*. This is done in the following manner: Filter the aqueous infusion of the supposed opium, treat it with excess of solution of acetate of lead, and set aside in a tall vessel for the precipitate of meconate of lead to subside; the clear liquor holds in solution acetate of morphine. Pour off the supernatant fluid, and collect the precipitate on a filter. Test the clear filtrate for morphine by evaporating to dryness with potassium carbonate, abstracting the morphine with alcohol, and applying to it the tests as given under morphine (see *Morphina*). Test the precipitate for meconic acid by suspending it in water and decomposing the lead salt by a current of hydrogen sulphide gas or with diluted sulphuric acid; filter, and in the first case, expel the excess of gas by warming on the water-bath, and apply to the solution the tests for meconic acid (see *Meconic Acid*, p. 1413).

Purchasers of opium in former years relied almost exclusively on external characters, as color, odor, taste, texture, moisture, and freedom from obvious admixture. In recent years, the quality of a given opium is judged mainly by its morphine contents, ascertained by reliable assay methods.

As stated above, the *U. S. P.* demands good opium to contain, in its natural moist condition, not less than 9 per cent of morphine. This is to be ascertained by the following official process:

ASSAY OF OPIUM, U. S. P.—"Opium, in any condition to be valued, ten grammes (10 Gm.) [154.3 grs.]; ammonia water, three and five-tenths cubic centimeters (3.5 Cc.) [57 ♏]; alcohol, ether, water, each, a sufficient quantity. Introduce the opium (which, if fresh, should be in very small pieces, and if dry, in very fine powder) into a bottle having a capacity of about 300 Cc., add 100 Cc. of water, cork it well, and agitate frequently during 12 hours. Then pour the whole as evenly as possible upon a wetted filter having a diameter of 12 Cm., and, when the liquid has drained off, wash the residue with water, carefully dropped upon the edges of the filter and the contents, until 150 Cc. of filtrate are obtained. Then carefully transfer the moist opium back to the bottle by means of a spatula, add 50 Cc. of water, agitate thoroughly and repeatedly during 15 minutes, and return the whole to the filter. When the liquid has drained off, wash the residue, as before, until the second filtrate measures 150 Cc., and finally collect about 20 Cc. more of a third filtrate. Evaporate in a tared capsule, first, the second filtrate to a small volume, then add the first filtrate, rinsing the vessel with the third filtrate, and continue the evaporation until the residue weighs 14 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 20 Gm. Then add 10 Gm. (12.2 Cc.) of alcohol, shake well, add 25 Cc. of ether, and shake again. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during 10 minutes, and then set it aside, in a moderately cool place, for at least 6 hours, or over night.

"Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother water, and afterward wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc., or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass, and weigh them.

"The weight found, multiplied by 10, represents the percentage of crystallized morphine obtained from the opium"—(*U. S. P.*).

The characteristic feature of the foregoing process, which is practically that of Dr. E. R. Squibb (see *Ephemeris*, 1888, p. 967), consists in precipitating the morphine, by aqua ammoniæ, from a hydro-alcoholic solution of about 30 per cent alcohol. The addition of the latter has the purpose of keeping the coloring matter dissolved. The addition of alcohol is objected to, by E. Dietrich and others, because alcoholized mother liquors will retain a certain quantity of morphine in solution, at least more than an aqueous mother liquor would hold; the addition of alcohol also facilitates the precipitation of calcium meconate which will be added to the weight of, and counted as, morphine. It is believed, however, that these opposite sources of error about balance each other. Ether is used in the assay in order to remove narcotine, which is soluble, while morphine is nearly insoluble, in this solvent (see *Morphina*).

The *U. S. P.* assay process lacks directions for testing the purity of the morphine obtained. The degree of its purity may be judged by several methods: (1) Titration with volumetric acid solutions; (2) incinerating the assay morphine, calculating the weight of the ash as calcium meconate, and deducting this value from the weight of morphine employed; (3) treating the assay-morphine with 100 parts of lime-water and weighing the non-morphine residue; (4) separating the morphine from inorganic salts by means of alcohol. Regarding these methods, and the desirability of perfecting the *U. S. P.* assay method in general, see L. F. Kebler, *Amer. Jour. Pharm.*, 1895, p. 398, and 1896, p. 257; also F. X. Moerk, *ibid.*, 1894, pp. 433–446, and 1897, pp. 343–350. The *German Pharmacopœia*, following Dieterich's process (see *Pharm. Centralh.*, 1886, p. 541, and 1890, p. 597), avoids the use of alcohol. An aqueous infusion of opium (which contains the morphine as sulphate and meconate) is first treated with just sufficient diluted ammonia water to precipitate the bulk of narcotine; the filtrate is then treated with ether and sufficient ammonia water to precipitate the morphine.

Among the recently proposed methods for the assay of opium, the volumetric method of H. M. Gordin and A. B. Prescott (*Pharm. Archives*, 1898, p. 121) stands conspicuous. Its principle is as follows: The opium alkaloids are set free by trituration of the opium sample with a mixture of stronger ammonia water and alcohol, of each 1 part, ether 4 parts, and chloroform 2 parts. The free narcotine, papaverine, codeine, and thebaïne, are then removed by percolation with benzol, after which the morphine is taken out by percolation with acetone or pure amyl alcohol. This solvent is evaporated, the residue taken up with lime-water which completely dissolves and purifies the morphine. Filter the lime solution, acidulate it, to a very slight excess, with hydrochloric acid, and determine the morphine as *periodide* ($C_{17}H_{19}NO_3.HI.I_3$) by adding an excess of decinormal iodine volumetric solution, shaking thoroughly until the precipitate has subsided and the liquid is clear; the excess of iodine is then titrated back in an aliquot part of the liquid, with decinormal sodium thiosulphate solution. One Cc. of decinormal iodine solution corresponds to 0.00947937 gramme of morphine. This method gives higher results than the *U. S. P.* assay method (see *Proc. Amer. Pharm. Assoc.*, 1898, p. 372).

Chemical Composition.—The characteristic constituents of opium are its alkaloids, of which about 20 have been discovered. They occur mostly combined with sulphuric acid and with *meconic acid;* narcotine, being a weak base, seems to occur in the free state. Some opiums do not contain all these alkaloids. For example, specimens of French opium, according to Decharme (1862), were free from narcotine, narceïne and thebaïne. E. Kauder (*Archiv der Pharm.*, 1890, pp. 419–431) found eleven *crystallizable* alkaloids in opium, viz.: morphine, codeine, narceïne, narcotine, papaverine, thebaïne, and the rarer alkaloids, cryptopine (70), laudanine (20), protopine (3.5), laudanosine (1), and a new alkaloid, *tritopine* (2); the relative proportions of the latter being indicated by the numbers affixed. The alkaloids lanthopine, codamine, and hydrocotarnine of O. Hesse (1870 and 1871), were not observed in E. Kauder's opium material. Morphine, however, occurs in all opiums. Indifferent substances in opium are *meconin* ($C_{10}H_{10}O_4$), and *meconoiosin* ($C_8H_{10}O_2$). According to Flückiger (*Pharmacognosie des Pflanzenreichs*, 3d ed., 1891, p. 182), opium contains also small amounts of caoutchouc, wax, and sugar; mucilage, not identical with gum Arabic, albumen, pectin, coloring matter, and inorganic matter (3 to 5 per cent of ash). Starch, fat, and tannin, seem to be absent. The following table enumerates the peculiar constituents of opium:

Name.	Formula.	Discoverer.	Per cent.	Notes.
ALKALOIDAL				
Narcotine	$C_{22}H_{23}NO_7$ (Matthiessen and Foster, 1863)	Derosne, 1803 Robiquet, 1817	2 to 10	*Opianine* of Hinterberger; weak base.
Morphine	$C_{17}H_{19}NO_3+H_2O$ (Laurent)	Sertürner, 1811	2.7 to 22.8	(See *Morphina*.
Codeine	$C_{18}H_{21}NO_3+H_2O$ (Gerhardt	Robiquet, 1832	0.2 to 0.75	Methyl-morphine (see *Codeina*
Narceïne	$C_{23}H_{29}NO_9$ Anderson	Pelletier, 1832	0.1 to 0.4	Weak base; not very poisonous.
Thebaïne	$C_{19}H_{21}NO_3$. (Anderson)	Thibouméry, 1835	0.2 to 1	Strongly basic.

Name.	Formula.	Discoverer.	Per cent.	Notes.
ALKALOIDAL				
Pseudo-morphine	$C_{34}H_{36}N_2O_6$	Pelletier and Thiboumery, 1835	0.02 or traces	Identical with Polstorff's *Oxy-dimorphine* (1880) see *Morphina*.
Papaverine	$C_{20}H_{21}NO_4$	Merck, 1848	0.5 to 1	Not very poisonous.
Rheadine	$C_{21}H_{21}NO_6$	Hesse, 1865	2.1	From red poppy *Papaver rhœas*; weak base; sublimable.
Cryptopine	$C_{21}H_{23}NO_5$ (O. Hesse, 1871	T. & H. Smith 1867	0.003 hydrochloride	*Pharm. Jour. Trans.*, Vol. VIII, p. 595.
Codamine	$C_{20}H_{25}NO_4$	O. Hesse, 1870	....	Sublimable.
Laudanine	$C_{20}H_{25}NO_4$	O. Hesse, 1870	....	Acts like strychnine.
Lanthopine	$C_{23}H_{25}NO_4$	O. Hesse, 1870	....	Not basic.
Meconidine	$C_{21}H_{23}NO_4$	O. Hesse, 1870	....	Amorphous.
Protopine	$C_{20}H_{19}NO_5$	O. Hesse, 1871	....	Also in *Chelidonium* and *Sanguinaria* (see *Amer. Jour. Pharm.*, '90, p. 13).
Hydrocotarnine	$C_{12}H_{15}NO_3+\frac{1}{2}H_2O$	O. Hesse, 1871	....	Obtainable from narcotine.
Laudanosine	$C_{21}H_{27}NO_4$	O. Hesse, 1871	....	Resembles tritopine.
Oxy-narcotine	$C_{22}H_{23}NO_8$	Beckett and Wright, 1875	....	From the mother liquors of narceïne.
Gnoscopine	$C_{22}H_{23}NO_7$	T. & H. Smith 1878, 1893	....	Isomeric with narcotine.
Tritopine	$C_{42}H_{54}N_2O_7$	E. Kauder, 1890	....	*Amer. Jour. Pharm.*, 1890, p. 492.
Xanthaline	$C_{37}H_{36}N_2O_9$	T. & H. Smith 1881, 1893	....	*Amer. Jour. Pharm.*, 1893, p. 240.
NON-ALKALOIDAL				
Meconic acid	$C_7H_4O_7+3H_2O$	Sertürner, 1805	2.5 to 5.5	
Meconin	$C_{10}H_{10}O_4$	Dublanc, 1828 Couerbe, 1832	0.01 to 0.086	Or *opianyl*; bitter, neutral; by reduction of narcotine.
Meconoiosin	$C_7H_4O_7$	T. & H. Smith, 1878	....	*Pharm. Jour. Trans.*, Vol. VIII, p. 981.
Opionin	Nitrogen free	O. Hesse, 1885	....	*Amer. Jour. Pharm.*, 1885, p. 425.

The separation of these substances is effected, according to the method of Gregory, Robiquet, and Anderson (see *Morphina*). (For details, see Husemann and Hilger, *Pflanzenstoffe*, p. 669.) An analytical scheme of separating opium alkaloids has been devised by P. C. Plugge (*Amer. Jour. Pharm.*, 1887, p. 511, and *Pharm. Jour. Trans.*, Vol. XVIII, 1888, p. 692).

I. NARCOTINE (*Narcotia*) ($C_{22}H_{23}NO_7$, Matthiessen and Foster) may be obtained by extracting opium, first with cold ether, which removes wax and fatty matter, then with warm ether, and recrystallizing the narcotine from alcohol. It crystalizes in rhombic prisms, is tasteless and odorless, little soluble in boiling water, soluble in 100 parts of cold, in 20 parts of boiling 85 per cent alcohol, in 166 parts of cold, in 48 parts of warm ether, and in 2.69 parts of chloroform, in 60 parts of acetic ether, in 22 parts of benzol, and 300 parts of amyl alcohol; insoluble in cold, but soluble in hot solution of caustic potash or lime.

Narcotine is a weak base, forming with acids uncrystallizable, bitter, and soluble salts of acid reaction, decomposable by excess of water, or by evaporation if combined with a volatile acid. Concentrated sulphuric acid dissolves narcotine first colorless and then yellow, and later reddish-yellow; the colorless solution, gradually heated, turns orange-red and exhibits beautiful blue-violet streaks, finally a red-violet color. Neutral narcotine solutions, *e. g.*, in chloroform, are optically lævo-rotatory; in acid solution the rotation is reversed to the right. *Narcotine*, when oxidized with sulphuric acid and manganese dioxide, yields needles of *cotarnine* ($C_{12}H_{13}NO_3+H_2O$), little soluble in water, and crystallizable, bitter *opianic acid* ($C_{10}H_{10}O_5$), soluble in hot water (Wöhler, 1844). The latter acid yields upon further oxidation *hemipinic acid* ($C_{10}H_{10}O_6$), and upon reduction with nascent hydrogen *meconin* ($C_{10}H_{10}O_4$). *Cotarnine* is a soporific, and is also a motor paralyzant. The complete graphic formula of narcotine is now known; according to Roser, it is closely related to hydrastine (see A. R. L. Dohme's report in *Western Druggist*, 1895, p. 58). The effects of *narcotine* upon the system are but imperfectly known. Magendie states that a grain of it dissolved in olive oil and administered to a dog, was followed by death in about 24 hours, while 24 grains, dissolved in acetic acid, diluted, produced no effect. It is very probable that pure narcotine does not possess any very active narcotic powers, and that the first experiments were made with an impure article. Undoubtedly, some morphine is often present in narcotine. Three grains of narcotine, dissolved in diluted hydrochloric acid, and repeated 3 times daily, have been strongly recommended as a powerful antiperiodic, acting without occasioning constipation, uneasiness, and cephalalgia, but frequently causing copious diaphoresis (*Br. and For. Med. Rev.*, Vol. VIII, p. 263 . Upon animals narcotine exhibits convulsive effects, but not upon man. Bartholow compares its action upon man to the actions of the alkaloids of the berberine class; upon animals to those of strychnine, etc.

II. MORPHINE (*Morphia*) ($C_{17}H_{19}NO_3$) (see *Morphina*).—*Apomorphine* (*Apomorphia*) ($C_{17}H_{17}NO_2$) is the name given to an artificial base derived from morphine by Matthiessen and Wright. It is white or grayish-white, non-crystalline, but soon turns green when exposed to the air, is partly soluble in water, soluble in alcohol, ether and chloroform, yielding different colored solutions with each menstruum, and in very small doses is a powerful, non-irritant emetic and contrastimulant. Its crystallized hydrochlorate is now official (see *Apomorphinæ Hydrochloras*).

III. CODEINE (*Codeia, Methyl-morphine*) ($C_{18}H_{21}NO_3.H_2O$). (See *Codeina*.)

IV. NARCEINE (*Narceia*) ($C_{23}H_{29}NO_9$).—It is obtained from the mother liquors remaining from the preparation of morphine. It crystallizes in rhombic prisms or needles, is first bitter, afterward styptic, and without odor. Very divergent melting points have been found. The crystals contain some water which it is difficult to expel at 100° C. (212° F.). They are soluble in boiling water and boiling alcohol, insoluble in ether, benzol, petroleum ether, slightly soluble in amyl alcohol and chloroform. Narceine is more soluble in diluted alkalies and ammonia water than in cold water. Narceine is a weak base, but forms with diluted acids crystallizable and soluble salts. When exposed to heat, a smell resembling that of herring-brine (*trimethylamine*) is evolved. Concentrated sulphuric acid colors pure narceine brown, but the solution is light-yellow, and changes to deep red. If rhœadine, thebaine, or papaverine are present, a blood-red or blue color will result. Narceine dissolves in concentrated nitric acid with blood-red color. Diluted solution of iodine colors it blue. If narceine is treated with a little concentrated sulphuric acid, and a small amount of sodium nitrite is added, a brown-green coloration is formed, turning blue at the edges; upon heating, a blue-violet color arises. The therapeutical properties of *narceine* are not well known; it is supposed, however, to influence the inferior part of the spinal marrow, diminishing sensation and mobility in the inferior extremities. It was once thought to be equal to morphine, but free from the unpleasant effects of the latter. Five grains or more of it act as a feeble hypnotic in man. It is not convulsant, and by some is regarded as wholly inert.

V. THEBAÏNE (*Thebaina* of Couerbe, 1835; *paramorphia* of Pelletier, 1832) ($C_{19}H_{21}NO_3$), was discovered by Thiboumery, in 1832, in Pelletier's chemical establishment. It may occur in rectangular scales or needles, or crystalline granules It has an acrid, styptic taste, and is of a strong alkaline reaction, forming water-soluble salts with acids, crystallizable from alcohol and ether. Thebaïne melts at 193° C. (379.4° F.), and becomes negatively electric upon friction. It is insoluble in water and diluted alkalies; soluble in boiling alcohol, and ether, in about 10 parts of benzol and 60 parts of amyl alcohol; little soluble in chloroform, insoluble in petroleum ether. Boiling with diluted hydrochloric acid converts thebaine into the amorphous bases *thebenine* and *thebaïcine*. Both turn blue with concentrated sulphuric acid. Thebaïne is dissolved by concentrated sulphuric acid with blood-red color, changing to yellow-red. (See additional reactions of this and all other opium bases in Charles E. Sohn, *Dictionary of the Active Principles of Plants*, London, 1894; also see discussion of the probable graphic formula of *thebaine* by Prof. Freund, in *Chem. Centralblatt*, Vol. II, 1897, p. 314. *Thebenine* has the formula $C_{18}H_{19}NO_3$ (Freund).

Thebaïne is considered to be a poison analogous to strychnine, occasioning, in a small dose, tetanic symptoms resembling those produced by that alkaloid. One and one-half grains, hypodermatically, produce in man anodyne and hypnotic effects without nausea or headache, being equal in power to ¼ grain of morphine.

VI. PAPAVERINE (*papaverina*) ($C_{21}H_{21}NO_4$).—Pure papaverine crystallizes from alcohol in the form of a network of acicular, white crystals, insoluble in water, but readily soluble in boiling alcohol or ether, in 37 parts of benzol and 76 parts of amyl alcohol; also soluble in warm petroleum ether. Chloroform abstracts it both from acid and alkaline solutions (Dragendorff). It melts at 147° C. (291.4° F.). Papaverine forms crystallizable salts with acids, soluble with difficulty in water. From solution of papaverine in diluted hydrochloric acid addition of strong hydrochloric acid precipitates a heavy oil, the hydrochloride, which soon solidifies to a crystallized mass. Papaverine is colored a deep blue by concentrated sulphuric acid; the solution becomes violet and slowly fades. Potassium permanganate colors this solution green, which changes to a slate color. Strong sulphuric acid containing 0.1 per cent of sodium molybdate, produces with papaverine a beautiful violet coloration changing to blue, and fading within 24 hours. Papaverine has been recommended as a sedative and soporific in mental affections, mania, etc., by certain physicians; while on the other hand, others state that it does not possess any therapeutical virtues. The graphic formula of papaverine has been elucidated by Goldschmidt (see Dohme, *loc. cit.*).

VII. RHŒADINE ($C_{21}H_{21}NO_6$) was discovered by Hesse in 1865. Besides being a constituent of opium, and the ripe capsules of *Papaver somniferum*, it is found in all parts of *Papaver rhœas*. It forms tasteless, non-poisonous, white, prismatic crystals, melting at 232° C. (449.6° F.), and sublimes in the form of long crystals at a slightly higher heat. It is indistinctly alkaline, almost insoluble in water, alcohol, ether, benzene, chloroform, and ammonia water. Moderately strong hydrochloric or sulphuric acids dissolve *rhœadine* with a deep purple-red color. This alkaloid is thereby differentiated into a colorless, crystallizable isomer of rhœadin called *rhœagenine*, and a red coloring matter. *Rhœagenine* is distinctly basic to litmus, and forms salts with acids. The coloring matter is sufficiently intense to be still visible in a dilution of 1 in 800,000. *Rhœadine* is dissolved by concentrated sulphuric acid with olive-green, by concentrated nitric acid with yellow color.

VIII. CRYPTOPINE (*Cryptopia*) ($C_{21}H_{23}NO_5$) was discovered, in 1867, by T. & H. Smith, of Edinburgh (see process in *Amer. Jour. Pharm.*, 1867, p. 421), in minute, silky, white, hexagonal prisms or plates, inodorous, slightly bitter, but soon followed by a peculiar sense of coolness recalling the taste of oil of peppermint. When heated it is volatile without residue; it fuses at 217.3° C. (422° F.). It is decidedly alkaline, perfectly neutralizing the strongest acids, and forming salts, of which the sulphate, acetate, hydrochlorate, etc., have been obtained in distinct crystals; however, they all have a tendency to form a jelly. Cryptopine is almost insoluble in water, ether, and benzol; it is soluble in alcohol, or chloroform; insoluble in benzin, oil of turpentine, ammonia water, and caustic mineral alkalies, but readily soluble in diluted acetic, nitric, sulphuric, or hydrochloric acids. Concentrated sulphuric acid gives a blue color with it; but the slightest tinge of purple (or blood-red) indicates the presence of thebaïne. A small particle of niter (potassium nitrate) added to the blue acid solution produces a permanent green color. Papaverine would change through green to orange-red. Cryptopine is anodyne and hypnotic, acting upon man similarly to morphine without the disadvantages of the latter. Said to be four times weaker than morphine; upon the lower animals it is reputed tetanizing and convulsant.

As regards the rarer opium bases, *laudanine*, *laudanosine*, *codamine*, *protopine*, etc., see O. Hesse (Liebig's *Annalen*, Vol. CLIII, p. 47, and Supplement, Vol. VIII, p. 261); and O. Kauder (*Archiv der Pharm.*, 1890, p. 419), as well as the references given in the above table.

IX. MECONIC ACID ($C_7H_4O_7.3H_2O$).—This acid may be obtained from an aqueous infusion of opium by precipitating it with calcium or barium chloride, as calcium or barium meconate, and decomposing these salts by means of sulphuric or oxalic acids (compare *Morphina*). Meconic acid crystallizes from water in the form of micaceous scales or rhombic prisms, which lose their water of crystallization at 100° C. (212° F.). Meconic acid tastes sour, and reddens blue litmus paper. It is little soluble in cold water, easily soluble in 4 parts of boiling water, also in alcohol; insoluble in chloroform, not easily soluble in ether. Meconic acid is dibasic, and accordingly forms two series of salts with bases; only the neutral alkali and ammonium meconates are soluble in water; the salts of other metals are insoluble. Thus meconic acid forms insoluble white meconates with silver nitrate, barium chloride, and lead acetate, the precipitates being soluble in nitric acid. A green precipitate of copper meconate is formed when solution of meconic acid is mixed with solution of ammoniated copper sulphate. Morphine seems to combine with meconic acid only in one proportion, forming the neutral dimorphine meconate ($[C_{17}H_{19}NO_3]_2.C_7H_4O_7.5H_2O$) (see *Morphinæ Bimeconas*).

A characteristic reaction for meconic acid consists in the blood-red coloration it yields with a neutral solution of ferric chloride. This reaction is similar to that produced when ferric chloride is mixed with potassium sulphocyanate (*rhodanate*). The ferric meconate, however, is insoluble in ether, while the ferric rhodanate is soluble; solution of corrosive sublimate destroys the rhodanate of iron, while it does not affect the meconate. Boiling the solution of ferric meconate does not cause a precipitate or discoloration; while solution of ferric acetate which is of a similar color, would precipitate brown ferric oxyacetate, while the solution would become colorless.

When exposed to about 120° C. (248° F.), meconic acid is decomposed into carbonic dioxide and crystallizable *comenic acid* ($C_6H_4O_5$), upon further heating, sublimable *pyromeconic acid* ($C_5H_4O_3$) is formed, with additional loss of carbon dioxide, water, acetic acid, and benzol. Meconic acid partly undergoes the first-named decomposition even when heated in aqueous solution.

Action and Toxicology.—Opium is narcotic and stimulant, acting under various circumstances as a sedative, antispasmodic, febrifuge, diaphoretic, and an inspissant of the mucous secretions. Topically, it is a direct stimulant and indirect sedative of the nervous, muscular, and vascular systems. A medium dose, taken while in health, augments the volume and velocity of the pulse, increases the heat of the surface, gives energy to the muscles, renders the mind more acute, and produces a general excitement of the whole system: the brain is especially acted upon, the faculties becoming more clear, the ideas more brilliant, precise, and under control, the power of application more intense, the conversational energies augmented, and frequently a state of frenzy or hallucination is induced. After a time this stimulation abates, leaving a calm, careless, indifferent, pleasurable sensation, with a series of obscure fleeting ideas, which is succeeded, after a longer or shorter period, by sleep, which may continue for several hours, and is followed by giddiness, languid pulse, sickness at stomach, cephalalgia, tremblings, want of appetite, and other indications of derangement of the nervous system. Other effects likewise occur during the period of its influence upon the system, thus—the mucous secretions become suspended, constipation is induced, the cutaneous secretion is increased, and the urinary and biliary secretions may be unaffected, or merely inspissated, in consequence of their discharges being impeded. The retention of urine and constipation, sometimes exist for several days. Generally, no serious results occur from this action of opium, except from a repetition of the dose, so often as to impair the vital powers by continuous over-stimulation. The unpleasant symptoms following the sleep caused by opium may be removed by lemon-juice, strong coffee, or a cathartic.

The effects of opium vary in different persons, and not unfrequently in the same individual under dissimilar circumstances. In some persons the smallest dose will cause nausea, emesis, and gastro-intestinal spasm; in others it will occasion feverishness, headache, watchfulness, restlessness, startling, disagreeable visions, delirium, anxiety, and afterward, an aggravated degree of the more familiar subsequent effects of this drug; these phenomena constitute what is called the *idiosyncratic action of opium*. Though commonly the result of idiosyncrasy, yet these symptoms are often induced in persons with whom opium in general agrees, simply because the specific indications for the drug are unheeded. Lemon-juice or vinegar renders the action of opium more favorable and less liable to produce the above disagreeable consequences. An unpleasant prickling sensation on the surface of the body, or a troublesome itching, occasionally accompanied with a slight eruption, is sometimes produced by opium, or more readily by salts of morphine. Occasionally, the rash resembles that produced by scarlatina, and desquamation follows. Again, the efflorescence may be of an urticarial nature. The narcotic power of opium is lessened by certain states of disease, as in the advanced stage of pneumonia, or peritonitis, by profuse hemorrhage, especially uterine, by severe dysentery, delirium tremens, some varieties of mania, tetanus, and severe pain or spasm of any kind. It is also modified by the conjunction of other remedies; camphor is thought to diminish the chance of its subsequent or idiosyncratic effects; and given with ipecacuanha, three or four times the ordinary hypnotic dose may be administered without inducing sleep, but with the effect of bringing on sweating with much greater certainty. Belladonna is antagonistic in its effects to those of opium and has been used in cases of poisoning by the latter agent, as an antidote; but when used for this purpose the means hereafter named must not be omitted. Persons who are ordinarily very nervous are very susceptible to the effects of opium. Females are more easily impressed by it than males, and it should be remembered that infants are extremely susceptible to it, even very small doses having been energetic enough to produce death. Nursing infants may be narcotized by the mother's milk while opiates are being taken. On account of the imperfect eliminative powers, opium and its derivatives should be cautiously used upon the aged.

Through whatever channel opium is introduced into the body—the stomach, the rectum, a wound, vein, excoriation, blistered surface, etc.—its remote action is exerted on the brain. It acts most energetically when it is promptly absorbed. When opium, or any of its preparations, is applied freely to a blistered, excoriated, or inflamed surface, its effects should be attentively watched, for dangerous accidents have occasionally happened in this way.

In large doses, opium is a poison, producing death if the proper remedies are not promptly and unremittingly resorted to. The state of stimulation and vivacity, if caused at all, is of short duration, being speedily followed by depression of the circulation, and of the functions of the brain, as manifested by diminution of the frequency of the pulse, but not of force, prostration of muscular power, slow, stertorous, and afterward soft or almost imperceptible respiration, flaccidity of the extremities, languor, drowsiness, torpor, or coma, first livid or turgid, afterward pale features, livid lips, excessively contracted pupils, coldness of the limbs, generally retention of the urine, and frequently profuse, cold perspiration, together with an almost entire apathy to external agencies. This state ends in death, unless speedily relieved. Convulsions may precede death, especially in children, and the pupils dilate just previous to death. It is said that in children the strong pupillary contraction may persist until dissolution. Death is due to respiratory paralysis or asphyxia. Post-mortem examination may reveal cerebral congestion, the brain sometimes being ecchymosed in spots. The cerebral convolutions have been observed to be flattened, and serum may or may not be collected in the ventricles and at the base of the brain, between the membranes. Extravasation of blood on the brain is rarely found, but upon cutting the cerebral substance minute drops of dark blood may ooze from the divided capillaries. The vessels of the spinal cord may be engorged with blackish blood. The spleen, liver, heart, and lungs are sometimes filled to distension with dark blood, and this is especially true when convulsions have preceded death. Great lividity of the skin is frequently observed, and the pupils are often dilated. Taylor observes (*Med. Jurisprudence*, p. 180) that there is nothing specially indicative of opium poisoning but "fullness of the vessels of the brain;" and this is not always present. If vomiting freely occurs before stupor supervenes, there is a fair chance of recovery. Four grains of opium killed a man of thirty-two, convulsions preceding death, while 2 drachms of laudanum have produced death in an adult. Hypodermatically, $\frac{1}{6}$ grain of morphine has killed an adult. Instances are common where persons addicted to the morphine or opium habit have taken enormous doses without injury; but in those unaccustomed to these drugs, the ordinarily recognized medicinal doses should never be exceeded, and treatment should always be begun with the minimum amounts. When a toxic dose of morphine is injected, narcotism ensues very speedily. Opium may kill within 2 hours, though from 6 to 18 hours usually lapse before death ensues (Taylor). The majority die in from 6 to 12 hours. It must not be forgotten that death may occur after the patient has apparently recovered, this being due to syncope, or to pulmonary congestion.

The remedies are, emetics of mustard and lobelia seed, zinc or copper sulphate, ipecac, or apomorphine subcutaneously, with strong coffee, stomach-pump, external counter-irritation, cold applications to the head and spine, forced exercise, galvanism, and artificial respiration. As soon as the stomach has been properly evacuated by emesis, internal stimulants must be administered, the best of which are brandy and carbonate of ammonium. Alcoholic stimulants should be given in small amounts, lest they increase the narcosis. The importance of keeping the patient in motion must not be overlooked. This may be accomplished by walking the patient between two attendants. The pleadings of the patient to rest must not be heeded, but he should be forced to move and keep awake by flagellations, electric shocks, and alternate dashings of warm and cold water upon the spine. Tickling the throat with a feather may assist in provoking emesis. Sometimes, when vomiting can not be produced, the shock to the nervous system produced by the means employed to prolong wakefulness, will so impress the nerve centers that they will so far recover their powers as to allow emesis to be produced. The respiration must not be allowed to flag. Ammonia may occasionally be inhaled. As before stated, belladonna is antagonistic to opium. Indeed, atropine is regarded as the best antagonist to poisoning by opium and morphine. Repeated small doses, $\frac{1}{70}$ to $\frac{1}{40}$ grain of atropine should be subcutaneously injected at intervals until the pupils begin to dilate. This method is preferable to giving a large dose at once, and is attended with results not otherwise obtainable. Stramonium may be used; also gelsemium, giving it short of sedation. Strychnine and cocaine have also been advised, and nitrate of amyl has some advocates. Permanganate of potassium is said to destroy the activity of morphine, and thus prevents its toxic effects. This requires further confirmation. As soon as consciousness is once fairly restored, an active cathartic, with the continuation of the forced exercise, generally completes the cure. The same toxicological treatment should be pursued in case of poisoning by any of the salts of morphine.

Physiologically, opium and its chief alkaloid affect chiefly the functions of the cerebro-spinal tract. In man, the cerebral functions are most impressed; in animals, the spinal axis. The motor and sensory, as well as the higher nerve-centers, are affected, and the terminal nerve-organs respond to its action. It, at first, stimulates and then paralyzes the cardiac motor ganglia and the end-organs of the vagus. The action of the heart and arteries are, at first, increased, and, secondarily, lowered by these drugs. The overstimulation of the spinal cord observed in the lower animals is not generally observed in the human species, and, when occurring, children being generally the individuals so affected. Opium depresses the sexual functions, and impotence in the male and cessation of the menses are not uncommon in opium habitues.

Medical Uses and Dosage.—The special uses of opium are so numerous that it is impossible to do more here than mention the most important of them. In all *febrile* and *inflammatory diseases*, it was formerly given either alone, or in combination with ipecacuanha to produce diaphoresis. While, in some instances, it will prove useful, as a rule it is now seldom used in *fevers*, as we possess better agents to accomplish the results formerly sought from the use of opium. In cases of *painful inflammatory affections*, however, it is of considerable value. But to prescribe opium and its derivatives intelligently, it is necessary to understand the conditions which are benefited by them, and those in which they produce harmful effects. The patient with the *hard*, small pulse, the dry tongue, dry, contracted skin, the flushed face, bright eye, and contracted pupil, is always injured by the administration of opium. On the contrary, the patient will be benefited when the pulse is *soft* and open, or when small, the waves are short and give a sensation of fullness and always lacking hardness, the skin is soft, the tongue moist, the face pale, and the eyes dull, expressionless, immobile, or dilated. In the last case the drug will act kindly, both in relieving *pain* and *spasm*, as a cerebral and spinal stimulant, and as a stimulant to the vegetative processes, and one need not fear the untoward effects usually attributed to idiosyncrasy. When, in *typhoid* and other *low fevers*, an exhausted state of the nervous system supervenes, then opium, in stimulant doses only, may be employed. In *intermittents*, it sometimes aids the action of quinine. While it has been used in the *exanthematous diseases*, to hasten the appearance of the eruptions, this use of it is not extensive, for better agents are possessed by us, and the use of opium in children's affections should be avoided as far as possible.

As an anodyne-diaphoretic opium, with ipecac, is likewise beneficial in *rheumatic*, *neuralgic*, and *gouty diseases*, in *nervous irritability*, *morbid vigilance*, *restlessness*, *diarrhœa*, and *dysentery*. Opium, as a pain-reliever, is of inestimable value when properly used, while, when improperly administered, it still relieves the pain, but may mask conditions of disease so that the physician may be unable to properly watch the progress of the case, the amount of pain often being his best guide to the seriousness and extent of the trouble. When opium, in stimulant doses, relieves pain, no untoward results need be expected, for, in these cases, it does not relieve the pain unless indicated. The danger lies in its employment as a sedative and narcotic. Fortunately, *neuralgia*, in which opium is so extensively and beneficially used, depends, as a rule, upon a state, the symptoms of which are those in which the drug is specifically indicated. There is nervous debility and often anemia, and opium or morphine acts kindly.

As an antispasmodic, opium is valuable in *asthma*, *colic*, *cholera*, *hysteria*, *tetanus*, some forms of *dyspepsia*, *spasmodic* and *convulsive affections*, especially in spasms accompanying the passage of *biliary* and other *calculi*, or which are present during an attack of *nephritis* or *gout*. Not only does opium relieve the pain, but it also relaxes the spasm attending the passage of the concretions. Here large doses may be necessary. In fact, when no contraindications are present, it is one of our most valued agents in *spasmodic disorders*. Morphine is generally employed in place of opium where pain and spasm are very severe. Hypodermatic injections of full doses of morphine form the best known treatment of *puerperal eclampsia;* its action may be assisted by the inhalation of chloroform and other internal treatment as indicated. When opium or morphine are previously administered, anæsthetization is more easily accomplished with chloroform, and much less of the latter is required. Opium is often useful after severe *surgical operations* to prevent shock and irritative febrile reaction. In *respiratory* and *digestive affections* opium, when indicated, will allay cough, soothe pain, relieve nausea, overcome tenesmus, and calm nervous irritability. It is of much utility in checking abnormal and increased discharges, as in *chronic catarrh*, *excessive secretions from the pulmonary mucous membranes*, *diarrhœa*, *uterine* and other *hemorrhages*, etc. In those painful conditions of the digestive tract, in which the food acts as an irritant and causes distress, bismuth or nux with opium generally relieves. Morphine with bismuth subnitrate is frequently demanded in *gastralgia*. In *diarrhœa*, opium is frequently indicated, and its tincture injected into the rectum, with starch-water, is the only agent, sometimes, that will give relief from tenesmus in *acute dysentery*. At the same time, the proper internal treatment must be pursued. An injection of morphine is the promptest agent for the relief of *cholera morbus*. In the exhausting *choleraic diarrhœa*, rendering one liable to an attack of true *Asiatic cholera*, during the prevalence of that dreaded disease in this country, Prof. Locke employed the following combination with the best of results: ℞ Tincture of opium, tincture of camphor, essence of peppermint, tincture of kino, aa, fl℥j; tincture of capsicum, fl℥ss; neutralizing cordial, fl℥iijss. Mix. Dose, a teaspoonful every $\frac{1}{2}$ hour in severe cases, 3 times a day in mild cases. But little of fluids should be taken, and a mustard plaster applied to the abdomen. In true *cholera*, stimulant injections of morphine often check the cramps, vomiting, and diarrhœa. When *constipation* is due to spasm of the bowels, opium relieves it. Opium, in well-selected cases, is one of the best remedies in *peritonitis* and *enteritis*. Aconite, veratrum, and bryonia will also usually be indicated, but opium, in the form of the diaphoretic or Dover's powder, or even morphine, will give rest from pain and peristaltic movements. In *nervous affections*, opium is a very important remedy, and many of the symptoms of other disorders partake largely of the nervous element. Indeed, it will be found valuable in all symptoms or forms of disease characterized by pain, wakefulness, inflammation, increased nervous excitability, increased mucous secretions, or spasmodic action.

Probably opium formerly killed more individuals suffering from *delirium tremens* than all other agents combined. This was owing to the enormous doses administered without regard to conditions. If the patient can not sleep or can not take food, he will die; if there is kidney disease, opium will probably kill the patient; if there is a flushed countenance, bloodshot eyes, wild and furious delirium, pain in the head, red and turgid tongue, and full, bounding pulse, opium will kill the delirium tremens patient; if, on the contrary, the skin is relaxed and moist, the circulation feeble, the face pale, and the tongue moist and dirty, opium is a safe remedy, for here it stimulates and sustains the nervous powers, and favors sleep. Here morphine is generally employed in a ⅛ or not more than ¼ grain dose, every 3 or 4 hours until sleep is induced (Locke, *Mat. Med.*, p. 241). In *traumatic tetanus*, opium is less valuable than morphine; the patient should be kept fully under the influence of the latter until the spasms are over. Though opium and its preparations should be carefully used in *affections of the heart*, it is one of the very best agents for the relief of *angina pectoris*. Here it, or morphine, which is usually preferred, is to be given in stimulant doses only. Under its use the pain and dyspnœa are relieved, and the action of the heart strengthened. Opium is not a remedy for continuous and persistent *dyspnœa*, but that form which is paroxysmal and occurring particularly upon going to bed. In *asthma*, morphine is one of the palliatives, and may be employed until the action of other agents may be obtained. It is occasionally resorted to in alleviating the distressing *cough of phthisis*. In *threatened abortion*, from over-exertion or nervous agitation, ½ drachm of tincture of opium, injected into the rectum, frequently prevents the accident. Dover's powder may also be used. Opium may be employed in *insomnia*, where cerebral stimulation is required. Of all conditions, it is here that the specific indications must be closely followed. The small or stimulant dose only should be given. The same may be said of it in *insanity*, in the puerperal form of which it seems to give the best service. Opium and morphine are the direct antagonists to the *poisonous effects of atropine*, *belladonna*, *physostigma*, *stramonium*, and *strychnine*.

Opium should not be used internally in cases of excessive inflammatory action, without having first allayed this action considerably by other means; or, if opium be administered, it should be combined with ipecacuanha, as in the compound powder of ipecac and opium, for the purpose of modifying its influence and promoting a determination to the surface. In phrenitis, cerebral congestion, accumulation of blood in the vessels of the head, inflammation of the mucous tissues with diminished secretion, and in ordinary states of costiveness, its employment is not proper. If the costiveness be due to spasmodic action, it may then be given as an antispasmodic in combination with a laxative. Opium is often eaten by persons until it becomes a habit exceedingly difficult to overcome; when taken to excess in this manner it may be known by the deadly pale or sallow aspect, with tokens of emaciation, and a gradual loss of the energies and activity of the whole system. A morphine habitue does not regard truth, and will say and do anything to get the coveted drug. Nervousness, trembling, neuralgic pains, insomnia, loss of appetite, spasms, hyperæsthesia, hallucinations, impotence, cessation of the menses, excessive perspiration, and tendency to self-destruction are among the effects of the habitual use of opium or its alkaloid, by mouth or subcutaneously. Some, however, take them for years without uncomfortable effects only when the supply of the drug is deficient. When the habit can be cured it is usually accomplished by the gradual withdrawal of the drug, and the substitution of small amounts of atropine until the full effects of the latter are obtained. Tonics, capsicum, good feeding, amusements, exercise in the open air, and pleasant society do much to assist in the cure. There is, however, a strong tendency to return to the habit. When the nervous system can withstand the shock it is best to wholly withdraw the drug at once. Murrell very properly remarks that "a good cook is half the battle," for good, stimulating, and nourishing food must be taken and assimilated if good results are to be expected. De Quincy, in his work entitled "*Confessions of an English Opium-eater*," states that he has taken 8,000 drops of laudanum, or 210 grains of opium daily; and attributes his cure of this lamentable vice to the use of the ammoniated tincture of valerian as a substitute for his opiate stimulant. Probably any other stimulant would have answered the same purpose (see also *Morphinæ Sulphas*).

Externally, opium is employed chiefly to subdue *pain*, and arrest *local inflammatory action;* it is applied in the form of lotion, liniment, or plaster, and is of service in *neuralgia*, *rheumatism*, some forms of *cutaneous diseases*, *irritable blistered surfaces*, *diseased mucous surfaces*, and in *erysipelatous inflammations.* It is likewise added to topical preparations for *inflammation of the eye*, and to *gonorrhœal injections.* There is much variety of opinion among physicians as to the use of this drug as a medicine, some contending against its use and others in its favor. That it is a useful agent in many diseases, and exerts an influence not possessed by any other one, no person will attempt to deny; neither does it, when given in the proper medicinal doses, leave the seeds of after-disease in the system, as is the case with mercurial preparations, which in small doses decompose the constituents of the body; therefore, although its present results may be disagreeable, yet. as they are not permanent, there is no good reason why we should dispense with an agent so well calculated to lessen the effects of disease upon the human system. When we administer the almost death-like prostrating emetic, lobelia, the energetic, prostrating, and nauseating hydragogue, resin of podophyllum, etc., etc., it is too much like prejudice without reason to oppose opium because its effects continue for a few days, or improper doses and carelessness in its use have resulted in death, and which may, in a degree, be said of every active remedy in the materia medica (J. King). In suppository it is useful in *hemorrhoidal* and other *rectal troubles*, as well as some *bladder* and *urethral disorders*, and to allay *reflex vomiting* therefrom.

Dose of opium in pill or powder, from ¼ to 3 grains, according to its influence upon the patient, the character of the disease, and the object to be accomplished. Sometimes larger quantities are given, as in severe tetanic, or other nervous affections, and in cases of severe pain. The medium dose to ease pain and produce sleep, is 1 grain. The dose of the tincture is from 10 to 50 drops. When it can not be taken by mouth, as in cases of *persistent vomiting*, and in *strangury*, severe pain accompanying *diseases of the kidneys*, *bowels*, or *uterus*, and *painful tenesmus*, it may be injected into the rectum with much benefit, adding to it a small quantity of water, flaxseed or elm infusion, starch-water, mucilage of gum Arabic, etc. When thus given the quantity may be twice that exhibited by the mouth—yet the practitioner should be cautious, as some patients are more powerfully influenced by it than others. (For the action of the opium constituents, see respective alkaloids under the chemical composition of opium, and under Morphina and Codeina.)

Specific Indications and Uses.—To give rest from pain and spasm, and to stimulate the vegetative functions and restrain secretions when the pulse is soft and open, or with short waves, the skin soft and moist, and the tongue moist and sometimes dirty.

Some Opium Preparations. Poppy capsules are much weaker in their action than opium; they are occasionally used in the form of syrup or decoction among children, but are in every way inferior to opium itself prepared similarly. The decoction, or the poppy capsules, are used for emollient and anodyne fomentations (see *Papaveris Capsulæ*).

Syrup of Poppies.—A *syrup of poppies* may be made by depriving of their seeds, poppy-heads, 9 ounces, reduce them to a coarse powder, moisten them thoroughly with diluted alcohol and digest for 48 hours; then transfer the whole to a percolator, and gradually pour upon it diluted alcohol until 2 pints of the filtered liquor are obtained; then evaporate by means of a water-bath to 8 fluid ounces, filter, add sugar, 15 ounces; proceed in the manner directed for simple syrup. When cool, add best French brandy, 2 fluid ounces, and mix (C. W. Epting). (See also *Syrupus Papaveris.*)

Sydenham's Laudanum.—*Sydenham's laudanum* is a vinous tincture of opium, made according to the *Parisian Codex*, by macerating for 2 weeks in 1 pint of sherry wine, 2 ounces of opium, 1 ounce of saffron, and 1 drachm each of bruised cinnamon and cloves; then filter. A fluid drachm of this laudanum is equivalent to 3 grains of opium (see also *Tinctura Opii*).

Rousseau's Laudanum.—*Rousseau's laudanum* is made by exposing a vessel, in which 6 ounces of honey have been dissolved in 1½ pounds of hot water, to a temperature of about 26.6° C. (80° F.), until fermentation commences; then add 2 ounces of good opium previously diffused in 1 pound of water, and again expose to a temperature of 26.6° C. (80° F.), for a month; express, filter, and evaporate to 5 ounces, to which 1 ounce of alcohol should be added. Six drops of this preparation are equivalent to 1 grain of opium.

Black Drop.—*Black*, or *Quaker's drop*, is variously made; the Edinburgh formula is: "Take of opium, 4 ounces; distilled vinegar, 16 fluid ounces. Cut the opium into small fragments, triturate it into a pulp with a little of the vinegar, add the rest of the vinegar, macerate in a closed vessel for 7 days, and agitate occasionally. Then strain and express strongly, and filter." The aromatics added in some formulæ are unnecessary (see also *Acetum Opii*).

Related Preparation.—PAPINE. A specialty of Battle & Co., of St. Louis, Mo., containing the anodyne principle of opium without the narcotic and convulsive constituents. Used to control *pain* and *acute inflammatory disorders*. One fluid drachm, the dose for an adult, equals in pain-relieving power ⅛ grain of morphine; for infants under 1 year, from 2 to 10 drops.

Related Species and Product.—*Eschscholtzia californica*, Chamisso; *California poppy*. This papaveraceous plant, the adopted flower of the state of California, is reputed analgesic and soporific without the dangers attending opiates. Prof. G. F. Walz years ago (1844) found in it two alkaloids, one acrid, the other bitter, besides *sanguinarine* and some succinic acid. Bardet and Adrian, in 1888, found in it a glucosid and two alkaloids, one of which gave the reactions for morphine. According to E. Schmidt and L. Reuter (*Pharm. Centralhalle*, 1889, pp. 590 and 611), the morphine-like body is *protopine*, one of the alkaloids of opium. By some the alcoholic extract has been used to the extent of 185 grains in a day, commencing with a 12-grain dose. Its action is pronounced valuable, quieting pain and producing calm sleep. Respiration is depressed by large doses, while toxic quantities impress the spinal cord.

METHYLTHEBAINE ($C_{20}H_{23}NO_3$), a derivative of thebaine, found by physiological tests to act similarly to, but less energetically, than thebaine.

ORIGANUM.—ORIGANUM.

The plant *Origanum vulgare*, Linné.

Nat. Ord.—Labiatæ.

COMMON NAME: *Wild marjoram.*

Botanical Source.—*Origanum vulgare*, or *Wild marjoram*, is a perennial herb, with erect, leafy, hairy, purple, quadrangular, corymbose stems, from 6 inches to 2 feet in height. The leaves are opposite, petiolate, broad-ovate, obtuse, subserrate, hirsute, rounded at the base, green on both sides, sprinkled with resinous dots, and paler beneath; the petioles hairy, and one-fourth as long as the leaves. The flowers are numerous, purplish-white, in smooth, erect, roundish, panicled, and fasciculate spikes, accompanied with ovate, purplish bracts longer than the calyx. Calyx ovate-tubular, striated, with 5 nearly equal teeth, and hairy in the throat. Corolla funnel-shaped, about the length of the calyx, and slightly 2-lipped; upper lip suberect, flat, and emarginate, the lower trifid, with lobes nearly equal. Stamens 4, exserted, somewhat didynamous, with double anthers; stigma bifid and reflexed. Achenia dry and somewhat smooth (G.—W.—L.).

History and Chemical Composition.—Wild marjoram is common to Europe and America. It is found in limestone regions, on dry banks, and in dry fields and woods, flowering from May to October. The whole herb is medicinal, but it is seldom collected, except for the purpose of procuring its volatile oil (see *Oleum Origani*), on which its virtues depend, and which may be separated by distillation with water. The plant has a strong, peculiar, rather agreeable balsamic odor, and a warm, bitterish, aromatic taste, which properties are imparted to alcohol, or boiling water by infusion. This plant contains a bitter body and some tannin.

Action and Medical Uses.—Origanum is gently stimulant, tonic, and emmenagogue. A warm infusion produces diaphoresis, and tends to promote menstruation, when recently suppressed from cold. It is sometimes employed externally in fomentation.

Related Species.—*Origanum Majorana*, Linné (*Majorana hortensis*, Moench), or *Sweet marjoram*, possesses properties similar to the above species. It is a native of Portugal, but cultivated in our gardens, and much used in cookery as a seasoning. Its leaves are oval or obovate, obtuse, entire, petiolate, hairy, pubescent, flowers pink-colored, in compact, roundish, pedunculate, terminal spikes, with roundish bracts. It flowers a month earlier than the preceding species. Its odor is stronger and more agreeable, and its taste more camphoraceous (W.). It yields a volatile oil (see *Oleum Majoranæ*, under *Oleum Origani*). Used in cookery and for the same purposes as origanum.

Origanum creticum, Linné.—South Europe. Leaves pungent and aromatic. Flowers whitish. It yields a volatile oil, used like those above.

Origanum hirtum, Link.—This plant yields an essential oil, often substituted in commerce for the oil of the preceding species (see under *Oleum Origani*).

Origanum Dictamnus, Linné, Levant.—Deep-purple flowers. Plant pungent and aromatic.

Lippia origanoides, Kunth (*Nat. Ord.*—Verbenaceæ). Mexico. This plant is known among the native Mexicans as *origano*.

Lippia Mexicana.—An evergreen shrub of Mexico. In ½ to 1 drachm doses a saturated tincture (1 in 4) of the stalks and leaves has been used as a demulcent expectorant

ORYZA.—RICE.

The seeds, deprived of their husks, of *Oryza sativa*, Linne.

Nat. Ord.—Gramineæ.

COMMON NAME: *Rice.*

Botanical Source.—Rice is an annual plant, with several jointed culms or stems, from 2 to 10 feet in height. The leaves are long, slender, and clasping. The panicle is terminal, diffuse, and bowing when the seed is weighty. The spikelet is hermaphrodite and 1-flowered. Glumes 2, and small. Paleæ 2, and adhering to the ovary. Scales 2, smooth; stamens 6; ovaries sessile; styles 2; stigma feathery. Caryopsis compressed, and inclosed by the paleæ (W.—G.—P.).

History and Chemical Composition.—Rice is supposed to have been originally a native of China, from whence it came to the East Indies; it is at present cultivated in nearly all parts of the world where the soil and climate are favorable. The harvesting of the new rice in India is introduced by religious worship. Rice, in order to thrive, requires a marshy, moist soil, and is accordingly now grown with success in Florida. Several species of cultivated rice are recognized. The husked seeds of the plant constitute the ordinary commercial rice. When boiled with water, the grains swell up, become soft, and absorb about twice their weight of water. Carolina rice, on analysis, has been found to consist of 85.07 per cent of starch, 3.60 of nitrogenous matter, 0.71 of gum, 0.29 of uncrystallizable sugar, 0.13 of fatty oil, 4.80 of woody fiber, 5.00 of water, and 0.40 of saline matters (Braconnot, *Jour. Pharm. Chim.*, 1817, p. 314).

J. König (*Die Menschl. Nahrungs- und Genussmittel*, 3d ed., 1893, p. 527) records the average of 35 analyses of ordinary cooking rice as follows: Water, 12.55 per cent; nitrogenous matter, mostly albuminous substance, 7.88 per cent; fat, 0.53 per cent; nitrogen-free extractive matter, 77.79 per cent (containing 75.79 per cent of starch, 1.3 per cent of sugar, gum, etc.); crude fiber, 0.47 per cent, and ash, 0.78 per cent. Of all cereals, the rice grain is richest in pure starch. The ash of rice grain contains much potassium phosphate and magnesium salts. Manganese is also contained in the ash. Rice is used as food by millions of people in China and certain parts of India (see consular report on the rice crop in India, *Amer. Jour. Pharm.*, 1898, p. 272). In addition to its employment for culinary and medicinal purposes, it is used in making ardent spirits (*Arrack*, see *Alcohol*), or *rice beer;* in Japan, a wine is made from it, called *sake* or *saki*. What is known as Chinese "rice paper," is obtained from the pith of *Aralia papyrifera*, by skillfully slicing it with a sharp knife (see *Amer. Jour. Pharm.*, 1878, p. 340).

Action and Medical Uses.—Rice is nutritious, and boiled in water until perfectly soft, is very useful in cases of *debilitated stomach* or *bowels*, and *diarrhœa;* it is likewise reputed a valuable article of food to overcome the diarrhœa so common to those who, for the first time, use the river waters of the western states. It is, by some, considered injurious to the eyes when used in any quantity, but this is an erroneous opinion, as many nations employ it almost exclusively as a diet, without any such effects. A decoction of rice (*rice-water*) is an excellent soothing and nutritive drink in *febrile diseases*, and likewise in *inflammations of the internal organs.*

OSMORRHIZA.—SWEET CICELY.

The root of *Osmorrhiza longistylis*, De Candolle (*Uraspermum Claytoni*, Nuttall).

Nat. Ord.—Umbelliferæ.

COMMON NAMES: *Sweet cicely, Smoother sweet cicely.*

Botanical Source.—This plant has a perennial, thick, fleshy, branching root, of an agreeable, aromatic flavor, and an erect, nearly smooth stem, branching above, and from 2 to 3 feet high. The leaves are large, decompound, the ultimate divisions often pinnate; radical leaves on long, slender petioles, cauline sessile The leaflets are irregularly divided by clefts and sinuses into lobes and teeth; the lobes broadly ovate and slightly pubescent. The flowers are white, in axillary and terminal umbels, about 5-rayed; central ones barren, outer ones fertile. Calyx-margin obsolete; petals oblong, nearly entire, with a short inflexed point. Involucres of linear bracts longer than the rays. The style is as long as the villose germ, filiform, erect, and deflexed. The fruit is linear-oblong, about an inch in length, angled, tapering downward into a stalk-like base, contracted at the sides, blackish, and crowned with the persistent styles. Carpels with 5 equal, acute, upwardly bristly ribs; commissure with a deep, bristly channel; intervals without vittæ (W.—G.).

History and Chemical Composition.—This plant grows in various parts of the United States, in rich moist woods, on the sides of low meadows, on the banks of running streams, and on the borders of low woodlands. It flowers in May and June. The root is the part employed; it has a sweet smell and taste, resembling anise seed. By distillation of the root with water, L. Eberhardt (*Pharm. Rundschau*, 1887, p. 149) obtained 0.63 per cent of an oil heavier than water, of specific gravity, 1.0114 at 10° C. (50° F.). The oil solidified at 10° to 12° C. (50° to 53.6° F.), and was chiefly composed of *anethol* (see *Oleum Anisi*). The air-dry root contained about 12 per cent of moisture, much sugar, some fat, resin, tannin, but no alkaloids. The ash referred to dried substance was 4.6 per cent. Mr. H. L. Green (*Amer. Jour. Pharm.*, 1882, p. 149) records 68.5 per cent of moisture in the fresh root.

Action, Medical Uses, and Dosage.—Sweet cicely is aromatic, stomachic, carminative and expectorant. Useful in *coughs*, *flatulence*, and as a gentle stimulant tonic to *debilitated stomachs;* the fresh root may be eaten freely, or it may be used in infusion with brandy or water.

OSMUNDA.—BUCKHORN BRAKE.

The rhizome of *Osmunda regalis*, Michaux (*Osmunda spectabilis*, Willdenow).
Nat. Ord.—Filices.

Common Names: *Buckhorn brake*, *Royal flowering fern.*

Botanical Source.—This fern has a hard, scaly, tuberous rhizome, beset with numerous fibers, and having a whitish core in the center. The fronds are several, erect, 3 or 4 feet high, doubly pinnate, smooth, bright green; primary divisions or pinnæ from 6 to 10, nearly opposite, remote, and hardly a span long. The leaflets are more numerous, often alternate, sessile or nearly so, oblong, bluntish, entire or obscurely-crenate, with 1 rib, and numerous transverse veins; base dilated, heart-shaped, or somewhat lobed. Some of the upper leaflets are cut, and as it were, partially transmuted, into dense clusters or spikes of innumerable, small, light-brown, veiny, globular, 2-valved thecæ, entirely covering the segments; several of the upper divisions of the leaf consisting entirely of such thecæ, composing a compound panicle. Spores green (L.—W.—G.).

History and Description.—This beautiful fern is found in meadows and low moist grounds, throughout the United States, flowering in June. The main root or caudex is the medicinal part; it is about 2 inches long, and has the shape of a buck's horn. It is composed of a number of layers or scales, which are elongated, imbricated, with satiny, translucent margins, and throws out a mass of entangled, delicate radicles. It contains an abundance of mucilage, which is extracted by boiling water. The ash of osmunda consists, to about 50 per cent, of silica. The roots should be collected in August, or about the latter part of May, and dried with great care, as they are apt to become moldy.

The *Osmunda cinnamomea*, or *Cinnamon-colored fern*, is inferior to the preceding, but is frequently used for the same purposes. Its root is similar, but much larger, and when its stems are young, during the spring months, they present a white or cinnamon-colored, pubescent appearance, with the leaves circinate and downy.

Action, Medical Uses, and Dosage.—Mucilaginous, tonic, and styptic. Used in *chronic coughs* with profuse perspiration, *diarrhœa*, and *dysentery;* also as a tonic during convalescence from exhausting diseases. One root, infused in a pint of hot water for half an hour, will convert the whole into a thick jelly. Very valuable in *leucorrhœa*, and other female weaknesses, and said to be an almost certain cure for *rickets*, in doses of 3 drachms of the root, 3 times a day. The mucilage mixed with brandy is a popular remedy as an external application for *subluxations* and *debility of the muscles of the back*. For internal use, the roots may be infused in hot water, sweetened, and ginger, cinnamon, brandy, etc., added, if not contraindicated.

OSTRYA.—IRON-WOOD.

The inner wood and bark of *Ostrya virginica*, Willdenow.

Nat. Ord. Cupuliferæ.

COMMON NAMES: *Iron-wood, Hop-hornbeam, Lever-wood.*

Botanical Source.—This is a small tree from 25 to 30 feet in height, remarkable for its fine, narrow, longitudinally divided, and brownish bark. The wood is white, hard, and strong. The leaves are oblong, ovate, subcordate, acuminate, unequally serrate, and somewhat downy; the buds acute. The sterile flowers are in cylindrical aments; scales orbicular-ovate, acuminate, ciliate, 1-flowered; filaments somewhat united irregularly; anthers bearded at the summit. The fertile flowers are in pairs, numerous, in a short, oblong, pendulous, loosely imbricated, linear, terminal ament, with small, deciduous bracts; scales none, but each flower is inclosed in a membranous sac-like involucre, bristly hairy at the base, and which enlarges, forming a bladdery closed bag in fruit, these being imbricated to form a sort of strobile appearing like that of the hop. The ovary is 2-celled, 2-ovuled, crowned with entire and bearded border of the perianth, forming a small and seed-like, smooth nut. Styles 2, united at the base; nut lance-oblong, somewhat compressed, and included in the enlarged, imbricated, bladder-like sac (G.—W.).

History.—This is a tree common to the United States, growing in rich woods, and flowering in April and May. The flowers are green, and appear with the leaves, and the large and handsome oval-oblong strobiles are matured in August. The inner wood and bark are the parts used; they are bitter and yield their virtues to water. Prof. Trimble found it to contain 6.5 per cent of tannin referred to dried substance (*Bull. of Pharm.*, 1895, p. 412).

Action, Medical Uses, and Dosage.—Iron-wood is antiperiodic, tonic, and alterative. It has been used with efficacy in *intermittent fevers, neuralgic affections, dyspepsia, scrofula*, and all diseases where an antiperiodic tonic is indicated. Dose of the decoction, 1 or 2 fluid ounces, 3 or 4 times a day; of the fluid extract, 1 fluid drachm.

Related Species.—*Carpinus americana*, Michaux. This is another tree known as *Iron-wood* and *Hornbeam*, closely resembling the above. It grows from 10 to 20 feet high, has a smooth gray bark, with an irregularly ridged trunk, and very fine-grained, compact, white wood. The scales of the fertile aments are 3-parted, the middle segment being much the largest, oblique, with a lateral tooth, persistent, and becoming foliaceous. The nut small, ovoid, bony, ribbed, with a simple, one-sided, enlarged, and open leaf-like involucre. This tree is not bitter, and must not be confounded with the *Ostrya* (G.—W.).

OXALIS.—WOOD-SORREL.

The whole herb of *Oxalis Acetosella*, Linné.

Nat. Ord.—Geraniaceæ.

COMMON NAME: *Wood-sorrel.*

Botanical Source.—Wood-sorrel is a small, perennial, acaulescent herb, with a creeping, scaly-toothed root-stock. The leaves are numerous, radical, palmately 3-foliate, on long, weak, hairy stalks; leaflets broadly obcordate, with rounded lobes entire, pubescent, of a yellowish-green color, but frequently purplish beneath; they close and droop at night-fall. The scape is longer than the petioles, and 1-flowered, with 2 scaly bracts near the middle. The flowers are white, yellowish at the base, delicately veined with purple, and scentless. Stamens 10, monadelphous at the base, alternately shorter; sepals 5, persistent; style as long as the inner stamens. Capsule 5-lobed, 5-celled, and oblong; seeds several, with an elastic testa (G.—W.).

History and Chemical Composition.—Wood-sorrel is indigenous to Europe and this country, growing in woody and shady places, and flowering from April to June. It is inodorous and has a pleasantly acid taste, which is somewhat impaired by drying. The acidity is due to the presence of *oxalic acid* in combination with potassium forming *acid potassium oxalate*, sometimes called *potassium binoxalate* (HKC_2O_4). In some parts of Europe this salt was formerly separated from the plant, and sold under the name of *salts of sorrel* (sometimes under the name *salt of lemons*), for the purpose of removing ink spots and iron marks from linen. This salt is poisonous when taken internally. It can now be conveniently prepared from oxalic acid.

Fig. 187.

Oxalis Acetosella.

Action, Medical Uses, and Dosage.—The several varieties of sorrel are cooling and diuretic. Useful in *febrile diseases*, *hemorrhages*, *gonorrhœa*, *chronic catarrh*, *urinary affections*, and in *scurvy;* it may be used in infusion, or it may be infused in milk to form whey, or the herb may be eaten, but in neither case to excess, on account of the potassium binoxalate they contain. Externally, the bruised leaves or inspissated juice have been found useful as an application to *scrofulous*, *malignant*, and *indolent ulcers*. The *Rumex Acetosa*, or Garden sorrel, *R. Acetosella*, or Sheep sorrel, and *R. vesicarius*, possess similar properties (which see). The antidote to poisoning by any of the species of Oxalis, or by oxalic acid or potassium binoxalate, is a mixture of chalk with water.

Related Species.—There are other species of *Oxalis* possessing analogous properties, as the *Oxalis stricta*, Linné, and *O. violacea*, Linné. They all have ternate leaves with obcordate leaflets, and with the exception of *O. violacea*, bear yellow flowers.

Oxalis crassicaulis.—Peru. Root edible; the syrup of an astringent, acidulous juice expressed from the leaves, has been employed in *catarrhal troubles*, *gonorrhœa*, and *hemorrhages*.

Oxalis corniculata, Linné.—Europe. This species has properties similar to *Oxalis Acetosella*.

OXYDENDRON.—SOURWOOD TREE.

The leaves of *Oxydendron arboreum*, De Candolle (*Andromeda arborea*, Linné). *Nat. Ord.*—Ericaceæ.

Common Names: *Sourwood*, *Sorrel tree*.

Botanical Source.—Oxydendron arboreum is a tree growing from 40 to 50 feet high, with a trunk from 10 to 15 inches in diameter. The leaves are oblong-lanceolate, acuminate, serrate, petiolate, deciduous, from 5 to 6 inches long, from 1 to 2 inches broad, villous when young, at length smooth, with a distinctly acid taste, and early in autumn they turn bright scarlet. The flowers are pedicellate, secund, spreading, at length reflexed; panicles terminal, consisting of numerous spicate racemes. Calyx without bractlets. The corolla is ovate-oblong, narrowed at the summit, 5-toothed, and pubescent externally. The filaments are thickened; anthers awnless, the cells long and pointed. The capsule pyramidal and pentangular; the seeds are ascending from the base, linear, with a loose coat and taper-pointed at both ends; and bracts and bractlets minute and deciduous (W.—G.).

History.—This elegant tree inhabits rich woods from New York to the Gulf of Mexico, and in the Allegheny valleys, and bears white flowers in July. The leaves are the parts used. They have an agreeable tartness, and yield their properties to water. According to Plugge and De Zaayer (1889), no andromedotoxin occurs in this plant.

Fig. 188.

Oxydendron arboreum.

Action, Medical Uses, and Dosage.—Sorrel tree leaves are tonic refrigerant, and strongly diuretic. Fever patients will find a decoction of the leaves a pleasant, cooling, and diuretic drink. A tincture of the leaves and twigs in whiskey is said to have been a popular remedy in Kentucky for the *kidney* and *bladder ailments* of aged men, being employed to increase the renal secretion, and to relieve the unpleasant symptoms attending *prostatic enlargement, vesical calculi*, and *chronic irritation of the neck of the bladder*. The remedy was specially recommended in the treatment of *dropsies* by Dr. J. W. Davis, of Lewisburg, Ky., in 1881 (*Ec. Med. Jour.*, 1881, p. 497). Its strong diuretic powers were generally recognized, and several experimenters reported remarkable success from its employment in *anasorca, hydrocele, pleuritic effusions*, and *hydropericardium*. It was asserted to give marked relief in urinary troubles, with frequent desire to urinate, with burning pain at urethral outlet, and the urine passing in drops, mixed with blood. It was subsequently employed in *bowel troubles* from exposure to cold, as when a determination of blood to the viscera occurred, causing *diarrhœa* or *dysentery*. It undoubtedly acts by giving increased tone to relaxed capillaries. Pills of a solid extract, containing 3 to 6 grains may be given every 2 hours; specific oxydendron, 1 to 20 minims every 2 or 3 hours.

Specific Indications and Uses.—Anasarca, ascites, and other forms of dropsy; the urinary difficulties of old men; painful micturition, with scanty renal secretion.

Related Species.—(Compare *Kalmia* and *Rhododendron*.) Some species of *Andromeda* are poisonous, *e. g.*, *Andromeda nitida*, Bartram, an elegant evergreen, known as *Fetter-bush*; *Andromeda polyfolia*, Linné, the *Wild rosemary*, growing in boggy situations, and containing *andromedotoxin*; *Andromeda mariana*, Linné, *Stagger-bush*, a seaboard plant, found also in Tennessee and Arkansas, and said to produce staggers in calves and lambs (see illustration in Meehan's *Native Flowers and Ferns*, Vol. II, p. 185); and *Andromeda angustifolium*, Pursh, a swamp growth. The blossoms and leaves of the *Andromeda speciosa*, Michaux, have a pulverulent substance upon their surface, which is reputed a strong sternutatory.

OXYGENIUM.—OXYGEN.

SYMBOL: C. ATOMIC WEIGHT: 15.96.

History.—Oxygen, the most abundant of the elements, was discovered, in 1774, by Priestley, of England, and Scheele, of Sweden, independently of each other. Lavoisier, of France, first recognized its function in the phenomena of combustion. He named it oxygen from two Greek words, meaning "I produce sour"—*i. e.*, a generator of acids. The waters of the globe consist of 88.87 per cent of oxygen. From 33 to 45 per cent of the whole weight of the earth has been estimated to consist of this element. It is one of the chief constituents of animal and vegetable structures. In gaseous form, it constitutes about 21 per cent, by volume, of the atmosphere, the balance being nitrogen, argon, and a small portion of carbon dioxide.

Preparation.—Oxygen is prepared from certain oxides or other oxygen compounds, which readily part with their oxygen under the influence of heat or reagents. Thus oxygen may be produced by subjecting mercuric oxide to a red heat in a glass retort: $2HgO = Hg_2 + O_2$. Likewise manganese dioxide is decomposed by heat with evolution of oxygen, thus: $3MnO_2 = Mn_3O_4 + O_2$. The usual mode of obtaining oxygen is to heat, in a retort, powdered potassium chlorate ($KClO_3$), the reaction being broadly expressed by the equation: $2KClO_3 = 2KCl + 3O_2$. In practical operation, the powdered chlorate is mixed with about one-fifth or one-fourth its weight of pure manganese dioxide. This must previously be ascertained to be free from charcoal or antimony sulphide, else dangerous explosions may occur. The purpose of the addition of manganese dioxide is to bring the temperature at which the oxygen commences to be given off, below the melting point of the salt, which is about 350° C. (662° F.); the gas is then disengaged at as low a temperature as 200° C. (392° F.). The manganese dioxide remains unchanged in this process. Otto Brunk has shown (*Amer. Jour. Pharm.*, 1894, p. 144) that the chlorine-like odor observed in this process is due to ozone, the quantity of which is 0.3 per cent of the oxygen evolved, if equal amounts of potassium chlorate and manganese dioxide are taken. Pure potassium chlorate, when heated, yields no ozone, but when it contains traces of impurities, even potassium chloride, evolution of ozone takes place. The gas must be washed by passing it through a strong solution of caustic soda.

Oxygen (containing ozone) is also produced by the electrolysis of water, being liberated at the positive pole. Other methods of producing oxygen are enumerated in every text-book on chemistry. Several methods, based on the action of hydrogen peroxide upon reducible substances, such as potassium permanganate. or ferricyanide, or chlorinated lime, have also been proposed (see *Amer. Jour. Pharm.*, 1882, p. 407; 1889, p. 565; 1890, p. 489; also see paper on oxygen and its medicinal applications, by Mr. J. W. England, *ibid.*, 1892, p. 11).

Description.—Oxygen is a colorless, odorless, and tasteless gas, whose density when compared to air, is 1.1056. The weight of 1 liter oxygen at 0° C. (32° F.) and 760 Mm. atmospheric pressure is 1.43028 grammes. Cailletet and Pictet, in 1878, succeeded in condensing oxygen to a liquid, a pressure of 475 atmospheres and a temperature of —130° C. (—202° F.), being necessary to accomplish it. Metals in the molten state, especially silver, absorb oxygen, but give it off again upon cooling. It is slightly soluble in water and alcohol. With the possible exception of fluorine it combines with all the elements, forming *oxides*. When a substance combines with oxygen, the process is called *oxidation*. If this process is accompanied with emission of light or flame, it is termed *combustion*. Processes of oxidation producing no light or flame, are termed *slow combustion*. An instance of the latter is the chemical change in the human body of venous to arterial blood, effected by the oxygen taken in during respiration. The chief supporter of combustion is oxygen, and substances burn more readily in pure oxygen than in ordinary air. A piece of wood glowing without flame ignites when held into a current or an atmosphere of oxygen. The gas is recognized by this reaction. A glowing piece of iron wire held in pure oxygen gas, burns with a display of brilliant sparks.

Oxides are of three classes, according to the chemical nature of the element with which the oxygen combines, and according to the combining quantity of the latter. Thus we have: (1) *basic oxides*, mostly those of the metals, *e.g.*, sodium oxide (Na_2O), calcium oxide (CaO), chromic oxide (Cr_2O_3); they form *bases* or *hydroxides* with the elements of water; (2) *acid-forming oxides*, mostly those of non-metallic elements, such as sulphur trioxide (SO_3), forming with water sulphuric acid (H_2SO_4); phosphorus pentoxide (P_2O_5), forming phosphoric acid (H_3PO_4); chromic trioxide (CrO_3), forming chromic acid (CrO_4H_2), etc. These oxides are also called *anhydrides*, *e. g.*, chromic anhydride; (3) *peroxides*, mostly those of metals, rarely of non-metals, as sodium peroxide (Na_2O_4); barium dioxide (BaO_2); lead dioxide (PbO_2); manganese dioxide (MnO_2), etc. They contain an excess of combined oxygen, with which they easily part. They are therefore typical *oxidizers*. Oxidizers should not be triturated with easily combustible material. It is dangerous to triturate together such substances as chlorate or nitrate of potassium and sulphur.

Other well-known oxidizers are chromic acid or potassium bichromate in sulphuric acid solution, potassium permanganate, ozone (see below), hydrogen peroxide, etc. The term *oxidizer*, in its broadest sense, includes also substances capable of producing oxygen available for oxidation; thus chlorine, although it contains no oxygen, is a strong, though indirect oxidizer, in the presence of water, because it combines with its hydrogen, for which it has great affinity, thus setting free the oxygen of the water. Substances which have a tendency to combine with oxygen and to abstract it from oxygen-bearing compounds, are called *reducing substances* or *deoxidizers*, such as glowing charcoal, sulphurous acid (H_2SO_3), nascent hydrogen, etc.

Action, Medical Uses, and Dosage.—Since the researches a few years ago of Smith, Richardson, Buchheim, and others, proving that no more oxygen than that proportion which is present in atmospheric air could be appropriated by the blood through the respiratory organs, the use of oxygen as a food to the system and vivifying agent seems to have been on the wane. Large doses, instead of acting as a vivifying stimulant, appear to relax and consequently debilitate the system, and even induce a narcotic condition if carried sufficiently far. That a certain amount of it inhaled admixed with the air, however, appears to increase the appetite, quicken the circulation, increase bodily weight, and slightly elevate temperature, seems established. Notwithstanding the fact that it is asserted to have been overrated as a therapeutic agent, it has been successfully employed in several forms of *anemia*, particularly those resulting from *hemorrhages* and *suppurative diseases.* It is also thought useful, though not curative, in many exhausting and wasting conditions. Some claim that it augments the appetite, lessens expectoration, hectic, and *colliquative sweats*, and increases weight in *phthisis*, but does nothing more. In *asthmatic seizures* and *diseases of the lungs* attended with symptoms of asphyxiation, life is occasionally saved, and often prolonged by its judicious inhalation. *Asphyxia from carbonic acid fumes, narcotic poisoning*, and *noxious gases* have been reported restored by oxygen inhalations. In *diabetes* it decreases the renal secretion and lessens the production of sugar, but fails to cure; the quantity of albumen appears to be lessened by it in *albuminuria*. The disorders, however, in which the oxygen treatment appears to possess real merit, are *post-scarlatinal nephritis*, and in *chlorotic dyspepsia*. Oxygen water (water charged with oxygen gas) may be given by mouth, and the pure gas inhaled from the rubber bag in which it is usually stored. This bag should be furnished with a tube supplied with valves and a stop-cock. Ozone has similar uses, and is particularly lauded in *anemia*.

Ozone.—ACTIVE OXYGEN. Formula: O_3. Molecular Weight: 47.88. Ozone was observed as early as 1785 by Van Marum, who passed an electric spark through oxygen and noticed the peculiar smell of the gas and its property of tarnishing a bright surface of mercury. In 1840 Schönbein made a detailed study of ozone, and gave it its name, from a Greek verb, meaning "to smell." Ozone is produced by slow oxidation of phosphorus, or by the passage of a silent electrical discharge through oxygen gas. Electrical discharges during thunder showers produce ozone in the atmosphere, although the fact must not be overlooked that the higher oxides of nitrogen are also formed, and behave toward potassium iodide starch paper in the same manner as ozone. Ozone is also generated when manganese dioxide is heated in a current of oxygen or with potassium chlorate (O. Brunk, see *Oxygen*). 1.55 per cent cent of ozone was produced when the proportion of manganese dioxide and potassium chlorate was 25 to 1. Ozone has not been obtained in the pure state; it is always diluted with oxygen. In recent years the manufacture of ozone by electric discharges is being very greatly perfected.

Ozone is quite soluble in many essential oils, *e. g.*, oil of turpentine, oil of cinnamon, etc., and is sparingly soluble in water. It is a powerful oxidizer, decolorizes indigo and blood, and destroys albumen and even caoutchouc and gutta-percha, tarnishes bright metallic surfaces, *e. g.*, silver or mercury, and converts alcohol (C_2H_6O) into aldehyde (C_2H_4O). From potassium iodide it liberates iodine; thus the most delicate test for ozone (which distinguishes it from hydrogen peroxide) is the blue coloration imparted to a paper saturated with a solution of potassium iodide in starch water. It colors alcoholic tincture of guaiac blue (see *Guaiacum*). Ozone is a colorless gas, but may be liquefied by pressure to an indigo-blue liquid (Hautefeuille and Chappuis). Liquid ozone boils at —119° C. (—182.2° F.), at atmospheric pressure (L. Troost, *Chem. Zeitung*, 1898, p. 543).

The researches of Andrews and Tait (1860) have shown that ozone is an allotropic modification of oxygen, *i. e.*, consisting of the same substance, but possessing different properties. The formation of ozone from oxygen is attended by a condensation of 3 volumes (or molecules) of oxygen to 2 volumes (or molecules) of ozone, according to the equation: $3O_2 = 2O_3$; hence the molecule of ozone must be regarded as consisting of 3 atoms of oxygen, and has been aptly called *peroxide of oxygen* (O_2O). Vice versa, 2 volumes of ozone, when heated to about 300° C. (572° F.), yield again 3 volumes of ordinary oxygen. In its chemical reactions, only one-third of the oxygen is available. Thus, for example, when ozone acts upon potassium iodide solution only one-third of its oxygen liberates iodine, while ordinary oxygen is formed as follows: $O_3+IK+H_2O=O_2+2KOH+I$. The resultant volume of oxygen is the same as the original volume of ozone, because one-third of the latter, being in combined form, has disappeared as a gas. The medicinal uses of ozone are the same as those of oxygen.

OXYMEL.—OXYMEL.

SYNONYMS: *Oxymel simplex, Mel acetatum.*

Preparation.—This is prepared according to the *British Pharmacopœia* (1898), by heating to liquefaction 40 ounces (Imp.), or 800 grammes, of clarified honey, and mixing with it 5 fluid ounces each, or 100 cubic centimeters each, of acetic acid and distilled water, the finished product to have the specific gravity 1.320. The *German Pharmacopœia* (1872) directed a simple mixture of acetic acid, sp. gr. 1.040 (1 part), with clarified honey (40 parts). The *French Codex* orders virgin honey, 4 parts, and white wine vinegar, 1 part. Concentrate and clarify with paper pulp.

Action and Medical Uses.—This represents a popular gargle for *sore throat.* It is also used as a vehicle for expectorant preparations, such as ipecacuanha, squill, etc., and in fever-drinks.

OXYMEL SCILLÆ.—OXYMEL OF SQUILL.

Preparation.—Mix 2 pounds (av.) of clarified honey, with 1 pint (Imp.) of vinegar of squill. Evaporate, by means of water-bath, until the product when cold, has a specific gravity of 1.32. This accords with the *Br. Pharm.*, 1885 and 1898. Honey (2 parts), vinegar of squill (1 part). Evaporate to 2 parts and strain (*Ger. Pharm.*, 3d ed.). Honey (4 parts), vinegar of squill (1 part). Clarify with pulp of paper and evaporate to specific gravity 1.26 (*French Codex*).

The *National Formulary* directs: "Vinegar of squill (*U. S. P.*), fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; honey, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix them in a tared porcelain capsule or enameled iron vessel, and apply the heat of a water-bath until the mixture has been reduced to the weight of one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Then strain, allow it to cool, and transfer it to bottles, which should be well corked"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Used for the same purposes for which squill is employed (see *Scilla*). Dose, as an expectorant, for infants, 1 to 15 drops; for an adult, 20 to 60 drops.

PÆONIA.—PEONY.

The root of *Pæonia officinalis*, Linné.

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Peony, Piney.*

Botanical Source.—Peony has many thick, long-spreading, perennial roots, running deep into the ground, with an erect, herbaceous, large, green, and branching stem, 2 or 3 feet high. The leaves are large; the lower ones bipinnately divided; the leaflets ovate-lanceolate, smooth, and variously incised. The flowers are large, red, terminal, and solitary; the sepals 5, and unequal. Petals red, cordiform; stamens numerous, mostly changed to petals by cultivation. Carpels 3; stigmas double and persistent; follicles fleshy, and many-seeded; seeds black, numerous, dry, and round (W.—R.).

History and Description.—This plant is indigenous to southern Europe, and is cultivated in gardens in the United States and elsewhere, on account of the elegance of its large flowers, which appear from May to August. The root is the medicinal part; it consists of a root-stalk, from ½ to 1 inch in diameter, from which proceed fusiform tubers, gradually terminating in delicate fibers. These, together with the seeds, have, when recent, a strong, rather unpleasant odor, and a sweetish, mawkish taste, succeeded by a sub-acrid bitterishness and slight astringency; drying nearly removes these properties. The recent flowers have a similar, but feebler, odor, and a more herbaceous taste. They all yield their virtues to diluted spirits.

Chemical Composition.—The fresh root has the odor of bitter almonds, and contains starch, fat, sugar, a small quantity of tannin, oxalates, malates, and phosphates (Morin). Wiggers (*Handbuch der Pharmacognosie*, 1864) obtained, by distillation of the fresh root with water, a distillate possessing the odor of bitter almonds. Ether removed therefrom a small quantity of an oil having the same odor, and producing, in aqueous or alcoholic solution, a blood-red color with ferric chloride. Dragendorff found in the seeds of *Pæonia officinalis* tannin and *peonia-fluorescin* (see *Related Species*).

Action, Medical Uses, and Dosage.—Peony is antispasmodic and tonic. It is asserted to have been successfully employed in *chorea, epilepsy, spasms*, and various *nervous affections.* In combination with white snakeroot, or black cohosh, it has proved valuable in *pertussis.* An infusion may be made by adding 1 ounce of the root, in coarse powder, to 1 pint of a boiling liquid, composed of 1 part of good gin, and 2 parts of water, which may be sweetened. Dose, 2 or 3 fluid ounces, 3 or 4 times a day. Dose, of the expressed juice of the recent root, 1 or 2 drachms; of the powdered root, 1 drachm, 3 or 4 times a day; of the powdered seeds, from

30 to 40 grains. The seeds, taken night and morning, have been successfully used in removing *nightmare* attendant upon dropsical persons. They are also reputed emetic, cathartic, and antispasmodic. It undoubtedly relieves *nervous irritation*, and should be restudied. A tincture of the fresh root (℥viii to alcohol, 76 per cent, Oj) may be given in doses of 1 to 30 drops.

Related Species.—*Pæonia Moutan*, Simson; *Botan-root.* Japan. The root of this plant yielded Jagi (1878), by extraction with ether, a crystallizable body, *peonol*, melting at 45° C. (113° F.), said to be closely related to caprinic acid. It is readily dissolved by alcohol and ether, and believed to be a ketone.

Pæonia peregrina, Miller.—The root of this species, according to analysis of Mandelin and Johannson (*Archiv der Pharm.*, 1879, p. 535), contains starch (14.25 per cent), moisture (15.5 per cent), sugar, gum, resins, tannin, fat, ash, and a small quantity of an alkaloid. The seeds, according to Dragendorff and Stahre (*ibid.*, 1879, pp. 412 and 531), contain fatty oil (23.6 per cent), *peonia-resinic acid*, with indifferent *peonia-resin* (1.13 per cent), *tannic acid* (less than 1 per cent), the coloring matters, *peonia-fluorescin* and *peonia-brown* (a phlobaphene) (of each about 4 per cent), *legumin*, sugar, mucilage, and an alkaloid.

PANAX.—GINSENG.

The root of *Aralia quinquefolia*, Decaisne and Planchon (*Panax quinquefolium*, Linné; *Ginseng quinquefolia*, Wood).

Nat. Ord.—Araliaceæ.

Common Name: *Ginseng.*

Illustration: Johnson, *Med. Bot. of N. A.*, Fig. 132.

Botanical Source.—Ginseng has a perennial, fusiform, whitish, thick, and fleshy root, transversely wrinkled, and terminating in fibers; its upper portion slender and marked with the scars of the former shoots. The stem is round, smooth, green, often with a tinge of red, about 1 foot high, regularly divided at top into 3 petioles, with a flower-stalk in their center. The petiole is round, smooth, and swelling at the base. Leaves 3, ternate, quinate, or septentate. Leaflets pedicellate, obovate, sharply serrate, acuminate, smooth on both sides, with scattered bristles on the veins above. Flowers small, greenish, in a simple umbel, supported by a round, slender peduncle, which rises from the top of the stem, in the center of the petioles. The involucre is composed of a multitude of short, subulate bracts, interspersed among the flower-stalks, which are so short as to give the appearance of a head rather than an umbel. Calyx with 5 small, acute teeth. Petals 5, oval, reflexed, and deciduous. Stamens 5, with oblong anthers. Styles 2, reflexed and persistent. Ovary large, inferior, ovate-cordate, and compressed. The berries are kidney-shaped, retuse at both ends, compressed, of a bright-scarlet color, crowned with a calyx and styles, and contain 2 and sometimes 3 semicircular seeds. The outermost florets ripen first, and their berries often obtain their full size before the central ones are expanded; the central florets are frequently abortive (L.—W.).

Fig. 189.

Aralia quinquefolia.

History and Description.—Ginseng is a native of most of the middle and northern states, and extends on the mountains far south, growing in rich soil and in shaded situations, and flowering in July. C. S. Rafinesque (*Med. Flora of the U. S.*, Vol. II, 1830, p. 53) states that the Jesuits, knowing the plant from their sojourns in Tartary, found it afterward, toward 1718, in Canada, and instituted the trade in this root with China. The root is somewhat fusiform, 2 or 3 inches in length, and about ½ an inch in diameter, and sends off a few delicate fibers. When dried, it consists of a soft, yellowish-white, corrugated bark, inclosing a central, woody substance. It has a faint smell, and its taste is sweetish, somewhat bitter, mucilaginous, and feebly aromatic. Water or alcohol takes up its properties. Large quantities of it are now gathered and sent to China, where it commands an enormous price, as the Chinese ascribe wonderful medicinal virtues to it. The American drug is cheapest (about $1.86 per pound), next ranks Corea ginseng ($16.50 per pound), and highest in price is the genuine Chinese ginseng. The latter is seldom found in the stores, and the finest qualities command the price of from $60 to $100 for a weight of about 580 grains. In Corea, the cultivation and trade in ginseng is a government monopoly (*Amer. Jour. Pharm.*, 1887, p. 597; 1897, p. 551, and 1898, p. 251). Ginseng is also grown in Japan, but is considered inferior to Corea ginseng. The genuine *Chinese ginseng* is the root of *Aralia Ginseng*, A. Meyer (*Panax Ginseng*, Nees), an east Asia plant. Altogether, 5 commercial grades of ginseng are distinguished in China. It is often adulterated by mixing it with the root of some species of Convolvulus and other roots. (On the cultivation of ginseng in America, see *Amer. Jour. Pharm.*, 1891, p. 411.) Ginseng is becoming very scarce and, unless a method of cultivation becomes practical, bids fair to be exterminated. The price now is from $4.00 to $7.50 per pound and advancing.

Chemical Composition.—Rafinesque (*loc. cit.*) states that the roots have a pleasant, camphorated smell, and that they owe their active properties to a peculiar substance similar to camphor, which he calls *panacine*—white, pungent, soluble in alcohol and water, more fixed than camphor. The roots also contain a volatile oil, sugar, mucilage, resin, etc. S. S. Garrigues (*Amer. Jour. Pharm.*, 1854, p. 511) obtained from an aqueous infusion a sweetish-bitter, amorphous yellow principle, which he calls *panaquilon*. It is soluble in ether and alcohol, insoluble in water. Concentrated sulphuric acid dissolves it with purple-red color. If the solution is poured into water, a white precipitate (*panacon*) results (see Davydow, *Amer. Jour. Pharm.*, 1890, p. 338).

Action, Medical Uses, and Dosage.—A mild tonic and stimulant. Useful in *loss of appetite*, *slight nervous debility*, and *weak stomach*. Continued for some length of time, for its temporary administration gives but little benefit, it is a very important remedy in *nervous dyspepsia*, and in *mental exhaustion from overwork*. It gives fairly good results in *nervous prostration*, and in *cerebral anemia*. By some, it is considered useful in *asthma*, *gravel*, *convulsions*, *paralysis*, to invigorate the virile powers, etc. It gives fairly good results in *atonic laryngitis*, *bronchitis*, and some relief in *phthisis*, being a secondary remedy for these complaints. Dose, of the powder, from 10 to 60 grains; of the infusion, from 2 to 4 fluid ounces; specific panax, 5 to 60 drops.

Specific Indications and Uses.—Nervous dyspepsia; mental and other forms of nervous exhanstion from overwork.

PANCREATINUM (U. S. P.)—PANCREATIN.

"A mixture of the enzymes naturally existing in the pancreas of warm-blooded animals, usually obtained from the fresh pancreas of the hog (*Sus scrofa*, Linné [*Class:* Mammalia. *Order:* Pachydermata])"—(*U. S. P.*).

Source.—The *pancreas* (meaning *all flesh*) is a long, flat, conglomerate gland, analogous in its structure to the salivary glands, and which is situated transversely across the posterior wall of the abdomen, behind the epigastric and the two hypochondriac regions. It secretes a fluid termed the *pancreatic juice*, which is injected into the duodenum, and there mixing with the bile from the liver, and the chyme from the stomach, it helps to convert the latter pulpy substance into *chyle*. The pancreatic juice is a colorless, odorless, strongly alkaline, viscid liquid (specific gravity 1.008 or 1.009), containing from 1.5 to 2.5 per cent of soluble albuminous matters (*enzymes*), resembling ptyalin in action. They may be precipitated from aqueous solution by alcohol, and still be soluble again in water (difference from albumen). Pancreatic juice has the power to emulsify fats, also to dissociate them into glycerin and fatty acids, to convert starchy matters into dextrin and sugar, and to dissolve albumen and fibrin (see below).

Pancreatin is the name given to the purified dried juice of the pancreas, or to the precipitated albuminoids of this juice.

Preparation.—The *National Formulary* (1st ed., 1888) directs as follows: "Take pancreas of the hog, fresh, water, alcohol, each, a sufficient quantity. Reduce the fresh pancreas of the hog, freed as much as possible from fat and membranes, to a fine paste by means of a suitable chopping machine. Mix it with half its weight of cold water, and knead it thoroughly and frequently during 1 hour, then transfer the mass to a strainer of canton flannel, and add to the filtrate an equal volume of alcohol. Collect the precipitate, drain it, and free it by pressure from as much of the adherent liquid as possible. Then spread it on shallow trays, and dry it by exposure to warm air, at a temperature not exceeding 40° C. (104° F.). Triturate the dry product, in a mortar, with 4 times its weight of pure benzin; transfer the mass to a dry filter, and when the liquid has passed below the surface of the powder, follow it with enough fresh benzin to displace the retained portion. Lastly, dry the powder between bibulous paper. *Note.*—If larger quantities of pancreas are operated upon, and there is risk of its decomposition in presence of the water, it is advisable to saturate the latter with chloroform, which will retard decomposition for a long time. * * * In place of pancreatin, prepared by the formula above given, any other commercial preparation of the pancreas may be used, provided it reaches the standard of peptonizing power prescribed for the former"—(*Nat. Form.*, 1st ed.). (See also note to *Pulvis Pancreaticus Compositus.*)

For R. V. Mattison's process of preparing *saccharated pancreatin*, based on the precipitation of pancreatin by sodium chloride solution, see *Amer. Jour. Pharm.*, 1873, p. 532. Pancreatin possesses the power of emulsifying a very large amount of fat or oil.

Description and Tests.—The *U. S. P.* describes pancreatin as "a yellowish, yellowish-white, or grayish, amorphous powder, odorless, or having a faint, peculiar, not unpleasant odor, and a somewhat meat-like taste. Slowly and almost completely soluble in water, insoluble in alcohol. Pancreatin digests albuminoids, and converts starch into sugar; prolonged contact with mineral acids renders it inert. If there be added to 100 Cc. of tepid water, contained in a flask, 0.28 Gm. of pancreatin and 1.5 Gm. of sodium bicarbonate, and, afterward, 400 Cc. of fresh cow's milk, previously heated to 38° C. (100.4° F.), and if this mixture be maintained at the same temperature for 30 minutes, the milk should be so completely peptonized, that, if a small portion of it be transferred to a test-tube and mixed with some nitric acid, no coagulation should occur. Peptonized milk, prepared in the manner just described, or even when the process is allowed to go on to the development of a very distinct, bitter flavor, should not have an odor suggestive of rancidity"—(*U. S. P.*).

Pancreatin absorbs moisture from the atmosphere and deteriorates when exposed to air for a long time; it becomes inert when heated to temperatures higher than 50° C. (122° F.).

Chemical Composition.—Pancreatin is a proteid substance containing soluble ferments (*enzymes*). The pancreatic juice holds at least 4 ferments, as follows: (1) *Trypsin* (of Kühne), which digests albuminoids, changing them to peptones, *leucin*, *tyrosin*, etc., and acting best in neutral or alkaline media, unlike pepsin, which requires an acid medium. It also acts in feebly acid solution, but stronger acids and the gastric juice render it wholly inert. The most favorable temperature for its action is at about 38° C. (100.4° F.) (see above *test*). (2) *Amylopsin* digests carbohydrates and acts upon starch with greater energy than ptyalin, which it resembles, producing maltose and dextro-glucose. It also closely resembles diastase. (3) *Steapsin*, the digester of fats, is probably the chief emulsifying agent, and resolves fats into fatty acids and glycerin and esters—*e. g.*, *salol*—into their component alcohol and acid—in this case, phenol and salicylic acid (see *Amer. Jour. Pharm.*, 1892, p. 404). (4) A *milk-coagulating* or *rennet-like ferment*, probably the same as that contained in the fourth stomach of the calf.

Action, Medical Uses, and Dosage.—Pancreatin has been recommended in *atonic dyspepsia*, due either to impaired secretion or defective composition of the juices secreted; in *acid dyspepsia*, the result of the abnormal transformation of the food in the stomach, from morbid conditions of the gastric juice; in *flatulent dyspepsia*, and in the *dyspepsia of children*, who are fed chiefly upon milk and amylaceous diet, and who often suffer therefrom, with emaciation and diarrhœa. It may be employed where there is *chylous* or *fatty diarrhœa*, with abdominal uneasiness, and in *intestinal dyspepsia*. *Infantile dyspepsia*, *jaundice*, with imperfect digestion of fats, *scrofula*, *diabetes*, *rickets*, *anemia*, *leukæmia*, *chlorosis*, *incipient tuberculosis*, and *dyspepsia*, with nausea, vomiting, diarrhœa, flatulence, and abdominal pain, are cases in which it has been administered by stomach. In *organic diseases of the œsophagus and stomach*, and in *nervous vomiting* and *vomiting of pregnancy*, a pancreatic enema has been administered with the effect of being absorbed and sustaining the life of the patient. Luebe's enema consists of about equal parts of lean meat, grated to a fine pulp, and chopped pancreas, beaten in a mortar or bowl, gradually adding luke-warm water until a pap-like mixture results. If fat is needed, it may be added in proportion of one-sixth of the quantity of meat employed. From 5 to 10 ounces may be used as an enema, and should be injected per rectum with a large-mouthed syringe and retained as long as possible.

As nature has furnished the pancreatic juice to effect the conversion of chyme into chyle, in the duodenum, and probably with the aid of the presence of bile; and as the pancreatin must certainly undergo some change from the action of the juices of the stomach previous to its entrance into the duodenum, it is somewhat puzzling to clearly understand the utility of pancreatin in the stomach, at least until the food has been wholly converted into chyme; besides, when digestion is sluggish or becomes difficult, this is not entirely owing to the deficiency of the gastric, pancreatic, or intestinal juices, but generally to a more radical change in the secretion and composition of these juices, dependent upon an abnormal condition of the organ secreting them. However, pancreatin is an inoffensive agent, and may be conveniently tested in the cases in which it has been advised; and if, after 10 or 12 days, no benefit is derived from it, its use should be suspended. It should be remembered that it gives temporary aid only, and that it has failed to fulfil all the demands for which it was introduced. Its dose is 3 or 4 grains, about an hour after meals. It may be made into pills of 3 grains each, with a sufficient amount of honey; or 1 drachm of it may be mixed with 15 grains of phosphate of calcium, and the mixture be divided into 10 doses. Chopped pancreas may be given in desertspoonful doses with the food. The latter should not be hot. It is frequently given with sodium bicarbonate.

Trypsin is a reputed solvent for *diphtheritic membranes*, a spray of 30 grains of trypsin and 10 grains of sodium bicarbonate in 1 fluid ounce of water, being employed for this purpose. An injection of it has been proposed to dissolve blood-clots in the bladder (Webster).

Specific Indications. and Uses.—Intestinal indigestion, with diarrhœa of fatty or chylous feces, and with flatulence, abdominal pain, nausea, and vomiting; in diseases of mesenteric glands. For temporary effects only.

Preparations.—LIQUOR PANCREATICUS (N. F.), *Pancreatic solution.* "Pancreatin (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; sodium bicarbonate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; compound spirit of cardamom (F. 347), thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; alcohol, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Triturate the pancreatin and the sodium bicarbonate gradually with six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏] of water, add the alcohol, compound spirit of cardamom and purified talcum; mix them thoroughly by shaking, and pour the mixture upon a wetted filter, returning the first portions of the filtrate, until it runs off clear. Wash the filter with enough water to obtain seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏] of filtrate. To this add the glycerin. Each fluid drachm represents 1 grain of pancreatin (*U. S. P.*)"—(*Nat. Form.*).

PULVIS PANCREATICUS COMPOSITUS (N. F.), *Compound pancreatic powder, Peptonizing powder.*—"Pancreatin (*U. S. P.*), twenty grammes (20 Gm.) [309 grs.]; sodium bicarbonate, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]. Mix them by trituration. *Note.*—If pancreatin of proper strength is not available, any other commercial preparation of pancreas, as, for instance, the extract, may be used in place of it, provided it attains the required standard. Twenty-five (25) grains of this powder are sufficient to peptonize 1 pint of fresh cow's milk, by proceeding in the following manner: Add the compound pancreatic powder to 4 fluid ounces of tepid water contained in a suitable flask, and, afterward, add 1 pint of fresh cow's milk, previously heated to 38° C. (100.4° F.). Maintain the mixture at this temperature during 30 minutes, then transfer the flask to a cold place. Milk thus peptonized should not be used when it has been kept over 24 hours, or when it has developed a bitter taste"—(*Nat. Form.*).

EXTRACTUM PANCREATIS presents the digestive ferments of the pancreas in the form of a dry, whitish powder. It contains these principles in such a degree of activity, that their action upon various food substances can be quickly demonstrated—viz., the action of trypsin upon albumen, of diastase upon starch, of the emulsive ferment upon fats and oils, and the milk-curdling ferment. Extractum pancreatis is a specialty of Fairchild Bros. & Foster, New York, who also offer *Trypsalin*, a preparation which presents the ferment, trypsin, in a form especially designed for application to the throat and mucous membrane.

ENZYMOL.—A purified solution of the proteolytic enzyme obtained by direct solution from the gastric glands in sterilized and aromatized menstruum. It is practically an artificial gastric juice, intended for external use only, being a painless solvent for all dead tissues and septic matter, and a corrector of offensive odors. It may be used, diluted with an equal bulk of water and applied by a spray, compress, or injection, upon all *ulcers*, *wounds*, or in *abscess cavities*. A specialty of Fairchild Bros. & Foster, New York City.

Panopepton.—This is a predigested, albuminous, and farinaceous artificial food-product, prepared from bread and beef peptones, and preserved in agreeable solution in sherry wine. It is specially adapted as a food for delicate individuals, convalescents, and infants with faulty digestion. It is very readily retained by the most irritable of stomachs. It is a specialty of Fairchild Bros. & Foster, New York City.

PAPAVERIS CAPSULÆ.—POPPY CAPSULES.

The nearly ripe capsules of *Papaver somniferum*, Linne.

Nat. Ord.—Papaveraceæ.

Synonyms: *Papaver* (*U. S. P.*, 1870), *Fructus papaveris*, *Poppy-heads*.

Illustration: Bentley and Trimen, *Med. Plants*, 18.

Botanical Source and History.—The poppy is an annual plant with a tapering and white root. The stem is round, erect, smooth, with occasionally a few hairs on its upper part, glaucous, branched, leafy, and from 2 to 4 or 5 feet in height. The leaves are alternate, 4 to 8 inches in length, 2 or 3 inches broad, amplexicaul, slashed, repand, with rather blunt teeth, sessile, ovate-oblong, and glaucous beneath. The flowers are large, brilliantly white or silvery gray, double by cultivation, on long, terminal, leafless peduncles, with bristly hairs. The calyx consists of 2 smooth, convex, deciduous sepals. The corolla is composed of 4 petals, very large, sometimes with a deep purple spot at the base. Stamens numerous; anthers oblong and compressed; style, 1; stigmas, 4 to 20, radiating, and sessile upon the crown of the nearly globular ovary. The capsules are obovate or globose, smooth, about the size of a middling apple, rather hard and brittle, 1-celled, opening by pores beneath the lobes of the stigma, and filled with numerous parietal placentæ. Placentæ many-seeded. The seeds are reniform, oily, white, or gray, sweet, and edible (L.—W.).

Formerly, distinction was made between the *black* and the *white* variety of poppy, based on the color of the seeds, and to some extent on that of the petals, those of the latter variety being white, of the former violet or red. Cultivation has produced grades intermediate between these varieties sometimes difficult to distinguish. Boissier (1867) established three well-marked varieties, viz: (1) *Papaver somniferum*, Linné, var. *setigerum* (*Papaver setigerum* of De Candolle). This is the wild variety of poppy, beset with long, stiff bristles; leaves acutely toothed; 7 to 8 stigmas. This variety occurs in the Peloponnesus, Corsica, Cyprus, and the Hières Islands; (2) *P. somniferum*, var. *glabrum*, smooth, with subglobular capsule and from 10 to 12 stigmas, cultivated in Asia Minor and Egypt (see *Opium*); and (3) *P. somniferum*, var. *album* (*Papaver officinale* of Gmelin), with more or less egg-shaped capsules devoid of apertures; it is cultivated in Persia (see *Pharmacographia*).

The white poppy is considered the official variety; it is probably a native of Persia, but is also extensively cultivated in many of the warmer parts of the world. In Asia the flowering season is in February; in this country and Europe it is during the months of June, July, and August; the official parts of the plant are the capsules, and opium, or the concrete juice from the capsules (see *Opium*); the seeds are employed for obtaining their fatty oil (see page 1434).

Description.—Papaveris Capsulæ. The capsules of the poppy, or *poppy-heads*, should always be gathered before they have ripened; at this time they abound in the juice from which opium is formed, and which becomes greatly diminished when the capsule has fully matured. When dried, the unripe capsules possess the peculiar bitterness and narcotic qualities of opium, which are hardly observable in those that are allowed to ripen. The dried capsules are of various sizes, from that of a small egg to that of a large orange; they are of an ovate or globular form, flattened underneath, and surmounted by the persistent stigma. The capsules of the *white* poppy are larger than those of the *black*. They owe their virtues entirely to the opium contained in them. The *white* capsules are usually devoid of apertures (indehiscent) under the crowning circular disk generally oblong, though sometimes so depressed as to be broader than long. Some varieties have the lower end narrowed and prolonged. Where the fruit joins the stalk there is a tumid ring. The stigmas are peltate and sessile, from 8 to 20 in number, constituting sharp, angular ridges agreeing in number with the carpels. The placentæ are also of the same number, projecting into the 1-celled interior so as to form incomplete partitions. On their faces and edges are borne the minute kidney-shaped seeds in immense numbers.

The *black* capsules are smaller, globular-ovate, broadest below, usually about 1½ inches in diameter, and exhibit underneath the circular disc of stigmas, the apertures (dehiscences) which allow the seeds to be shaken out.

SEMINA PAPAVERIS.—*Poppy-seeds* or *Maw-seeds* are very numerous, a single capsule containing many thousands. They are reniform, white, bluish, grayish, or blackish, finely net-veined, oleaginous and emulsive, and yield by expression nearly 50 per cent of a yellowish fixed oil (*Oleum Papaveris, Oil of poppy-seeds*). Sacc, in 1849, obtained about 55 per cent of oil from the seeds, with 23 per cent of mucilage and 12.6 per cent of protein matter. The oil is odorless, has a pleasant, mucilaginous, bland taste, is pale-yellow and transparent, and destitute of narcotic properties. It has a specific gravity of 0.925, and becomes solid at —18° C. (0° F.). It is soluble in 25 parts of cold and 6 parts of boiling alcohol, and in ether. Upon saponification it yields 9½ per cent of glycerin. Upon exposure to the air for some time it easily dries, forming a varnish; it is therefore used by painters, also for culinary and for burning purposes, and as an adulterant of higher-priced oils, as olive oil. Its chief constituent, according to Hazura and Friedrich (1887), is the glyceride of *cannabinoleic acid* ($C_{18}H_{32}O_2$).

Chemical Composition.—The largest quantity of opium alkaloids is formed in the plant at the time when the seeds begin to accumulate oil and albuminous matter. The alkaloids are distributed over all parts of the plant, except the seeds, which, when clean from adhering particles of the capsule, are absolutely free from alkaloids. Young plants do not contain them (Clautrian, *Jahresb. der Pharm.*, 1889, p. 80). The unripe capsules contain the constituents of opium, only in a more diluted form; thus morphine is present to the extent of 1 to 2 per cent, and narcotine, codeine, rhœadine, narceïne, and meconic acid in correspondingly less quantities. The capsules also contain ammonium salts, tartaric and citric acids, mineral acids, mucilage and wax (Deschamps d'Avallon, 1864). Ripe capsules dried at 100° C. (212° F.) yielded Flückiger 14.28 per cent of ash, chiefly consisting of chlorides and sulphates of alkali metals.

Action and Medical Uses.—Poppy-heads are occasionally used externally in fomentations, though both for topical and internal use they have been supplanted by opium and its preparations, which are now prepared of definite strengths.

PARALDEHYDUM (U. S. P.)—PARALDEHYDE.

FORMULA: $C_6H_{12}O_3$. MOLECULAR WEIGHT: 131.7

"A polymeric form of ethylic aldehyde (C_2H_4O=43.9). Paraldehyde should be kept in well-stoppered, dark, amber-colored bottles, in a cool place"—(*U. S. P.*).

Preparation.—When hydrochloric acid, zinc chloride, sulphur dioxide, or carbonyl chloride ($COCl_2$) is allowed to act upon ethylic aldehyde at ordinary temperature, the liquid becomes heated and paraldehyde is formed by a process of polymerization. The new product is an agglomeration of 3 molecules of ethylic (acetic) aldehyde, whereby contraction of volume takes place. It is generally prepared by acting upon aldehyde with hydrochloric acid gas, or with a small amount of concentrated sulphuric acid, until the liquid no longer dissolves in an equal bulk of water. The product thus obtained is purified by alternate crystallization in the cold and subsequent distillation.

Description and Tests.—Paraldehyde is officially described as "a colorless, transparent liquid, having a strong, characteristic, but not unpleasant or pungent odor, and a burning and cooling taste. Soluble in 8.5 parts of water at 15° C. (59° F.), and in 16.5 parts of boiling water; miscible, in all proportions, with alcohol, ether, and fixed or volatile oils. When cooled to near 0° C. (32° F.), paraldehyde solidifies to a crystalline mass, which becomes liquid again at 10.5° C. (51° F.). It boils at 123° to 125° C. (253.4° to 257° F.), giving off inflammable vapors. Paraldehyde is neutral, or slightly acid, to litmus paper. When distilled with a small portion of sulphuric acid, paraldehyde is converted into ordinary aldehyde, boiling at about 21° C. (70° F.). On warming some silver ammonium nitrate T.S. saturated with paraldehyde, in a test-tube, a silver mirror will form on standing. On heating some paraldehyde on a water-bath, it should completely volatilize without leaving any disagreeable odor (absence of aldehyde derived from fusel oil). One Cc. of paraldehyde should form, with 10 Cc. of water, a clear solution, free from oily drops (absence of amylic alcohol, etc.), and this solution, when acidulated with nitric acid, should not be affected by silver nitrate T.S. (absence of hydrochloric acid), or barium chloride T.S. (absence of sulphuric acid). A mixture of 8 Cc. of paraldehyde and 8 Cc. of alcohol with 1 drop of phenolphtalein T.S. should acquire a pink color upon the addition of 0.5 Cc. of normal potassium hydrate T.S. (limit of free acid)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Paraldehyde is soporific rather than anodyne, acting better when wakefulness is pronounced than when a person enjoys the customary sleep. The sleep produced is peaceful and approaches a natural slumber, the individual upon awakening experiencing no headache nor tired sensations. The appetite is not disturbed by it, but the functions of circulation and respiration are slowed and the bodily heat lowered. It is eliminated chiefly by the breathing organs, and to some extent by the kidneys, imparting to both the urine and the breath the characteristic odor of one in drunkenness. It very much resembles chloral in action, though it is less depressing. Pain interferes somewhat with its action, for it is less anodyne than soporific. Its long-continued use may produce fatty changes in the liver and heart, and in disorders of the latter with feebleness, and especially cardiac dilatation accompanying emphysema, it is contraindicated. Like chloral, it produces disturbances of nutrition, resulting in obstinate nasal ulcerations, scarlatinoid, desquamative eruptions, ocular, faucial, and rectal irritation, and ulcers about the nails. Respiratory paralysis is the cause of death from toxic doses. Paraldehyde has been chiefly used as a hypnotic, being for this purpose comparatively safe, though it is not adapted to bring sleep when pain or fever exists. It is nauseous and apt to disturb the stomach, though the appetite generally remains unaffected. It has been successfully used to calm and produce sleep in *acute mania*, *melancholia*, and other forms of *insanity*, *mental exhaustion*, and *delirium tremens*. It is said to be suited to all forms of insanity, and all ages, but appears best adapted to acute cases, exhibiting maniacal excitement and *insomnia with great agitation*. It is generally contraindicated in cases lacking this excitement. It has been especially used in violent forms of *chronic insanity*, *dementia*, etc. The ordinary dose ranges from 5 to 60 grains, in water (sweetened), or flavored whiskey, brandy, or other alcoholic fluid, or masked in some tincture of a bitter drug. An elixir is often prescribed. One after Wearn is prepared as follows: "Take of paraldehyde 3 parts, alcohol 10 parts. Solve. Add orange-flower water 4 parts, simple syrup 10 parts, and enough distilled water to make 32 parts. Color with 5 minims of burnt sugar.

Related Preparations.—ALDEHYDE, *Acetic aldehyde*, *Acetaldehyde* ($C_2H_4O=CH_3.CHO$). Molecular weight: 44. Aldehyde is an oxidation product of alcohol, and was isolated and its relation to alcohol shown by Liebig, in 1835, who gave it its present name (*alcohol dehydrogenatum*, from 2 atoms of hydrogen being oxidized away). It was previously observed by Scheele in 1774. Acetic aldehyde may be formed in various ways. On a large scale it is obtained in the manufacture of alcohol, being found in those fractions distilling at lowest temperatures. In the laboratory, acetic aldehyde may be prepared by the dry distillation of a mixture of calcium acetate and formiate, as follows: $(CH_3.COO)_2Ca + (H.COO)_2Ca = 2CH_3.CHO + 2CaCO_3$, or more frequently in the wet way, by carefully distilling alcohol with an oxidizing mixture, *e. g.*, sulphuric acid and potassium bichromate. Alcohol, aldehyde, ether, and other products pass over. The distillate is rectified by cautious redistillation with calcium chloride, and pure aldehyde is obtained by converting it, in ethereal solution, into a crystallizable ammonium compound by means of dry ammonia gas, decomposable into its constituents by distillation with diluted sulphuric acid. (For details of these operations, see Roscoe and Schorlemmer's *Chemistry*, Vol. III, Part I, 1882, p. 475.)

Aldehyde is a clear, colorless liquid, of a peculiar and powerful ethereal odor, of specific gravity 0.79 at 18° C. (65° F.), and boiling at 21° C. (70° F.). It is neutral, inflammable, and mixes in all proportions with water, alcohol, and ether. It rapidly absorbs oxygen, being oxidized to acetic acid as follows: $CH_3.CHO + O = CH_3.COOH$. Aldehyde also has the property of reducing metallic silver from its ammoniated nitrate solution; the silver firmly adheres to the glass wherein it is reduced, and forms a mirror upon it. Silver mirrors may be made in this manner. Acetic aldehyde combines with ammonia gas, forming a crystallizable compound, *aldehyde-ammonia*, as follows: $CH_3CHO+NH_3=CH_3CHOH.NH_2$. When heated with caustic potash, aldehyde is rapidly converted into *resin of aldehyde*, which swims on the surface of the liquid in the retort in the shape of a brownish, plastic substance, which, when heated to boiling, evolves a disagreeable odor.

Aldehyde inhaled, even in small amounts, asphyxiates, but when mixed with air it acts as an anæsthetic, though its irritant action upon the tissues has led to the abandonment of the idea of ever again using it as such on man. Taken into the stomach it irritates, and has produced dangerous results. It quickly and deeply intoxicates, and it is to the presence of aldehyde that the first distillate of inferior grades of spirits owe their rapid and dangerous action. The heart's action is but little interfered with by its inhalation, but even small doses quicken respiration, and larger doses may induce respiratory paralysis. Aldehyde possesses greater anti-putrefactive qualities than alcohol, a very dilute solution of it perfectly preserving meat from decay.

METALDEHYDE ($C_{12}H_{24}O_6$), a reputed hypnotic sometimes used like aldehyde, is occasionally deposited in the form of crystals from aldehyde at ordinary temperature. Liebig found it to have the same percentage composition as aldehyde, and to be a polymerized form of the latter. It is produced by acting upon acetic aldehyde with polymerizing agents, such as acids, carbonyl chloride, etc., at the freezing point of water, or with calcium chloride at ordinary temperatures. It crystallizes in white needles, is not soluble in water, but dissolves easily in ether or alcohol. It sublimes without fusing at 100° C. (212° F.), but when heated in a closed tube to a higher temperature, it is converted into ordinary acetaldehyde.

PAREIRA (U. S. P.)—PAREIRA.

"The root of *Chondodendron tomentosum*, Ruiz et Pavon"—(*U. S. P.*). (*Cocculus Chondodendron*, De Candolle; *Cissampelos Abutua*, Vellozo; *Botryopsis platyphylla*, Miers.)

Nat. Ord.—Menispermaceæ.

COMMON NAMES: *Pareira brava*, *Pareira root.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 11.

Botanical Source.—This plant is "a lofty climbing shrub, with long, woody stems, and leaves as much as a foot in length. The latter are of variable form, but mostly broadly-ovate, rounded or pointed at the extremity, slightly cordate at the base, and having long petioles. They are smooth on the upper side; on the under, covered between the veins with a fine, close tomentum of ashy hue. The flowers are unisexual, racemose, minute, produced either from the young shoots or from the woody stems. The fruits are ¾ of an inch long, oval, black, and much resembling grapes in form and arrangement" (Hanbury, *Pharmacographia*).

History and Description.—This plant was introduced into Europe by the Portuguese in the second half of the seventeenth century. Its true origin was made known by Hanbury, in 1873, after it having been believed, for more than a hundred years, to be the product of *Cissampelos Pareira*, Linné (see D. Hanbury, *Amer. Jour. Pharm.*, 1873, p. 449). It is a woody, climbing vine of Brazil and Peru, being plentiful in the neighborhood of Rio Janeiro. In Brazil it is called *abutua*. It is much subject to adulteration, one of the most frequent substitutions at one time having been the worthless stem for the root (see E. R. Squibb, *Amer. Jour. Pharm.*, 1872, p. 107; and John Moss, *ibid.*, 1874, p. 335). Occasionally, substitutes of unknown origin turn up (see Ringer and Brooke, on "True and Commercial Pareira, *Amer. Jour. Pharm.*, 1892, p. 255). Spurious drugs may be known by their non-conformity to the pharmacopœial requirements.

True pareira brava is officially described as follows: "In subcylindrical, somewhat tortuous pieces, about 10 to 15 Cm. (4 to 6 inches) long, varying in thickness from 2 to 10 Cm. (⅘ to 4 inches); externally dark brownish-gray, with transverse ridges and fissures and longitudinal furrows; internally pale brown, and, when freshly cut, having a waxy lustre; bark thin; wood porous, in 2 or more somewhat irregularly concentric circles, with rather large medullary rays, and no distinct central pith; inodorous; taste bitter. Pieces having a bright-yellow color, or the woody portion of which is grayish, hard, and nearly tasteless, should be rejected"—(*U. S. P.*).

Chemical Composition.—F. A. Ringer and E. Brooke (*Amer. Jour. Pharm.*, 1892, p. 255) made a comparative analysis of true pareira and a spurious variety from Bahia, of unknown botanical origin. The distinguishing feature was the petroleum-ether extract (fats and fatty acids), which amounted in the true root to

8.67 per cent; in the false to only 0.28 per cent. Both drugs also contained starch, gum, tannin (1.26 per cent in the true), phlobaphene (0.52 per cent), and an alkaloid (0.819 per cent). The spurious drug contained only 0.143 per cent of the latter. Both alkaloids were insoluble in water, but soluble in alcohol and ether.

Charles Morrison (*Amer. Jour. Pharm.*, 1878, p. 430) records the presence of two alkaloids in a specimen of false pareira brava, having a bright-yellow wood; one of the alkaloids was similar to, but not quite identical with berberine. Wiggers, in 1839, named an amorphous, white alkaloid, which he found in a probably undetermined species of pareira brava, *pelosine;* it was insoluble in water, soluble in alcohol and acids, and of an intensely bitter taste. *Pelosine* was subsequently found by Flückiger (*Neues Jahrbuch der Pharmacie*, 1869, pp. 257–276) in notoriously genuine *Cissampelos Pareira*, associated with an indifferent body, *deyamittin*. Pelosine was proven by Flückiger to be identical with the alkaloids *beberine* and *buxine* (which see).

Action, Medical Uses, and Dosage.—Tonic, diuretic, and aperient. To the kidneys it is a decided stimulant and tonic, relieving irritation of the urinary tract, being indicated by abdominal uneasiness, with desire to pass urine frequently. Used in *chronic inflammation of the bladder, pyelitis,* and various disorders of the urinary organs. Also recommended in *calculous affections, leucorrhœa, dropsy, rheumatism,* and *jaundice.* Dose, of the infusion, from 1 to 4 fluid ounces; of the extract, from 10 to 20 grains. A strong tincture (bark, ℥viii to alcohol, 76 per cent, Oj) may be administered in doses of from 1 to 10 drops for specific purposes.

Specific Indications and Uses.—Chronic cystitis and pyelitis; irritation of urinary tract, with abdominal uneasiness; frequent desire to urinate, which act is accomplished with pain in urethra and glans penis.

Other Drugs Known as Pareira Brava.—ROOTS AND STEMS OF:

I. CISSAMPELOS PAREIRA, Linné (*C. microcarpa*, De Candolle); illustration in Bentley and Trimen's *Med. Plants*, 15.—This was thought originally to be the source of pareira brava. It is also termed *Velvet-leaf* and *Ice vine*, and is a shrub with a round, ligneous root, stems either smooth, or with close-pressed down, and climbing over trees. Leaves large, nearly orbicular, peltate, aristate at the point, when full grown smooth above, underneath covered with silky pubescence, but not truly downy. Flowers diœcious, hispid, in racemes; sepals 8, 4 inner united into a cup, with usually an entire margin; peduncles solitary or in pairs, branching from the base, as long as the petiole, or longer, racemose corymbose, with divaricating, downy ramifications. Racemes, in the female plant, longer than the leaves, bearing the flowers in spiked fascicles. Bracts sessile, somewhat orbicular, scarcely mucronate. Ovary solitary, and surmounted with 3 stigmas. Berries scarlet, round, reniform, compressed, shriveled, thinned to the edge, all over hispid with long hairs (L.). This plant is a native of the West India Islands and the Spanish Main. The root and stem seldom attain the diameter of 1 inch, and are more often the size of a quill. No concentric rings are shown on cross-section. It is very bitter, not sweetish nor astringent. This variety is made up chiefly of stems with some sections of root.

II. COMMON FALSE PAREIRA BRAVA.—This is derived from undetermined plants of the natural order *Menispermaceæ*, and is the drug that yielded *pelosine* to Wiggers, in 1839. According to Hanbury, "the drug consists of a ponderous, woody, tortuous stem and root, occurring in pieces from a few inches to a foot or more in length, and from 1 to 4 inches in thickness, coated with a thin, hard, dark-brown bark. The pieces are cylindrical, 4-sided, or more or less flattened, sometimes even to the extent of becoming ribbon-like. In transverse section, their structure appears very remarkable. Supposing a piece to be *stem*, a well-defined pith will be found to occupy the center of the first-formed wood, which is a column about ¼ of an inch in diameter. This is succeeded by 10 or 15 or more concentric, or oftener eccentric, zones, $\frac{1}{10}$ to $\frac{1}{20}$ of an inch wide, each separated from its neighbor by a layer of parenchyme, the outermost being coated with true bark. In pieces of the *true root*, the pith is reduced to a mere point. Sometimes the development of the zones has been so irregular that they have formed themselves entirely on one side of the primitive column, the other being coated with bark. The zones, including the layer around the pith (if pith is present), are crossed by numerous small medullary rays. These do not run from the center to the circumference, but traverse only their respective zones, on the outside of which they are arched together. The drug, when of good quality, has its wood firm, compact, and of a dusky, yellowish-brown hue, and a well-marked, bitter taste. It exhibits, under the knife, nothing of the close, waxy texture seen in the root of *Chondodendron*, but cuts as a tough, fibrous wood"—*Pharmacographia*. This root is unaffected by iodine. This kind possesses medicinal value, but has been largely superseded by an inert drug, devoid of bitterness, in cylindrical sticks of light weight, dull color, splitting readily, and having two easily detached layers of bark. D. Hanbury advocates returning to the use of the original pareira brava, which gave the drug its reputation.

III. STEMS OF CHONDODENDRON TOMENTOSUM (By far less efficient than the root (see P. R. Squibb, *Amer. Jour. Pharm.*, 1872, p. 107). It is also known as *Pa*[illegible].

IV. White Pareira Brava.—Stems and roots of *Abuta rufescens*, Aublet. A tasteless and odorless drug, not found in commerce, whose decoction turns strongly blue when treated with iodine. The root, on transverse section, shows white, amylaceous, concentric zones, marked with handsome, dark, wedge-shaped medullary rays.

V. Yellow Pareira Brava.—Probably derived from *Abuta amara*, Aublet, of Guiana. Internally, it is bright-yellow, and has eccentric zones. It is probably the specimen analyzed by Morrison (see above).

PARTHENIUM.—FEVERFEW

The flowering herb of *Pyrethrum Parthenium*, Smith (*Matricaria Pyrethrum*, Linné; *Chrysanthemum Parthenium*, Persoon; *Tanacetum Pyrethrum* Schultz).

Nat. Ord.—Compositæ.

Common Names: *Feverfew, Featherfew.*

Botanical Source.—Feverfew is a perennial, herbaceous plant, with a tapering root, and an erect, branched, leafy, round, furrowed stem, about 2 feet high. The leaves are alternate, petiolate, flat, bipinnate, or tripinnate, hoary green, the segments or leaflets inclining to ovate, decurrent, gashed, and dentate. The flowers are white and compound. The panicle is corymbose, sometimes compound; peduncles long-naked, single-flowered, and swelling upward. Flower-heads erect, about ½ inch broad, with a convex, yellow disk, and numerous short, broad, abrupt, 2-ribbed, white rays; often wanting; sometimes multiplied, and the disk being obliterated, constitutes a double flower. The involucre is hemispherical, imbricate, pubescent, with the scales scarious at the edge; the receptacle flat or convex, and naked; the achenia wingless, angular, uniform, crowned by a coronetted pappus, which is usually toothed, and occasionally auriculate (L.—W.).

History.—This is a European plant, and is common to the United States; found occasionally in a wild state, but is generally cultivated in gardens, and flowers in June and July. It imparts its virtues to water, but much better to alcohol. Bees are said to dislike this plant very much, and a handful of the flower-heads will cause them to keep at a distance.

Chemical Composition.—J. Chautard, in 1863, obtained from this plant, by distillation with water, an oil which deposits upon standing in the cold, a lævorotatory camphor, *pyrethrum-camphor* ($C_{10}H_{16}O$), distinguished from ordinary camphor by its opposite optical rotation. Besides, the volatile oil contains an oxygenated liquid, and possibly a terpene hydrocarbon.

Action, Medical Uses, and Dosage.—Tonic, carminative, emmenagogue, vermifuge, and stimulant. This agent is one of the pleasantest of the tonics, influencing the whole intestinal tract, increasing the appetite, improving digestion, and promoting secretion, besides having a decided action upon the renal and cutaneous functions. The warm infusion is an excellent remedy in *recent colds*, *flatulency*, *worms*, *atonic dyspepsia*, *irregular menstruation*, *nervous debility*, *hysteria*, *suppression of the urine*, and in some *febrile diseases*. In *hysteria* or *flatulency*, 1 teaspoonful of the compound spirits of lavender forms a valuable addition to the dose of the infusion, which is from 2 to 4 fluid ounces. The cold infusion or extract makes a valuable tonic. The leaves in poultice are an excellent local application in *severe pain* or *swelling of the bowels*, etc.

Related Species.—*Parthenium integrifolium*, Linné; *Cutting almond*. This plant, also known by the name of *Nephritic plant*, is indigenous and perennial, with an erect, striate, pubescent stem, from 3 to 6 feet in height. Leaves alternate, lance-ovate, hispid-scabrous, coarsely dentate-crenate, coriaceous, lower ones petiolate, upper sessile, sometimes clasping, 4 to 12 inches long, about half as wide. Radical petioles a foot long. Heads many-flowered, tomentose, corymbed; ray-flowers 5, somewhat ligulate, fertile; disk-flowers tubular, sterile. Involucre hemispherical, 5-leaved; scales in 2 series, outer ovate, dilated, inner orbicular; receptacle minute, conical, chaffy; achenia 5, obovate, compressed, cohering with 2 contiguous paleæ. It is sometimes known as *Prairie dock* (W.). This plant grows in the middle and western states, in dry soils, flowering from July to September. The root is the part used. Its growth is singular; it issues from a head or caudex, at first small, but gradually increases in size, and terminates very abruptly, giving off other roots of a similar form, each being a distinct root, about the size and shape of a radish, but growing horizontally, and sending up stems from near the large ends of the principal roots, which are blackish outside, and bluish-gray within. According to analysis by Frank B. Meyer (*Amer. Jour. Pharm.*, 1881, p. 490), the bitterness of the drug is due to a crystallizable substance obtained by abstracting the powdered drug first with petroleum benzin, which removes a dark-green wax; then with ether, and taking up the ethereal extract with boiling water. The crystals turn deep-red with ferric chloride, and do not reduce Fehling's solution. The liquid preparations of the drug possess an agreeable orange-like odor. Diuretic. A cold infusion of the root, in wineglassful doses, 3 or 4 times a day, will be found very beneficial in *heat of the urine*, *strangury*, *dysuria*, *gonorrhœa*, *gravel*, and *diseases of the kidneys and bladder* generally. It is highly recommended by some practitioners in these diseases. Likewise said to be an aromatic bitter and stimulant. The flowering tops have been used as an antiperiodic. Two fluid ounces of their infusion have no unpleasant influence on the nervous system, and are said to be equal to 20 grains of sulphate of quinine (Houlton).

Parthenium Hysterophorus, Linné, is employed like feverfew. It resembles cutting almond, and is indigenous to Louisiana, Florida, and the West Indian Islands. It is a common weed in Jamaica. Dr. José R. Tovar, of Cuba, employed *parthenin* obtained from this plant in cases of *facial neuralgia* with much success (*Therap. Gazette*, 1885, p. 359). M. Guyet (*Proc. Amer. Pharm. Assoc.*, 1886, p. 416) points out the complex composition of this active constituent, which he states is not a definite body. Dr. Carlos Ulrici (see *Amer. Jour. Pharm.*, 1886, p. 451, and Merck's *Bulletin*, Oct., 1888, p. 53) found in the drug five alkaloids, *parthenine* being the active, bitter and crystallizable principle, quite readily soluble in hot water. Uncrystallizable *parthenic acid* is likewise present. Dr. Harry V. Arny observed that the plant is richest in the active bitter principle in the months of June and July, when about 1 per cent may be obtained therefrom in large crystals. It is not a glucosid as was first supposed, nor an alkaloid. A volatile oil containing a camphor was obtained by distillation with steam (*Amer. Jour. Pharm.*, 1897, p. 169). Small doses (3 grains) of the total active principle quicken, and larger doses (15 grains) retard cardiac movements. Large doses (50 grains) slow the respiration, reduce arterial tension, and bring down the temperature.

PASSIFLORA.—PASSION FLOWER.

The root and stem-base of *Passiflora incarnata*, Linne.

Nat. Ord.—Passifloraceæ.

Common Names: *Passion flower*, *May pops*.

Botanical Source.—A pubescent, climbing shrub, reaching a height of from 20 to 30 feet, and supporting 3 to 5-cleft leaves, the lobes being serrated, and the petiole bearing above 2 glands. The involucre is 3-parted. The flowers are large, wonderful, and handsome, being about 2 inches broad, and of a nearly white color, the crown being triple and of a purplish and flesh-colored or roseate hue. The fruit is the size of a hen's egg, oval, and orange-yellow. It is a perennial herb (G.—W.).

Botanical History.—The genus *Passiflora* inhabits mainly the tropical portions of America. They are climbing herbs or shrubs, usually with tendrils having alternate, generally palmately divided (some undivided) leaves, with stipules. The flowers are perfect; the calyx is of 5 sepals united at the base to form a cup, and usually have the color of the petals at least on their inner surface. The 5 petals are inserted on the calyx throat, which is a complex, double or triple filamentous crown. The filaments of the 5 stamens are united to form a tubular sheath for the long-stalked ovary, upon which are the 3 club-shaped styles. The anthers are large and fixed by their middle. The many-seeded, 1-celled berry-like fruit is often edible. The seeds are invested by a pulpy substance (Gray).

Two species of this genus have been used to some extent in this country, *P. incarnata* and *P. lutea*. The former has now become an important remedy. This species is found within our borders, thriving in dry soils from Virginia to Florida, and from thence westward to Missouri and Arkansas. The common name in our southern states for the fruit is *May-pops*. The generic name *Passiflora* is, according to Gray, "an adaptation of *flos passionis*, a translation of *fior della passione*, the popular Italian name early applied to the flower from a fancied resemblance of its parts to the implements of the crucifixion." The fruit is orange-colored, about the size of a hen's egg, and filled with a sweetish-yellow pulp. The juice of the leaves of this species, together with those of *Passiflora pallida* and *Passiflora maliformis*, were long ago used by the Brazilians for intermittent fevers. The entire plant is used in medicine. Prof. Goss, who introduced it to the Eclectic profession, employed the root and its preparations. We know of physicians who prefer the tincture of the leaves, and others still, who desire the root with a few inches of the stem attached. Passiflora contains small amounts (often traces only) of an alkaloid. Its constituents seem not to possess any decided chemical characteristics.

Passiflora was introduced into medicine in 1839 or 1840 by Dr. L. Phares, of Mississippi, who, in the *New Orleans Medical Journal*, records some trials of the drug made by Dr. W. B. Lindsay, of Bayou Gros Tete, La. The use of the remedy has been revived within recent years, Prof. I. J. M. Goss, M. D., of Georgia, having introduced it into Eclectic practice.

Action, Medical Uses, and Dosage.—The physiological action of passiflora has not been well-studied. Medicinal doses produce no special physiological impressions, but we have observed even small doses to occasionally provoke emesis, Some individuals appear to be very susceptible to this effect. Moderate doses act as an antispasmodic and are somewhat narcotic. Dr. Phares, who introduced the drug, stated that he was satisfied that it possessed no narcotic properties. It is, at least, hypnotic. Excessive doses are said to have produced in animals both spasms and paralysis.

The clinical application of passiflora has been with most observers satisfactory. Its force is exerted chiefly upon the nervous system, the remedy finding a wide application in *spasmodic disorders* and as a rest-producing agent. It is best adapted to debility and does not act so well in sthenic conditions, although not contraindicated in such. It is specially useful to allay *restlessness* and overcome *wakefulness*, when these are the result of exhaustion, or the nervous excitement of debility. It proves specially useful in the *insomnia* of infants and old people. It gives sleep to those who are laboring under the effects of mental worry or from mental overwork. It relieves the nervous symptoms due to reflex sexual or menstrual disturbances, and the *nervous irritability* resulting from prolonged illness. We have employed it with good results to allay the restlessness of *typhoid fever*, although its action appears to be slow, but sure. The sleep induced by passiflora is a peaceful, restful slumber, and the patient awakens quiet and refreshed. A further study of the drug will undoubtedly give us a better guide to its adaptation as a nerve sedative and hypnotic. An atonic condition appears to be the keynote to its selection.

Passiflora is a remedy for *convulsive movements*. One of its first successful applications in medicine was for the relief of *tetanus*, both in man and the horse. If given in full doses in *epilepsy* when the aura gives warning of an approaching attack, the remedy is said to be of considerable value, but after the convulsions have begun it has little or no effect. Some, however, have reported success in all stages of the disease. Passiflora is praised for its control over the *spasms of childhood*, whether from dentition, *worms*, or undigested aliment; it has also been successfully employed in *trismus nascentium*. Spasms, dependent upon *meningeal inflammation*, have been controlled with it. It appears not to be contraindicated in any form of spasm. Dr. Holmes (*Ec. Med. Jour.*, 1896, p. 55) reports a case of *post-partum puerperal eclampsia* relieved after but two convulsions by the hypodermatic use of 2 drachms of passiflora. The remedy has given good results in *chorea*, especially in girls approaching the menstrual age. When *whooping-cough* is associated with convulsions, passiflora has given relief, and in *hysteria* with spasmodic movements it is reputed equally successful.

Passiflora is a remedy for *pain*, particularly of the neuralgic type. Thus it has relieved *neuralgic* and *spasmodic dysmenorrhœa*, *rectal pain*, *cardiac pain*, facial and other forms of *neuralgia*, many *reflex painful conditions* incident to *pregnancy* and the menopause, and other forms of pain accompanied or not with spasmodic action. *Sick* or *nervous headache*, the *headache of debility*, or from cerebral fullness are often relieved by passiflora. All such cases show marked atony of some part or function.

Passiflora has been employed to relieve many of the nervous phenomena attending *la grippe*, and both internally and externally has been given to mitigate the ravages of *erysipelas* (particularly when facial) and *syphilis*. Prof. Scudder long ago characterized passiflora as a remedy to relieve irritation of the nerve centers, and to improve sympathetic innervation, improving the circulation and nutrition, and stated that it might be used "in *torpidity of the liver* with hemorrhoids, and in *congestion of ovaries and uterus*." He employed for the latter purpose fractional doses of the drug (*Spec. Med.*, *p.* 197). It has been used to check *diarrhœa* and *dysentery*. An aqueous extract has been lauded as an application to recent *burns* and *scalds*, and to *hemorrhoids;* also to *ulcerating carcinomata*, *painful ulcers*.

chancres and *chancroids*. A pledget of cotton saturated with passiflora and introduced into a carious tooth has promptly allayed violent *toothache*. The dose of specific passiflora is from a fraction of a drop to 2 fluid drachms.

Specific Indications and Uses.—Irritation of brain and nervous system with atony; sleeplessness from overwork, worry, or from febrile excitement, and in the young and aged; neuralgic pains with debility; exhaustion from cerebral fullness, or from excitement; convulsive movements; infantile nervous irritation; nervous headache; tetanus; hysteria; oppressed breathing; cardiac palpitation from excitement or shock.

Related Species.—*Passiflora lutea*, Linné. Smooth and slender; summit of the leaves obtusely 3-lobed and lobes entire; glandless petioles and greenish-yellow flowers an inch broad. Damp thickets from Pennsylvania to Florida, and west to Illinois, Missouri and Louisiana. The fruits are acidulous and edible. Used by Dr. Phares, of Mississippi, like *Passiflora incarnata*.

Passiflora cærulea, Linné. Leaves 5-lobed and entire; flowers fringed and greenish, bluish, purplish, or white; fruit, orange-yellow. A native of Brazil, and often cultivated in warm countries for ornamental coverings for walls, houses, and arbors. The fruit is not eaten.

Fig. 190.

Passiflora cærulea.

Passiflora lyræfolia, Tussac.—Leaves unequally 3-cleft at top; flowers red; fruit like a cherry.

Passiflora rubra, Linné.—Leaves, 2-lobed; flowers whitish and light red; scarlet berries. Reputed narcotic by inhabitants of Jamaica and the Caribbee Islands.

Passiflora edulis.—Fruit large, orange-purple externally, orange-colored within. Has an acidulous, orange-flavored taste. Edible.

Passiflora alata.—An extract of the leaves with aloes was reputed beneficial in atrophy of various parts.

Passiflora capsularis.—Reputed emmenagogue.

Passiflora fetida, Cavanilles.—Leaves 3-lobed; flowers whitish, with purple crown; odor fetid. Said to be antispasmodic, emmenagogue, and expectorant. Used in poultices.

Passiflora laurifolia, Laurel-leaved granadilla.—West Indies. Known also as *Water lemon* and *Honey-suckle* by the English, *Pomme de Liane* by the French, and in South America as *Granadilla* and *Murucuja*. Fruit about the size of a hen's egg. Yellow and dotted with white; the pulp is whitish and watery, and the juice, which is peculiarly flavored and agreeably acid, is sucked by Europeans and natives through an opening made in the tough, thin rind. "It is said that it quenches thirst, allays heat, induces an appetite, and elevates the spirits" (Hogg). The leaves are bitter, and considered anthelmintic and moderately astringent.

Passiflora maliformis, Linné, *Apple-fruited granadilla*, or *Sweet calabash.*—Flowers white and fringed with blue. Fruit is dull yellow and resembles an apple in size and shape. Pulp gelatinous, pale yellow, very agreeably acid, and usually eaten with wine and sugar. Juice of the leaves used in Brazil in *intermittent fevers* (Hogg).

Passiflora contrayerva.—Root sweetish, pungent and fragrant. Reputed "counter-poison, deobstruent and cordial."

Passiflora quadrangularis, Linné.—Branches 4 angled and winged. Fruit large as a goose egg, and of a greenish-yellowish color. Native of Jamaica and South America and known as the *Common granadilla*, or *Granadilla vine*. The sweet, acidulous, purple-colored pulp is the edible portion. The root is reputed very poisonous, causing emesis, convulsions, paralysis and death. Small doses of the root are said to act as an anthelmintic. An active principle, somewhat like morphine, has been isolated from the root and named *passiflorine*.

Murucuja ocelatta.—West Indies. "Anthelmintic, diaphoretic and antihysteric" (Hogg). An infusion and syrup are used in Jamaica, like laudanum. A vinous or spirituous tincture of the flowers is employed under the name of *Bull-hoof* or *Dutchman's laudanum*, as an efficient and easy narcotic.

Modecca palmetta.—Reputed tonic and pectoral, and *Modecca integrifolia*, beaten with butter, is said to "heal *hemorrhoids*."

Adenia venenata.—Africa. A climber known as *Passion flower* in its habitat. Lauded as a vesicant by Schweinfurth.

PENTHORUM.—PENTHORUM.

The whole herb of *Penthorum sedoides*, Linné.

Nat. Ord.—Crassulaceæ.

COMMON NAMES: *Virginia stone-crop, Ditch stone-crop.*

Botanical Source. This is an erect, perennial herb, about a foot high, found growing in creeks and wet situations throughout the United States and Canada. The stem is smooth, round at the base, but angular above, and often branched.

It has numerous scattered, thin leaves, from 2 to 3 inches long, about ⅓ as wide, and attached to the stem at an acute angle. They are lanceolate, smooth, finely and sharply serrate, tapering regularly to an acute apex, and at the base to a very short leaf-stalk. The flowers are small, inconspicuous, and arranged in terminal naked cymes, consisting of from 2 to 4 slender, simple, 1-sided branches, which unroll as the flowers expand. The flowers are supported on short peduncles about ¼ of an inch long, and consist, each, of a 5-parted calyx, 10 stamens, and 5 pistils, which are united at the base. The petals are generally wanting. The fruit consists of 5 dry, 1-celled capsules, beaked with the persistent style, and united at the base. They open, when ripe, at the summit, and are filled with numerous minute seeds. The genus Penthorum, which differs from its allies of the Crassulaceæ in not having fleshy stems, consists of only 2 species—the one described above, indigenous to North America, the other found only in China.

Fig. 191.

Penthorum sedoides,

History and Chemical Composition.—Penthorum sedoides was mentioned by some of the older authorities, but its more recent introduction into medicine may be ascribed to Dr. F. H. Briggs (*Ec. Med. Jour.*, 1875, p. 479). The fresh herb has an astringent, slightly acid taste, and, when bruised, an herb-like odor. The properties of the fresh plant are best extracted by alcohol, and seem chiefly to depend upon a form of tannin which, in alcoholic solution with ferrous sulphate, first turns blue and then precipitates black. With ferric sulphate, it forms a deep-green solution. Neither the tincture, nor the tincture freed from tannin, shows the slightest indication of an alkaloid with the ordinary reagents. When the herb is distilled with water, the distillate is free from volatile oil.

Action, Medical Uses, and Dosage.—Dr. Briggs states that "the older authorities gave this agent as a demulcent and laxative, and it does not seem to exert the astringent action common to agents containing tannic acid. The impression upon the mouth is that of an astringent, but, on examining the mucous membrane, it does not seem corrugated, but very fresh and rosy, and it would undoubtedly prove a valuable tooth and mouth wash." The fluid extract and specific medicine have been employed successfully in the treatment of *cholera infantum*, *diarrhœa*, and *hemorrhoids*. Prof. J. M. Scudder observes that mucous membranes, especially when they have suffered from inflammatory action, are peculiarly influenced by this agent, which gradually removes irritation, promotes normal functional activity, and restores the tissues to their normal condition. He found it not only an excellent remedy in *diarrhœa*, but likewise in *chronic nasal catarrh*, in *chronic pharyngitis*, in *chronic bronchitis*, with increased secretion, and in *chronic vaginitis*, with or without leucorrhœal discharge. He employs it internally and locally, when this can be effected, in spray; also as a topical application to *chronic ulcers*. It is not, as a rule, as well adapted to acute as to chronic disorders, and must be used for a length of time to obtain its best effects. As a reliever of irritation of mucous surfaces, its best results have been obtained in *chronic affections of the posterior nares, pharyngeal vault*, and *Eustachian tubes*. It may be used both internally and by atomization. It has been of benefit in *indigestion* and *nervous dyspepsia*. Its effects upon the gastric membranes have been compared to those of small doses of ipecac. The dose of the fluid extract is from 10 to 60 minims, repeated every 3 or 4 hours; of the specific penthorum, 1 to 30 minims, in a teaspoonful of water. Penthorum is a remedy of undoubted power, and deserves a more careful study than has been hitherto bestowed upon it. It is best adapted to chronic conditions, being of little service in acute phases.

Specific Indications and Uses.—Pharyngeal and nasal disorders of a chronic type, with fullness, dryness, and irritation, with a purplish, congested appearance; catarrhal inflammations, with profuse secretions; catarrhal gastric disorders; catarrhal diarrhœa; spongy gums.

PEPO (U. S. P.)—PUMPKIN SEED.

"The seed of *Cucurbita Pepo*, Linné"—(*U. S. P.*).

Nat. Ord.—Cucurbitaceæ.

COMMON NAME: *Pumpkin seed.*

Botanical Source.—Cucurbita Pepo is an annual plant, hispid and scabrous, with a procumbent stem and branching tendrils. Its leaves are large, cordate, palmately 5-lobed, or angled and denticulate. The flowers are yellow, large, axillary, and the males long-pedunculate. Corolla campanulate; the petals united and coherent with the calyx. The calyx of the male flowers is 5-toothed; of the female the same, the upper part being deciduous after flowering; the stigmas are 3, thick, and 2-lobed; the pepo, or fruit, subligneous, very large, roundish, or oblong, smooth, yellow when ripe, furrowed and torulose, containing yellowish seeds, somewhat resembling those of the watermelon in form (W.).

History.—The pumpkin flowers in July, and matures its fruit in September and October. It is a native of the Levant, and is extensively cultivated as a kitchen vegetable, and for cattle. The seeds of this plant are used in medicine, and have long been popular with the laity as a remedy for worms. An oil may be obtained from the pumpkin seeds by expression. The West India seeds are more active as an anthelmintic than our own.

Description.—The seeds are "about 2 Cm. (⅘ inch) long, broadly-ovate, flat, white or whitish, nearly smooth, with a shallow groove parallel to the edge; containing a short, conical radicle, and 2 flat cotyledons; inodorous; taste bland and oily"—(*U. S. P.*).

Chemical Composition.—Pumpkin seeds are composed of 25 per cent of husks and 75 per cent of kernels, and contain upward of 33 per cent of a reddish fixed oil, which, according to Kopylow (*Amer. Jour. Pharm.*, 1877, p. 23), consists of the glycerides of palmitic, myristic, and oleic acids. These also occur partly in the free state. No alkaloid was found in the seeds, nor the glucosid, *cucurbitin*, of Dorner and Wolkowitsch (1870). According to Dr. L. Wolff (*Amer. Jour. Pharm.*, 1882, p. 382), the active (tænifuge) principle is a greenish-brown, acrid, bitter resin (Heckel, 1875) not contained in the petroleum-benzin extract of the seeds, but in the extract obtained with ether. It is also soluble in alcohol and chloroform. Its dose, as a tænifuge, is 15 grains, in pill form. The fatty oil is soluble in absolute, but not in 95 per cent alcohol (W. E. Miller, *ibid.*, 1891, p. 385). Air-dried pumpkin seeds contain about 3.7 per cent of ash. The juice of pumpkin pulp contains 1.6 per cent of dextrose and 0.9 per cent of cane sugar (Mr. Both, in Dragendorff's *Heilpflanzen*, 1899, p. 650). The coloring matter of the pumpkin is due to *carotin* (*Jahresb. der Pharm.*, 1896, p. 84).

Action, Medical Uses, and Dosage.—Mucilaginous, tænicide, and diuretic, and of service in *strangury* and *urinary affections*, also in *gastritis*, *enteritis*, and *febrile diseases*. The infusion may be drank freely. The expressed oil of the pumpkin seeds, in doses of 6 to 12 drops, several times a day, is said to be a most certain and efficient diuretic, giving quick relief in *scalding of urine*, *spasmodic affections of the urinary passages*, and has cured *gonorrhœa*. Half a fluid ounce of oil of pumpkin seeds, taken upon a fasting stomach, repeated in 2 hours, and in another 2 hours followed by a dose of castor oil containing ½ fluid ounce of the pumpkin-seed oil, has been effectual in removing *tapeworm*. The following mixture has been found efficient in the removal of tapeworm: Take of the ethereal oil of pumpkin seeds, 1 fluid ounce; ethereal extract of male fern, 1 fluid drachm; sugar, 2 drachms; water, 4 fluid ounces; rub the oil with the sugar, then the extract, and finally add, gradually, the water. One-fourth of this is a dose, to be repeated every hour. An infusion of the seeds has also been found effectual in removing tapeworm. The method now chiefly pursued is to have the patient fast for a day and take a saline cathartic to wash the intestinal mucus, etc., from the worm. Then, the patient being kept in bed to prevent emesis, administer to him 3 doses of ⅓ of a pint each, every 2 hours, of an emulsion prepared from the fresh seeds beaten with pulverized sugar and diluted with milk or water. After a few hours, a purgative, like castor oil, may be administered to aid in the expulsion of the worm. This is also effectual in removing the *roundworm*. It was formerly believed that the tænifuge properties resided in the external covering of the seeds, but later investigations do not confirm this view.

Specific Indications and Uses.—Tapeworm; roundworm; ardor urinæ.

Related Species.—*Citrullus vulgaris*, Schrader (*Cucurbita Citrullus*, Linné; *Cucumis Citrullus* of Seringe); *Watermelon*. This is a native of Africa and southern Asia, and is cultivated in this country for its large and delicious fruit, which is usually ripened in August, the flowers appearing in June and July. The fruit contains many obovate, smooth, compressed seeds, thickened at the margin, and of a black or yellowish-white color (W.). The fleshy, juicy pulp of the watermelon is diuretic, and forms a grateful article of diet for febrile patients, when not contraindicated. Watermelon seeds possess properties similar to pepo, and, as a diuretic (infusion of bruised seeds) is one of the mildest and best we possess. Acetate of potassium added to it, increases its efficiency and augments the excretion of the solid constituents of the urine. F. Popow (*Jahresb. der Pharm.*, 1888, p. 51) found the edible portion of the watermelon to consist of water (94.96 per cent) and dry substance (5.04 per cent); the latter was composed of nitrogenous matter (0.67 per cent), dextrose (3.67 per cent), lævulose (0.46 per cent), mucilage (0.05 per cent), fat (0.06 per cent), cellulose (0.10 per cent), and mineral matter (0.28 per cent). The seeds contain resin (2.3 per cent), albumen (6 per cent), and dextrose (3 per cent) (Dragendorff's *Heilpflanzen*, 1899, p. 650).

Lagenaria vulgaris, Seringe (*Cucurbita Lagenaria*, Linné); *Gourd*, or *Calabash*.—Pulp is occasionally bitter and purgative (A. De Candolle, 1882).

Cucumis sativus, Linné; *Cucumber*.—This plant is too well known to require description. Both the fruit and seeds are employed. The latter contain, besides mucilage, a bland, fixed oil, of a pale-yellow color, to the amount of about 32 per cent. Prof. Procter proposed, in 1853, a *cucumber ointment*, prepared as follows: Take green cucumbers, 7 pounds; suet, 15 ounces; lard, 24 ounces. Grate the fruit and express the juice. Then melt together the lard and suet, and, when sufficiently cooled so as to form a semisolid mass, gradually incorporate with it the cucumber juice, adding about one-third of it each time. After some time, melt the whole mixture, strain, and keep in glass containers, covering the ointment with rose-water. Close the jar securely. When needed, take out a portion, and mix it to a white, creamy paste by triturating it with a small amount of rose-water. Cucumber seeds have been used for diuretic purposes like other seeds of this class. The ointment is emollient, and may be applied to *cuts, abrasions*, etc. Dr. J. M. Scudder (*Spec. Med.*, p. 119) advised a tincture of green cucumber, prepared with 98 per cent alcohol for "irritation of the urinary passages, sharp pain in the loins, and rheumatic pains in the shoulders." Cramp-like pains in the shoulder and loins, with inability to urinate, are the indications given by Dr. O. H. Rohde (*Trans. of N. Y. Ec. Med. Assoc.*, Vol. XVII, p. 165).

Momordica balsamina, Linné; *Balsam-apple*.—This long-ovate fruit, tapering at each extremity, has been used considerably as a vulnerary. It is verrucose, orange or bright-red, rather angular and spontaneously divides laterally, displaying an interior containing oval, flat, brown seeds, somewhat rugose, and imbedded in a fleshy arillus of a red color. The root and fruit are both purgative. Two drachms of balsam-apple are said to have killed a dog. A preparation of the fruit (without the seeds), infused in almond or olive oil, has been employed considerably in *prolapsus ani, hemorrhoids, burns, scalds, chapped hands*, and *old ulcerations*. An extract of it has been praised for its curative effects in *dropsy*. Balsam-apple, infused in whiskey, is quite largely employed by the German population of this country as a vulnerary. It is often applied to *chilblains*. Internally, an alcoholic tincture and a jelly have been employed for the relief of pain in the chest from *acute colds*, and in *pulmonary congestion*. Proper doses relieve gastro-intestinal irritation, and give relief in gastro-intestinal pains, particularly in *colic*.

Cucurbita Melopepo, Linné; *Squash*.

Cucumis Melo, Linné; *Muskmelon*.—The seeds of this and the foregoing species possess similar properties to those of pepo, but in a milder degree. The seeds contain 39 per cent of fatty oil. From the root an emetic principle, *melon-emetine*, was isolated, in 1887 (*Pharm. Centralhalle*, p. 600), by Heberger and Jorosiewicz.

Cucurbita maxima, Duchesne.—Improperly called *Gourd*. Seeds contain sugar, gum, an aromatic body, a soluble organic acid, yellow, bland fixed oil (25 per cent), and emulsin, but no alkaloid nor a glucosid (Cadenberg, 1881). The seeds give, on rubbing with water, a bland, white emulsion.

PEPSINUM (U. S. P.)—PEPSIN.

"A proteolytic ferment or enzyme obtained from the glandular layer of fresh stomachs from healthy pigs, and capable of digesting not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumen, when tested by the process given below. If it be desired to use a diluent for reducing pepsin of a higher digestive power to that required by the Pharmacopœia, sugar of milk should be employed for this purpose"—(*U. S. P.*).

Source, History, and Preparation.—Pepsin is a peculiar, probably non-albuminous principle, occurring in the gastric juice, and possessing the power, in the presence of hydrochloric or other acids, to dissolve coagulated albumen and muscular fiber, converting them into the modified proteids known as *peptones*. The name *pepsin* was first used about 1836, by Schwann, who obtained the "digestive principle" by macerating cleaned stomachs in acid water, precipitating the liquid with mercuric chloride, and separating the mercury with sulphide of hydrogen. Commercial pepsin was first prepared by drying the granular layer of the stomach of the pig or calf, at low temperatures, and powdering the product. Pepsin is not known in the absolutely pure state. Besides being soluble in water, it is also soluble in glycerin; according to Wittichs, it may be extracted from the mucous membrane of the stomach by means of glycerin acidulated with 0.1 per cent of hydrochloric acid and then precipitated by alcohol. By the process of the *British Pharmacopœia* (1885), the washed mucous lining of the fresh stomach of a sheep, calf, or pig, is scraped with a blunt instrument, the viscid pulp is immediately spread in a thin layer on glass plates or glazed earthenware, and dried at a temperature not to exceed 37.8° C. (100° F.). This product is sparingly soluble in water, because it naturally contains much inert animal matter. A more active pepsin may be obtained by this method if the inner coating of the stomach wherein the pepsin glands are imbedded, be utilized, *i. e.*, washed, dried, and powdered. (For Scheffer's process, based upon the precipitation of pepsin by sodium chloride solution, see *Pepsinum Saccharatum;* see also an interesting article on the manufacture of pepsin, in *Amer. Jour. Pharm.*, 1893, p. 140, from *Pharm. Jour. Trans.*, and *ibid.*, 1892, p. 562.)

Description and Chemical Properties.—"A fine, white, or yellowish-white, amorphous powder, or thin, pale-yellow or yellowish, transparent or translucent grains or scales, free from any offensive odor, and having a mildly acidulous or slightly saline taste, usually followed by a suggestion of bitterness. It slowly attracts moisture when exposed to the air. Soluble, or for the most part soluble, in about 100 parts of water, with more or less opalescence; more soluble in water acidulated with hydrochloric acid; insoluble in alcohol, ether, or chloroform. On heating a solution of pepsin in acidulated water to 100° C. (212° F.), it becomes milky, or yields a light, flocculent precipitate, and loses all proteolytic power. In a dry state it can bear this temperature without injury. Pepsin usually has a slightly acid reaction. It may be neutral, but should never be alkaline"—(*U. S. P.*). Pepsin having a foul odor should be rejected. Aqueous solution of pepsin will to a slight extent dissolve coagulated albumen, but the addition of a few drops of hydrochloric acid (about 0.1 to 0.3 per cent) renders it at once an active solvent; while pancreatin is active only in alkaline media. Pepsin is not destroyed by the process of digestion. After it has ceased to act, the addition of another supply of acid apparently regenerates it, and renders it capable of again performing the part of a digestive agent. Pepsin curdles 80,000 parts of milk (*Amer. Jour. Pharm.*, 1872, p. 49). Neutralization suspends the action of pepsin; alkalies and alcohol injure it; boiling destroys it. Precipitated dry pepsin, obtained according to Mr. Scheffer's method, resembles parchment paper, or "sole leather," the color ranging from light-straw to brown. Pepsin, after having been dried, swells in water, dissolves slowly, but in small proportion. When freshly precipitated, it is very soluble. Solution of pepsin is almost neutral, yields a transparent, gelatinous precipitate with alcohol without losing its peptonizing power, and coagulates on boiling. Bichloride of mercury and nitrate of lead give white precipitates with it.

Valuation of Pepsin.—"Prepare, first, the following three solutions: *A.* To 294 Cc. of water add 6 Cc. of diluted hydrochloric acid. *B.* In 100 Cc. of solution *A* dissolve 0.067 Gm. of the pepsin to be tested. *C.* To 95 Cc. of solution *A*, brought to a temperature of 40° C. (104° F,), add 5 Cc. of solution *B*. The resulting 100 Cc. of the liquid will contain 2 Cc. of diluted hydrochloric acid, 0.00335 Gm. of the pepsin to be tested, and 98 Cc. of water. Immerse and keep a fresh hen's egg during 15 minutes in boiling water; then remove it and place it in cold water. When it is cold, separate the white, coagulated albumen, and rub it through a clean sieve having 30 meshes to the linear inch. Reject the first portion passing through the sieve. Weigh off 10 Gm. of the second cleaner portion, place it in a flask of the capacity of about 200 Cc., then add one-half of solution *C*, and shake well, so as to distribute the coherent albumen evenly throughout the liquid. Then add the second half of solution *C*, and shake again, guarding against loss. Place the flask in a water-bath, or thermostat, kept at a temperature of 38° to 40° C. (100.4° to 104° F.), for 6 hours, and shake it gently every 15 minutes. At the expiration of this time the albumen should have disappeared, leaving at most only a few, thin, insoluble flakes. (Trustworthy results, particularly in comparative trials, will be obtained only if the temperature be strictly maintained between the prescribed limits, and if the contents of the flasks be agitated uniformly, and in equal intervals of time.) The relative proteolytic power of pepsin stronger or weaker than that described above may be determined by ascertaining, through repeated trials, how much of solution *B* made up to 100 Cc. with solution *A* will be required exactly to dissolve 10 Gm. of coagulated and disintegrated albumen under the conditions given above"—(*U. S. P*).

The *National Formulary* (1st ed.) made less strict requirements, demanding only that pepsin should be capable of dissolving not less than 500 times its own weight of hard-boiled egg-albumen, giving explicit directions for its valuation. (For the results of the valuation of 15 commercial samples of pepsin by the *U. S. P.* assay method, see *Proc. Amer. Pharm. Assoc.*, 1895, p. 244.)

Action, Medical Uses, and Dosage.—Previous to the introduction of pepsin, it was a common course among several nations, and in domestic practice, to collect the gizzards of chickens, ducks, turkeys, pigeons, and other birds, remove their inner mucous membranes, dry them, and then reduce them to powder; and this powder, now called *ingluvin*, either alone or in combination with other substances, was administered in derangements of the digestive organs. Pepsin, properly prepared, answers a much better purpose, but to be of efficacy, it must not be united with starch, bismuth, wine, alcohol, or other substances that impair or destroy its peculiar properties. The articles with which it may be combined without injury are, in the form of powder, sugar of milk, or silica, and in fluid form, glycerin, or acidulated water and glycerin, which will preserve it for a considerable period. Pepsin, while aiding or correcting digestion, exerts no influence upon the various lesions upon which the impaired digestive process depends; though it may, in certain cases, afford such relief to this process as to permit the natural recuperative energies of the system to effect recovery. It frequently affords relief in various forms of *indigestion*, or of *dyspepsia*. Infants of delicate constitution, suffering from gastric derangements either previous to or during the period of *dentition*, as manifested by tumid abdomen, emaciation, diarrhœa, and often a tendency to vomit, will derive much benefit from its use, during the administration of which these symptoms will disappear, and the sufferings from dentition will be greatly mitigated. Among those infants raised artificially upon cow's milk, and with whom this fluid does not readily digest, pepsin has likewise been recommended; it may be serviceable in some instances of this kind, though it appears to me that liquid rennet would answer a much better purpose (J. King). It should be remembered that its continued use tends to enfeeble gastric digestion, and thus defeats the purposes for which it is given.

In cases of *sick headache* due to *gastric acidity*, large doses of pepsin, taken shortly after meals, will tend greatly to postpone or prevent the cephalalgic attack. It will also be of value in the feeble or tardy digestion attending convalescence from exhausting *febrile* or *inflammatory disorders*, and that present during long-standing *chronic diseases*. According to M. Liebreich, pepsin is contraindicated in carcinoma, and ulceration of the stomach, in which its administration would tend to hasten the process of thinning the diseased portion of the gastric walls. M. Castro (1868) has successfully used hypodermatic injections of an acid solution of pepsin for the removal or diminution of *tumors*, passing the injection directly into their substance. Pepsin, to be of service, must be pure and reliable, and the more recent its preparation the more satisfactory will be its effects. The dose of saccharated pepsin is from 10 to 60 grains, taken shortly after each meal; it may be taken alone, washed down with a draught of water, or it may be mixed in equal parts of water and pure glycerin; of pure pepsin, from 2 to 10 grains; of liquid pepsin, from 2 fluid drachms to 2 fluid ounces.

Related Preparations.—See *Pepsinum Saccharatum* [*U. S. P.*], and *Vinum Pepsini* (N. F.).

LIQUID PEPSIN (Scheffer).—"Take of saccharated pepsin, 64 grains; water, 5 fluid ounces; hydrochloric acid, 1 fluid drachm; after solution, add glycerin, 3 fluid ounces, then mix and filter. One fluid ounce dissolves 90 grains of coagulated albumen"—(*Nat. Form.*).

Pepsinum Aromaticum (N. F., *Aromatic pepsin.*—"Saccharated pepsin (*U. S. P.*), ninety-seven grammes (97 Gm.) [3 ozs. av., 184 grs,]; aromatic fluid extract (*U. S. P.*), six cubic centimeters (6 Cc.) [97 ♏]; tartaric acid, one and one-half grammes (1.5 Gm.) [23 grs.]; sodium chloride, one and one-half grammes (1.5 Gm.) [23 grs.]. Mix the ingredients by trituration, dry the product by exposure to warm air, and keep it in well-stoppered bottles"—(*Nat. Form.*).

Pulvis Pepsini Compositus (N. F.), *Compound powder of pepsin, Pulvis digestivus.*—"Saccharated pepsin (*U. S. P.*), fifteen grammes (15 Gm.) [231 grs.]; pancreatin (*U. S. P.*), fifteen grammes (15 Gm.) [231 grs.]; diastase, one gramme (1 Gm.) [15 grs.]; lactic acid (*U. S. P.*), one cubic centimeter (1 Cc.) [16 ♏]; hydrochloric acid (*U. S. P.*), two cubic centimeters (2 Cc.) [32 ♏]; sugar of milk, sixty-six grammes (66 Gm. [2 ozs. av., 143 grs.]. Add the acids gradually to the sugar of milk, and triturate until they are thoroughly mixed. Mix the pepsin, pancreatin, and diastase, and then incorporate this mixture, by trituration, with the sugar of milk. Finally, rub the mixture through a hair-sieve, and preserve the powder in bottles. *Note.*—The best commercial variety of diastase, capable of converting the largest comparative amount of starch into dextrin and glucose, should be used for this preparation"—(*Nat. Form.*).

Glyceritum Pepsini (N. F., 1st ed.), *Glycerite of pepsin.*—Pepsin, 640 grs.; hydrochloric acid, 80 ♏; purified talcum, 120 grs.; glycerin, 8 fl℥; water, enough to make 16 fluid ounces. Mix the pepsin with 7 fluid ounces of water and the hydrochloric acid, and agitate until solution has been effected. Then incorporate the purified talcum with the liquid, filter, returning the first portions of the filtrate until it runs through clear, and pass enough water through the filter to make the filtrate measure 8 fluid ounces. To this add the glycerin, and mix. Each fluid drachm represents 5 grains of pepsin (N. F.). *Note.*—For filtering the aqueous solution of pepsin first obtained by the above formula, as well as for filtering other liquids of a viscid character, a filter paper of loose texture (preferably that known as 'Textile Filtering Paper'), or a layer of absorbent cotton placed in a funnel, or percolator, should be employed"—(*Nat. Form.*, 1st ed.).

PEPSINUM SACCHARATUM (U. S. P.)—SACCHARATED PEPSIN.

Preparation and History.—"Pepsin, ten grammes (10 Gm.) [154 grs.]; sugar of milk recently dried, and in No. 30 powder, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]. To make 100 grammes (100 Gm.) [3 ozs. av., 231 grs.]. Triturate the pepsin with the sugar of milk to a fine, uniform powder. Keep the product in well-stoppered bottles. Saccharated pepsin, when tested by the process given under Pepsin (see *Pepsinum*), with the modification that 0.67 Gm. of it are to be taken in preparing solution *B*, should digest 300 times its own weight of freshly coagulately and disintegrated egg albumen."—(*U. S. P.*).

In 1872 (*Amer. Jour. Pharm.*, 1872, p. 49), Prof. E. Scheffer, of Louisville, announced the formula for making saccharated pepsin now generally used by manufacturers, a process that is easy and practical. It is carried out as follows: Dissect the mucous membrane from well-cleaned hogs' stomachs, chop it fine, and macerate it for several days, in water acidulated with hydrochloric acid; strain the resulting liquid, and mix it with its bulk of saturated solution of chloride of sodium. The pepsin now separates, will rise to the surface, and must be skimmed off, drained upon a muslin strainer, and submitted to strong pressure to rid it of salt; then, while still moist, it is to be mixed with milk sugar, in such proportion that ten grains dissolved in one fluid ounce of water acidulated with hydrochloric acid, will dissolve one hundred and twenty grains of coagulated albumen, at about 38° C. (100° F.), in from 4 to 6 hours.

Action, Medical Uses, and Dosage.—Those of Pepsin. (See *Pepsinum.*)

Related Preparations.—The following preparations and plant are employed as aids to digestion:

Liquor Pepsini (*U. S. P.*) (N. F.), *Solution of pepsin.*—"Saccharated pepsin (*U. S. P.*), forty grammes (40 Gm. [1 oz. av., 180 grs.]; hydrochloric acid (*U. S. P.*), twelve grains (12 Gm. [185 grs.]; glycerin, three hundred and twenty-five cubic centimeters (325 Cc. [10 fl℥, 475 ♏]; water, six hundred and fifty cubic centimeters (650 Cc.) [21 fl℥, 470 ♏]. Dissolve the saccharated pepsin in the water, previously mixed with the hydrochloric acid, add the glycerin, let the mixture stand 24 hours, and filter"—(*Nat. Form.*).

Liquor Pepsini Aromaticus (N. F.), *Aromatic solution of pepsin.*—"Pepsin (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; oil of cinnamon, four (4) drops; oil of pimenta, four (4) drops; oil of cloves, eight (8) drops; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; alcohol, thirty-five cubic centimeters (35 Cc.) [1 fl℥, 88 ♏]; hydrochloric acid (*U. S. P.*), ten cubic centimeters (10 Cc. [162 ♏]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl℥, 218 ♏]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏]. Mix the pepsin with five hundred cubic centimeters (500 Cc. [16 fl℥, 435 ♏] of water and the hydrochloric acid, and shake the mixture frequently until the pepsin is dissolved. Then add the purified talcum and the oils, previously dissolved in the alcohol; mix the whole thoroughly, by agitation, and filter it through a wetted filter, returning the first portions of the liquid until it runs through clear. Pass enough water through the filter to make the filtrate measure seven hundred and fifty cubic centimeters (750 Cc.) [25 fl℥, 173 ♏]. To this add the glycerin. Each fluid drachm represents 1 grain of pepsin (U. S. P.)"—*Nat. Form.*).

Liquor Seriparus (N. F.), *Liquid rennet.*—"Calves' rennet, fresh, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sodium chloride, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; alcohol, two hundred cubic centimeters (200 Cc.) [6 fl℥, 366 ♏]; water, eight hundred cubic centimeters (800 Cc.) [27 fl℥, 25 ♏]. Dissolve the sodium chloride in the water, add the alcohol, and macerate in this mixture the rennet (or the washed mucous membrane of the fresh stomach of a suckling calf), during 3 days, under frequent agitation, then filter. *Note.*—If this liquid is to be used merely for curdling the milk, without separating the whey as a distinct layer, it should be added to the milk, previously warmed to a temperature of about 35° C. (95° F.), and the mixture should then be set aside undisturbed, until it coagulates. If the whey is to be separated, the liquid rennet should be added to the milk while cold, and the mixture heated to about 35° C. (95° F.), but not exceeding 40° C. (104° F.) One part of the liquid should coagulate between 200 and 300 parts of cow's milk"—(*Nat. Form.*).

Ingluvin.—This is the essential digestive principle of the domestic chicken, introduced to physicians by Wm. R. Warner & Co., of Philadelphia and New York. It is said to depend upon a bitter principle for its therapeutic effects. Ingluvin has, for a number of years, been sucessfully used as a gastric tonic and digestant, in *indigestion* and *flatulent dyspepsia*, and is one of the few agents which have been found most successful in controlling the *vomiting of pregnancy*. It has superseded pepsin, to some extent, in the treatment of *indigestion*. Dose, 5 to 20 grains.

Ananassa sativa, Schult.; *Pineapple.*—This well-known fruit has been proven an active digestant of albuminous material (Marcano, Chittenden). Its active ferment, to which the name *bromelin* (from *Bromelia*, the name given the plant by Linné), is said to resemble trypsin more nearly than it does pepsin. Fresh pineapple juice is a quick digestant, acting best in neutral solution, though still active in acid or alkaline media. Between 50° and 60° C. (122° and 140° F.), it shows greatest digestive power, and at 70° C. (158° F.), its effects are arrested. It has been considerably employed in *gastric debility*, and to dissolve the *diphtheritic membrane*.

PETROLATUM.—PETROLATUM.

Source and History.—Three varieties of petrolatum are now official, as follows:

I. Petrolatum Liquidum (*U. S. P.*), *Liquid petrolatum.*—"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue when it has the desired consistence"—(*U. S. P.*).

II. Petrolatum Molle (*U. S. P.*), *Soft petrolatum* (*Petrolatum, Pharm.*, 1880), *Soft petroleum ointment.*—"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue when it has the desired melting point. When petrolatum is prescribed or ordered without further specification, soft petrolatum (*Petrolatum Molle*) is to be dispensed"—(*U. S. P.*).

III. Petrolatum Spissum (*U. S. P.*), *Hard petrolatum* (*Petrolatum, Pharm.*, 1880), *Hard petroleum ointment.*—"A mixture of hydrocarbons, chiefly of the marsh-gas series, obtained by distilling off the lighter and more volatile portions from petroleum and purifying the residue when it has the desired melting point"—(*U. S. P.*).

These forms of petrolatum are obtained by distilling off the more volatile, lighter portions from petroleum, either in a vacuum or by means of superheated steam. The residual oil is termed *reduced oils*, and is purified by passing it through long columns of granular, well-dried animal charcoal while being warmed to from 40° to 55° C. (104° to 131° F.). At first a colorless portion passes, subsequently followed by colored products. Or, petrolatum may be obtained from deposits sometimes formed in crude petroleum. Commercial varieties of petrolatum are known as *vaseline*, *cosmoline*, etc. (For a detailed account of the manner of obtaining petrolatum, see S. P. Sadtler's *Handbook of Indust. Org. Chem.*, 2d ed., 1895.)

Description and Tests.—I. Petrolatum Liquidum (*U. S. P.*), *Liquid petrolatum* (*Liquid paraffin, Ger. Pharm.*): "A colorless or more or less yellowish, oily, transparent liquid, without odor or taste, or giving off when heated, a faint odor of petroleum. Specific gravity, about 0.875 to 0.945 at 15° C. (59° F.). Insoluble in water, scarcely soluble in cold or hot alcohol, or in cold absolute alcohol; but soluble in boiling absolute alcohol, and readily soluble in ether, chloroform, carbon disulphide, oil of turpentine, benzin, benzol, and fixed or volatile oils. When heated on platinum, liquid petrolatum is completely volatilized, without emitting any acrid vapors. The alcoholic solution of liquid petrolatum is neutral to litmus paper. If 5 Gm. of liquid petrolatum be digested, for half an hour with 5 Gm. of sodium hydrate and 25 Cc. of water, the aqueous layer separated, and supersaturated with sulphuric acid, no oily substance should separate (absence of fixed oils or fats of animal or vegetable origin, or of resin). If 2 volumes of concentrated sulphuric acid be added to 1 volume of liquid petrolatum, in a test-tube, placed in hot water, and the contents occasionally agitated during 15 minutes, the acid should not acquire a deeper tint than brown, nor lose its transparency (limit of readily carbonizable, organic impurities)"—(*U. S. P.*). Mr. G. M. Beringer (*Amer. Jour. Pharm.*, 1894, p 15) points out that liquid petrolatum is nearly insoluble in castor oil. The analogous preparation of the *British Pharmacopœia* (1898) is *Paraffinum Liquidum*, a non-fluorescent liquid of specific gravity 0.885 to 0.890, boiling at a temperature not below 360° C. (680° F.). "A mixture of 4 Cc. with 2 Cc. of absolute alcohol, and 2 drops of a clear saturated solution of lead oxide in solution of sodium hydroxide, should remain colorless when kept at 70° C. (158° F.) for 10 minutes (absence of sulphur compounds)"—(*Br. Pharm.*, 1898).

II. PETROLATUM MOLLE (*U. S. P.*), *Soft petrolatum* (*Petrolatum, U. S. P.*, 1880), *Soft petroleum ointment*, *Adeps petrolei*, *Paraffinum unguinosum*, *Paraffinum molle*, *Soft paraffin*, *Paraffin jelly*.—"A fat-like mass, of about the consistence of an ointment, varying from white to yellowish, or yellow, more or less fluorescent when yellow, especially after being melted, transparent in thin layers, completely amorphous, and without odor or taste, or giving off, when heated, a faint odor of petroleum. If a portion of soft petrolatum be liquefied and brought to a temperature of 60° C. (140° F.), it will have a specific gravity of about 0.820 to 0.840. The melting point of soft petrolatum ranges between about 40° and 45° C. (104° and 113° F.). In other respects soft petrolatum has the characteristics of, and should respond to the tests given under liquid petrolatum (see *Petrolatum Liquidum*)"—(*U. S. P.*). None of nine samples of commercial Petrolatum Molle analyzed by Mr. L. F. Kebler (*Amer. Jour. Pharm.*, 1895, p. 142), contained any saponifiable matter, while the melting points conformed more nearly to the requirements of the *U. S. P.* (1880) (40° to 51° C. or 104° to 125° F.) than to those of the present Pharmacopœia. *Paraffinum Molle* of the *British Pharmacopœia* (1898), melts at 35.5° to 38.9° C. (96° to 102° F.), and has a specific gravity of 0.840 to 0.870 at the melting-point.

III. PETROLATUM SPISSUM (*U. S. P.*), *Hard petrolatum* (*Petrolatum*, (*U. S. P.*, 1880), *Hard petroleum ointment*.—"A fat-like mass, of about the consistence of a cerate, varying from white to yellowish or yellow, more or less fluorescent when yellow, especially after being melted, transparent, in thin layers, completely amorphous, and without odor or taste, or giving off, when heated, a faint odor of petroleum. If a portion of hard petrolatum be liquefied, and brought to a temperature of 60° C. (142° F.), it will have a specific gravity of about 0.820 to 0.850. The melting point of hard petrolatum ranges between about 45° and 51° C. (113° and 125° F.). In other respects hard petrolatum has the characteristics of, and should respond to the tests given under liquid petrolatum (see *Petrolatum Liquidum*)"—(*U. S. P.*). (For the *Paraffinum Durum* of the *British Pharmacopœia*, 1898, see *Paraffin*, under *Petroleum*.)

Action, Medical Uses, and Dosage.—Petrolatum is employed chiefly as a non-irritating ointment base, for which it is admirably adapted. It does not turn rancid like fats. It may be employed wherever an oily protective is demanded, and also for lubricating purposes. A semisolid, crude form, known as "*rod wax*," that which concretes on the casings of the oil wells, has been administered in 3 grain pills, in *chronic bronchial affections* and in *phthisis*. Vaseline, cosmoline, etc., are slightly laxative, and are said to allay gastro-intestinal irritation, and even inflammation. Used with a spray apparatus, liquid petrolatum is employed locally to allay *inflammatory conditions of the nasal*, *pharyngeal*, *laryngeal*, and *bronchial mucous surfaces*. Soft petrolatum is an excellent agent to prevent *falling of the hair*, and for that dry condition of the scalp which allows the formation of *dandruff*. For this purpose it is not sufficient that it be merely applied to the hair as a pomade, but it should be rubbed in upon the scalp, at the roots of the hair, taking small areas that it may be well applied. It should be used about once a week.

PETROLEUM.—PETROLEUM.

A bituminous, combustible fluid issuing from the earth.

SYNONYMS: *Oleum petræ*, *Rock oil*, *Naphtha*.

History and Source.—This fluid now so universally used, has come into prominence only since the boring of the first oil well in the Pennsylvania oil fields, at Titusville, in 1859, although oil had previously been observed in the United States to exude with salt springs. Bituminous exudations from the earth have been known, moreover, from early historical times. Pliny and Dioscorides report on the use of petroleum in certain parts of Sicily for lighting purposes. It occurs in the earth in all strata, from the lower silurian to the tertiary period, in limestone and sandstone formations, mostly collected in large subterranean cavities. When freshly struck, the oil sometimes gushes forth to a considerable height. American oil fields are those in western Pennsylvania and New York (Seneca Lake); in Ohio, near Lima; in West Virginia, Kentucky, Tennessee, and California, and the Canadian province of Ontario, near Euniskillen. The Russian petroleum district of Baku, on the Caspian Sea, began to be exploited in 1866, and now ranks second in importance to the Pennsylvania fields. Petroleum is also obtained in large quantities in Galicia, and is found in Hannover, Alsatia, in Italy, Persia, Java, Burmah (Rangoon), Japan. and the West Indies.

The geological origin of petroleum is not known with certainty. Some claim that it is formed by the dry distillation of beds of coal, which is disputed by others. Advocates of the chemical theory believe it to be formed by chemical processes, *e. g.*, the interaction of water and iron carbide at a white heat (Mendelejeff), while others assume it to be formed by the decomposition of organic bodies. Thus C. Engler, in 1888 and 1889, showed that by destructive distillation of fish-oils under pressure, a distillate is formed possessing all the qualities of petroleum; accordingly, he believes that petroleum is formed under similar conditions from huge fish-like animals. This theory should be enlarged so as to include the possible formation of petroleum from vegetable oils. Prof. S. P. Sadtler (*Amer. Jour. Pharm.*, 1896, p. 466) observed in the destructive distillation of linseed oil some 40 per cent of a neutral hydrocarbon oil of greenish fluorescence, from which paraffin oil and paraffin could be isolated. Prof. Edward Orton (*Pharm. Jour. Trans.*,Vol. XXII, 1891–92, p. 1066) believes the Lima and California oils, which contain nitrogen and sulphur, to be of animal, the Pennsylvania oil of vegetable origin, *i. e.*, indirectly derived from the resinous spores of marine vegetations. Quite recently, G. Kraemer (*Chemiker Zeitung*, No. 80, 1899, p. 843) shows the formation of petroleum and paraffin by the vegetative action of diatoms. Petroleum is now extensively used in the manufacture of illuminating and lubricating oils and paraffin.

Description and Chemical Composition.—Crude petroleum is an oily liquid varying from the thinness of water to the consistency of butter, and has all shades of color from light to dark-red and black. It often has a blue fluorescence. The specific gravity of the oil varies from 0.78 to 0.91. The Russian and German oils have a higher specific gravity than the Pennsylvania oil. The American petroleum is also chemically different from the Russian oil. It consists chiefly of hydrocarbons of the paraffin series ($C_nH_{2n}+_2$), which vary from the gaseous methane (CH_4), to the solid paraffin ($C_{30}H_{62}$). Besides, hydrocarbons of the unsaturated series (olefines, C_nH_{2n}) are present. Petroleum, when exposed to the air, loses its volatile constituents; the residue, by partial oxidation, thickens, and is converted into *asphaltum* (see below). The oil obtained near Lima, Ohio, has a peculiar unpleasant smell, and contains sulphur compounds, on account of which special methods for purification are required. The Russian petroleum contains 10 per cent of benzol hydrocarbons and 90 per cent of peculiar hydrocarbons (C_nH_{2n}) called *naphtenes* (Markownikoff). (See detailed paper on these naphtenes by Dr. R. Wischin, Baku, in *Chemiker Zeitung*, 1899, pp. 916–926.)

Action, Medical Uses, and Dosage.—Petroleum, or rock oil, is not an active poison, unless it contains sulphur, which is the case with crude petroleum from Canada and Lima, Ohio. Even with children, the fatal dose must be very large. death being due to its secondary gastro-intestinal effects, rather than to any results of absorption of the hydrocarbons (Taylor, *Med. Jurisp.*). The toxic effects are vomiting, dizziness, a sense of fullness, pain and constriction in the head, thirst, burning in fauces and stomach, cardiac palpitation, faintness, pallor and coldness of surface, cold sweats, weak pulse and symptoms of collapse, occasionally followed by somnolence. Sometimes tetanic convulsions take place, and, as a rule, diarrhœa does not occur. Often vomiting does not ensue. The vapor of the various products included under the name petroleum intoxicate, and various cases of intoxication have lately been recorded from the intentional inhalation of gasoline. The local application of coal oil must be guarded, for, if air be excluded extensive and dangerous blistering and ulceration may result (Felter, *Ec. Med. Jour.*, 1897, p. 110).

Therapeutically, petroleum appears to possess stimulating properties, and has been recommended as a remedy in various diseases. It is decidedly antiseptic, and somewhat antispasmodic, expectorant, and diuretic. A mixture, composed of 16 drops of petroleum and 24 drops of tincture of asafœtida, to be taken at 1 dose, and repeated 3 times a day, has been advised in the treatment of *tapeworm*. Petroleum has also been recommended in various *diseases of the lungs and air-tubes*, when not accompanied with inflammatory symptoms. Internally, it has been advised in *bronchitis*, and in other conditions attended with increased secretion of mucus. For internal use, the crude oil is preferred to the purified, and has been used for the relief of *whooping-cough* and *croup*. Its dose is from 10 to 30 drops, in wine, milk, syrup, etc. Externally, it has been employed as a stimulating embrocation in *lepra*, *psoriasis*, and other *scaly diseases of the skin*, *atonic chronic rheumatism*, *chilblains*, *sprains*, *synovitis*, *tumors*, *burns*, *stiffness and contraction of the joints*, *local paralysis*, etc. It is asserted to dissolve the *diphtheritic membrane*. It destroys the *itch insect* and *pediculi*.

British oil is composed of 4 fluid ounces, each, of oil of turpentine and oil of linseed; 2 fluid ounces, each, of oil of amber and oil of juniper; 1½ fluid ounces of Barbadoes petroleum, and ½ fluid ounce of American petroleum or Seneca oil.

Coal oil (*Kerosene*, see *Derivatives*, below) is reputed to drive away crickets, cockroaches, bedbugs, rats, mice, etc., if sprinkled around their haunts. It is considerably used as a popular local remedy for *piles*, *itch*, *rheumatism*, *painful affections*, *sprains*, etc., and has been recommended internally in several diseases.

Mecca oil, a mineral oil from a place named Mecca, Ohio, is said to be useful in *bronchial*, *laryngeal*, and *pulmonary affections*, and was formerly sold at most extravagant prices for such purpose. The dose varies from 5 to 30 drops, repeated 2 or 3 times a day.

Dr. Andreosky asserts to have used *petroleum naphtha*, in doses of 10 to 20 drops, in 2 or 3 fluid ounces of wine or mint-water, with benefit in *Asiatic cholera*.

Derivatives of Petroleum.—Crude petroleum, by rectification, is differentiated into several constituents of commercial importance. The most valuable constituent is the burning oil fraction, which formerly, in American oil, amounted to from 35 to 55 per cent, while from 20 to 30 per cent of lubricating oil was obtained. By means of a peculiar process, whereby the vapors are allowed to become superheated (*cracking*), the yield of burning oil is increased at the expense of the lubricating fraction. Thus the yield is now 75 to 80 per cent of the former and about 6 per cent of the latter (Prof. S. P. Sadtler, *Handbook of Indust. Org. Chem.*, 2d ed., 1895, p. 19). The principal fractions of the crude oil are the *benzine distillate*, *burning oil distillate*, and *residuum*; the latter is redistilled in so-called tar-stills, and yields *block paraffin*, *lubricating oil*, yellow wax and coke. In Baku, distillation is continuous, and is not carried to coking; the residual mass is used in the same process as fuel.

Benzine Distillate amounts to 12 per cent of the crude oil, and is separated into a great number of commercially important fractions—*e. g.*, (1) *Cymogene*, boiling at 0° C. (32° F.), hence a gas at ordinary temperature. It is used in the making of artificial ice. (2) *Rhigolene*, boiling at 18.3° C. (65° F.), hence an exceedingly volatile and inflammable liquid, having a specific gravity of 0.60. As it reduces the temperature to −28.3° C. (−19° F.), by evaporation, it is recommended in the form of a spray by Dr. H. J. Bigelow (*Amer. Jour. Pharm.* 1866, p. 363), as a substitute for ether as a local freezing anæsthetic. It has not come into general use. (3) *Petroleum ether* (*Sherwood oil*), boiling from 40° to 70° C. (104° to 158° F.). It is used as a solvent, especially for caoutchouc and fats, and to propel gas motors. (4) *Gasoline* (*canadol*), boiling from 70° to 90° C. (158° to 194° F.). It is used as a solvent for oil from seeds, and was suggested as an effective and cheap agent to free the cutaneous surfaces and subjacent tissues. (5) *Petroleum naphtha* boils from 80° to 110° C. (176° to 230° F.), and has a specific gravity of 0.69 to 0.70. It dissolves wax, caoutchouc, oils, pitch, etc., and is used in the manufacture of oil-cloth and of varnishes. (6) *Ligroine* boils from 80° to 120° C. (176° to 248° F.), has a specific gravity of 0.71 to 0.73, and is chiefly used as a solvent

Burning Oil Fraction (*Kerosene, Coal oil*).—The commercial illuminating and burning oils occur under varied and often fanciful names. They are distinguished mainly by their color and their fire test. In order to remove color and empyreumatic odor from the crude fractions, they must be purified by shaking with 1½ to 2 per cent of sulphuric acid, washing with water and with solution of caustic soda. The most important test for burning oils is that which ascertains the degree of safety in burning; it is known as the fire-test, and includes the determination of the *flashing point* and the *burning point* of the oil. The flashing point is that temperature at which the oil gives off vapors which, when mixed with air, will explode in the presence of an open light—*e. g.*, a spark—yet without igniting the oil; at a somewhat higher temperature—the burning point—the oil will be ignited by the explosion. Many methods have been devised to determine the flashing point of petroleum with greatest possible accuracy, for which see details in Prof. S. P. Sadtler's *Handbook of Indust. Org. Chem.*, 2d ed., 1895, p. 34. The official apparatus used in England and Germany is that devised by Sir Frederick Abel, and the operation is known as the Abel test; in this a closed oil-cup is used. In the United States, a modified, open-cup test is used; this gives results somewhat too high as compared with the other test. It is stated that the oils going to the continent of Europe, to China and Japan, have a flashing point of 43.3° C. (110° F.); the "head-light," used in America, a flashing point of 65.5° C. (150° F.). It is a matter of regret that the official standard in Germany and England and other countries is as low as 21° C. (69.8° F. by the Abel test. In this connection, see an exceedingly interesting article on the flashing point of petroleum, by Lobry de Bruyn, in *Chemiker Zeitung*, 1896, pp. 251–265 and 623–626, wherein it is earnestly advocated to raise the official flashing point to 40° C. (104° F.) by the Abel test.

Paraffin is a solid mixture of hydrocarbons of the paraffin series (C_nH_{2n-2}), occurring chiefly in crude petroleum, especially the thick variety, from which it is often deposited upon standing. It was discovered, in 1830, by Reichenbach in the tar resulting from the destructive distillation of beech wood; it is also formed by the dry distillation of peat, bituminous shales, and coals—*e. g.*, cannel coal, boghead coal—and occurs in nature in the form of the "minerals" *ozokerite* or *earth wax*, in Galizia, and *neft-gil*, in Persia; of the former it constitutes about 50 per cent, and, when obtained from it, resembles wax, and is called *ceresine*. Paraffin also occurs native in Utah and Texas. On a commercial scale, it is obtained either from petroleum, by fractionally distilling the burning oil residue in tar stills, purifying the distillate, and separating the solid paraffin from the liquid paraffin oil by chilling and pressing, or, as is done in Germany and in Scotland, by the dry distillation of bituminous shales at low temperatures, whereby benzene, naphtha (*photogene*), and burning oil (*solar oil*) are likewise obtained (see details in Prof. Sadtler's *Handbook*, 2d ed., pp. 21, 25, and 27). The preparation of petrolatum (*U. S. P.*), from petroleum, is considered under *Petrolatum*.

Paraffin is a white, microcrystalline mass, resembling wax or spermaceti, inodorous and tasteless, and slightly greasy to the touch. The melting point of paraffin varies considerably, according to its origin. The *Br. Pharm.* (1898) demands for *Paraffinum Durum* (*Hard paraffin*) a melting point of 54.4° to 57.2° C. (130° to 135° F.), while the *Ger. Pharm.* (1890) requires for *Paraffinum Solidum* the unusually high melting point of 74° to 80° C. (165.2° to 176° F.). Paraffin varies in specific gravity from 0.82 to 0.94 (*Br. Pharm.*). It is insoluble in water, slightly soluble in absolute alcohol, almost entirely soluble in ether. It is also soluble in oil of turpentine, ether, benzol, and hot olive oil; does not dissolve camphor, naphtalin, or pitch, when fused with them, but may be readily mixed with stearin, spermaceti, beeswax, and common resin. Lard and suet separate from it on cooling. Sulphide of carbon dissolves its weight of paraffin, and chloroform about one-fifth its weight. It is a good insulator of electricity. When ignited, it burns with a bright flame, leaving no residue. When heated to temperatures above 300° C. (572° F.), it may be distilled without being decomposed. The *Ger. Pharm.* directs that, if 3 Gm. of paraffin be heated, on the water-bath, with 3 Cc. of concentrated sulphuric acid for 10 minutes, with repeated shaking, the acid should but slightly turn brown, and the paraffin should not be altered. One part of alcohol, boiled with 1 part of paraffin, should not redden blue litmus paper. Paraffin is indifferent toward acids and alkalies at ordinary temperatures, hence its name, from *parum affinis*, meaning of little affinity. Bromine, however, readily evolves hydrobromic acid upon warming with paraffin, chlorine also acts upon this substance at a higher temperature. Paraffin is used in the manufacture of paraffin candles and Swedish matches; in the manufacture of sugar, to prevent the syrup from foaming and boiling over, to produce gloss on paper and fabrics, to prevent surfaces of vessels from being attacked by corrosive liquids, and for many other purposes.

Asphaltum, *Asphalt*, also known as *Mineral pitch*, *Pitch of Judea*, is a bituminous product, resulting from petroleum by evaporation of the lighter hydrocarbons and partial oxidation of the residue. In liquid form (*maltha*) it is found in Alsatia, in California, Utah, Kentucky, Tennessee, and Texas. Solid asphalt is chiefly obtained from the asphalt lake of Trinidad, in the West Indies, which supplies most of the asphalt used in the United States, and from Venezuela, South America (Bermudez asphalt). Other deposits of solid asphalt are in Cuba, Switzerland, Hannover, and the Dead Sea in Palestine. Asphalt has the appearance of pitch, and is brownish-black in color. Its bituminous part is insoluble in acids, alkalies, water, and alcohol, and soluble in fatty oils, oil of turpentine, petroleum, carbon disulphide, chloroform, acetone, and ether. The total quantity of bitumen is determined by extraction with carbon disulphide. That part of the extracted bitumen, soluble in petroleum naphtha, called [illegible], is tough and elastic, and, for paving purposes, is the only valuable part; the rest is brittle *asphaltene*. Trinidad asphalt contains about 39.8 per cent of bitumen, and 34 per cent of mineral matter, while Bermudez asphalt contains over 90 per cent of bitumen and only 2.6 per cent of mineral matters (S. P. Sadtler, *loc. cit.*, p. 17). For paving purposes, asphalt is mixed with limestone and sand. This addition prevents the mass from being inflammable, and, when properly prepared, permits expansion and contraction, in hot or cold weather, without cracking. Asphalt is also used in the making of varnishes.

PETROSELINUM.—PARSLEY.

The root of *Petroselinum sativum*, Hoffmann (*Apium Petroselinum*, Linné).

Nat. Ord.—Umbelliferæ.

COMMON NAME: *Parsely, Common parsley.*

Botanical Source.—Parsley is a biennial plant with a fleshy, spindle-shaped root, and a round, striated, erect, smooth, branching stem. The radical leaves are biternate, bright-green, and borne on long, channeled petioles; the leaflets are rhomboidal-ovate, wedge-shaped at the base, deeply incised, the segments mucronate and sometimes rounded. The upper leaves gradually become more entire and narrower, till the uppermost are simply ternate with linear segments. Umbels terminal and axillary, pedunculated, with 5 to 8 rays. General involucre none, or 1 or 2 subulate, minute bracts; partial involucre with 6 or 8 setaceous bracts, much shorter than the pedicels, erect, forming a perfect whorl. The flowers are white or greenish; the petals rounded, incurved, and scarcely emarginate; the calyx with the limb obsolete; the disk short, conical, and somewhat crenulate; the styles diverging. The fruit is ovate, about a line long, compressed, pale greenish-brown, the back occupied by three elevated, pale primary ridges, the two others quite on the margin at the side. The stamens are longer than the corolla (L.).

History.—Parsley is a European plant, and was known as early as the first century. It is now cultivated in nearly all moderate climates as a culinary vegetable. The plant has a grateful aroma. The seeds, herb, and root, are the medicinal parts; the root has rather an agreeable odor, and a saccharine, slightly spicy taste, and should be used while fresh. The root and herb contain small quantities of a volatile oil; larger quantities are contained in the seeds.

Chemical Composition.—The root, besides sugar, starch, mucilage, and 0.08 per cent of essential oil, contains a peculiar body, named by Braconnot (1843) *apiin*. The essential oil from the root has a specific gravity of 1.049, and upon standing, deposits crystals, probably of *apiol* (see below). Parsley seeds contain fatty oil (about 22 per cent, Rump, 1836), volatile oil containing the well-defined crystallizable body *apiol*, tannin, gelatinous *apiin* (of Braconnot), and an oily substance *apiol* (Joret and Homolle, *Jour. Pharm. Chim.*, 1855, p. 212). Parsley seeds yield, upon distillation with water about 2.8 per cent (4.27 per cent, H. C. Whitney, 1880) of an essential oil (*oil of parsley*), part of which is heavier than water. Crystals of *apiol* (formerly called *parsley camphor*) are formed by exposing the oil to a low temperature. Some oils are semisolid, owing to the presence of large quantities of apiol. *Apiol* ($C_{12}H_{14}O_4$) melts at 30° C. (86° F.), and boils at 294° C. (561.2° F.), hence is not easily volatilized with the vapors of boiling water. It has the characteristic taste, but only a faint odor of parsley. Its chemical composition was cleared up, by Ciamician and Silber (1888 and 1890). It is soluble in alcohol and ether; almost insoluble in water. Oil of parsley also contains *lævopinene* (v. Gerichten, 1876).

APIOL, of Joret and Homolle, is an oily liquid which has the odor and taste of parsley; it is not miscible with water, has a specific gravity of 1.078, and was introduced as a febrifuge capable of supplanting quinine. It is probably not a uniform body, and is prepared by abstracting an alcoholic extract of the seeds, with chloroform or ether, removing fat by triturating the evaporated residue with lead oxide, and after 48 hours filtering through charcoal. The oil thus obtained is probably identical with the heavy part of the volatile oil from the seeds. Also see paper on this subject by H. C. Whitney (*New Remedies*, 1880, p. 7).

APIIN may be isolated from the seeds by extracting them with alcohol and removing apiol from the alcoholic extract by means of ether. The residue is purified by repeated solution in alcohol and precipitation with water. Similarly, apiin may be obtained from the herb, wherein it was first discovered. It is a white, tasteless, microcrystalline powder, soluble in warm alcohol and boiling water. Upon cooling it falls out, forming a jelly in as dilute a solution as 1 in

1500. It is soluble in alkalies, and is precipitated therefrom by acids. Aqueous solutions of apiin produce a deep blood-red coloration with ferric chloride (Braconnot). It is a glucosid, and is decomposed by the action of diluted acids into dextrose and *apigenin* (Lindenborn, 1867; v. Gerichten, 1876).

Action, Medical Uses, and Dosage.—Parsley. Diuretic, relieving urinary irritation. Very useful in *dropsy*, especially that following *scarlatina*, and other *exanthematous diseases*. Also used in *retention of urine*, *strangury*, and *gonorrhœa*. Parsley seeds have a powerful odor, somewhat like that of turpentine, and a spicy, pungent taste, and have been used as a carminative, and for the same purpose as the root—they are said to be very poisonous to the parrot. The seeds as well as the leaves, sprinkled on the hair, in powder, or in the form of an ointment, will effectually destroy vermin; the leaves, applied as a fomentation, will, it is asserted, cure the *bites* or *stings of insects*. The leaves, bruised, are a good application to *contusions*, *swelled breasts*, and *enlarged glands*—reputed to "dry up the milk" of wet-nurses. The oil is efficient as a diuretic, in doses of 3 or 4 drops a day; dose of the infusion, 2 to 4 fluid ounces, 3 or 4 times a day.

Apiol.—In doses of from 7 to 15 grains apiol occasions a cerebral excitement similar to that caused by coffee, a sensation of vigor and composure, and warmth about the stomach; in doses of from 30 to 60 grains it causes intoxication, giddiness, flashes of light, vertigo and ringing in the ears, etc. It is highly recommended as a substitute for quinine in *intermittent fevers*, and has proved very efficient. It has likewise been found valuable in *menstrual derangements*; as *fetid menstruation*, *neuralgic dysmenorrhœa*, *neuralgic uterine colic*, *amenorrhœa*, etc.; also in the *night-sweats of consumption*. The dose is 3 to 6 grains, several times a day, beginning a couple of days prior to menstruation, given in gelatin capsules, or formed into pills with medicinal amygdalin soap, and magnesia, gum, or yellow of egg.

Related Species.—*Apium graveolens*, Linné; *Celery*. This well-known garden plant is indigenous to European countries, where it is found growing wild in meadows and ditches. The fruit is used under the name *fructus apii* or *celery-seed*. The leaves and root contain mannit; the whole plant contains mucilage, fat, sugar, and essential oil. The latter has the characteristic odor of celery, a specific gravity of 0.870 to 0.895, and contains 90 per cent of hydrocarbons, among these *dextro-limonene* but no pinene. The odor of celery oil is due to *sedanolid* ($C_{12}H_{18}O_2$), and the *anhydride of sedanonic acid* ($C_{12}H_{16}O_2$) (Ciamician and Silber, 1897). Both substances are volatilized with difficulty, and the greater part of them may often be obtained from the residue of distillation (see Gildemeister and Hoffmann, *Die Ätherischen Öle*, 1899, p. 713). An infusion of the roots or herbs has been employed for *rheumatic complaints*, *chronic bronchial affections* and in *intermittents*. The seeds and plant are reputed nerve tonics, and are used for about the same purposes as parsley. The seeds enter into the formation of many medicines intended as nerve tonics. Locally, the infusion or the bruised plants have been employed as a stimulant, anodyne poultice.

Conioselinum canadense (*Selinum canadense*, B. and H.). Wet woods of northern United States. Used, under the name *Hemlock parsley*, in *dysentery*.

PHELLANDRIUM.—WATER FENNEL.

The fruit of *Œnanthe Phellandrium*, Lamarck (*Phellandrium aquaticum*, Linne). *Nat. Ord.*—Umbelliferæ.

Common Names: *Water fennel*, *Fine-leaved water hemlock*, *Water dropwort*.

Botanical Source.—This plant is a biennial or perennial, umbelliferous herb, having a thick, spindle-shaped root, with many whorled fibers. The stem is hollow, furrowed, half immersed in the water, very bushy, with numerous spreading, leafy branches, and from 2 to 4 feet in height. The leaves are petioled, spreading, repeatedly pinnate, cut, with innumerable fine, expanded, dark-green, shining, acute segments. The umbels are opposite to the leaves, on shortish stalks, about 5-rayed, without any general bracts. Partial umbels are very dense, of numerous short rays, accompanied by many narrow, taper-pointed bracts. The flowers are white, numerous, all fertile, outer ones largest and most irregular; innermost more certainly prolific. Styles long, filiform, spreading, and capitate. Fruit ovate, rather compressed, purplish, smooth, oblong, crowned with the minute spreading calyx, and rather short, permanent, slightly spreading styles; the dorsal ridges distinct, but little elevated, the lateral ones much broader and thicker; all confluent below the calyx. The pedicels are shorter than the fruit (L.).

History and Description.—This plant is common to Europe, growing in ditches and wet places, and its leaves are reputed harmful to cattle, causing a species of palsy after eating it. It is poisonous, but not so dangerously so as the *Œnanthe Crocata* (*Dead-tongue*, or *Hemlock dropwort; see Related Species*), which is considered the most energetic poison of the narcotico-acrid Umbelliferæ. By desiccation, they lose much of their poisonous properties. The *Œ. Phellandrium* is occasionally found in this country. The seeds are the parts used. They are about $\frac{1}{12}$ inch long, of a yellowish-green color, elliptical, slightly curved, flat on one side and gibbous on the other, striated with 10 filiform ribs, and terminate in small, 5-toothed heads, the remains of the calyx and styles. They have a peculiar, strong odor, somewhat resembling *angelica*, and an acrid, spicy taste, owing to a volatile oil, which they contain in abundance.

Chemical Composition.—The seeds contain about 1.5 per cent of volatile oil and 19.5 per cent of fatty oil. Indications of an alkaloid have been variously observed (see Flückiger, *Pharmacognosie*, 3d ed., 1891, p. 953). It is probably the poisonous *phellandrin* of earlier chemists. The volatile oil has a penetrating, aromatic odor, a specific gravity of about 0.87, and contains 80 per cent of the terpene hydrocarbon *phellandrene*. It was discovered by Pesci (1883) in the seeds of this plant, from which it was named. It is present as *dextro-phellandrene*, which also occurs in other oils, while *lævo-phellandrene* is the chief constituent of certain Eucalyptus and other oils—*e. g.*, *Eucalyptus amygdalina*. Phellandrene forms a characteristic nitrite, melting at 103° C. (217.4° F.). It is an unstable terpene, capable of polymerization into solid *diphellandrene*, or of being converted into the optically inactive isomer, *dipentene*.

Action, Medical Uses, and Dosage.—Water fennel is a mild narcotic stimulant, expectorant, alterative, and diuretic. In large doses, it produces dizziness, inebriation, and dull pains in the head. The seeds have been most successfully used in chronic affections of the air-passages, as *laryngitis*, *asthma*, *hemoptysis*, *catarrh*, etc.; also in *periodical febrile diseases*, *dyspeptic affections*, and in *indolent ulcerations*. They are given in powder, commencing with 4 or 5 grains, every 1 or 2 hours throughout the day, cautiously increasing the dose to 8 or 10 grains. Two parts each of powdered gum Arabic and sugar of milk may be mixed with 1 part of the powdered seeds, and divided into doses of 25 grains each, which may be repeated every 2 or 3 hours. Dr. Turnbull, of Liverpool, used the following tincture and extract: Take of well-bruised seeds of phellandrium, 16 ounces; alcohol, a sufficient quantity to displace by percolation 32 fluid ounces. The dose is from $\frac{1}{2}$ to 1 fluid drachm. For the alcoholic extract, take of the seeds of phellandrium, bruised, 16 ounces; alcohol, 3 parts; displace by percolation, distill off $2\frac{1}{2}$ pints of alcohol, and evaporate the remainder to the consistence of an extract. The dose is from 3 to 5 grains, in pill. He recommended it highly in *consumption* and *bronchitis*, to relieve troublesome cough, render expectoration less and easier, and produce sleep at night. He believed the above preparations to contain all the beneficial properties of the seeds, and to act with more certainty and power.

Related Species.—*Œnanthe Crocata*, Linné (*Œnanthe apiifolia*), *Nat. Ord.*—Umbelliferæ; *Water hemlock*, *Water lovage*, *Water dropwort*, *Hemlock dropwort*, *Dead-tongue*. Indigenous to England, France, Spain, and Sweden, thriving in swamps and moist situations. The root of this species is medicinal. This is an exceedingly poisonous plant. The active poisonous principle is a resinous matter, soluble in ether and alcohol, insoluble in water. An alkaloid could not be isolated (A. Vincent, *Jour. Pharm. Chim.*, 1864, p. 140; also see microscopical investigation by H. W. Jones, *Pharm. Jour. Trans.*, Vol. XVI, 1885, p. 357). The plant produces severe gastro-intestinal disturbances and convulsions. A number of cases of poisoning, some fatal, are recorded in Hale's *New Remedies—Therapeutics*. Small doses of the tincture have been advised in *epilepsy* by several writers in the *Eclectic Medical Journal*, *Eclectic Medical Gleaner*, and other journals. Doses of even 5 drops sometimes produce violent headache and other unpleasant symptoms, in which case the dose will have to be lessened.

PHENACETINUM.—PHENACETIN.

FORMULA: $C_6H_4.OC_2H_5.NHC_2H_3O$. MOLECULAR WEIGHT: 178.63.

SYNONYMS: *Para-acetphenetidin*, *Para-ethoxy-acetanilid*, *Phenacetine*.

History and Preparation.—This compound was introduced to the profession by Kast and Hinsberg, in 1887. It is produced by a series of chemical processes, by which its molecule is gradually built up. The successive steps are as follows: Phenol (carbolic acid, $C_6H_5.OH$) is converted into para-nitro-phenol ($C_6H_4.OH.NO_2$) by means of nitric acid; of this compound the sodium salt ($C_6H_4.ONa.NO_2$) is prepared, and converted by double decomposition with ethyl-iodide (C_2H_5I) into para-nitro-phenetol ($C_6H_4.OC_2H_5.NO_2$), which yields, upon reduction of the nitro-group by means of nascent hydrogen, *para-amido-phenetol*, or *paraethoxy-aniline* ($C_6H_4.OC_2H_5.NH_2$). Upon boiling this compound with glacial acetic acid ($CH_3CO.OH$), the amido-group is acetylized, and phenacetin ($C_6H_4.OC_2H_5.NH.CH_3CO$) results.

Description and Tests.—Phenacetin consists of white, tasteless, inodorous, glistening, scaly crystals, neutral to litmus. It dissolves in boiling alcohol (1 in 2), cold alcohol (1 in 6), boiling water (1 in 70), and very sparingly in cold water (1 in 1400); melting point 135° C. (275° F.). When heated on platinum foil, it should volatilize without leaving a residue. It dissolves without color in sulphuric acid. When 0.1 Gm. of phenacetin is boiled with 2 Cc. of hydrochloric acid for half a minute, the liquid diluted with 20 Cc. of water, cooled and filtered, the filtrate assumes a deep-red coloration upon the addition of solution of chromic acid (*Br. Pharm.*, 1898). In this reaction, phenacetin is hydrolyzed into acetic acid and *para-phenetidin* ($C_6H_4.OC_2H_5.NH_2$), which yields red color-reactions with oxidizers. This test, slightly modified, is also official in the *German Pharmacopœia*. To establish the absence of para-phenetidin, the *British Pharmacopœia* gives the following test: "A mixture of 0.3 Gm. of phenacetin with 1 Cc. of alcohol (90 per cent), should not acquire a red tint when diluted with 3 times its volume of water, and boiled with 1 drop of volumetric solution of iodine (absence of para-phenetidin)"—(*Br. Pharm.*, 1898). The *German Pharmacopœia* tests for *acetanilid* as follows: Dissolve 0.1 Gm. of phenacetin in 10 Cc. of hot water, allow to cool, filter, and add to the filtrate bromine water, until the solution is yellow. The absence of turbidity, which would consist of para-brom-acetanilid, will indicate the absence of acetanilid. The latter is more readily soluble in water than phenacetin.

Action, Medical Uses, and Dosage.—Phenacetin is probably the best of the coal-tar products which have been introduced and so wonderfully multiplied in the last few years. However, while ordinarily safe in proper doses, in large amounts, and sometimes even with the regulation doses, it is capable of producing serious symptoms, if not death. Among the toxic symptoms are vomiting, chills, profuse sweating, quickened respiration, sleepiness, marked reduction of the temperature, and almost stoppage of the heart's action. Cyanosis is marked. After the internal administration of phenacetin, the urine contains a substance reducing Fehling's solution.

Therapeutically, it is analgesic, diaphoretic, and antipyretic. In *local congestions* and *inflammation*, it has a tendency to reduce the swelling in proportion as it controls the pain. The sweating produced is not as severe as that caused by antipyrin, nor is it so apt to produce the cutaneous eruptions and aural symptoms that sometimes follow the use of the latter and other antipyretics. It is of of some value in *fevers*, and gives comfort in, but does not in the least shorten the duration of *typhoid fever*. Here the smaller doses should be employed. In 2-grain doses, it controls the high-temperature of *phthisical patients*, without producing excessive diaphoresis. One of its most important uses with us is to produce that moistened condition of the skin and tongue necessary to render the patient capable of being benefited by the action of quinine. A dry skin and tongue and an irritable nervous system are, with us, contraindications for the latter drug. But in *malaria* and other disorders, in which quinine, when properly administered, does good service, phenacetin readily puts the patient in condition for the kindly reception of the antiperiodic. Its use, however, as a primary antipyretic is not favored by the Eclectic profession.

Phenacetin promptly controls *pain*, acting best when independent of structural change. It is adapted to either acute or chronic conditions. It is one of the popular remedies for *headaches*, particularly of the nervo-congestive and catarrhal forms. As an antirheumatic, its action in relieving pain is pronounced, and for the property of controlling muscular pain, it has been extensively employed in *la grippe*, *ague*, *tonsillitis*, and *febrile* and *inflammatory diseases*. It controls the pains of *dysmenorrhœa*, *articular rheumatism*, *neuralgia*, *pleurisy*, and *acute nephritis*, but should be used with care. *Muscular spasm* is relaxed by it, and it lessens the irritability of the congested larynx in *pertussis* and *laryngitis*, and is claimed of value in *hysteria*, *asthma*, and *epilepsy*, acting as an antispasmodic. As an antithermic, the dose is from 1 to 5 grains; as an analgesic, 3 to 20 grains, beginning always with the smaller dose. It may be given in powder upon the tongue, or floating upon water, or preferably, in capsules. If given in powder, in water, it should be first moistened with a few drops of some alcoholic fluid to prevent its adherence to the glass or spoon. Owing to its sparing solubility phenacetin is somewhat unmanageable (Murrell). Contraindicated by debility.

Specific Indications and Uses.—Sthenic conditions; severe muscular pain; pain from congestion; neuralgic pains; nervo-congestive or catarrhal headache; high temperature; preparator for quinine administration.

Related Compounds and Derivatives.—METHACETIN ($C_6H_4.OCH_3.NHC_2H_3O$), *Para-acetanisidin*, *Para-methoxy-acetanilid*. This compound is analogous to phenacetin, the ethyl group of the latter being replaced by the methyl group. Hence it is produced exactly in the same manner as phenacetin, excepting that methyl iodide (or chloride) is substituted for ethyl iodide (or chloride). It forms colorless or faintly reddish, odorless, lustrous scales, fusing at 127° C. (260.6° F.), and vaporizing unchanged at a greater heat. It dissolves readily in boiling water (1 in 12), but sparingly in cold water (1 in 526). Alcohol, chloroform, acetone, glycerin, and the fixed oils dissolve it readily. If heated with less water than is required to dissolve it, it melts to an oily liquid, which becomes solid again when cooled. This serves to distinguish it from phenacetin, which falls out in the form of crystals. Methacetin is reputed antipyretic, antiseptic, and analgesic. It is an unsafe remedy, however, for it powerfully reduces the temperature and pulse-rate in febrile conditions, frequently producing excessive sweating, cyanosis, and dangerous collapse. It has been employed in *phthisis*, *articular rheumatism*, *neuralgia*, and *typhoid fever*, with rather unfavorable results. It should never be given to debilitated individuals. The dose for one day is from 7 to 15 grains.

LACTOPHENIN is an antipyretic, analgesic, and antineuralgic agent, the specialty of C. F. Boehringer & Soehne, New York City. It is a derivative of phenetidin, containing a lactic acid constituent in place of the acetic acid constituent of phenacetine. Chemically it is lactyl-paraphenetidin ($C_6H_4OC_2H_5.NH.CO.CH[OH]CH_3$). It is a crystalline powder, slightly bitter, and soluble in about 300 parts of water; acids and alkalies decompose it. Therapeutically, it acts as an *antipyretic*, reducing temperature gradually, with no effect on the heart; and as an *analgesic*, and as a mild *hypnotic*. Its range of application is indicated by these properties; according to clinical reports it has been used with marked success in *typhoid fever*, *articular rheumatism*, *neuralgia*, *headache*, *migraine*, *influenza*, etc.; reports of its safety and desirability in children's practice have been frequent. The dose for adults is from 4 to 15 grains, with daily maximum of 30 to 45 grains.

PHENOCOLL HYDROCHLORIDE, *Glycocoll paraphenetedin hydrochloride*, *Phenocoll hydrochlorate* ($C_6H_4.OC_2H_5.NH.COCH_2.NH_2.HCl$).—Phenocoll results from the interaction of glycocoll (amido-acetic acid) and phenetidin (para-amidophenetol) (see *Phenacetin*). Its hydrochloride forms a very fine white, crystalline powder soluble in cold water (1 in 20) with neutral reaction. Alcohol and hot water dissolve it more freely. From hot water it crystallizes in cubical crystals; from boiling alcohol in acicular crystals. It is practically insoluble in benzol, chloroform, and ether. Volatile and fixed alkalies and their carbonates precipitate the base phenocoll from solutions of phenocoll hydrochloride. When anhydrous the base fuses at 100.5° C. (213° F.); the hydrated compound (with 1 molecule of water) at 95° C. (203° F.). Acetate (soluble in water, 1 in 4), carbonate, and salicylate of phenocoll have also been produced. This compound has been employed as an antipyretic and analgesic. It is said to be a fairly safe remedy for *rheumatic* and *neuralgic conditions*, allaying pain, reducing the temperature, and promoting sleep. The urine becomes dark-colored under its administration. It is apt to produce excessive sweating. Its use in *influenza*, *malarial intermittents*, *phthisis*, and *typhoid fevers* is hardly justified by results. From 5 to 15 grains, administered in powder, capsules, or in water, from 3 to 5 times a day, is the usual dose.

IODOPHENIN, *Iodophenine*, *Iodo-phenacetin*. This product, which contains about 50 per cent of iodine, is closely related to phenacetin, probably being an iodine addition-compound of the latter (3 atoms of iodine to 2 molecules of phenacetin). It is prepared by adding an aqueous potassium-iodide solution of iodine to a mixture of aqueous solution of phenacetin (cold and saturated) and hydrochloric acid. The presence of the latter is essential. This gives a chocolate-colored precipitate composed of fine crystals. Warm glacial acetic acid is substituted for water as a better solvent for phenacetin; in this case, steel-blue crystals result. Iodophenin has a burning, sharp taste, a faint iodine odor, and fuses under decomposition at 130° C. (266° F.). It imparts a yellow stain to the skin. Water does not dissolve it. The compound is readily soluble in alcohol, boiling hydrochloric acid, and glacial acetic acid, little soluble in chloroform and benzol. This agent is antiseptic and a topical irritant. It is not of much value in medicine. It is used locally only. When internally administered iodine is liberated in the intestines, resulting in iodine poisoning. Iodine is readily split off upon boiling with water or upon treatment with sodium thiosulphate or caustic soda (*Pharm. Centralhalle*, 1891, p. 312; also compare *ibid.*, p. 406).

Hydracetin, *Acetylphenylhydrazine* ($C_6H_5HN—NHC_2H_3O$).—To prepare this compound, acetic anhydride and phenylhydrazine are heated together, the product is dissolved in boiling water, and allowed to crystallize. It forms nearly tasteless, odorless, colorless, prismatic crystals, melting between 128° and 129° C. (262.4° and 264.2° F.). Boiling with concentrated acid decomposes it into its constituents, phenylhydrazine and acetic acid. The commercial compound known as *pyrodin* or *pyrodine*, is impure hydracetin. It is soluble in alcohol, cold water (1 in 50), and in boiling water (1 in 8 or 10). Sulphuric acid dissolves it colorless, but the solution becomes blood-red when a drop of nitric acid is added to it (difference from methacetin and phenacetin). Like phenylhydrazine, hydracetin reduces Fehling's solution. It is a cumulative poison, destroying the blood-corpuscles. It has nevertheless been employed for a brief period in ¾-grain doses, twice a day, as an antipyretic and antirheumatic agent. Even externally applied, as has been recommended for *psoriasis* (5 to 15 per cent lanolin ointment of hydracetin), it has produced deleterious effects. It should have no place in medicine.

Phenylhydrazine ($C_6H_4.NH.NH_2$).—This is an oily, colorless fluid obtainable by various methods, *e. g.*, by reduction of diazobenzene chloride ($C_6H_5.N:N.Cl$), with stannous chloride and hydrochloric acid. The following reaction takes place: $C_6H_5N:N.Cl+2SnCl_2+4HCl=C_6H_5NH.NH_2.HCl$ (phenylhydrazine hydrochloride) $+2SnCl_4$. Phenylhydrazine boils at 233° C. (451.4° F.). At a low temperature it solidifies in the form of tabular crystals, which fuse at 23° C. (73.4° F.). Alcohol and ether easily dissolve it, while it is soluble with difficulty in water. It is a basic substance, forming salts with acids. It has the characteristic property of entering into combination with aldehydes and ketones and their derivatives, notably with members of the sugar group. The remarkable achievements in the chemistry of the sugar group by Prof. Emil Fischer are due to the discovery of the characteristic behavior of phenylhydrazine toward the sugars. With dextrose it forms a characteristic crystallizable yellow compound called *phenyl-glucosazone*, and is recommended accordingly as a delicate test for sugar in urine. Phenylhydrazine enters into the manufacture of antipyrine and allied substances. This body is too poisonous for use in medicine.

PHOSPHORUS (U. S. P.)—PHOSPHORUS.

Symbol: P. Atomic Weight: 30.96.

A non-metallic element, obtained from calcium phosphate by reduction with charcoal.

"Phosphorus should be carefully kept under water, in strong, well-closed vessels, in a secure and moderately cool place, protected from the light"—(*U. S. P.*).

Source and History.—Phosphorus was accidentally discovered in 1669, by Brandt, of Hamburg, as he was attempting to extract from human urine a liquid capable of converting silver into gold. In the year 1769, Gahn discovered it in bones, and very soon after, Scheele devised a process for obtaining it from them, which is essentially the process now pursued. It is a constituent also of nerves, brain, etc.; it is also found in the form of phosphates in various plants, combined with calcium, potassium, or iron, etc., and in this form is also met with in the mineral kingdom.

Preparation.—Take animal bones, calcine them in an open fire till all the charcoal is burned out and they become white. In this state they contain from 75 to 80 per cent of phosphate of calcium $(PO_4)_2Ca_3$. Reduce the calcined bones to a fine powder, and to 10 parts of this powder add 30 or 40 parts of water, and gradually stir in 6 parts of concentrated sulphuric acid. After 24 hours, 50 or 60 parts of water are added to the mixture, and the whole well stirred and digested for 1 or 2 days. The liquid is then strained and evaporated to the consistence of thick syrup, and then contains acid phosphate of calcium, which is formed according to the following equation: ($[PO_4]_2Ca_3+2H_2SO_4=2CaSO_4+[PO_4]_2H_4Ca$). The syrup is now mixed with one-fourth of its weight of powdered charcoal, placed in an iron pot, and dried by exposure to a dull red heat, which converts the acid phosphate into calcium metaphosphate $(PO_3)_2Ca$. This dried mass is then placed in a stoneware or iron retort, the neck of which ends in a wide bent tube which dips a little under water, in a bottle or receiver, and is gradually heated to whiteness. Two-thirds of the phosphoric acid in the mass is reduced by the charcoal, and phosphorus is set free, which distills over and condenses under the water. The reduction takes place as follows: $3(PO_3)_2Ca+10C=10CO+(PO_4)_2Ca_3+4P$). This equation also shows that carbonic oxide gas (CO) is disengaged in large quantity. Owing to the presence of water in the mass, part of the phosphorus is liable to be disengaged in combination with hydrogen, forming a spontaneously combustible gas. Care must, therefore, be taken to avoid explosions. The phosphorus first obtained is usually of a reddish-brown color, owing to the presence of phosphide of carbon, formed during the process; to purify it, it is melted under water, and while liquid, squeezed through chamois leather, which separates impurities. It is lastly melted under water and molded into sticks by running it under water into glass tubes and allowing to cool. To make the process more economical, the organic matter of the bones is previously utilized (see *Gelatin*); or the bones are first subjected to dry distillation whereby *bone-black* (*animal charcoal*) is yielded, which is used on a large scale in sugar refineries; after it has become useless for this purpose, it may be completely incinerated and used in the manufacture of phosphorus as described.

Wöhler obtained phosphorus by distilling 2 parts of bone-black with 1 of quartz sand at a white heat. The silicic acid of the sand decomposed the phosphate of calcium contained in the bone-black, and disengaged the phosphoric acid which was reduced by the carbon. A. Rossel (1893) prepares phosphorus by reducing glacial phosphoric acid or sodium- or calcium-metaphosphate with aluminum or zinc. This requires a much lower heat for the liberation of phosphorus than the older method. In recent years, phosphorus is obtained by distilling a mixture of calcium phosphate and coke in an electrical furnace (*Amer. Jour. Pharm.*, 1898, p. 595, from *Scient. Amer.*).

Description.—Phosphorus exists in three allotropic modifications—namely, as the ordinary, octohedral, poisonous; the red, amorphous, non-poisonous; and the metallic, or rhombohedral phosphorus.

Ordinary, or yellow phosphorus is produced in the form of cylindrical sticks of a light-amber color, and a crystalline structure. The *U. S. P.* describes it as a "translucent, nearly colorless solid, of a waxy lustre, having, at ordinary temperatures, about the consistence of beeswax. By long keeping, the surface becomes red, and occasionally black. It has a distinctive and disagreeable odor and taste (*but should not be tasted, except in a state of great dilution*). When exposed to the air, it emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic. On long exposure to the air, it takes fire spontaneously. Specific gravity 1.830, at 10° C. (50° F.). Melting point, 44° C. (111.2° F.). Phosphorus is insoluble or nearly so in water, to which, however, it imparts its characteristic, disagreeable odor and taste. Soluble in 350 parts of absolute alcohol at 15° C. (59° F.), in 240 parts of boiling absolute alcohol, in 80 parts of absolute ether, in about 50 parts of any fatty oil, and very soluble in chloroform, or in carbon disulphide, the latter yielding a solution which must be handled with the greatest of care to prevent danger from fire"—(*U. S. P.*). From solutions in the latter two solvents phosphorus may be obtained in the form of well-developed crystals of the regular system.

Phosphorus is somewhat flexible at ordinary temperatures, and may be easily cut with a knife, but is brittle at 0° C. (32° F.). The presence of 0.3 per cent of sulphur, or even much less, renders it brittle at ordinary temperatures. Friction will cause phosphorus to ignite. When the atmosphere is excluded, phosphorus boils when heated to 290° C. (554° F.), but evaporates and sublimes at a much lower temperature (about 104° C., or 219.2° F.). Phosphorus combines with chlorine, bromine, and iodine, spontaneous combustion taking place in the reaction. The luminosity of phosphorus, when exposed to moist air, is due to slow oxidation, whereby phosphorous acid (H_3PO_3) is formed. It is strange, however, that phosphorus is not in the least oxidized when in contact with pure oxygen even for months. The luminosity produced by phosphorus is destroyed by alkalies, alcohol, carbolic acid, etc. Phosphorus also imparts luminosity to the vapors of water, with which it is distilled, and may thus be identified. Heated in oxygen, phosphorus burns with a dazzling light. The heavy, white cloud which forms when phosphorus burns in the air, consists of *phosphorus pentoxide* (P_2O_5), the anhydride of *phosphoric acid* ($P_2O_5+3H_2O=2PO_4H_3$) (also see *Acidum Phosphoricum*). Upon slow oxidation of phosphorus, the volatile, white *tri-oxide* (P_2O_3) is formed, which is the anhydride of *phosphorous acid* ($P_2O_3+3H_2O=2PO_3H_3$). The anhydride of *hypophosphorous acid* (PO_2H_3) (see *Acidum Hypophosphorosum*), which would have the formula (P_2O), does not exist.

Yellow phosphorus is a very dangerous substance to handle, and occasions painful and slow-healing sores when in contact with the skin. When small pieces are dried between filtering paper, they soon ignite. Phosphorus should be preserved under water in well-stoppered vessels, and kept in a dark place.

Phosphorus is used as a poison for rats and vermin, and finds extensive application in the manufacture of matches. In the laboratory, it is employed for many chemical processes, *e. g.*, the preparation of pure phosphoric acid and other pharmaceutical compounds.

Impurities and Tests.—Phosphorus sometimes contains arsenic or sulphur or both. "To test for arsenic and sulphur, proceed as follows: Add 3 Gm. of phosphorus to 15 Cc. of nitric acid diluted with 15 Cc. of distilled water in a flask having the capacity of 50 Cc., and digest the mixture at a gentle heat on a water-bath, until the phosphorus is dissolved. Transfer the solution to a capsule, and evaporate it until no more nitrous vapors are given off, and then dilute the solution to 30 Cc. with distilled water. Heat 20 Cc. of the diluted solution to about 70° C. (158° F.) for half an hour, passing hydrogen sulphide through it during the half-hour's heating, and then until the liquid has become cold. If the liquid be now allowed to stand at rest during 24 hours, not more than a very small quantity of lemon-yellow precipitate should be visible (limit of arsenic). On adding barium chloride T.S. to the remainder of the liquid, not more than a slight opalescence should be produced (limit of sulphur)"—(*U. S. P.*).

Allotropic Modifications.—Amorphous, or Red Phosphorus. Ordinary, or yellow phosphorus, exposed to sunlight or violet light, turns into red phosphorus. Exposure to temperatures between 240° and 250° C. (464° and 482° F.) accomplishes the same result, while a heat above 260° C. (500° F.) revives ordinary phosphorus. The best method to obtain the red modification is to heat ordinary phosphorus in a closed vessel above its boiling point, *i. e.*, to 300° C. (572° F.). It forms a deep-reddish powder or mass, having a metallic lustre, is absolutely stable in the atmosphere, does not ignite when rubbed, is insoluble in the solvents for ordinary phosphorus, has a higher specific gravity (2.106), and is non-poisonous, because it is not absorbed by the system. It is not fusible, but vaporizes at 260° C. (500° F.). When heated in the presence of nitrogen to 450° C. (842° F.), it is converted into vitreous (ordinary) phosphorus. Commercial red phosphorus is liable to contain traces of ordinary phosphorus, which should be removed by boiling with caustic soda. The crude article should, therefore, be kept under water.

Metallic, or Rhombohedric Phosphorus, is obtained by exposing phosphorus with metallic lead in closed vessels to a red heat for 40 hours, allowing to cool, and dissolving out the lead with diluted nitric acid. It forms lustrous, dark scales, or microscopic rhombohedra, has a specific gravity of 2.34, and is converted into ordinary phosphorus again by heating it to 358° C. (676.4° F.).

Black Phosphorus.—The so-called black phosphorus of Thénard, obtained by rapidly cooling melted phosphorus, is due to the probable formation of metallic phosphides. Another variety of "black phosphorus" obtainable by the action of ammonia and heat upon ordinary powdered phosphorus, was shown by Flückiger (1892) to be *arsenic* originating from the sulphuric acid employed, and held dissolved in the phosphorus.

Action and Toxicology.—In minute doses, and properly diluted, phosphorus becomes absorbed and acts as a stimulant and tonic to the nervous, vascular, and secreting organs. It excites the mental faculties and the sexual feelings, raises the temperature of the skin, increases the frequency and volume of the pulse, and promotes the secretions. Cell growth, particularly of the skin, is quickened by it. In large doses, it operates as a poison, causing gastro-enteritis, becomes absorbed, and produces tissue changes and convulsions, insensibility, and death. Tardieu and Roussin state that phosphorus is poisonous of itself, and acts only on the economy in a state of isolation and purity. Fatty degeneration of the liver and heart, are chief among its results. According to Mialhe, the absorption of phosphorus (and also of sulphur) is due, not to the chemical action of the alkalies present in the intestinal juices, but to the fatty matters contained in the alimentary substances, which, after effecting its solution, serve as the vehicle for its introduction into the economy. The phosphorus so absorbed may remain several days within the body without undergoing any sensible change, as its union with the fatty matters enables it to almost completely escape the action of the chemical agents with which it comes in contact, and to diffuse itself throughout the system in the same manner as poisons soluble in water. Hence, the reason for the phosphoresence, and the garlicky odor observed at the autopsy of persons who have been poisoned by phosphorus. Phosphoretted hydrogen acts similarly, as when introduced into the blood, it gives rise to the production of water, and to a precipitate of phosphorus in a state of minute division eminently suited for the development of its deleterious action.

As a poison, phosphorus acts both locally (as an irritant) and specifically. The symptoms of acute poisoning from the ingestion of phosphorus are as follows: Within a few minutes, or, more generally, after a few hours, the victim experiences a disagreeable, alliaceous, or garlicky taste, and the breath is observed to be alliaceous. Burning pain (not intense) in the stomach, with a sense of oppression in that organ follows, and there is general malaise and eructations of garlicky vapors of the drug. The vapors may show luminosity if the room be dark. Vomiting of luminous, coffee-colored, yellowish, or bilious material is common, and often violent and frequent. The abdomen is hot, distended, and tender upon palpation. Purging is not a common occurrence (constipation at first being the rule), but when taking place the stools are loose, dark, or sanguineous, and painful. The stools are often phosphorescent in the dark. When death occurs early, the symptoms rapidly intensify until collapse, followed by death, takes place. Should death be delayed, however, for several days, as is frequently the case, and particularly when active symptoms are late in developing, jaundice supervenes and becomes rapidly progressive. The irritant symptoms usually subside, forming an apparent intermission for the better, but the danger is as great as ever. The pulse and temperature, which are at first above normal, soon become subnormal, great prostration ensues, the pulse becomes feeble and rapid, and sometimes the radial pulse is almost imperceptible, the skin is cold, the urine scanty, albuminous, and contains tube-casts. At this stage the stools are usually abundant and dark-greenish or bloody. The skin may show hemorrhagic areas and petechial spots, and wounds or sores upon the surface bleed freely and easily. The nervous symptoms follow the establishment of jaundice. Coma ensues, associated with jactitation or convulsive muscular movements, and death occurs usually about 5 or 6 days after the ingestion of the poison.

When phosphorus vapors come in direct contact with bone, necrosis of the part generally results. Formerly, it was quite common for those manufacturing lucifer matches to be thus affected (particular the jaw bones), but improved methods have largely overcome the danger from this source. This necrosed condition is now believed to be rare, unless the phosphorus can come into direct contact with the bare bone, as through carious teeth, or ulcers of the mouth. However, it has been known to produce caries of the teeth, with abscesses, and thus become extended to the alveolar processes. The foregoing bone effects and the following symptoms constitute *chronic phosphorus poisoning:* Nauseous eructations, vomiting, purging, burning pain in the stomach, hypersensitiveness to cold, stiffness, numbness, and pain in the limbs and joints, wasting, dyspepsia, straw-colored or grayish skin, and hectic fever, with respiratory irritation and cough. The patient may die of the effects of the phosphorus direct, or he may die of dyspepsia or phthisis. The chief post-mortem changes from phosphorus poisoning are fatty degeneration of the liver, heart, kidneys, and other organs, as well as of the voluntary muscles; some surface disorganization of tissue may be observed, chiefly in the stomach. The blood is thick and dark-colored. The liver is deep-yellow, interspersed with reddish patches, and altogether closely resembles the effects of yellow atrophy of the liver, which disease poisoning by phosphorus most nearly resembles. The whole interior of the body is phosphorescent, and the luminosity may persist for months. (For further post-mortem appearances, consult Taylor's *Medical Jurisprudence*.)

In phosphorus poisoning, death does not usually take place until several days have elapsed. The shortest period on record is one-half hour (Habershon, in Taylor's *Med. Jurisp.*). Less than 1 grain ($\frac{1}{8}$ grain, Wormley) has caused death. Only white or ordinary phosphorus is poisonous, red or amorphous phosphorus being non-toxic. Locally, phosphorus produces dangerous burns quite difficult to heal. The pregnant woman invariably aborts when poisoned by phosphorus.

In poisoning by phosphorus the stomach should be evacuated as speedily as possible. For this purpose sulphate of copper, which is itself one of its best chemical antidotes (forming the black phosphide of copper), may be given in 2 or 3-grain doses, every 5 minutes, until vomiting ensues. Apomorphine hydrochlorate may be used subcutaneously if desired, to induce emesis. After vomiting has freely occurred, small doses of the copper sulphate (2 grains) should be continued every half hour, so that any free phosphorus may be converted into the black phosphide, at the same time endeavoring to prevent further vomiting by means of ice or of small doses of morphine sulphate. After full emesis by copper sulphate, copper carbonate followed by vinegar, has been successfully used as an antidote. Following the use of the copper sulphate, administer French oil of turpentine, 2 fluid drachms of which may be given in mucilage of acacia every 15 minutes until 1 ounce has been taken. Old (ozonized) oil should be preferred. Ordinary turpentine is not effective unless old or ozonized. (For Dr. P. E. Andant's use of turpentine, see previous editions of this *Dispensatory*.) The use of magnesia (Pareira, X. Landerer) has been advised, as has a draught of calcined magnesia, 4 grains; chlorine water, 16 grains, and distilled water, 224 grains. The alkalies, however, are but feebly effective. In phosphorus poisoning no albuminous or oily bodies (except French oil of turpentine) should be given, lest by their attenuation of the poison they favor its toxic action. Oxygenated water and the inhalation of oxygen have been advised as true antidotes, as has also potassium chlorate. M. Mialhe advised, in cases of poisoning by phosphorus, to expel this agent as rapidly as possible from the system by means of acidulated laxative drinks, with abstinence, or, at all events, a prohibition of any kind of food containing fatty matter. He considered the solution of phosphorus in ether or chloroform as more apt to act dangerously than the solution in oil. After the use of the antidote free purgation should be produced by means of magnesium sulphate, magnesium citrate, or Rochelle salts. No remedy is effective as an antidote after degeneration of tissue has begun. The best preventives of chronic phosphorus poisoning among those engaged in the manufacture of lucifer matches are a wetted sponge over the mouth, good ventilation of the factory, and personal cleanliness.

Medical Uses and Dosage.—Though accredited with various therapeutical properties, phosphorus may be said to be chiefly a remedy for nerve exhaustion with prostration of the vital powers. Though a powerful nerve stimulant, it is still a question whether its action is temporary, tiding the patient over a critical period, or whether it primarily produces a permanent tonic effect. That its effects are but temporary is the view held by most observers, and tonic effects follow this reassertion of nerve power. The cases for phosphorus are those of atony, adynamia, debility, low nerve force, or nerve exhaustion. The phosphorus patient is weak, digestion and blood-making are imperfect, the glandular secretions and the excretions are defective, there is languor, lassitude, sexual debility in the adult, brain-fag, and general apathy. Sympathetic innervation is below par, the skin is dull and inactive, the tongue lifeless in appearance, and the whole system shows a lack of activity and evidence of imperfect elaboration of the blood, and defective nutrition of the nerve centers. In such conditions, through its primary stimulating power, it may prove tonic and restorative. Prof. Locke says of phosphorus that "it bears the same relation to the nervous system that iron does to the blood."

Bearing in mind the indications above given, phosphorus becomes an important remedy in many *nervous diseases*. It was early employed as a stimulant in *convulsive* and *old paralytic cases*, and for *progressive locomotor ataxia*. In all such cases inflammation should be absent. When *paralysis of spinal origin* is functional, it is often more serviceable than strychnine (Locke). It frequently proves the best remedy for long-standing, obstinate *neuralgia*, particularly in the aged. In such cases nerve exhaustion is a marked symptom. It occasionally benefits in *epilepsy* with the same nerve debility, or when due to sexual excesses, or abuse. Ordinarily, however, it is of little value in this disease. In *neurasthenia*, due to debility or to physical or mental overwork, or to sexual weaknesses, and in *degenerative nerve-changes* due to senility, it often proves a good remedy. When *insomnia* is due to cerebral anemia, phosphorus frequently gives rest and sleep, and it occasionally proves useful in the *debility* due to acute and chronic alcoholism, the morphine habit, and in *melancholia*, *dementia*, and *hysteria*. For *mental failure*, *mental aberrations*, *paralysis agitans* due to imperfect nutrition or to degenerative changes, and in *atheroma of the cerebral vessels*, the remedy has been highly endorsed. Though not an analgesic proper, it relieves *pain* of a neuralgic and rheumatic character, particularly *rheumatic headache*, when due to great debility, and when the pain suddenly subsides in some other part of the body and quickly attacks the head. It is a good remedy for *intercostal neuralgia* in the debilitated, and a good agent for the relief of *nervous headache* in similar subjects.

The sexual and urinary apparatus are impressed by phosphorus. Its effects in sexual weakness are probably not due so much to a special affinity for these parts as to its general stimulating effects upon the body at large. However, it appears to improve the circulation and innervation of the genito-urinary tract, and it is a good remedy to improve *vesical*, *prostatic*, and *testicular irritation*, whether arising from or associated with sexual excesses (Scudder). It has given good results in "*chronic cystitis*, *chronic prostatitis*, *enlarged and pendulous testes*, *gleet*, *chronic ovaritis*, and *vaginitis*" (Scudder). To these we may add *chronic irritation of the kidneys and ovaries*, and *atonic dysmenorrhœa;* also *chronic nephritis*, with atony and the voiding of milky urine. "In the treatment of disease from sexual abuse, as in *involuntary seminal emissions* with marked atony and morbid irritability, it is the very best remedy known" (Locke, *Syllab. of Mat. Med.*, p. 199). It has long been used as a remedy for *impotency* due to excesses or to debility of sexual organs or of the whole system.

Phosphorus in minute doses (gtt. iij to v in aqua ℥iv; teaspoonful every hour) is a valuable agent in low grades of *pneumonia* and *bronchitis*. It is a better agent in the second stage of pneumonia than aconite. It is an agent of great power in *lung hepatization*. In *chronic pneumonia* with secretion of muco-pus and expectoration of blood—the patient hastening on to consumption—this remedy or the hypophosphites will be found of great value. In the extreme debility of *typhoid pneumonia*, no agent is more efficient than phosphorus. Rust-colored sputa is one of the strongest indications for phosphorus; hacking, dry cough in the early stage of *phthisis* is also an indication for this drug. *Chronic bronchitis*, with bloody and muco-purulent expectoration and *chronic laryngitis*, with marked dryness and sense of heat in the throat, and associated with nervous depression, call for small doses of phosphorus. *Pleurisy*, in some subjects, and especially in the chronic form, may require phosphorus to assist in the absorption of the effusion. In such cases the patient is extremely weak, the pulse feeble, tongue pasty, and appetite and digestion much impaired.

Phosphorus has been used as a stimulant to the nervous centers in *low fevers* with low, muttering delirium, unconsciousness, and involuntary passage of the fecal and urinary discharges. It is also useful as a cutaneous stimulant in some *exanthematous diseases* in which the eruption has receded from the skin. It has also been advised, chiefly in conjunction with arsenic, for *boils*, *carbuncles*, *scrofulous abscesses*, *acne*, *herpes zoster*, *scald-head*, *lepra*, *lupus*, *psoriasis*, *fistulæ*, *osseous caries*, and *enlarged glands*. In the so-called *scrofulous diathesis* it is sometimes useful, and in such a state it relieves *amenorrhœa*, *dysmenorrhœa*, *leucorrhœa*, *chlorosis*, *nasal catarrh*, *colliquative sweating* and other debilitating discharges in *phthisis*, especially the *diarrhœa of phthisis*. Ten or 20 minims of specific phosphorus, added to 4 fluid ounces of water, and given in teaspoonful doses every 2, 3, or 4 hours, have been found by Prof. J. M. Scudder, M. D., very useful in *cholera infantum*, where there was nervous exhaustion, the discharges from the bowels being slimy and frothy, with tympanites. Phosphorus has been endorsed as a remedy for *pernicious anemia*, but often fails. Prof. Locke advises minute doses of phosphorus for "*muscular weakness*, as in children who are slow in learning to walk." In *fatty degenerations of the brain*, *spinal cord*, *heart*, *liver*, and *kidneys*, it has been with some physicians a favorite remedy. In *fatty hepatic degeneration* with a pale, waxy countenance, and in *malignant jaundice*, with delirium and marked prostration, it is a serviceable remedy. In fatty degenerations the dose must be minute. It is a remedy for *osteomalacia* and *rickets*, and has been advised in *proctitis* and in *diabetes mellitus*.

In ocular and aural therapeutics, phosphorus is sometimes useful. Thus, in *functional inner ear disorders*, associated with general neurasthenia, it sometimes benefits, and *tinnitis aurium*, is occasionally overcome by it. The dose is about $\frac{1}{100}$ grain, 4 times a day (Foltz). In eye affections it frequently aids in a cure, particularly if there be a scrofulous or tubercular taint. It quickly relieves *retinal hyperemia* and *retinitis*. It has also benefited *disseminated choroiditis* and *retinochoroiditis*. Foltz (*Dynam. Therap.*) declares that it will rapidly increase visual acuity in *functional* or *reflex amblyopia*, provided no morbid process is present, and that it is the best remedy for *insufficiency of the internal recti* and *paralysis of the ocular muscles*. The dose for this purpose is from $\frac{1}{200}$ to $\frac{1}{100}$ grain. Others have pronounced it a good remedy for *asthenic amaurosis* of functional character.

Phosphorus may be given in solution in alcohol, ether, olive, almond, or cod-liver oil, chloroform, glycerin, or in pill. An elixir of phosphorus and phosphorated oil are now official. The dose of phosphorus ranges from $\frac{1}{250}$ grain, cautiously and gradually increased to $\frac{1}{16}$ grain, from $\frac{1}{100}$ to $\frac{1}{60}$ grain being the usual range of dosage. Elixir of phosphorus, 15 minims to fl℥j=($\frac{1}{260}$ to $\frac{1}{65}$ grain); phosphorated oil (1 per cent phosphorus) 1 to 10 minims; specific phosphorus is the form usually employed in Eclectic practice, the most common prescription reading: R Specific phosphorus gtt. v to xx, aqua fl℥iv. Dose, 1 teaspoonful, every 2 to 4 hours. One minim of specific phosphorus represents $\frac{1}{240}$ grain of white phosphorus. As phosphorus appears to accumulate in the system, its action should be carefully watched, and as soon as vomiting, diarrhœa, or other symptoms of derangement of the digestive organs appear, the use of the remedy should be temporarily ceased, and, after 2 or 3 days, be again commenced with the smallest dose, as before. Indeed, when no symptoms whatever manifest themselves, it will be prudent to cease its administration every 15 or 20 days, recommencing its use in 4 or 5 days, and so on.

Specific Indications and Uses.—Nervous exhaustion; atony: vesical and prostatic irritation, with mucoid discharges; sense of fullness and dragging in the perineum; sense of weariness in lower extremities; mucoid rectal discharges; low muttering delirium in low fevers, with involuntary discharges; chronic bronchial and pulmonic affections, with heat, dryness, hacking cough, and difficult expectoration of muco-purulent or sanguineous sputa; rusty sputa; pulmonary hyperemia; pinkish countenance with staring eyes; expressionless pasty tongue; insufficiency of the internal recti muscle of the eye; sexual debility.

Preparations of Phosphorus.—Aqua Phosphorica, *Phosphorus water*. M. Stanislas Martin, has suggested the internal use of aqua phosphorica, the water which is kept standing over phosphorus. I have derived benefit from it in cases of *impotency*, *premature seminal emissions*, and in some *nervous affections*. It may be taken in doses of from 5 to 10 minims, repeated 3 times a day, in some syrup of the hypophosphites (J. King).

Pil. Aphrodisiaca, or *Pil. damiana cum phosphoro et nuce vomicæ*.—This pill is a specialty of Eli Lilly & Co., Indianapolis, Ind., and contains extract of damiana, extract of nux vomica, and phosphorus. It is extensively prescribed as an aphrodisiac and nerve tonic in *impotency*, *sexual debility*, *nervousness*, and *mental overwork*.

Phosphorus Paste.—Phosphorus is very useful for destroying rats, mice, cockroaches, bugs, and other vermin; the following paste is considered the best for this purpose, as it does not ferment on keeping: Triturate to liquefaction 6 parts of phosphorus and 1 part of pure sulphur, with 6 parts of cold water, that is added in portions; afterward add 2 parts of mustard flour, 10 parts of cold water, 8 parts of sugar, and 12 parts of rye flour. Stir it to the consistence of a soft paste, and keep it in pots closely covered (*Amer. Jour. Pharm.*, Vol. XXVII, p. 473).

PHYSALIS.—GROUND CHERRY.

The berries of *Physalis viscosa*, Linné.

Nat. Ord.—Solanaceæ.

Common Names: *Ground cherry*, *Yellow henbane*.

Botanical Source.—This plant is indigenous, perennial and pubescent, having an herbaceous, decumbent stem, about a foot high, and which is often viscid as well as the whole plant. The branches are somewhat dichotomous and angular. The leaves are very variable, even in the same plant, solitary or in pairs, ovate or lanceolate-ovate, cordate or acute at base, often obtuse at the apex, repand-toothed or entire, petiolate, from 1 to 4 inches in length, and ½ or ⅔ as broad, or even of equal breadth; when they occur in pairs, one of them is much smaller. The flowers are solitary, axillary, and pendulous; the corolla campanulate-rotate, twice as long as the calyx, tube very short, limb obscurely 5-lobed, greenish-yellow, with 5 brownish spots at the base inside. Calyx 5-cleft, persistent, enlarged, inflated, and angular; stamens 5, connivent; anthers opening lengthwise. The fruit is a yellow or orange-colored berry, inclosed in the calyx. There are many varieties of this plant, some of which have been unnecessarily divided into species, as *P. obscura*, *P. pubescens*, *P. pennsylvanica*, and *P. philadelphia* (W.—G.).

History.—This plant is common in many parts of the country, and is found growing in dry fields, hillsides, and roadsides, flowering in July and August. Its root is fusiform, white, and bitter, and will probably act as a bitter tonic. The fruit or berries are slightly acid and edible, with a faint bitterness. Water or proof-spirit extract their properties.

Action, Medical Uses, and Dosage.—Tonic, laxative, and diuretic, said also to be sedative. The juice of the berries, or a strong infusion, is reputed very beneficial in *gravel*, *difficult urination*, and several *urinary disorders*. Dose, of the juice of the berries, 1 or 2 fluid ounces. It will be found very useful in *febrile* and *inflammatory diseases*, attended with considerable vascular excitement, high-colored or scanty urine, restlessness or wakefulness, and torpor of the bowels.

Related Species.—*Nicandra physaloides*, Gaertner, is known as *Apple of Peru*.

Withania coagulans, Dunal, of India.—Sometimes confused with alkekengi. It contains a powerful coagulating principle, and is used by the natives, in place of rennet, to coagulate milk. For medical uses in India, see Dymock, *Materia Medica of Western India*.)

Physalis Alkekengi, *Alkekengi*, or *Winter cherry*, of Europe, has the stem somewhat branching below, the leaves in pairs, entire, acute; flowers white; calyx of the fruit red or reddish, with acid and somewhat bitter berries. It grows about a foot high, and possesses similar properties to physalis, and is recommended as a febrifuge (W.). It is naturalized and sometimes cultivated in the United States, being known as *Strawberry tomato*. Dessaignes and Chautard, in 1852, obtained the bitter principle of *Physalis Alkekengi*, which they call *physalin* ($C_{14}H_{16}O_5$), and which has been employed with success in *intermittent fever*. Pure *physalin* is a white, amorphous powder, with a faint tinge of yellow; its taste is at first faintly, afterward permanently bitter. It is sparingly soluble in cold water, more soluble in hot water, chloroform, and alcohol, and sparingly soluble in ether and acids. It is dissolved without chemical alteration by ammonia, but is precipitated from alcoholic solution by an ammonical solution of acetate of lead. The fruit of Physalis Alkekengi contains citric acid and sugar.

PHYSOSTIGMA (U. S. P.)—PHYSOSTIGMA.

"The seed of *Physostigma venenosum*, Balfour"—(*U. S. P.*).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Calabar bean* (*Faba calabarica*), *Ordeal bean of Calabar*.

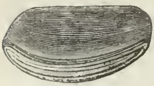
Botanical Source.—This is a large, herbaceous, climbing perennial, with the stem woody at the base, about 2 inches in diameter, twining, and sometimes 50 feet long. The leaves are large and pinnately-trifoliate; and the leaflets ample, ovate, and acuminate, with stipels. The flowers are large, about an inch long, in pendulous, fascicled racemes, on axillary peduncles, pale-pink or purplish, and beautifully veined. The bracts generally fall early, and the flower-stalk or rachis is covered with tuber-like knots. Corolla crescentiform, papilionaceous; vexillum round-ovate, recurved; apex bilobed, base angustate, margins auriculate; alæ oblong-obovate, free, incurved; keel obovate and produced into a twisted beak. The calyx is campanulate, quadrifid, 5-toothed, short, broad, the two upper nearly united. Upper stamens free; anthers all alike. Ovary raised on a stipe, 2 or 3-ovuled. Style thickened within the beak of the keel, and twisted with it, bearded along the inner side, and bearing a hood-like appendage at the apex covering the stigma. The legume is broad-linear, flattened, but convex on both sides, 2-valved, and slightly constricted between the seeds, which are oblong, with a long, linear hilum.

Fig. 192.

Physostigma venenosum.

History.—This plant, the Ordeal bean of Calabar, is a native of Calabar, in the Gulf of Guinea, on the western coast of Africa, and, according to Dr. Mery, around the sources of the river Coma, near Gabon. It is the only known species of the genus, unless we include the *Mucuna cylindrosperma*, Welwitsch, by some called *Physostigma cylindrospermum*, whose seeds were found with the commercial drug by Holmes, in 1879. It grows along the banks of rivers, climbing upon the adjacent trees and shrubs, and when the seeds become ripe they frequently fall into the rivers, are carried down the stream, and collected by the natives residing on the borders. The Calabar negroes call the seed *eséré*, and use it as an *ordeal* for the purpose of deciding the guilt or innocence of persons accused of crimes. It has been a very difficult matter to procure these beans, as the natives were averse to giving them to foreigners, hence their high price. In this connection, see a more detailed account of the Calabar bean and its uses, by J. U. Lloyd, in the *Western Druggist*, 1897, p. 249. Calabar bean is a violent poison, but did not attract attention on the part of the medical profession until its power of contracting the pupil of the eye was discovered. The first important notice on the subject was made by Dr. Christison before the Royal Society of Edinburgh, February 5, 1855, and which is published in their proceedings. Dr. Thomas R. Fraser was the first to discover, in 1862, its peculiar property of contracting the pupil, and subsequently Dr. Argyll Robinson made a more complete analysis of its ophthalmic properties. The present botanical name of the plant was given to it by Dr. Balfour, of Edinburgh. The powder, the tincture, specific physostigma, eserine, and the extract of Calabar bean (see *Extractum Physostigmatis*) are employed for internal use.

Fig. 193.



Calabar bean: fruit of Physostigma venenosum.

Description.—The bean or seed is the part used, and is officially described as "about 25 to 30 Mm. (1 to 1¼ inches) long, 15 to 20 Mm. (⅗ to ¾ inch) broad, and 10 to 15 Mm. (⅖ to ⅗ inch) thick; oblong, and somewhat reniform; testa granular, chocolate-brown, with a broad, black groove extending over the entire length of the convex edge; embryo with a short, curved radicle, and 2 large, white, concavo-convex cotyledons; inodorous; taste bean-like. On moistening the embryo with potassium hydrate T.S., it becomes pale-yellow"—(*U. S. P.*). The latter test serves to distinguish this bean from that of *Physostigma cylindrospermum*, which produces with the alkali an almost orange color, turning to greenish (see E. M. Holmes, *Pharm. Jour. Trans.*, Vol. IX, 1879, p. 913). The average weight of the seed is about 4.1 grammes (63 grains). Alcohol takes up its virtues entirely, water but partially. The kernel is brittle and constitutes the most poisonous part of the seed, the episperm being nearly inert; but it is exceedingly difficult to completely separate the latter.

Chemical Composition.—Calabar bean contains starch (48 per cent), mucilage, albumen (23 per cent), fatty oil (2.5 per cent), and salts, mainly potassium phosphate. The chief active principle of physostigma is the alkaloid *physostigmine*, discovered, in 1864, by Jobst and Hesse. Vée and Leven (1865) claimed to have obtained it in crystallized form, and named it *eserine*, from ésére, the African term for the ordeal bean. Jobst and Hesse prepared it by treating an alcoholic extract of the seeds with solution of sodium bicarbonate, and shaking out the alkaloid with ether, abstracting it with diluted sulphuric acid and again treating this solution with sodium bicarbonate and ether. The *French Codex* uses the name *eserine* exclusively.

PHYSOSTIGMINE ($C_{15}H_{21}N_3O_2$) (*Eserine*) forms colorless, hygroscopic, thin plates, slightly soluble in water, easily soluble in alcohol, ether, chloroform, benzol and carbon disulphide. It is strongly basic, and forms salts with acids, some of which are crystallizable. Physostigmine is an unstable body when exposed to light and air, and especially at a higher temperature (100° C. or 212° F.), it turns red, and is converted into Duquesnel's *rubreserine* ($C_{13}H_{16}N_2O_2$, Ehrenberg, 1894), a deep-red substance insoluble in ether, but soluble in chloroform. Free alkali and ammonia favor this change, while sodium bicarbonate hardly affects the alkaloid. The salts of physostigmine yield precipitates with alkaloidal reagents (see color reactions under *Physostigminæ Sulphas* and *Salicylas*). This alkaloid is too poisonous for general use. It may cause death when absorbed by the conjunctiva; the $\frac{1}{65}$

of a grain injected hypodermatically, or $\frac{1}{16}$ of a grain introduced into the stomach, will, with the adult, cause symptoms of intolerance; a larger dose will produce graver symptoms. It is not a counter-poison to strychnine. It merely changes the symptoms of the poisoning and the results of the autopsy without retarding the death.

A second alkaloid, *calabarine*, was discovered in Calabar bean, in 1876, by Harnack and Witkowski, distinguished from eserine principally by its being insoluble in ether. It is soluble in alcohol and water, and its toxic power is about one-sixth that of eserine. It resembles strychnine in its physiological action more nearly than physostigmine, producing tetanic movements in animals of the lower order. Ehrenberg (*Chem. Centralblatt*, 1894, p. 439) believes that calabarine is a decomposition product of physostigma alkaloids. Eber, in 1888, found in the Calabar bean an alkaloid, *eseridine* ($C_{15}H_{23}N_3O_3$), distinguished by its property of liberating iodine from iodic acid. Ehrenberg (*loc. cit.*) finally isolated the crystallizable alkaloid, *eseramine* ($C_{16}H_{25}N_4O_3$), which is physiologically inactive. By extracting Calabar bean with petroleum ether, Hesse (1878) obtained *phytosterin*, a substance closely related to the alcohol cholesterin in animal fats.

Action, Medical Uses, and Dosage.—Calabar bean, when administered in poisonous doses to animals, appears to produce a depressing influence, as manifested by a slight tremor, followed by paralysis of the limbs, slow and irregular respiration, with stertor, muscular twitchings, more or less complete loss of sensation, contraction of the pupils, frothy mucus escapes from the mouth, and finally there is only a gasping inspiration previous to death. Consciousness is preserved during the whole time, until the power of expression is lost. Reflex action can not be produced by either pricking or pinching the skin. Immediately after death the pupils dilate. With 45 children who were accidentally poisoned by the Calabar bean and taken to the Southern Hospital of Liverpool, the more prominent symptoms were loss of mobility, extreme prostration, slowness and feebleness of pulse, profuse sweats, coldness of the extremities, vomitings, and with some, severe diarrhœa. One of the children died, with whom there was neither nausea nor vomiting. These symptoms, with most of the children, disappeared in the course of 6 or 7 hours. Some look upon Calabar bean as a respiratory poison causing asphyxia; others, as interfering with contractions of the heart and producing syncope. Calabar bean appears to be a spinal paralyzer, lessening excitability of the peripheral extremities of the motor nerves, destroying excitability of the muscles, and directly diminishing reflex action. Its action on blood-vessels is, firstly, to contract them; secondly, to dilate them. It diminishes the pulsations of the heart (Fraser). Retention of the urine is sometimes produced owing to the sphincter contraction induced by the drug.

There is no known antidote to poisoning by Calabar bean except atropine, which should be injected in $\frac{1}{80}$ grain doses; one indispensable condition is an evacuation of the poison; for, when used as an ordeal among the Calabar negroes, those who vomit do not die; so it was with the children above referred to. As to other measures, they must be based upon general principles according to the symptoms presenting, such as artificial respiration, electricity, coffee, stimulants, etc.

Calabar bean was introduced into medical practice as a valuable local agent in certain conditions of the eyes, since which it has been successfully employed internally in certain nervous disorders. The alcoholic extract of the bean was the preparation formerly used in ophthalmic practice as a local application to the eye, while at the present day the alkaloid eserine has largely supplanted the use of the extract; when brought into contact with the conjunctiva, physostigmine causes lachrymation, and in about 5 minutes later contraction of the pupil, followed by contraction of the ciliary muscles; this contraction reaches its height in half an hour, and continues for about 12 hours (sometimes less pronounced for days), without, however, producing complete immobility of the pupil. It counteracts the effect of atropine, and also acts if there is paralysis of the pupil. The contraction of the pupil and ciliary muscle thus produced, generally causes pain, which may be very severe and continue for hours. If the eye be used, or efforts at accommodation be made, the pain increases. It appears, according to the views of some observers, to act by depressing the functions of the spinal cord, and thus preventing the transmission of nervous impulses through the cord to and from the iris; others, however, believe that it does not primarily affect the spinal axis, but acts directly upon the muscles and their controlling nerves. The pupillary contraction is thought to be due to dilatation of the blood vessels supplying the iris. The effects of physostigmine may be confined to the eye to which it is applied. It has been successfully employed as a local application in *mydriasis*, from atropine or other cause, in *iritis* and inflammations of neighboring structures, when desirable to produce alternate contraction and dilatation of the pupils, thus preventing adhesions; *paralysis of the ciliary muscle*, *retinitis* with photophobia, *photophobia* with *strumous ophthalmia*, *granular and irritable lids*, *ulceration of the margin of the cornea*, *prolapsus of the iris*, and in all cases where pupillary contraction is indicated, or where it is desired to improve the accommodative power of the eye for distant vision. *Glaucoma* is palliated by the use of physostigmine, especially if it be induced by the use of atropine. It is a remedy for *episcleritis*. In *corneal ulcerations* with feeble recuperative powers, in *indolent*, *non-vascular*, *corneal ulcers*, and in *hypopyon ulcers*, it is extremely valuable.

Physostigmine is the agent to be selected to control excessive ocular tension after *traumatisms*. It subdues *neuralgic pains in the eyeball*, sometimes relieves *convergent strabismus*, and is often employed to overcome *spasm of the muscles of accommodation* when persistent. Gelatin discs of physostigmine (*Lamellæ Physostigminæ*) containing about $\frac{1}{1000}$ grain of the alkaloid are occasionally used, and readily dissolve when placed upon the conjunctiva of the lower lids. The local effect ceases in from 12 to 24 hours. Generally, the solution (1 in 1000) is employed. A glycerin solution (1 part in 5) of the extract was formerly, and is still used to some extent.

The internal administration of the extract has also been found useful in *chorea*, *centric* or *eccentric tetanus*, *epilepsy*, *reflex neuralgia*, *reflex paralysis*, etc. However, its therapeutical effects in these diseases, are not fully decided. It is, however, a useful remedy in *diseases of the brain and spinal cord*, when administered in minute doses, the usual prescription being: ℞ Specific physostigma gtt. v, aqua ℥iv. Mix. Dose, a teaspoonful every 2 to 4 hours. The indications for its use here are a cool surface, cold extremities, feeble, tremulous pulse, and contracted pupils. Occasionally the dilated pupil will lead to its use if the associate symptom is a rapid, small, tense pulse. Dullness of intellect, pupillary contraction, and the small, weak pulse are the symptoms of *cerebro-spinal meningitis*, which call for its exhibition. The same state of the pulse with a forcible upturning of the eyes, points to its use in *puerperal convulsions*, which it sometimes relieves. Larger doses than for the above-named nervous conditions are required in *tetanus*. As large a dose as 5 drops of specific physostigma may be repeated every 1 or 2 hours in this complaint.

In one case of *traumatic tetanus*, Watson gave 2 grains every hour. Fraser does not think the powder advisable in tetanus, the functions of the stomach being considerably impaired in this disease. The ordinary tincture is an uncertain preparation, and should not be used. The alcoholic extract must be administered with great care; its commencing dose should not exceed $\frac{3}{8}$ of a grain in 24 hours, and at no time should its dose exceed 2 grains in 24 hours. It may be given in pill form, or dissolved in diluted alcohol, spirit, wine, or glycerin. Watson advises a preparation made by dissolving 8 grains of the alcoholic extract in $\frac{1}{2}$ fluid ounce of boiling water, then gradually adding $1\frac{1}{2}$ fluid ounces of alcohol, and filtering; 10 minims of this contain $\frac{1}{12}$ of a grain of the extract, which is a good dose to begin with in an adult. When used in subcutaneous injection the extract may be rubbed up in water, and a little chloride of sodium or a few drops of liquor potassæ be added. In a severe case of traumatic tetanus, Ashdown made use of a subcutaneous injection of $\frac{1}{3}$ of a grain of the extract in 18 minims of water; repeating the injection every 2 hours. But great care is required in determining the amount of extract necessary in any given case; when *physostigmine* is employed for this purpose, a solution of 1 part to 1000 is amply sufficient, of which a few drops only should be injected, repeating the operation according to the effects produced.

Physostigmine has also been proposed as an antagonist to *poisoning by belladonna* or *atropine*. I have found its internal use decidedly successful in several cases of *impotence*, the result of masturbation, also in cases of imperfect erection with premature seminal discharge on attempting coition; in which affections I am not aware its use has been heretofore tested. The dose of the powder is usually about 4 or 5 grains, during the 24 hours, in water, emulsion, or pill form (J. King). Extract of physostigmine ($\frac{1}{10}$ grain) and eserine ($\frac{1}{60}$ grain) have been successfully employed in *excessive sweating*, while the internal use of the former has been suggested in *cholera, diarrhœa, fecal accumulation* due to *intestinal dilatation*, and in *gastralgia, chronic constipation, intestinal, renal*, and *cystic catarrh, phthisical night sweats, dyspnœa, emphysema, bronchial dilatation*, and *asthma*. Commencing dose of the extract, $\frac{1}{10}$ grain; of the powder, 1 grain; for specific uses in nervous diseases, a fraction of a drop of specific physostigma; for other purposes a fraction of a drop to 5 drops; of eserine, $\frac{1}{100}$ grain, carried as high as $\frac{1}{25}$ grain; for local ocular purposes, a few drops of a solution of eserine (1 in 1000); for hypodermatic use, a solution of eserine (1 in 1000).

Specific Indications and Uses.—Eserine: Locally to induce contraction of the pupil in mydriasis or injuries to the eye; iritis, corneal ulcers, iridal prolapse, and ocular inflammations. Physostigma: Pulse feeble and tremulous, surface cool, extremities cold, and pupils contracted; or pupils dilated with small, rapid, tensive pulse; mental torpor in cerebro-spinal meningitis; breathing difficult with sense of constriction.

Related Drugs and Substitutions.—ANTIARIS, *Upas antiar*. A gummy-resinous exudate from *Antiaris toxicaria*, Leschenault (*Nat. Ord.*—Urticaceæ). The tree furnishing this poison is one of the large forest trees of Java, Celebes, and the islands near by. It is well known on account of the term *Deadly upas* applied to it, for it is said to exhale, like the poisonous species of Rhus, a volatile matter which affects some individuals, causing swellings and eruptions upon the skin. The milk-white or yellowish exudate flows when the tree is wounded; this upon exposure becomes brownish in color. It forms the bulk of the *Upas antiar* or so-called *Javanese arrow-poison*, and is identical with the *Ipoh poison* of the Malays (see *Nux Vomica*). Upas antiar is a waxy, reddish-brown body having an acrid, and excessively bitter taste. Alcohol and ether partially dissolve it; with water it forms an emulsion. It contains besides albumen, wax, and gum, the following peculiar principles: (1) The toxic, crystallizable, glucosid, *antiarin* ($C_{27}H_{42}H_{10}+4H_2O$, Kiliani, 1896), discovered in 1824 by Pelletier and Caventou; it is soluble in 27.4 parts of boiling alcohol, in 254 parts of water at 22.5° C. (72.5° F.), and in 2792 parts of ether (Mulder). It has a high melting point (225° C. or 437° F., Kiliani). When heated with diluted hydrochloric acid, it is decomposed into *antiarigenin* and *antiarose*, isomeric with rhamnose (Kiliani). (2) *Antiarol* ($C_9H_{12}O_4$, Kiliani), soluble in warm water, melting at 146° C. (294.8° F.). (3) *Antiaresin* ($C_{24}H_{36}O$, Kiliani), crystallizing from hot alcoholic solution in long needles, melting at 173.5° C. (344.3° F.) (see *Jahresb. der Pharm.*, 1896, p. 46).

The effects of upas antiar and antiarin are decidedly different from those produced by other bodies also known as *upas*. Thus the *Upas Tieuté* (which see) gives the tetanizing effects of strychnine, which it contains. Upas antiar does not appear to act upon the brain or spinal axis, but upon voluntary and involuntary muscles and the larger nerve trunks. It does not produce convulsions or tetanize, but all voluntary movements are impaired or wholly suspended by it according to the amount of the poison absorbed. Even small doses act upon the vasomotor centers, producing increased arterial tension, while large doses paralyze the heart muscle, death taking place from this effect. In effects it more closely resembles physostigma than any other agent, but has not yet been applied therapeutically.

CANJOURA.—The seeds of a creeper of Salvador, from which the inhabitants prepare a paste, said to act violently upon the nervous system. A state of delirium lasting a week or more is said to have been induced by it.

CALI NUTS, or CALI BEANS.—These are worthless substitutes for Calabar beans, mostly derived from certain papilionaceous plants of the genus *Entada, e. g., E. scandens* (see article with illustration by W. B. Hay, in the *Western Druggist*, 1898, p. 101). They bear no resemblance to Calabar beans (see articles on Cali beans in *Chem. Zeitung*, 1887, p. 633; 1890, p. 34; 1891, p. 825).

PHYSOSTIGMINÆ SALICYLAS (U. S. P.)—PHYSOSTIGMINE SALICYLATE.

FORMULA: $C_{15}H_{21}N_3O_2C_7H_6O_3$. MOLECULAR WEIGHT: 412.17.

"The salicylate of an alkaloid obtained from physostigma. It should be kept in small, dark, amber-colored and well-stoppered vials"—(*U. S. P.*).

SYNONYM: *Eserine salicylate*.

Preparation.—This salt may be prepared, according to Hager, by dissolving in boiling distilled water (35 parts) pure salicylic acid (1 part) and physostigmine (2 parts). Strain the solution, if necessary, and allow the salt to crystallize.

Description and Tests.—This salt is officially described as "colorless or faintly yellowish, shining, acicular, or short, columnar crystals, odorless, and having a bitter taste. It acquires a reddish tint when long exposed to light and air. Soluble, at 15° C. (59° F.), in 150 parts of water, and in 12 parts of alcohol; in 30 parts of boiling water, and very soluble in boiling alcohol. When heated to about 179° C. (354.2° F.), the salt melts. Upon ignition, it is consumed, leaving no residue. The salt usually has a faintly acid reaction on litmus paper. On adding a small portion of the salt to colorless, concentrated sulphuric acid, the latter assumes a tint not deeper than yellow. If a minute portion of the salt be added to a few cubic centimeters of ammonia water, in a small capsule, the liquid will acquire a yellowish-red color. On evaporating the liquid on a water-bath, a blue residue will be left which yields, with alcohol, a blue solution, becoming violet-red upon supersaturation with acetic acid, and exhibiting a strong, reddish fluorescence. The aqueous solution of the salt, when mixed with ferric chloride T.S., assumes a deep-violet color"—(*U. S. P.*). The solutions of this compound, both alcoholic and aqueous, exposed to light, turn reddish more quickly than the dry salt. This compound has the advantage over the sulphate, particularly in not being deliquescent. The blue color formed in the above test is known as *physostigmine blue*.

Action, Medical Uses, and Dosage.—This agent is designed for hypodermatic use, but as it does not readily dissolve in water, and is apt to decompose when exposed to light, its utility is doubtful. *Diarrhœa* and *dysentery* have been treated with it. Its other uses are those of physostigma. The dose should not be more than $\frac{1}{75}$ grain, though as high as $\frac{1}{12}$ grain has been recommended; for local use upon the eye, a solution of from $\frac{1}{2}$ grain to 2 grains to the ounce of distilled water may be employed.

Other Physostigmine Salts.—PHYSOSTIGMINÆ HYDROBROMAS. *Physostigmine hydrobromate.* This salt is used like the preceding. It is less stable than the salicylate, but more permanent than the sulphate. It is crystalline.

Physostigmine tartrate and *P. hydrochlorate* have uses and doses similar to those of the salicylate.

PHYSOSTIGMINÆ SULPHAS (U. S. P.)—PHYSOSTIGMINE SULPHATE.

FORMULA: $(C_{15}H_{21}N_3O_2)_2H_2SO_4$. MOLECULAR WEIGHT: 646.82.

"The sulphate of an alkaloid obtained from physostigma. It should be kept in small, dark, amber-colored and well-stoppered vials"—(*U. S. P.*).

SYNONYM: *Eserine sulphate.*

Description and Tests.—This salt is more soluble than the salicylate, but on exposure it deliquesces and assumes the consistence of an extract, therefore it is not so convenient to dispense as the latter salt. The *U. S. P.* describes physostigmine sulphate as "a white or yellowish-white, micro-crystalline powder; odorless, and having a bitter taste. It is very deliquescent when exposed to moist air, and gradually turns reddish by exposure to air and light. Very soluble in water and in alcohol, at 15° C. (59° F.), and still more so at the boiling temperature of these liquids. At 105° C. (221° F.), the salt melts, and upon ignition it is consumed, leaving no residue. The salt is neutral to litmus paper. On adding a small portion of the salt to colorless, concentrated sulphuric acid, the latter should not assume a tint deeper than yellow. If a minute portion of the salt be added to a few cubic centimeters of ammonia water, in a small capsule, the liquid will acquire a yellowish-red color. On evaporating this liquid on a water-bath, a blue or bluish-gray residue will be left which yields, with alcohol, a blue solution becoming violet-red upon supersaturation with acetic acid, and exhibiting a strong reddish fluorescence. The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid"—(*U. S. P.*). It is distinguished from the salicylate by not producing a violet coloration with ferric chloride.

Action, Medical Uses, and Dosage.—Used like the salicylate of physostigmine, and in the same doses.

PHYTOLACCA.—PHYTOLACCA.

The root, leaves, and berries of *Phytolacca decandra*, Linné.

Nat. Ord.—Phytolaccaceæ.

Common Names: *Poke*, etc. (see below).

Botanical Source.—Phytolacca is a handsome plant growing from 3 to 9 feet high. It is indigenous, with a perennial root of large size, frequently exceeding a man's leg in diameter, usually branched, fleshy, fibrous, whitish within, easily cut or broken, and covered with a very thin brownish bark or cuticle. When young the stem is green, but as the plant matures it becomes more or less purple. The stem is annual, about 1 inch in diameter, much branched, smooth, stout, and hollow. The leaves are opposite, scattered, ovate, entire, 5 inches long by 2 or 3 wide, smooth on both sides, with ribs underneath. The flowers are numerous, arranged in long racemes opposite the leaves. There are no petals, but 5 rounded, incurved, petaloid sepals, whitish, or greenish-white in color. Stamens 10, shorter than the sepals. Styles 10, recurved. Ovary of 10 carpels, green, and united in a ring. The fruit is a handsome, flattened, black, or blackish-purple berry, 10-seeded, and contains a beautiful crimson juice.

Fig. 194.

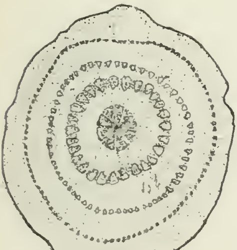
Phytolacca decandra.

Official Parts. Phytolaccæ Fructus (*U. S. P.*), *Phytolacca fruit* (*Phytolaccæ bacca*, *Pharm.*, 1880; *Poke-berry*). "The fruit of *Phytolacca decandra*, Linné (*Nat. Ord.*—Phytolaccaceæ")—(*U. S. P.*).

Phytolaccæ Radix (*U. S. P.*), *Phytolacca root*, *Poke-root*.—"The root of *Phytolacca decandra*, Linné (*Nat. Ord.*—Phytolaccaceæ)"—(*U. S. P.*).

History.—Phytolacca is the North American representative of a small family of plants—the *Phytolaccaceæ*. The plant also grows in North Africa, China, southern Europe, the Azores, and in the Sandwich Islands. Phytolacca is known by many common names, as Poke, Poke-weed, Poke-root, Virginian poke, Garget, Garget-weed, Scoke, Scoke-weed, Coacum, Coakum, Cocum, Mechoacan, Pigeon-berry, Cancer-root, Jalap cancer-root, Red nightshade, American nightshade, Red-weed, and Scoke jalap. The name *Phytolacca* is derived from the Greek *phyton*—a plant—and the modified Latin *lacca*, or French *lac*, meaning lake, having reference to the crimson color of the juice of the berries. Poke is common in the United States, growing in hedges, and along the borders of fields and clearings, along roadsides and in uncultivated fields and moist grounds. Its root is very tenacious of life. In this country it is regarded only as a weed, but in Europe is valued as an ornamental garden plant. The plant flowers from July to September, and the berries ripen in autumn. The young, green shoots, as they start in the spring and before the leaves have developed, are used as a table vegetable, being considered the best substitute for asparagus. They become cathartic as they advance to maturity. E. Preston (1884) calls attention to the peculiar and little-known property of phytolacca leaves to emit, in autumn, a phosphorescent light in the dark. Prof. E. Schär found the phenomenon to be due to an oxydizing enzyme,

Fig. 195.



Poke-root.

Fig. 196.

Section of Poke-root.

which he succeeded in isolating (see *Jahresb. der Pharm.*, 1896, p. 534). The official parts of this plant are the root and berries. The *root*, which is more commonly employed, should be gathered in the latter weeks of autumn, cleansed from dirt and impurities, sliced transversely, and carefully dried. The *leaves*, if they are to be used medicinally, should be gathered just previous to the ripening of the berries. The *berries* must be gathered when they are fully matured; they have a disagreeable, mawkish taste with a faint degree of acrimony, and are nearly inodorous. They contain an abundance of a beautiful dark-purple juice, which is turned yellow by an alkali, while an acid reinstates its purple color; the latter is of a very fugitive nature. The juice is said to have been used by the Turks for tinting sweetmeats (Landerer). The berries, though poisonous, lose their toxic qualities somewhat when cooked, and some have gone so far as to make pies of the fruit—a practice which, however, should be condemned. Severe purging has followed the eating of the flesh of pigeons which had fed upon the berries. Poke has long been used in domestic practice, principally as a poultice to discuss tumors. The berries steeped in gin have long been popular as a remedy for chronic rheumatism. The American Indians made use of this plant, but it must not be confounded with the plant known as *Indian poke*, which is the *Veratrum viride*. It is much used for the inflammatory condition of cow's udders, known as "garget," hence one of the names for this plant. Phytolacca yields its virtue to water and alcohol. The leaves and berries possess some medicinal activity, but the root is the part principally used. This root loses its medicinal properties with age, consequently only recent material should be used for making the fluid preparations. According to E. H. Cressler (*Amer. Jour. Pharm.*, 1875, p. 196), the inhalation of the powdered root produces soreness of the throat and chest, severe coughing and inflammation of the eyes.

Description.—I. PHYTOLACCÆ FRUCTUS (*U. S. P.*), *Poke-berries.* "A depressed-globular, dark-purple, compound berry, about 8 Mm. (⅓ inch) in diameter, composed of 10 carpels, each containing 1 lenticular black seed; juice purplish-red; inodorous; taste sweet, slightly acrid"—(*U. S. P.*).

II. PHYTOLACCÆ RADIX (*U. S. P.*), *Poke-root.*—"Large, conical, branched and fleshy; mostly in transverse or longitudinal slices, wrinkled, grayish, hard; fracture fibrous, the wood-bundles in several distinct, concentric circles; inodorous; taste sweetish and acrid"—(*U. S. P.*).

Chemical Composition.—The *berries*, according to Terreil (*Comptes Rendus*, 1880), contain *phytolaccic acid*, which is gummy, non-deliquescent, soluble in water and alcohol with acid reaction, hardly soluble in ether. Haverland (*Dissert.*, 1892) likewise obtained it, with small quantities of acetic, citric, and tartaric acids. W. Cramer (*Amer. Jour. Pharm.*, 1881, p. 598) found the juice of the berries to contain gum, sugar, malic acid, and coloring matter. The *coloring matter* was isolated in comparatively pure form by Herman Harms (*Amer. Jour. Pharm.*, 1893, p. 1) as a purplish-red powder, insoluble in absolute alcohol, ether, and chloroform, but readily soluble in water. It is destroyed by ferric chloride, chlorine water, hydrogen sulphide, etc. It reduces Fehling's solution direct. Alkalies dissolve it with yellow color which is turned red by acids. *Phytolaccin* is an indifferent crystallizable principle isolated by Edo Claassen (*New Remedies*, 1879, p. 326) from the seeds of phytolacca berries; it is soluble in chloroform and alcohol, slightly soluble in water. It was also obtained by Harms (*loc. cit.*) and analyzed by Haverland (1892), who found it to be free from nitrogen and related to the tannins.

The *root* of phytolacca is remarkable for the great amount of potassium it contains. A splinter of the root imparts to the Bunsen flame a violet coloration. G. B. Frankforter (*Amer. Jour. Pharm.*, 1897, p. 134) found in the dried root 13.38 per cent of ash, of which 41.6 per cent, or 5.56 per cent of the dried root, are potassium oxide. Part of the latter exists in the form of potassium nitrate (Pape, *Amer. Jour. Pharm.*, 1881, p. 597). A quantitative analysis of poke-root by G. F. Frankforter (*ibid.*, p. 281), showed it to have the following percentage composition: Fatty oil and wax 0.6, bitter resin 1, non-reducing sugar 9.46, reducing sugar 0.4, proteids 1.94, amido compounds 1.6, probably free formic acid 0.36, potassium formate 1.9, starch 11.68, calcium oxalate 6.2, nitrates 2.4, cellulose 16.4, lignin 3.2, gum coloring matter, ash, moisture 42.75. The absence of acetic, citric, malic, tartaric, benzoic, and salicylic acids are affirmed, likewise the absence of tannin and of chlorides. *Phytolaccic acid* is possibly present, but no alkaloid or glucosid could be isolated, although reactions were obtained with *some* alkaloidal reagents. Edmond Preston (*Amer. Jour. Pharm.*, 1884, p. 567) had obtained an alkaloid from the root, which he named *phytolaccine*, while N. Coscera (*Chem. Centralbl.*, 1887) found a glucosid. The root contains a substance probably closely allied to *saponin* (see H. Trimble, *Amer. Jour. Pharm.*, 1893, p. 273).

Action, Medical Uses, and Dosage. Physiologically, phytolacca acts upon the skin, the glandular structures, especially those of the buccal cavity, throat, sexual system, and very markedly upon the mammary glands. It further acts upon the fibrous and serous tissues, and mucous membranes of the digestive and urinary tracts. The drug is principally eliminated by the kidneys. Applied to the skin, either in the form of juice, strong decoction, or poultice of the root, it produces an erythematous, sometimes pustular, eruption. The powdered root when inhaled is very irritating to the respiratory passages, and often produces a severe coryza, with headache and prostration, pain in chest, back, and abdomen, conjunctival injection and ocular irritation, and occasionally causes violent emeto-catharsis. Phytolacca slows the heart's action, reduces the force of the pulse, and lessens the respiratory movements. It is a paralyzer of the spinal cord, acting principally on the medulla. In poisoning by this agent tetanic convulsions may ensue. Death results from carbonic acid poisoning, the result of respiratory paralysis. Upon the gastro-intestinal tract doses of from 10 to 30 grains of it act as an emetic and drastic cathartic, producing nausea which comes on slowly, amounting almost to anguish, finally after an hour or so, resulting in emesis. It then continues to act upon the bowels, the purging being prolonged for a considerable length of time. It is seldom used for emeto-cathartic purposes, on account of its tardy action, which, when established, continues for some time. It rarely causes cramps or pain. Large doses produce powerful emeto-catharsis, with loss of muscular power—occasionally spasmodic action takes place, and frequently a tingling or prickling sensation over the whole surface. Dimness of vision, diplopia, vertigo, and drowsiness are occasioned by large doses not sufficient to produce death.

Therapeutically, phytolacca is emetic, cathartic, narcotic, and alterative. In certain conditions of the system which might come under the head of *dycrasia*, it proves a most valuable alterative. *Scrofulous*, *syphilitic*, and *rheumatic conditions* are invariably benefited by it. It is best suited to *chronic rheumatism*, and *syphilitic* and *rheumatic joint affections*. As an antirheumatic quite large doses are necessary. The specific phytolacca may be used, or a saturated gin tincture of the berries. Preparations of the root are excellent for the removal of those severe *pains attending mercurio-syphilitic affections* (*osteocopus*), often being more beneficial than opium.

Phytolacca plays an important part in dermatological practice. It destroys the "*itch*" *insect*, consequently it is of value in *scabies*. The condition which calls for it is one of indolent action of the skin, usually associated with vitiated blood. There is a glandular difficulty—a scrofulous condition. There may be *scaly*, *vesicular*, *pustular*, or *tuberculous eruptions*, and *lymphatic enlargements with pain*. The skin may be inflamed, but does not itch because there is not activity enough in the part. It is often indicated in *chronic eczema*, *syphilitic eruptions*, *psoriasis*, *tinea capitis*, *favus*, and *varicose* and *other ulcers of the leg*. Associated with iris, it is a valuable agent in *acute sycosis*, *fissures*, *fistulæ*, *boils*, *carbuncles*, *dermal abscesses*, and all *ulcerations of the outlets of the body*. It relieves the pain of *burns* and promotes rapid healing. For skin diseases it should be employed internally and locally. ℞ Specific phytolacca ʒss, aqua ℥iv. Sig. Teaspoonful every 3 hours. Locally: ℞ Specific phytolacca ʒij, glycerin ℥j. Mix. Apply.

In *diseases of the mouth and throat* it is highly esteemed. It is useful in acute and chronic mucous affections, as, in *tracheitis*, *laryngitis*, *influenza*, *catarrh*, and especially in those affections where there is a tendency to the formation of false membrane, as *diphtheria*. There is a pallid, somewhat leaden-colored tongue, with but little coating, being a slick, glutinous coat, if covered at all. The mucous membranes present whitish erosions, or vesicular patches. With these conditions it may be employed in *tonsillitis*, *follicular pharyngitis*, *stomatitis*, *aphthæ*, *nursing sore mouth*, or *ordinary sore mouth*, and *syphilitic faucial ulcerations*. It should be taken internally and used locally as a gargle. It is one of our most valuable agents in *non-malignant diphtheria.* It is indicated by diphtheritic deposits. It stimulates the mucous surfaces, promotes glandular activity, and removes the diphtheritic membrane. It is a good remedy in *chronic tonsillar hypertrophy.* It is beneficial in difficult respiration produced by *bronchocele* (iris is useful here also) and associated with baptisia, does good service as a local wash in *ozena* and other forms of *nasal catarrh.* *Cough* resulting from inflamed or irritated sore throat is cured by it when the other indications for the drug are present.

In diseases of the glandular apparatus phytolacca and iris are our best drugs. Unlike iris, though, the former is best suited to hard, lymphatic enlargements. It is not the remedy for suppurative conditions of the glands. In such cases iris with baptisia renders the best service. No other remedy equals phytolacca in *acute mastitis.* If employed early it prevents suppuration, yet it acts kindly even when the abscess has to be opened, and the diluted specific phytolacca may be injected into the cavity. The remedy should be administered internally, alternated with specific aconite. Locally, specific phytolacca and glycerin may be applied when suppuration has not begun. Or the powdered root may be employed, moistened with water. *Parotitis* is almost always cured with phytolacca and aconite. *Metastasis of mumps* to the testes, as well as *orchitis*, from other causes, indicate this drug. *Sore nipples* and *mammary tenderness*, or morbid sensitiveness of the breasts during the menstrual period call for phytolacca. It is a good remedy for *ovaritis.* *Lymphoma* has been cured by it. *Subinvolution of the uterus*, *uterine* and *vaginal leucorrhœa*, and some cases of *membranous dysmenorrhœa* are cured by this agent. Applied as a poultice it has been greatly beneficial in the treatment of *felons*, and internally administered has cured *bronchocele* when iodine has failed.

Ulceration of the mucous crypts of the stomach and of *Peyer's patches* call for phytolacca. *Nasal catarrh*, *ozena*, and other ulcerated conditions of the nasal membranes are benefited by phytolacca associated with specific baptisia. It has been used with success in *gonorrhœa* and copious *nocturnal urination.* It relieves *conjunctival inflammations*, and *gonorrhœal* and *syphilitic sore eyes.* In *granular conjunctivitis* I have derived much advantage by bathing the eyes daily with a decoction of the root, applying it to the affected conjunctiva by means of a camel's hair pencil, at the same time administering the tincture of the recent root internally (J. King). It has been used for the cure of *piles*, *hydrophobia*, and *angina pectoris*, but we possess better agents for these conditions. *Headache*, whether rheumatic, nervous, syphilitic, or sympathetic (as, *sick headache* from gastric acidity and debility), is much benefited by it. It is also one of our most useful remedies in *asthenic hyperemia of the uterus*, *spleen*, *liver*, and other organs. Good results have followed its internal administration in *albuminuria*, and in those *dropsies* attended with albumen in the urine. The root, roasted in hot ashes until soft, and then mashed and applied as a poultice, is unrivaled in *felons* and *tumors* of various kinds. It discusses them rapidly, or, if too far advanced, hastens their suppuration. Associated with iris it may be employed in *mesenteric* and *splenic tuberculosis.* Several years ago it was noticed that birds lost their adipose tissue when feeding upon poke-berries. Recently, this agent, in the form of an extract of the berries, has been employed to reduce *obesity.* Reports for and against its virtues in this line are now appearing in journals, but its action is still doubtful. Some, believing that it does act in this way, have suggested its use in *fatty degeneration of the heart.* Probably it would be more clearly indicated if associated with a rheumatic diathesis. The root or leaves finely powdered, and added to lard to form an ointment, in the proportion of 60 grains to 1 ounce of lard, is very efficient in *scald-head*, and many other obstinate skin diseases, occasionally causing a slight degree of irritation when applied.

An infusion of the leaves taken internally is slightly cathartic; when bruised and applied locally, they are beneficial in *indolent ulcers.* A strong decoction of the leaves is of much benefit in *hemorrhoids;* if injected into the rectum 2 or 3 times a day, and a fomentation of the leaves applied to the part, it will almost always give relief, and eventually effect a cure. A fluid drachm or two may be taken internally at the same time, and repeated 2 or 3 times a day; should any narcotic effects be produced, its use may be omitted for 1 or 2 days, and then commenced in smaller doses. The inspissated juice of the leaves has been recommended in *indolent ulcers*, and as a remedy in *cancer;* in this last disease, Dr. Bone combined it with gunpowder. Quite recently, the inspissated juice of the leaves has been lauded as a new local remedy for the removal of *carcinoma*. The treatment, however, is not new, having been referred to by American medical writers early in the present century (see Felter, *Ec. Med. Jour.*, 1896, p. 335). The usual prescription for specific uses is: R Specific phytolacca gtt. x to xxx, aqua ℥iv. Mix. Sig. Teaspoonful every 1, 2, or 3 hours. As a glycerole: R Specific phytolacca ʒii, glycerin ℥i. Mix. Apply in chronic skin diseases. The dose of specific phytolacca ranges from 1 to 10 drops.

Specific Indications and Uses.—Pallid mucous membranes with ulceration; sore mouth with small blisters on tongue and mucous membrane of cheeks; sore lips, blanched, with separation of the epidermis; hard, painful, enlarged glands; mastitis; orchitis; parotitis; aphthæ; soreness of mammary glands, with impaired respiration; faucial, tonsillar, or pharyngeal ulceration; pallid sore throat, with cough or respiratory difficulty; secretions of mouth give a white glaze to surface of mouth, especially in children; white pultaceous sloughs at corners of mouth or in the cheek; and diphtheritic deposits.

Related Species and Pharmacal Preparations.—*Phytolacca dioica*, Linné (*Pircunia dioica*, Moquin-Tandon). A tree about 25 feet high and from 6 to 10 feet in circumference; native of Brazil or Mexico, and naturalized in Algeria. The wood is spongy. The berries grow in racemes, are yellowish-green, 12 to 15-celled, each cell containing a flattened seed. According to Balland (*Jour. Pharm. Chim.*, 1881, p. 232), the berries are sweet and edible, and yield by expression 74 per cent of a juice which contains resin, volatile oil, dextrose (3.20 per cent), saccharose (11.2 per cent), an undetermined organic acid (perhaps *phytolaccic acid*) (2.6 per cent), gum (4.4 per cent), etc. The resin is soluble in ether, and very acrid, but exists only in minute quantity. Also see *Amer. Jour. Pharm.*, 1882, p. 13.)

Phytolacca acinosa.—This plant is said to be violently toxic. The Japanese use it as a diuretic. A non-crystalline resin, *phytolaccotoxin* ($C_{24}H_{38}O_8$), has been isolated from it by Dr. Kashimura. It produces spinal convulsions and is reputed to impress the vasomotor system, acting thereby as a stimulant to the circulatory apparatus.

ARTHROSIA.—This specialty of Wm. R. Warner & Co. (Philadelphia and New York) is a combination in pilular form of salicylic acid, extracts of colchicum and phytolacca, resin of podophyllum, quinine, and capsicum. It is antirheumatic, antilithic, tonic, and alterative, and is prescribed in *acute and chronic gout*, *rheumatism*, *neuralgia*, *sciatica*, *rheumatic headache*, and in some *renal* and *hepatic affections*. Dose, 2 pills, 3 times a day, an hour before meals.

SUCCUS ALTERANS is a combination of vegetable alteratives prepared after the formula of Dr. George W. McDade, by Eli Lilly & Co., of Indianapolis, Ind. It is very extensively used as an alterative in *syphilis*, *scrofula*, *anemia*, *eczema*, and other diseased conditions the result of impoverishment of the blood. It contains in combination, the juices of Stillingia sylvatica, Smilax Sarsaparilla, Phytolacca decandra, Lappa minor, and Xanthoxylum carolinianum.

PICROTOXINUM (U. S. P.)—PICROTOXIN.

FORMULA: $C_{30}H_{34}O_{13}$. MOLECULAR WEIGHT: 600.58.

"A neutral principle obtained from the seed of *Anamirta paniculata*, Colebrooke"—(*U. S. P.*). (*Anamirta Cocculus*, Wight and Arnott; *Menispermum Cocculus*, Linné; *Coccus suberosus*, De Candolle.)

Nat. Ord.—Menispermaceæ.

Botanical Source and History.—The seeds furnishing this body are known as *Cocculus indicus* (*Fructus cocculi*), *Fishberries* or *Indian berries*. The plant furnishing them is a strong, climbing shrub, with a corky, ash-colored bark, with deep cracks or fissures. The leaves are dense, smooth, shining, coriaceous, roundish, acute, very slightly cordate, if at all, sometimes truncate at the base, with 5 digitate ribs, about 6 inches long, and as many broad. The stalks are a little shorter than the leaves, tumid at both ends, especially the lower. Flowers diœcious; the female flowers being in lateral compound racemes. The calyx is composed of 6 sepals in a double series, with 2 closely-pressed bractioles. The stamens are united into a central column dilated at the apex. Anthers numerous, covering the whole globose apex of the column. The drupes, from 1 to 3 in number, are globose, 1-celled and 1-seeded. The seed is globose and deeply excavated at the hilum. Albumen fleshy. Cotyledons very thin, linear-oblong, distant, diverging, and very membranous (L.—W.—A.).

Cocculus indicus inhabits Malabar, the Eastern Islands, etc., of India. Other plants, especially the *Coccus lacunosus* of Celebes and the Molucca Isles, and a Malabar species, *Cocculus plunkenetii*, are stated by some authors to furnish a portion of commercial fishberries.

Fig. 197.

Anamirta paniculata.

The Fruit (*Fructus cocculi*).—The fruit, as met with in commerce, consists of a dry, light, roundish nut, nearly ½ inch in diameter, of a grayish-black color, wrinkled, inodorous, subreniform, and composed of an external, slightly bitter shell or layer, beneath which is a white, thin, ligneous endocarp, containing an oleaginous, whitish-yellow, odorless, but intensely bitter nucleus or seed of a semilunar form, within which arises a central placenta contracted at the base, but enlarged and divided into two cells superiorly.

Fig. 198.

Cocculus indicus: fruit of Anamirta paniculata

Preparation of Picrotoxin.—According to Prof. E. Schmidt (1883), the grains, coarsely powdered, are deprived of most of their fatty oil by warm pressure, boiled out with water, the solution precipitated with lead acetate, filtered, the lead removed from the filtrate by means of hydrogen sulphide, the liquid again filtered and evaporated to crystallization. The crude picrotoxin is recrystallized from water and strong alcohol. Picrotoxin may also be extracted by means of alcohol or petroleum ether. (For Wittstein's process, see details in this *Dispensatory*, preceding editions. The yield, according to this process is 1 ounce or 1½ ounces from 8 pounds of berries, or about 1.2 per cent.)

Chemical Composition.—The *husk* of cocculus grains contains two isomeric, non-poisonous, non-bitter, crystallizable alkaloids—*menispermine* and *para-menispermine* ($C_{18}H_{24}N_2O_2$, Pelletier and Couerbe, 1834). The former is soluble in ether, the latter insoluble. Both are insoluble in water, but soluble in warm alcohol. Menispermine is also soluble in diluted acids, forming well-crystallizable salts; it melts at 120° C. (248° F.). The husk also contains a yellow resin, fat, wax, chlorophyll, and the problematical *hypo-picrotoxic acid* of Pelletier and Couerbe, insoluble in boiling water and ether, readily soluble in alkalies with brown color.

The *seeds*, or nuclei, of cocculus grains contain resin, gum, starch, and large amounts of fat (23.6 per cent, Römer, 1882), of which more than one-third consists of free fatty acid, principally stearic acid. The seeds also contain the very poisonous, bitter principle, *picrotoxin* ($C_{30}H_{34}O_{13}$, Schmidt and Loewenhardt; Paterno and Oglialoro, 1881; *picrotoxic acid* of Pelletier and Couerbe), which was first isolated by P. Boullay (1812). It is accompanied by the crystallizable, tasteless *cocculin* or *anamirtin* ($C_{19}H_{26}O_{10}$, E. Schmidt and E. Loewenhardt, 1884), crystallizable from hot water, insoluble in alcohol and ether.

The chemical composition of picrotoxin agrees best with the formula $C_{30}H_{34}O_{13}$. Barth and Kretschy (1884) asserted that picrotoxin is not a uniform body, being a mixture of the poisonous *picrotoxinin* ($C_{15}H_{16}O_6$) and the bitter, non-poisonous *picrotin*, separation being effected by boiling with benzol, in which picrotoxinin is soluble, picrotin very little soluble. Schmidt and Loewenhardt (*Jahresb. der Pharm.*, 1883–84, p. 774), on the other hand, maintained that picrotoxin is a definite body, being decomposed by boiling benzol into the constituents named, as follows: $C_{30}H_{34}O_{13}$ (picrotoxin) $= C_{15}H_{16}O_6$ (picrotoxinin) $+ C_{15}H_{18}O_7$ (picrotin). Quite recently, Richard Joseph Meyer succeeded in obtaining picrotoxin, with all its characteristics synthetically, by the mere crystallization of a mixture of 2 molecules of picrotoxinin and 1 molecule of picrotin, and concludes that picrotoxin is a mixture of *picrotoxinin* ($C_{15}H_{16}O_6+H_2O$) and *picrotin* ($C_{15}H_{18}O_7$) in the approximate proportion of 2 molecules of the former and 1 molecule of the latter (*Berichte der Deutsch. Pharm. Ges.*, 1897, p. 16). He has also shown that the molecular weight of picrotoxin, as determined by the kryoscopic method, is only one-third of that represented by the formula $C_{30}H_{34}O_{13}$; that the above decomposition is not equimolecular, but picrotin invariably forms only one-third of the picrotoxin employed.

Description and Tests.—Picrotoxin is officially described as forming "colorless, flexible, shining, prismatic crystals, or a micro-crystalline powder; odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 240 parts of water, and in 9 parts of alcohol; in 25 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in solutions of the alkalies, and in acids. Very slightly soluble in ether or chloroform"—(*U. S. P.*). It is also soluble in amyl alcohol and glacial acetic acid. "Picrotoxin is neutral to litmus paper. When heated to 200° C. (392° F.), picrotoxin melts, forming a yellow liquid, and upon ignition it is consumed, leaving no residue. Concentrated sulphuric acid dissolves picrotoxin with a golden-yellow color, very gradually changing to reddish-brown, and showing a brown fluorescence. On mixing about 0.2 Gm. of powdered sodium nitrate with 3 or 4 drops of sulphuric acid, in a small, flat-bottomed capsule, sprinkling a minute quantity of picrotoxin over it, and then adding, from a pipette, concentrated solution (1 in 4) of sodium hydrate, drop by drop, until it is in excess, the particles of picrotoxin will acquire a brick-red to deep-red color, which fades after some hours. On diluting 2 Cc. of alkaline cupric tartrate V.S. with 10 Cc. of water, and adding a small portion of picrotoxin, red cuprous oxide will be separated within half an hour at ordinary temperatures, and much more rapidly upon the application of heat. The aqueous solution of picrotoxin should remain unaffected by mercuric or platinic chloride T.S., tannic acid T.S., mercuric potassium iodide T.S., or other reagents for alkaloids (absence of alkaloids)"—(*U. S. P.*).

The fact that picrotoxin may be shaken out from acidulated aqueous liquids by means of ether or amyl alcohol, facilitates its detection in certain articles of food, *e. g.*, beer, to which it has been fraudulently added in order to impart bitterness to it. Flückiger (*Pharmacognosie*, 3d ed., 1891, p. 790) recommends evaporating the sample to dryness with calcined magnesia, extracting with alcohol, dissolving the evaporated alcoholic extract with hot distilled water, acidulating with sulphuric acid, and shaking out with ether; recrystallize from water, and apply the tests for picrotoxin as given above.

Action, Medical Uses, and Dosage.—Cocculus indicus is occasionally given internally, though very poisonous. Given to animals it acts on the cerebro-spinal system, causing giddiness, staggering, tetanic convulsions, and coma. It also produces gastric irritation. The powder, or an ointment, has been applied in *barber's itch*, *scald-head*, *itch*, and other unyielding diseases of the skin, as well as to kill lice. Given to fish, it poisons them, depriving them of sensibility, and has been used for the purpose of catching them. Extraordinary claims have been made by Planat for cocculus, as an agent in *spasmodic disorders*, including *epilepsy*, *infantile convulsions*, *chorea*, etc. Others, however, claim that it aggravates, at least in epilepsy. It has likewise been employed in *paralysis of the sphincters and limbs*. By some physicians, cocculus and picrotoxin, in minute doses, are recommended in disorders for which strychnine and nux vomica are employed. It is also an antagonist to these drugs, and may be used in cases of poisoning by them. *Nervous debility*, *paresis*, mild forms of *paralysis*, *facial paralysis*, *paralysis agitans*, and *alcoholic tremor* are conditions in which minute doses have rendered good service. *Spasms of the muscles of locomotion*, with cold skin and deficient capillary circulation, are said to be benefited by cocculus. It has also been advised in *gastric atony* and *intestinal dyspepsia*, with torpor of the parts involved. Dr. John Fearn recommends 2-grain doses of the 3 x trituration as a certain remedy for *profuse sweating*. It has been endorsed by others as exceedingly efficient in *night-sweats*, the above doses being given every 2 hours, in the evening, for 3 or 4 days. An attenuation of cocculus, as employed by Homœopaths, is an efficient remedy to prevent the nausea and sickness incident to travel by rail and upon water (*sea-sickness*). The dose of picrotoxin ranges from $\frac{1}{150}$ to $\frac{1}{64}$ grain.

PILOCARPINÆ HYDROCHLORAS (U. S. P.)—PILOCARPINE HYDROCHLORATE.

FORMULA: $C_{11}H_{16}N_2O_2HCl$. MOLECULAR WEIGHT: 243.98.

"The hydrochlorate of an alkaloid obtained from pilocarpus. It should be kept in small, well-stoppered vials"—(*U. S. P.*).

Preparation.—The free alkaloid is first prepared, *e. g.*, by Petit's process. The coarsely-powdered leaves are percolated with alcohol of 80 per cent, containing about 0.8 per cent of hydrochloric acid. The alcohol is distilled off under reduced pressure, the aqueous hydrochloride solution separated from the fatty layer, the solution rendered alkaline with aqua ammoniæ, and shaken out with chloroform. The crude bases thus obtained are converted into the nitrates by carefully adding diluted nitric acid to very slight excess, and evaporating the solution to dryness. The crude nitrate is then repeatedly crystallized from alcohol, whereby *jaborine*, which forms no crystallizable nitrate, and the small quantities of *pilocarpidine* present remain in solution. Pilocarpine is then liberated from the purified salt, dissolved in slight excess of hydrochloric acid, and the solution evaporated to crystallization.

Description and Tests.—"Small, white crystals, odorless, and having a faintly bitter taste; deliquescent on exposure to damp air. Very soluble in water and in alcohol; almost insoluble in ether or chloroform. When heated to 197° C. (386.6° F.), the salt melts, and upon ignition it is consumed, leaving no residue. The aqueous solution (1 in 100) of the salt is neutral, or has a faintly acid reaction upon litmus paper"—(*U. S. P.*). It is practically insoluble in carbon disulphide and in benzol. It is soluble in 1½ parts of water, both cold and boiling, the solution remains clear, even after having been kept for some length of time. But 7 parts of cold alcohol and ⅖ part of boiling alcohol are required to dissolve it (Schuchardt). "Concentrated sulphuric acid dissolves the salt to a colorless liquid, with evolution of hydrochloric acid vapor. If a small fragment of potassium dichromate be added to a few drops of this solution, on a white porcelain surface, the dichromate will gradually dissolve with a vivid, dark-green color. Fuming nitric acid dissolves the salt with a faintly greenish tint. The aqueous solution (1 in 100) of the salt is precipitated by iodine T.S., bromine water, mercuric chloride T.S., and most other reagents for alkaloids. If the aqueous solution be slightly acidulated, the subsequent addition of ammonia water will produce no precipitate. Sodium hydrate T.S. produces a precipitate only in a concentrated solution of the salt. The aqueous solution yields with silver nitrate T.S. a white precipitate insoluble in nitric acid"—(*U. S. P.*). (Regarding the melting point of the hydrochloride, see paper by Paul and Cownley, *Amer. Jour. Pharm.*, 1897, p. 108.)

Action, Medical Uses, and Dosage.—(See *Pilocarpus.*) Dose, ⅕ to ¾ grain; hypodermically, ⅛ to ¼ grain.

Related Compound.—PILOCARPINÆ NITRAS ($C_{11}H_{16}N_2O_2HNO_3$). This salt is official in the *British Pharmacopœia*. According to the *British Pharmacopœia* (1885), it is prepared from extract of jaborandi by agitating the latter with chloroform and an alkali, evaporating the chloroform solution, neutralizing the residue with nitric acid, and recrystallizing. It forms a crystalline, white powder or needles. Nitrate of pilocarpine is soluble in 8 or 9 parts of water, at 15° C. (59° F.), freely soluble in boiling alcohol, but slightly soluble in cold alcohol. The solution of this salt is precipitated by chloride of gold, in fine needles, and by chloride of platinum, in prismatic crystals. It should leave no ash when burned with free access of air. A diluted solution applied to the eye, causes contraction of the pupil. Uses and doses, same as for Pilocarpine hydrochlorate.

PILOCARPUS (U. S. P.)—PILOCARPUS.

"The leaflets of *Pilocarpus Selloanus*, Engler (Rio Janeiro Jaborandi), and of *Pilocarpus Jaborandi*, Holmes (Pernambuco Jaborandi)"—(*U. S. P.*).

Nat. Ord.—Rutaceæ.

COMMON NAME: *Jaborandi.*

ILLUSTRATIONS: *Pilocarpus Jaborandi*—*Pharm. Jour. Trans.*, 3d series, Vol. V, 1874–75, p. 582; and H. Geiger, *Berichte der Deutsch. Pharm. Ges.*, 1897, p. 424, Plates. *P. Selloanus* and *P. pennatifolius*—*Pharm. Jour. Trans.*, 4th series, Vol. I, p. 521.

Botanical Source and History.—The jaborandi shrub is a native of Brazil, and grows to the height of from 6 to 10 feet. The genus is represented by about 19 described species, for an enumeration of which, see *Pharm. Jour. Trans.*, Vol. I, 1895, p. 541. They are natives of South America and the West Indies. Jaborandi was introduced to the medical profession by Dr. S. Coutinho, of Pernambuco, in 1874. The leaves were examined by Prof. Baillon, and the plant referred to the *Pilocarpus pennatifolius* of Lemaire, described by him, in 1852. Engler (1874) states that its leaves are pilose (hairy) beneath, while E. M. Holmes (1875) calls attention to the fact that commercial leaves are glabrous (devoid of hair). However, not much importance can be attached to this distinction, because Planchon (1875) has observed that the leaves of *Pilocarpus pennatifolius*, grown in Paris, may occur partly in the glabrous, partly in the pilose form. In 1875 (*Pharm. Jour. Trans.*, Vol. V, pp. 581 and 641), Mr. E. M. Holmes referred one of the two grades then in commerce (Rio Janeiro jaborandi) to *Pilocarpus Selloanus*, Engler, and, in 1893 (*ibid.*, Vol. XXIII, p. 1008; also, *ibid.*, Vol. I, 1895, p. 520) established for the other (Pernambuco jaborandi) a new species, *Pilocarpus Jaborandi*, Holmes, which he described from a specimen grown in the Cambridge Botanical Garden.

Engler's botanical description of *P. Selloanus*, as communicated by E. M. Holmes, is as follows: The stem is covered with thin, purple bark, and leafy toward the apex. The leaves are imparipinnate. The petiole of the leaf is semiterete, flattened a little above, quite glabrous. The leaflets are trijugate, oblong, distinct, nearly equal, obtuse, margin reflexed, membranaceous or subcoriaceous, grayish-green, quite glabrous on both sides, pellucid-punctate; mid-rib sulcate above, very prominent beneath; lateral nerves rather prominent beneath; petiole of leaflets short. The raceme is terminal, nearly three times longer than the leaves, terete, purple, quite glabrous, with slender pedicels, horizontally patent and slightly hairy, six times longer than the buds, and furnished at the middle and base with 2-minute, ciliolate bracts. The calyx is very short, with broad, rounded lobes, which are ciliolate. The petals are coriaceous, lanceolate, acute, furnished with a prominent mid-rib, inflexed at the upper margin and at the apiculus. The stamens are shorter than the petals. The ovary is depressed, globose, very smooth, half included in the disk, and crowned with a short, rather thick style (*Pharm. Jour. Trans.*, Vol. V, 1875, p. 641).

The new species, *P. Jaborandi*, Holmes, differs from *P. Selloanus*, to which it is most nearly allied, in having 4 pairs of leaflets; in the elliptic-oblong shape of the leaflets and their more fleshy consistence; in the veinlets being more prominent on the upper surface; in the slender, glabrous pedicels, only three times longer than the leaf-buds; in the minute bracts, being situated near the apex of the pedicel; in the rose color of the ovate petals, pedicels, and upper part of rachis; and in the rugose-crenate disc. The calyx is pentagonal, not lobed (*Pharm. Jour. Trans.*, Vol. XXII, 1892, p. 875).

The subsequent investigations of E. M. Holmes (*ibid.*, 1895, pp. 520 and 539), and, more lately, those of H. Geiger (*Berichte der Deutsch. Pharm. Ges.*, 1897, pp. 356 and 425), have shown that commercial jaborandi leaves, at present in the market, are to be referred to the following 5 species: (1) *P. Jaborandi*, Holmes (Pernambuco jaborandi), identical with *P. officinalis* (Poehl, 1879); (2) *P. pennatifolius*, Lemaire (Paraguay jaborandi), which, according to Geiger, is identical with *P. Selloanus*, Engler; (3) *P. trachylophus*, Holmes (Ceara jaborandi); (4) *P. microphyllus*, Stapf (Maranham, or Small jaborandi); and (5) *P. spicatus*, Saint-Hilaire (Aracati jaborandi). In 1896, a spurious jaborandi was referred, by Holmes, to a hitherto unknown plant, *Swartzia decipiens*. The nomenclature, according to the places of export, as adopted by Holmes, is abandoned by Geiger, because the commercial bales rarely even contain leaves of a single species.

Description.—Official jaborandi is thus described by the *U. S. P.*: "About 10 to 15 Cm. (4 to 6 inches) long, and 4 to 6 Cm. (1⅔ to 2¼ inches) broad, short-stalked, oval or ovate-oblong, entire, and slightly revolute at the margin, obtuse and emarginate, unequal at the base; dull-green, coriaceous, pellucid-punctate, mostly smooth; when bruised slightly aromatic; taste somewhat bitter and pungent"—(*U. S. P.*). Commercial jaborandi is usually mixed with leaf-stalks, twigs, and bark. The leaflets are almost odorless when entire; have a slightly aromatic taste, followed by a persistent acridity. (For a comparative histological study of jaborandi leaves, see Albert Schneider, *Journal of Pharmacology*, 1897, p. 141.)

Fig. 199.

Leaf of Jaborandi

Chemical Composition.—The active principle of jaborandi leaves is the alkaloid *pilocarpine*, which was discovered almost simultaneously by E. Hardy, in France, and A. W. Gerrard, in England, in 1875. Several other active principles were subsequently isolated from the mother liquors of pilocarpine—namely, the alkaloids *jaborine* (Hardy, 1875; Harnack and Meyer, 1880), *pilocarpidine* (Merck, 1885), *jaboridine* (Harnack, 1885), and volatile *jabonine* ($C_9H_{14}N_2$, Hardy and Calmels, 1887), as well as *jaboric* and *pilocarpic acids;* but it is somewhat doubtful whether these derivatives of pilocarpine preexist in the leaves. Other constituents are a volatile oil (0.56 per cent, Hardy), an acrid resin, tannin, and a volatile acid, forming large crystals.

Pilocarpine ($C_{11}H_{16}N_2O_2$, Harnack and Meyer, 1880) may be obtained as described under pilocarpine hydrochlorate (which see). It forms a viscid liquid, optically dextro-rotatory, soluble in water and alcohol, slightly soluble in cold ether or chloroform, and in acids, forming a series of salts, of which the acetate is soluble in ether. The nitrate crystallizes well; the hydrochloride is very deliquescent. Pilocarpine, boiled with water, is decomposed into *trimethylamine* ($N[CH_3]_3$) and *beta-pyridine-alpha-lactic acid* ($C_5H_4N.C[OH.CH_3].COOH$). Its synthesis was effected by Hardy and Calmels, in 1887 (see graphic formula in *Pharm. Jour. Trans.*, Vol. XVIII, p. 89). These observers, as well as Merck (1885), consider it to be *methyl-pilocarpidine* (see below). According to J. van de Moer (1895), pilocarpine also stands in close connection with the alkaloid *cytisine* (see *Baptisia*).

Jaborine ($C_{22}H_{32}N_4O_4$, Hardy and Calmels, 1887) is a strongly basic, amorphous alkaloid, indicated by Hardy (1875), and shown by Harnack and Meyer (*Chem. Centralblatt*, 1880) to correspond in its physiological action with atropine, while pilocarpine in this respect resembles nicotine. It is formed when alcoholic or acid solutions of pilocarpine are concentrated by evaporation, and is not contained originally in the fluid extract of jaborandi. Its formation explains the lack of uniformity of the physiological action of pilocarpine as first obtained. When pilocarpine is rapidly heated to 175° C. (347° F.), and kept at this temperature for half an hour, it is decomposed into ether-soluble *jaborine* and water-soluble *pilocarpidine* and *jaboric acid* ($C_{19}H_{25}N_3O_5$, Hardy and Calmels. *Pharm. Jour. Trans.*, Vol. XVII, 1887, p. 550). Jaborine is a brittle mass, insoluble in water, soluble in alcohol, ether, and a solution of jaboric acid. Its salts are uncrystallizable. Boiling with aqueous solution of caustic potash, converts it into pilocarpidine.

Pilocarpidine ($C_{10}H_{14}N_2O_2$, Harnack, 1885) was discovered by Merck (1885), and was considered by him and others to be the lower homologue of pilocarpine. This simple relation, however, does not seem to exist between these two bases (E. Merck, *Archiv der Pharm.*, 1898, p. 141), nor are they isomers, as was asserted by Petit and Polonowsky (*Pharm. Jour. Trans.*, Vol. V, 1897, p. 83). The aqueous solution of its salts is not precipitated by chloride of gold (difference from pilocarpine). It is a syrupy liquid, forming a well-crystallizable nitrate. The formula of *nicotine* being $C_{10}H_{14}N_2$, pilocarpidine may be regarded as dioxy-nicotine. It has been obtained synthetically as an intermediary product in the synthesis of pilocarpine (see above). It is easily converted into *jaboridine* ($C_{10}H_{12}N_2O_3$, Harnack, *Chem. Centralblatt*, 1885), which is probably identical with *jaborandine* of Parodi (1875) from *Piper Jaborandi*. It may also be formed from pilocarpine by treatment with fuming nitric acid (Chastaing, 1882). The chemistry of pilocarpine and derivatives is held by Petit and Polonowsky (1897) to be still doubtful.

The following table states the yield of total alkaloid and nitrate, as recorded by several observers:

Analyst.	Source of Jaborandi.	Per cent Pilocarpine.	Per cent crystallizable nitrate. Melting point.	Per cent recrystallizable nitrate Melting point.

Action, Medical Uses, and Dosage.—Jaborandi acts upon the glandular system, increasing the secretory action of the glands; however, its influence is more especially exerted upon the sudoriferous and salivary glands. A drachm or two of the powdered leaves and smaller branches infused in a cupful of boiling water, and the whole taken at a draught, will, in about 10 or 20 minutes afterward, occasion a tingling sensation with redness of the cutaneous surface; this sensation is at first experienced in the face, but soon extends over the whole surface, and is quickly followed by an abundant perspiration, which is apt to continue for 4 or 5 hours. Almost simultaneously with the sweating, the secretion of saliva increases to such an extent as to greatly embarrass speech, the person being often obliged to assume an inclined position that the escape of the saliva may be facilitated. During its salivary action 1 or 2 pints of saliva, and even more, may be secreted, and, not infrequently, there will be, in addition, an augmentation of the bronchial and lachrymal secretions. At times the mucous glands of the intestines will be so influenced as to occasion a diarrhœa, and it is not a rare circumstance that the submaxillary glands enlarge. After the administration of jaborandi, patients are often attacked with nausea, vomiting, vertigo, hiccough, heaviness of the head, and contraction of the pupils. According to S. Ringer and A. Gould, the temperature of the body becomes greatly lessened during the sweating, falling 1.4° F.; on the other hand, Green, Rabuteau, Gubler, Robin, Ambrosoli, and Riegel, state that it becomes considerably elevated. As the rule, at the termination of the diaphoresis, the temperature becomes the same as it was at the time the jaborandi was administered; in a few cases it has been slightly lower, but returned to the normal degree in the course of from 12 to 24 hours. From the commencement of the perspiration, the face becomes pale, the pulse fuller, and more frequent; the pulsations of the heart become irregular, and, with persons laboring under some cardiac affection, a kind of asystolia is observed. The effects of this agent have been found to occur more readily with adults than with children. In the exhibition of this article as a diaphoretic, the use of warm drinks, and other aids toward facilitating the sweating, are not required.

During the sudorific action of jaborandi, the quantity of urine is lessened, to a greater or lesser extent, and micturition frequently proves painful. As urea exists to a large extent in the saliva and sweat caused by jaborandi (no uric acid being found), a diminution of it occurs in the urine voided; but, after sweating, it gradually returns to its normal figure in the urine, and from this it would appear that the drug does not increase the combustions of the economy. Experiments with the sphygmograph, made at various periods during the action of the drug, have shown an almost complete asystolia with a very considerable diminution of vascular tension. M. Robin is led to believe that jaborandi has an especial action upon the vasomotors, which it paralyzes; from whence results the cardiac asystolia and the copious secretions of sweat and saliva. M. Gubler, while admitting this paralyzing action upon the vasomotors, maintains that it has, in addition, a special irritating influence upon the sudoriferous and salivary glands, and upon the renal glomerules, which stimulates their functional activity. Dryness of the mouth and throat, with a sense of fatigue and depression, most usually follow the cessation of its active effects. Administered in divided doses, jaborandi, instead of acting as a diaphoretic and sialagogue, becomes an active diuretic. When given in cases where there is a diminished secretion of milk, contrary to what might be anticipated, it increases the quantity of this mammary secretion. Martindale dissolved extract of jaborandi in glycerin, and applied it around the eye; a marked contraction of the pupil ensued. A similar result, with impaired vision, is apt to follow its internal administration in large doses, but this disappears on the cessation of the medicine. Pilocarpine is the active principle of jaborandi, having an action nearly identical; however, it causes less salivation, less vomiting, and is more certain in its effects—the hydrochlorate and the nitrate of this alkaloid are used; they may be employed internally, or by subcutaneous injections.

Therapeutically, jaborandi has been found of value in the removal of serous effusions, as in *hydrothorax*, *anasarca*, *ascites*, *chronic pleurisy*, etc., whether these be due to disorders of the heart, liver, kidneys, to chronic inflammatory conditions, to albuminuria, or exist as a sequence of exanthematous affections, etc. While in certain of these effusions it acts as a curative agent, in others it will prove useful as affording temporary relief, from time to time, until other indicated remedial agents have been enabled to overcome or to modify the abnormal conditions giving rise to such effusions. In *cardiac diseases*, from its tendency to diminish the contractility of the heart and arteries, and to favor their dilatation (diastole), thus conducing to dyspnœa and even to asphyxia; if used at all, great care and prudence should be observed. In those disorders, in which its employment from time to time is followed by persistent debility, it is contraindicated.

Jaborandi has been used with more or less success in the following diseases: *Asthma*, *bronchitis* (with or without emphysema), *albuminous diabetes*, *dropsies*, in cases of poisoning and diseases due to miasms or morbid poisons (*puerperal septicemia?*) *eruptive fevers* impeded in their evolution, etc. (Gubler); in *metastatic orchitis* (Czernicki); in *polyuria* (Laycock); in *chronic rheumatism*, *syphilitic rheumatism*, and in *acute articular rheumatism*, but in which the endocarditis was aggravated (Fereol)—this author has also observed an attack of gout, and an increase of the intensity of hemicrania, in cases where it was administered; in the albuminuria of pregnancy its use was followed with hematuria (Langlet); in *acute albuminous nephritis* (Bloch)—this author likewise states that jaborandi will be found efficient in *chronic parenchymatous nephritis*, especially when the renal lesions are not of long standing; that the existence of uræmic phenomena is not an absolute contraindication of the drug; that it is seldom of service in *interstitial nephritis;* and that it should be employed with the greatest caution when cardiac lesions are present. Petithau advises its employment in all *subacute* or *chronic catarrhal* or *rheumatic affections;* in *dropsies*, when there is no morbid change of the kidneys, and anemia is but slight; in *pernicious intermittent fevers:* in *psoriasis* and other dry forms of *cutaneous diseases:* in *chronic syphilitic affections*, etc.

According to M. Rabuteau, coffee is an antagonist of jaborandi: when given concurrently with it, it will prevent the nausea and vomiting, and likewise appears to diminish the perspiration as well as the excretion of the urea. The effects of jaborandi upon the human system are also counteracted by subcutaneous injections of solution of atropine; while those of belladonna or atropine are overcome by subcutaneous injections of pilocarpine. But this antagonism does not invariably appear, as the symptoms following the administration of one of these substances, are not always counteracted by the employment of the other; besides while the dose of jaborandi or pilocarpine may always be readily determined, that of belladonna, and especially of atropine, is so difficult to regulate, that extreme circumspection is required (J. King). Where depressing effects are produced by jaborandi, as sometimes occurs where there are valvular disease or fatty degeneration of the heart, or morbid pulmonic circulation, strychnine hypodermatically may sustain the heart-action. Digitalis, cactus, caffeine, or strophanthus may also be used. The profuse sweating may be checked by atropine. When pilocarpine acts like atropine, such effects are probably due to contaminating jaborine.

Since the foregoing uses, as recorded by the earlier investigators of jaborandi, were established, the drug has come into prominence in Eclectic practice chiefly through the writings of Webster, Ketchum, and Foltz. Added to its diuretic and sudorific qualities, jaborandi is sedative and antispasmodic, many preferring it to veratrum for the former purpose, and to lobelia or gelsemium for the latter. The indications for this drug, specifically considered, may be summed up as follows: It is a remedy for sthenic conditions, and must be avoided, or its use carefully guarded, in weakened conditions of the heart. Jaborandi is efficient in disorders exhibiting a dry, hot skin, with febrile reaction, especially when accompanied by acute suppression of the secretions, dry, parched mouth, full, strong, hard, and sharp pulse, deficient renal activity with deep-red urine, scanty in quantity and of high specific gravity; restlessness, and, with any of these symptoms, pain. Jaborandi is claimed by Prof. Webster to be adapted to almost any febrile or inflammatory condition, sthenic or asthenic, with or without a dry skin. Most observers however, prefer to limit its use to sthenic conditions only. As a remedy for pain and inflammation it has been highly endorsed in *mammitis*, with dry skin and suppressed lacteal secretion, in *acute articular inflammation* and *acute articular rheumatism*, the joint being extremely painful and swollen. In *erysipelas* with dry skin and elevation of temperature, it has rendered good service, and is particularly of value when locally applied. Webster declares that in *cerebro-spinal meningitis*, it has no equal. In *rheumatic complaints* its value is enhanced by its power to eliminate urea and uric acid from the system. Jaborandi is indicated by stiffness, soreness, and swelling of the joints, whether the parts show redness or pallor. One of its chief indications in such disorders is *puffiness of the tissues*. For *acute* (preferably) or *chronic muscular pain*, *pleurodynia*, *lumbago*, *muscular spasm*, *cardiac rheumatism* and *angina pectoris*, few remedies are more efficient. The specific indications, must, of course, be observed.

Jaborandi is recommended for *cough* when the throat is very dry and secretion checked. It is well recommended in *bronchial asthma* and *whooping-cough* with dryness of the respiratory passages. Small doses relieve "*winter cough*," and the cough of *chronic bronchitis* with lack of secretion, and dry, irritable, hoarse cough. In the early stage of *bronchitis*, and in the congestive stage of *pneumonia*, it rapidly relieves the local inflammation, and reduces the fever if it be given in diaphoretic doses. In respiratory troubles it does best service when associated with other indicated remedies, as bryonia, asclepias, lobelia, etc. In *acute tonsillitis* with secretion of tenacious pharyngeal mucus, it serves an excellent purpose. Foltz values it highly in *pharyngitis sicca* (*Eclectic Med. Gleaner*, Vol. V, p. 193). When exudation has taken place in *pleurisy*, jaborandi is one of the best agents to effect the removal of the fluid and promote resolution. It finds also, a place in the treatment of dry *croup*, *laryngismus stridulus*, *laryngeal diphtheria*, and so-called *membranous croup*. In the latter two affections, if the child is strong, jaborandi may be administered in doses sufficient to increase the secretions of the throat, and thus loosen the false membranes. Jaborandi has given good service in *metastatic* and *gonorrhœal orchitis*, *ovaritis*, and *metritis*, the specific indications for it being present. Jaborandi is one of the most useful of agents in properly selected cases of *la grippe* or *epidemic influenza*, and of *catarrhal fever*. In fact the drug acts admirably as a non-stimulating diaphoretic and sedative in many inflammatory and febrile conditions, provided the stomach is not too irritable to retain the medicine.

In *diseases of the kidneys,* jaborandi does effective work in throwing a part of the burden of elimination upon the skin. In this way the kidneys are relieved of excess of watery secretion, and of the elimination of a portion of urea. For this reason it has been employed in various forms of *nephritis*, particularly in *acute albuminuria*, and in so-called *Bright's disease.* It is undoubtedly the best remedy (using pilocarpine preferably) we possess for *uræmic poisoning*, but the full diaphoretic action must be obtained if good results are to be expected. Diaphoretic doses also benefit the *albuminuria of pregnancy.* It has been successfully employed in conjunction with ergot to control the excessive secretion of urine in *diabetes insipidus.*

Acting upon the theory that the act of parturition is favored by free diaphoresis, jaborandi and its alkaloid have been successfully used in cases of *tedious labor* due to a rigid, hard os uteri. In these cases the pains are severe yet ineffectual, the skin dry, pulse full, sharp, and hard, and there is some febrile reaction. These conditions are rectified by diaphoretic doses of the drug. A full dose or a couple of broken doses of jaborandi is accredited with the cure of *puerperal eclampsia.* In such cases it may be advantageously combined with other indicated agents.

Jaborandi has proved a useful drug in *exanthematous diseases* with tardy appearance or tendency to recession of the eruption, and by this action has been thought to avert the danger of post-scarlatinal dropsy. Many *skin disorders* of a dry character appear to be benefited by the internal and external use of jaborandi. Among these disorders are *eczema*, *pruritis*, particularly when occurring in a jaundiced skin, *prurigo*, *hyperhydrosis pedum*, *psoriasis*, and *rhus poisoning.* In the latter affection grindelia has been employed locally with jaborandi. This drug is accredited with the rather singular effect of causing the hair to become darker in color; and it is likewise said to be useful in *alopecia* to promote the growth of the hair. For this purpose pilocarpine may be employed, with or without cantharides, and mixed with lanolin. Copious and annoying *night-sweats* are said to be relieved by minute doses of jaborandi. Locally, the drug has given relief in *burns* and *scalds*, and internally and locally is of considerable value in *parotitis.* In small doses it has been lauded as an effective agent in *ptyalism* and *aphthous stomatitis.* In *local* and *general dropsies* the drug is sometimes useful, but as cautioned by Ellingwood, it should be used discretely, particularly in *hydrocephalus*, lest harm be done to the patient.

Pilocarpus and its alkaloidal salts have been used to counteract the *poisonous effects of belladonna, atropine, stramonium, daturine*, and *poisonous bites* or *stings*, and in *ptomaine poisoning* from canned fish and meats. In the latter instances it has no antidotal power, but favors elimination of the offending material. While often failing to counteract the toxic effects of atropine, it nearly always relieves the unpleasant dryness of tissue following the use of that alkaloid or of belladonna.

Prof. Foltz is an enthusiastic advocate of the use of jaborandi in *eye, ear, nose,* and *throat disorders*, particularly where there is a lack of the natural secretions of these parts. Full doses of jaborandi contract the pupils, impair accommodation, diminish intraocular tension, and increase secretion. Locally applied, the action is similar, the effects upon the pupil, however, being much less pronounced when the drug is internally administered. Dr. Foltz praises it in *rheumatic iritis*, and for the absorption of "*non-organized vitreous opacities.*" In *iritis* he always uses it, and believes that it shortens the duration of the disease, and if adhesions are present, assists in their absorption. *Optic neuritis, retinal detachment, choroiditis, episcleritis, tobacco* and *alcoholic amblyopia*, and *atrophy of the optic nerve* are also conditions in which he advises its use. After *traumatism*, with increased ocular tension, the latter as well as the pain, will be relieved by the local use of pilocarpine hydrochlorate. Instilled in the eye the same is useful in *keratitis* and *phlyctenular conjunctivitis*, both in the early stage. For ocular affections Foltz advises as a dose from 3 to 10 drops of specific jaborandi, every 2 or 3 hours; and as a collyrium, 1 to 2 grains of pilocarpine hydrochlorate to 2 fluid ounces of water In *ear disorders* jaborandi improves by increasing the secretions of the aural cavities and canals. *[illegible]* is frequently restored to its natural condition by the continued use of jaborandi. Jaborandi is the best remedy in *non-suppurative inflammation of the middle ear*, of the proliferous type (Foltz), and it proves a good drug for *nervous deafness, deafness following scarlet fever* and *diphtheria*, and with appropriate adjunct treatment, in *inner ear diseases of syphilitic origin* (Foltz). The alkaloidal salts (⅓ to ⅙ grain subcutaneously) have been employed in these disorders, but the parent drug is to be preferred in doses of 3 to 10 drops every 3 or 4 hours.

Pilocarpine.—The alkaloid pilocarpine has been used in the forms of hydrochlorate and nitrate in the same diseases as the infusion and alcoholic preparations of the leaves. The effects of the alkaloid are said to be more certain than when the leaves are used, and the tendency to nausea and vomiting is greatly diminished. Pilocarpine may be used in many of the aforementioned disorders, although jaborandi is preferred by the Eclectic profession. Outside of the special mentions of the use of the alkaloids given above, they may be used in the following conditions: For *uræmic convulsions* and in *puerperal convulsions* it is preferred by many to jaborandi. *Œdema of the larynx* is said to be promptly relieved by pilocarpine.

Beranger considers the hydrochlorate of pilocarpine of great value, therapeutically, in certain eye diseases; he uses it in instillations, and in subcutaneous injections, two very distinct effects being obtained, according to the methods employed. By injections, profuse discharges follow, accompanied with a diminution of ocular tension, and a more rapid renovation of the media of the eye; this form of use he considers indicated in *acute* and *chronic glaucoma, iritis, floating bodies in the vitreous humor*, certain *opacities of the cornea*, and in *poisonings*. Sometimes complete recovery will ensue; at others, great relief follows. His solution was made by dissolving 3 grains of the hydrochlorate of pilocarpine in 75 minims of cherry-laurel water, of which solution from 10 to 15 drops were injected at a time. It must be remembered, however, that pilocarpine injected into a tumor of the eye, has produced great weakness and emaciation, without in the least affecting the size of the growth (see Armaingaud, in previous editions of this *Dispensatory*). By instillations, he employs it as a powerful myotic in *mydriasis*, and prefers it to eserine, as it is accompanied with no irritation. He likewise prefers it in instillation, to eserine, in disturbances of vision associated with *secondary paralysis* and characterized by *asthenopia*, with *feebleness of the intrinsic muscles of the eye*, and also in certain cases of *presbyopia* which is not constant but returns at different periods. Dr. Landesberg, of Philadelphia, found both the fluid extract of jaborandi, internally, and the hydrochlorate of pilocarpine, by subcutaneous injection, more effective and reliable than any other known remedy, in *intraocular hemorrhages*, and in *opacities of the vitreous* and *aqueous fluids;* but he prefers eserine to pilocarpine, as a myotic, on account of the increased action of the lachrymal and salivary glands occasioned by the latter, when absorbed. Gillet de Grandmont, of France, has used the nitrate of pilocarpine, by subcutaneous injection, in the forearm, of from ¼ to ½ grain, in solution; and has found surprisingly good results to follow in *specific* or *rheumatic iritis*, either simple, or complicated with alterations of the cornea, in the *keratitis of Hutchinson*, in *dimness and hemorrhage of the vitreous body*, in *glaucoma*, in *atrophy of the choroid*, in *hemorrhages* and *plastic exudations of the retina*, and in *commencing atrophy of the optic nerve*. In all the above-named affections, the agent produced its usual results, as sweating, increase of the cardiac pulsations, etc.

The dose of jaborandi in infusion (45 grains to 2 fluid ounces of water) is 1 fluid ounce, which may, if necessary, be repeated every 10 or 15 minutes; of the fluid extract, from 10 drops to 1 drachm; of specific jaborandi, 1 to 30 drops; of pilocarpine or its salts, internally, from ¼ to ¾ grain; by subcutaneous injection, $\frac{1}{20}$ to ¼ grain, in solution. In cases where the internal exhibition of jaborandi by mouth, occasions nausea or vomiting, this may be avoided in giving the dose by rectal enema.

Specific Indications and Uses.—Deficient secretion; marked dryness and heat of skin and mucous tissues; pulse full, hard, sharp, and strong; muscular pain; muscular spasm; urine suppressed, of deep color and high specific gravity; elevated temperature with deficient secretion; puffiness of tissues; rigid, hard os-uteri; marked restlessness; dry, harsh cough; tenacious sputum; œdema; uræmic poisoning and convulsions; increased ocular tension; itching, with jaundice. Adapted chiefly to sthenic cases. Minute doses relieve colliquative sweating.

PILULÆ.—PILLS.

Preparation and History.—Eclectic physicians prefer liquid remedies when practicable, objecting to any form of pill, tablet, or confectionary, especially of galenicals. "The points demanded to prepare a proper pill mass are, to obtain sufficient consistency that the particles may cohere together, and to have them firm enough to retain a globular form; their component parts should be such as to prevent any tendency to moldiness, or any absorption of moisture when exposed to the atmosphere. Medicines which are deliquescent should never enter into a pill mass, and efflorescent salts should be previously exposed to heat so as to fall to powder, by the removal of their water. Ingredients which have a chemical reaction upon each other should not be added together in a pill mass, unless it be desired to secure the influence of the resulting compound.

"Gum-resins and inspissated extracts are sometimes soft enough to be made into pills without addition; where any moisture is requisite, a few drops of alcohol is more proper than syrups or conserves, as it unites more readily with them, without sensibly increasing their bulk. In some instances, where alcohol will not act upon the mass, water may be substituted" (Coxe).

Substances which do not admit of being made into a pill mass by themselves, must have certain inert matters added to them, called *excipients*, and such excipients only should be employed as will give the proper degree of consistence and tenacity to the mass, without interfering in any way with the action of its medicinal agents or rendering the pills too large or hard. Excipients vary much in their character, according to the nature of the articles to be made into pill form; the most common are syrup, glycerin, mucilage, soap, bread-crumb, conserve of roses, water, spirit, gum, sugar, magnesia, starch, molasses, etc. The dry excipients are used to give the required firmness to extracts, confections, oils, and other fluid or soft substances, while the moist excipients are intended for dry medicines, or agents which are insoluble, and among these molasses, syrup, and conserve of roses are the most esteemed, especially when the pills are to be kept for a length of time.

The addition of too much gum Arabic or tragacanth to the pill mass, is objectionable, as it often causes the pill to become so hard as to materially modify its operation, or perhaps cause it to pass through the intestines without being dissolved. Whenever the excipient is named by the physician in his prescription, the apothecary should adopt it if practicable; but, if it be not practicable, then he must follow his own judgment. Indeed, it would always be better in prescribing extemporaneous preparations of pills, if the physician would omit the excipient, and leave it to the more practical knowledge of the apothecary to supply the appropriate excipient.

The best excipients for dry powders, as jalap, rhubarb, ipecacuanha, ginger, digitalis, conium, etc., are molasses or conserve of roses; those for resinous extracts, resins and gum-resins, are soap, proof-spirit, alkaline solutions, and sometimes mucilage; and those for the volatile oils and oleoresins, are soap, magnesia, white wax, etc. The proper selection of these, however, depends entirely upon the peculiar nature of the medicines ordered, and requires a considerable degree of practical knowledge, not expected to be possessed by the practicing physician.

The medicinal ingredients of the pill mass should be perfectly mixed and incorporated, usually combining together the active ingredients first, and afterward the excipient, and the mass should be worked in the hand, on a pill slab, or in a mortar, until it is thoroughly homogeneous. If the mass be too hard, it may not be dissolved in the juices of the stomach; if too soft, there will be difficulty in forming it into pills. The pill mass being properly formed, is now to be divided into pills; certain portions of it are, by means of a spatula, or by the pill-machine, made into long, round, slender rolls, of the desired thickness, which are then divided into pills. If the pill-machine be used, the pills are accurately divided and made globular at the same time; if the spatula be used, the pills are to be rounded by the fingers. Most apothecaries are furnished with the pill-machines, which serve to expedite the process, as well as to secure a greater degree of accuracy.

Pills containing vegetable drugs usually weigh from 1 to 5 grains; containing heavy mineral preparations, 5 to 10 grains. A larger pill than these is denominated a *bolus;* a very small, sugar-coated pill, a *granule.*

PILL-COATING.—In order to cover the taste and odor of pills many plans have been devised; formerly they were covered with gold or silver leaf, but this is a very objectionable method, as pills thus prepared frequently pass through the bowels without being dissolved. Another mode is to dip each pill in a melted solution of pure glue, but this plan is tedious and requires considerable time for the drying of the pills. Collodion has been recommended as an agent for covering pills, but as the collodion will not readily dissolve in the stomach, its employment would be improper. Sugar is frequently used, combined with gum Arabic, and sometimes starch is likewise added, the proportions of each article being the same; the pills to be dipped in a thin syrup, and then rolled in the mixture. This process is most applicable to disagreeably odorous substances, as castor, asafœtida, valerian, etc., which are completely masked by it. When the gelatin is previously colored with carmine, the pills resemble hawthorn berries.

M. Calloud treats of the subject of enveloping medicinal substances in a covering to prevent unpleasant taste, in *Jour. de Pharm.*, Vol. XXIII, p. 301. He had recourse to the dried mucilage of flaxseed prepared with sugar. His method is: Take of flaxseed, 1 part; white sugar, 3 parts; spring water, a sufficient quantity. A thick mucilage is obtained by carefully boiling the seeds, the sugar is added, and the whole of the moisture evaporated by careful desiccation. The mixture is but slightly hygroscopic, may be reduced to fine powder, and employed for covering pills. This operation is effected extemporaneously with great facility. The pills, slightly moistened, are rolled in the mucilaginous powder, by which they are coated with a layer of the compound.

M. Calloud suggests another process, applicable in certain cases, which is the use of butter of cacao as a covering for pills, where, owing to gastric irritation, the unmasked pills will cause disagreeable symptoms. The process is very simple; the prepared pills are thrown into melted butter of cacao, then removed with a perforated skimmer, and finally rolled in finely-powdered sugar, or what is better, sugar of milk. He also prepares a powder, in which the pills, previously dampened externally with water, are agitated until sufficiently coated; it is prepared by mixing a clear mucilage of tragacanth (made of tragacanth, 1 part; water, 2 parts) with sugar of milk, 20 parts; spreading this thinly upon plates, and, when thoroughly dried, pulverizing it.

Blanchard's method, as improved by Baildon, consists of using a solution of balsam of tolu, 1 drachm, in chloroform, 3 drachms. Some of this is placed in a suitable box, the pills agitated in it, then turned upon a slab, and so arranged that they do not touch each other. In about 20 minutes they are dry and non-adhesive, and present a finished appearance. It not only conceals any unpleasant taste or smell, but it prevents the pills from becoming too hard (*Amer. Jour. Pharm.*, Vol. XXIX, p. 350).

The foregoing remarks are largely historical, and record the method of pill-coating in the apothecary shops, and may be useful still when it is desirable to coat a few pills extemporaneously. But, at present, the coating of pills is done on a large scale by manufacturing pharmacists, who supply not only simples, but compounds of every description capable of being made into pills. Two forms of pill-coating are used—sugar and gelatin—of which we prefer the latter. Sometimes admixtures of foreign bodies are employed, such as chalk or starch, and, in some cases, the pills are given a coating of shellac or rosin previous to the sugar. This is to prevent coloring of the sugar-coat, and is to be objected to because of its insoluble nature. The methods of each manufacturer are in part peculiar to himself, and are derived from his experience and skill, but all are an outgrowth of the hand-coating processes mentioned in this article.

Mr. H. C. Archibald describes the method pursued by manufacturers in sugar-coating pills and granules, in *Amer. Jour. Pharm.*, 1867, p. 199; and, in the same journal, 1867, p. 12, Prof. E. Parrish makes known a new process for preparing sugar-coated pills, but which is only practicable on a large scale. (For other *excipients* and *coatings*, see following pill formulæ.)

Pill-dusting.—Several substances are used for covering pills to prevent them from adhering to each other, as powdered elm-bark, powdered orris or liquorice roots, lycopodium, carbonate of magnesium, starch, etc., and these powders are also used during the formation of the pill to prevent them from sticking to the fingers or to the apparatus on which they are made. The powders ordinarily used are liquorice, lycopodium, and elm. Carbonate of magnesium can only be used in those instances where it occasions no decomposition with one or more active constituents of the pill.

Compressed Pills.—This class of preparations is usually prepared by means of a proper instrument, by compression of the desired material, in powder, without the addition of an excipient. Powders which are not deliquescent, yet easily soluble in water, are best adapted for compressed pills. Occasionally, for the sake of rendering the substance more easily compressible, or to facilitate the removal of the pills from the mold or instrument employed, very dry materials are combined with a very little of petrolatum, sugar, cacao butter, or alcohol. These pills are generally of lenticular shape. (See Remington's and Coblentz's *Prac. of Pharm.*)

Preservation.—Pills are much better preserved in small, loosely-stoppered glass bottles than in the common wood or pasteboard boxes, and should be dispensed in glass vials by the apothecary. As it is not always convenient to make a large amount of pill mass into pills at one time, the balance may be kept in a bladder, which should be moistened occasionally with some of the same kind of liquid the mass was made up with, or with some aromatic oil.

Tablet Triturates.—These are made by compressing mixtures of powders or of simple substances in powder form into discs of variable size and shape They are open to many objections as medicinal representatives of drugs, and cannot carry the values of substances which either disintegrate or evaporate on drying. For this reason, they can not correctly represent a large class of natural drugs. Tablets are easily made, and their manufacture, on a large scale, might properly become a part of the confectioner's art. In our opinion, for all plant preparations, such as extracts, gelatin-coated pills are preferable and fully as elegant. For such simples as chemicals, that do not alter by action of the air, tablets are suitable, providing they are not stamped so hard as to prevent them from dissolving. Great discrimination should be employed in the use of tablets, and if the physician is not qualified to judge of the remedy's nature, he should be very cautious concerning its use in tablet form. Sugar and other inert substances are employed in the making of tablets to give bulk to energetic bodies. In our opinion, much injury has been done by the indiscrete attempt of tablet makers to put into tablet form remedies that deteriorate or are destroyed by drying. These general remarks on tablets are offered in this place because of the fact that we have no special department for them.

Pilulæ (N. F.), *Pills*.—"In giving the formulas for pills, the quantities of the several ingredients required for one hundred (100) pills are given in metric weights in the first column, while the quantities required for each single pill are given in apothecaries' weight in the second column. When it is desirable to prepare a number of pills by the proportion given for the single pill, it is recommended that, upon multiplying by the number of pills required, the nearest whole number, or nearest convenient fraction, in each case, be chosen" (*Nat. Form.*).

This arrangement has been altered in this work so that the figures representing the amount in each pill follow the general formula. This is done to save space

PILULÆ ACONITI COMPOSITÆ.—COMPOUND PILLS OF ACONITE.

Preparation.—Take of extract of aconite, ½ drachm; extract of stramonium, 4 grains; valerianate of quinine, 20 grains. Mix thoroughly, form a pill mass, and divide into 60 pills.

Action, Medical Uses, and Dosage.—These pills are very efficient in *febrile* and *inflammatory complaints*, where *nervous irritability*, restlessness, or wakefulness is present; also in *nervous headache*, and other nervous affections. They are but little used at the present time. The dose is 1 pill every 2, 3, or 4 hours, according to the urgency of the symptoms, and the effect caused by the use of the pills (J. King).

PILULÆ ALOES (U. S. P.)—PILLS OF ALOES.

Synonym: *Pills of Socotrine aloes.*

Preparation.—"Purified aloes, in fine powder, thirteen grammes (13 Gm.) [201 grs.]; soap, in fine powder, thirteen grammes (13 Gm.) [201 grs.]; water, a sufficient quantity to make 100 pills. Beat the powders together with water, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Aloes*.) Dose, from 1 to 3 pills.

PILULÆ ALOES COMPOSITÆ.—COMPOUND PILLS OF ALOES.

Synonym: *Anti-dyspeptic pills.*

Preparation.—Take of extracts of boneset, mandrake, and ginseng, each, 2 drachms; aloes, in powder, 8 drachms; gamboge, castile soap, of each, in powder, 4 drachms; capsicum and lobelia seed, of each, in powder, 1 drachm; oil of cloves, 2 minims. Mix the extracts together, then add the soap, beating it well in a mortar, and finally thoroughly beat and work in the powders, and when the whole is well incorporated, add the oil of cloves. Divide the mass into pills of 4 grains each (T. V. Morrow, M. D.).

This pill is by many considered superior to the one originally given in Beach's *Amer. Prac.*, of which the following is the formula: Take of Socotrine aloes, in powder, 4 ounces; castile soap, colocynth, gamboge, of each, 2 ounces; extract of gentian, 4 ounces; oil of cloves, 2 drachms. Mix as above. Dose, same as above.

Action, Medical Uses, and Dosage.—This pill is cathartic in doses of from 2 to 4 pills. It has been found very useful in *dyspepsia*, *constipation*, *jaundice*, *amenorrhœa*, and in all ordinary cases where cathartics are required.

PILULÆ ALOES ET ASAFŒTIDÆ (U. S. P.)—PILLS OF ALOES AND ASAFETIDA.

Preparation.—"Purified aloes, in fine powder, nine grammes (9 Gm.) [139 grs.]; asafetida, nine grammes (9 Gm.) [139 grs.]; soap, in fine powder, nine grammes (9 Gm.) [139 grs.]; water, a sufficient quantity to make 100 pills. Beat the solids together with water, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This pill is applicable in *constipation* in nervous and hysterical individuals who suffer from *gastric debility* and *flatulence*. Dose, 2 to 5 pills.

PILULÆ ALOES ET FERRI (U. S. P.)—PILLS OF ALOES AND IRON.

Preparation.—"Purified aloes, in fine powder, seven grammes (7 Gm.) [108 grs.]; dried ferrous sulphate, seven grammes (7 Gm.) [108 grs.]; aromatic powder, seven grammes (7 Gm.) [108 grs.]; confection of rose, a sufficient quantity to make 100 pills. Beat the powders together with confection of rose, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This pill is employed in treating *amenorrhœa*, accompanied by *constipation*, in debilitated and anemic women. Dose, 1 to 3 pills. Small doses should be administered for some little time previous to the menstrual periods.

PILULÆ ALOES ET MASTICHES (U. S. P.)—PILLS OF ALOES AND MASTIC.

Preparation.—"Purified aloes, in fine powder, thirteen grammes (13 Gm.) [201 grs.]; mastic, in fine powder, four grammes (4 Gm.) [62 grs.]; red rose, in fine powder, three grammes (3 Gm.) [46 grs.]; water, a sufficient quantity to make 100 pills. Beat the powders together with water, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This is a modification of *Lady Webster's Dinner Pills.* The mastiche retards the solubility of the pill so that its chief action is exerted on the large intestine, hastening rectal evacuation. Used for *constipation* and *gastro-intestinal torpor.* Dose, 1 pill (each pill contains about 2 grains of aloes) at dinner or at bedtime.

Related Pills.—ANDERSON'S SCOTS PILLS. Take Barbadoes aloes, 12 ounces; colocynth, $\frac{1}{2}$ ounce; gamboge, $\frac{1}{2}$ ounce. All in very fine powder. Beat them with soap, 2 ounces, a little water, and oil of anise, fl℥ii. Divide into 3-grain pills.

HOOPER'S FEMALE PILLS.—Take aloes, 40 parts; ferrous sulphate (crystallized), 20 parts; myrrh, extract of black hellebore, and soap, āā, 10 parts; ginger and canella, both in powder, āā, 5 parts. Beat into a mass with water. Divide into $2\frac{1}{2}$-grain pills. Cathartic and emmenagogue.

PILULÆ AD PRANDIUM (N. F.), *Dinner pills.*—"I. When 'dinner pills,' under this or some other equivalent name, are prescribed without further specification, it is recommended that the *Pilulæ Aloes et Mastiches* of the *U. S. P.*, also called Lady Webster's Dinner Pills, be dispensed. *Note.*—Of other combinations bearing similar names, or used for similar purposes, the following appear to be those most commonly in use: II. *Chapman's Dinner Pills.*—"Purified aloes (*U. S. P.*), nine and seven-tenths grammes (9.7 Gm.) [150 grs.]; mastic, nine and seven-tenths grammes (9.7 Gm.) [150 grs.]; ipecac, in fine powder, six and one-half grammes (6.5 Gm.) [100 grs.]; oil of fennel, one and one-half cubic centimeters (1.5 Cc.) [25 ♏]. To make 100 pills. Each pill contains $1\frac{1}{2}$ grains of aloes, $1\frac{1}{2}$ grains of mastic, 1 grain of ipecac and about $\frac{1}{4}$ minim of oil of fennel" (see *Pilulæ*, N. F.). III. *Cole's Dinner Pills.*—"Purified aloes (*U. S. P.*), seven and eight-tenths grammes (7.8 Gm.) [120 grs.]; mass of mercury (*U. S. P.*), seven and eight-tenths grammes (7.8 Gm.) [120 grs.]; jalap, in fine powder, seven and eight-tenths grammes (7.8 Gm.) [120 grs.]; antimony and potassium tartrate, thirteen centigrammes (0.13 Gm.) [2 grs.]. To make 100 pills. Each pill contains $1\frac{1}{5}$ grains of aloes, $1\frac{1}{5}$ grains of blue mass, $1\frac{1}{5}$ grains of jalap, and $\frac{1}{50}$ grain of tartar emetic" (see *Pilulæ*, N. F.). IV. *Hall's Dinner Pills.*—"Purified aloes (*U. S. P.*), six and one-half grammes (6.5 Gm.) [100 grs.]; extract of glycyrrhiza, six and one half grammes (6.5 Gm.) [100 grs.]; soap, in powder, six and one-half grammes (6.5 Gm.) [100 grs.]; molasses, six and one-half grammes (6.5 Gm.) [100 grs.]. To make 100 pills. Each pill contains 1 grain of aloes, 1 grain of extract of liquorice, 1 grain of soap, and 1 grain of molasses" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ ALOES ET PODOPHYLLI COMPOSITÆ (N. F.), *Compound pills of aloes and podophyllum, Janeway's pills.*—"Purified aloes (*U. S. P.*), six and one-half grammes (6.5 Gm.) [100 grs.]; resin of podophyllum (*U. S. P.*), three and one-fourth grammes (3.25 Gm.) [50 grs.]; alcoholic extract of belladonna leaves (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]; extract of nux vomica (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]. To make 100 pills. Each pill contains 1 grain of aloes, $\frac{1}{2}$ grain of resin of podophyllum, $\frac{1}{4}$ grain of extract of belladonna leaves, and $\frac{1}{4}$ grain of extract of nux vomica" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ TRIPLICES (N. F.), *Triplex pills, Pilula triplex.*—I. "Purified aloes (*U. S. P.*), thirteen grammes (13 Gm.) [200 grs.]; mass of mercury (*U. S. P.*), six and one-half grammes (6.5 Gm.) [100 grs.]; resin of podophyllum (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]. To make 100 pills. Each pill contains 2 grains of aloes, 1 grain of blue mass, and $\frac{1}{4}$ grain of resin of podophyllum (see *Pilulæ*, N. F.). *Note.*—When *Pilula triplex*, under this name or some equivalent, is prescribed without further specification, it is recommended that the above preparation be dispensed. A formula devised by Dr. John W. Francis is also in use: II. *Francis' triplex pills.*—Purified aloes (*U. S. P.*), five and one-half grammes (5.5 Gm.) [85 grs.]; scammony, five and one-half grammes (5.5 Gm.) [85 grs.]; mass of mercury (*U. S. P.*), five and one-half grammes (5.5 Gm.) [85 grs.]; croton oil, thirty-two one-hundredths cubic centimeter (0.32 Cc.) [5 ♏]; oil of caraway, one and six-tenths cubic centimeters (1.6 Cc.) [25 ♏]; tincture of aloes and myrrh (*U. S. P.*), a sufficient quantity to make 100 pills. Each pill contains $\frac{5}{6}$ grain of aloes, $\frac{5}{6}$ grain of scammony, $\frac{5}{6}$ grain of blue mass, $\frac{1}{20}$ minim of croton oil, $\frac{1}{4}$ minim of caraway oil, and a sufficient quantity of tincture of aloes and myrrh" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ QUADRUPLICES (N. F.), *Quadruplex pills, Quatuor pills, Pilulæ ferri et quininæ compositæ.*—"Dried sulphate of iron, six and one-half grammes (6.5 Gm.) [100 grs.]; quinine sulphate, six and one-half grammes (6.5 Gm.) [100 grs.]; purified aloes (*U. S. P.*), six and one-half grammes (6.5 Gm.) [100 grs.]; extract of nux vomica (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]; extract of gentian (*U. S. P.*), a sufficient quantity to make 100 pills. Each pill contains 1 grain of sulphate of iron, 1 grain of quinine sulphate, 1 grain of aloes, $\frac{1}{4}$ grain of extract of nux vomica, and a sufficient quantity of extract of gentian" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ ALOES ET MYRRHÆ (U. S. P.)—PILLS OF ALOES AND MYRRH.

SYNONYM: *Rufus' pills.*

Preparation.—"Purified aloes, in fine powder, thirteen grammes (13 Gm.) [201 grs.]; myrrh, in fine powder, six grammes (6 Gm.) [93 grs.]; aromatic powder, four grammes (4 Gm.) [62 grs.]; syrup, a sufficient quantity to make 100 pills. Beat the powders together with syrup, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—As a laxative, 1 to 2 pills; purgative, 2 to 6 pills. Also employed in *uterine disorders* marked by *constipation* and *torpor.*

Related Pill.—PILULÆ FERRI COMPOSITÆ (N. F.), *Compound pills of iron* (*U. S. P.*, 1880). "Myrrh, nine and three-fourths grammes (9.75 Gm.) [150 grs.]; sodium carbonate, four grammes and eighty-five centigrammes (4.85 Gm.) [75 grs.]; sulphate of iron, 4 grammes and eighty-five centigrammes (4.85 Gm.) [75 grs.]; syrup, a sufficient quantity. To make 100 pills. Each pill contains $1\frac{1}{2}$ grains of myrrh, $\frac{3}{4}$ grain of sodium carbonate, and $\frac{3}{4}$ grain of sulphate of iron" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ ALOINI, STRYCHNINÆ, ET BELLADONNÆ (N. F.) PILLS OF ALOIN, STRYCHNINE, AND BELLADONNA.

Preparation.—"Aloin, one and three-tenths grammes (1.3 Gm.) [20 grs.]; strychnine, alkaloid, five centigrammes (0.05 Gm.) [$\frac{5}{6}$ gr.]; alcoholic extract of belladonna leaves (*U. S. P.*), eight decigrammes (0.8 Gm.) [12.5 grs.]. To make 100 pills. Each pill contains $\frac{1}{5}$ grain of aloin, $\frac{1}{120}$ grain of strychnine, and $\frac{1}{8}$ grain of extract of belladonna leaves (see *Pilulæ*, N. F.). *Note.*—These pills are also prepared with double the amount of strychnine. It is recommended that the stronger pills be dispensed only when specially demanded." Adapted from *Nat. Form.*

Action, Medical Uses, and Dosage.—These pills are very popular with physicians at the present day for the treatment of *habitual constipation*. Dose, 1 to 2 pills a day.

Related Pills.—PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ COMPOSITÆ (N. F.), *Compound pills of aloin, strychnine, and belladonnæ.* "Aloin, one and three-tenths grammes (1.3 Gm.) [20 grs.]; strychnine, alkaloid, five centigrammes (0.05 Gm.) [$\frac{5}{6}$ gr.]; alcoholic extract of belladonna leaves (*U. S. P.*), eight decigrammes (0.8 Gm.) [12.5 grs.]; extract of rhamnus purshiana, three and one-fourth grammes (3.25 Gm.) [50 grs.]. To make 100 pills. Each pill contains $\frac{1}{5}$ grain of aloin, $\frac{1}{120}$ grain of strychnine, $\frac{1}{8}$ grain of extract of belladonna leaves, and $\frac{1}{2}$ grain of extract of rhamnus (see *Pilulæ*, N. F.). *Note.*—If extract of rhamnus purshiana is not available, take fluid extract of rhamnus purshiana (*U. S. P.*), and evaporate it on a water-bath, to a pilular consistence. These pills are also prepared with double the amount of strychnine. It is recommended that the stronger pills be dispensed only when specially demanded." Adapted from *Nat. Form.*

PILULÆ ALOINI COMPOSITÆ (N. F.), *Compound pills of aloin.*—"Aloin, three and one-fourth grammes (3.25 Gm.) [50 grs.]; resin of podophyllum (*U. S. P.*), eight decigrammes (0.8 Gm.) [12.5 grs.]; alcoholic extract of belladonna leaves (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]. To make 100 pills. Each pill contains $\frac{1}{2}$ grain of aloin, $\frac{1}{8}$ grain of resin of podophyllum, and $\frac{1}{4}$ grain of extract of belladonna leaves" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ ANTIDYSPEPTICÆ (N. F.), *Antidyspeptic pills.*—"Strychnine, alkaloid, sixteen centigrammes (0.16 Gm.) [$2\frac{1}{2}$ grs.]; ipecac, in fine powder, sixty-five centigrammes (0.65 Gm.) [10 grs.]; alcoholic extract of belladonna leaves (*U. S. P.*), sixty-five centigrammes (0.65 Gm.) [10 grs.]; mass of mercury (*U. S. P.*), thirteen grammes (13 Gm.) [200 grs.]; compound extract of colocynth (*U. S. P.*), thirteen grammes (13 Gm.) [200 grs.]. To make 100 pills. Each pill contains $\frac{1}{40}$ grain of strychnine, $\frac{1}{10}$ grain of ipecac, $\frac{1}{10}$ grain of extract of belladonna leaves, 2 grains of blue mass, and 2 grains of extract of colocynth" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ ASAFŒTIDÆ (U. S. P.)—PILLS OF ASAFETIDA.

Preparation.—"Asafetida, twenty grammes (20 Gm.) [309 grs.]; soap, in fine powder, six grammes (6 Gm.) [92 grs.]; water, a sufficient quantity to make 100 pills. Beat the solids together with water, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*). This pill should be coated with sugar. Each pill contains 3 grains of asafœtida.

Action, Medical Uses, and Dosage.—Same as *Asafœtida.* Dose, 1 to 3 pills.

PILULÆ ASAFŒTIDÆ COMPOSITÆ (ECLECTIC).—COMPOUND PILLS OF ASAFETIDA.

Preparation.—Take of asafœtida, opium, carbonate of ammonium, each, 1 drachm. Mix the asafœtida and opium together by aid of a gentle heat, and, while soft, add the ammonium carbonate. Divide the mass into 75 pills.

Medical Uses and Dosage.—This pill is useful in many *nervous* and *hysterical disorders*. Each pill contains $\frac{4}{5}$ of a grain of opium. The dose is 1 or 2 pills, according to the severity of the case.

PILULÆ BAPTISIÆ COMPOSITÆ.—COMPOUND PILLS OF WILD INDIGO.

Preparation.—Take of extract of leptandra, 4 grains; resin of podophyllum, 8 grains; sanguinarine, 1 grain; alcoholic extract of wild indigo root, a sufficient quantity to form a pill mass. Mix thoroughly together, and divide into 16 pills.

Action, Medical Uses, and Dosage.—These pills are cholagogue, laxative, and antiseptic; they were formerly considered especially useful in *typhoid fevers*, and in all *typhoid conditions*, where it was required to keep the bowels regular. The dose is 1 pill, to be repeated every 2, 3, or 4 hours until a mild operation is produced; to be given daily, or every other day (J. King).

PILULÆ CAMBOGIÆ COMPOSITÆ.—COMPOUND PILLS OF GAMBOGE.

Preparation.—Take of gamboge and scammony, each, in powder, 12 grains; elaterium, 2 grains; croton oil, 8 minims; extract of hyoscyamus, a sufficient quantity. Mix together, and divide into 12 pills.

Action, Medical Uses, and Dosage.—This is a quick and certain cathartic, useful in *dropsy*, *obstinate constipation*, etc. The dose is 1 pill, repeated every 1 or 2 hours, until it operates. It is contraindicated when inflammation of any of the abdominal viscera is present.

PILULÆ CAMPHORÆ COMPOSITÆ.—COMPOUND PILLS OF CAMPHOR.

SYNONYM: *Cholera pill.*

Preparation.—Take of camphor, opium, kino, of each, in powder, 30 grains; capsicum, 5 grains; conserve of roses, a sufficient quantity. Mix together, and form a pill mass, and divide into 30 pills.

Action, Medical Uses, and Dosage.—These pills were much employed in *Asiatic cholera*, as a stimulant, antispasmodic, anodyne, and astringent, and with much success. One pill to be given after each discharge from the bowels, or oftener, if the urgency of the case requires it. When powders are preferred, the conserve of roses may be omitted, and the mixture be given in powder.

Related Pills.—PILULÆ OPII ET CAMPHORÆ (N. F.), *Pills of opium and camphor.* "Powdered opium, six and one-half grammes (6.5 Gm.) [100 grs.]; camphor, thirteen grammes [illegible] Gm.) [200 grs.]. To make 100 pills. Each pill contains 1 grain of opium and 2 grains of camphor" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.* Uses, similar to those of *Dover's powder.* Dose, 1 to 2 pills.

PILULÆ ANTINEURALGICÆ (N. F.), *Antineuralgic pills.*—I. *Gross' antineuralgic pills.* "Quinine sulphate, thirteen grammes (13 Gm.) [200 grs.]; morphin sulphate, thirty-two centigrammes (0.32 Gm.) [5 grs.]; strychnine, alkaloid, twenty-two centigrammes (0.22 Gm.) [3.3 grs.]; arsenous acid, thirty-two centigrammes (0.32 Gm.) [5 grs.]; extract of aconite leaves (U. S. P. 1870), three and two-tenths grammes (3.2 Gm.) [50 grs.]. To make 100 pills. Each pill contains 2 grains of quinine sulphate, $\frac{1}{20}$ grain of morphine sulphate, $\frac{1}{30}$ grain of strychnine, $\frac{1}{20}$ grain of arsenous acid, and $\frac{1}{2}$ grain of extract of aconite leaves (see *Pilulæ*, N. F.). *Note.* When 'antineuralgic pills,' or 'neuralgia pills,' without other specification, are prescribed, it is recommended that the above preparation be dispensed. Sometimes the morphine sulphate is directed to be omitted. II. *Brown-Séquard's antineuralgic* or *neuralgia pills*.—Extract of hyoscyamus (*U. S. P.*), four and one-half grammes (4.5 Gm.) [67 grs.]; extract of conium (*U. S. P.*), four and one-half grammes (4.5 Gm.) [67 grs.]; extract of ignatia (*U. S. P.*), three and two-tenths grammes (3.2 Gm.) [50 grs.]; extract of opium (*U. S. P.*), three and two-tenths grammes (3.2 Gm.) [50 grs.]; extract of aconite leaves (*U. S. P.*, 1870), two and two-tenths grammes (2.2 Gm.) [33 grs.]; extract of Indian cannabis (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]; extract of stramonium (*U. S. P.*), one and three-tenths grammes (1.3 Gm.) [20 grs.]; alcoholic extract of belladonna leaves (*U. S. P.*), one and one-tenth grammes (1.1 Gm.) [17 grs.]. To make 100 pills. Each pill contains ⅔ grain of extract of hyoscyamus, ⅔ grain of extract of conium, ½ grain of extract of ignatia, ½ grain of extract of opium, ⅓ grain of extract of aconite leaves, ¼ grain of extract of cannabis, ⅕ grain of extract of stramonium, and ⅙ grain of extract of belladonna leaves" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ CATHARTICÆ COMPOSITÆ (ECLECTIC).—COMPOUND CATHARTIC PILLS.

Preparation.—Take of extract of leptandra, gamboge, scammony, each, in powder, 1 drachm; resin of podophyllum, castile soap, each, ½ drachm. Triturate the powders thoroughly together, then add the soap; mix and beat the whole together till they are thoroughly incorporated. Divide the mass into 100 pills (J. King).

Action, Medical Uses, and Dosage.—This is a valuable pill in all cases where a cathartic is required, as in *constipation*, *torpor of the biliary apparatus*, *hepatic disease*, *intermittent* and *remittent fevers*, *jaundice*, etc. One pill will generally be found sufficient for a dose, rarely 2 pills will be required.

PILULÆ CATHARTICÆ VEGETABILES (U. S. P.)—VEGETABLE CATHARTIC PILLS.

Preparation.—"Compound extract of colocynth, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; extract of hyoscyamus, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; extract of jalap, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; extract of leptandra, fifteen grammes (15 Gm.) [231 grs.]; resin of podophyllum, fifteen grammes (15 Gm.) [231 grs.]; oil of peppermint, eight cubic centimeters (8 Cc.) [130 ♏]; water, a sufficient quantity to make 1000 pills. Mix the compound extract of colocynth intimately with the resin of podophyllum and incorporate the oil of peppermint. Rub the extracts of hyoscyamus, jalap, and leptandra with enough water to render them plastic, then beat them together with the mixture first prepared, using a sufficient quantity of water to form a mass, to be divided into 1000 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—As the name indicates, this is a vegetable cathartic. Dose, as a laxative, 1 pill; as a cathartic, 2 to 3 pills.

Related Pills.—PILULÆ CATHARTICÆ COMPOSITÆ (*U. S. P.*), *Compound cathartic pills*, *Antibilious pills*. "Compound extract of colocynth, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; mild mercurous chloride, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; extract of jalap, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; gamboge, in fine powder, fifteen grammes (15 Gm.) [231 grs.]; water, a sufficient quantity to make 1000 pills. Mix the powders intimately, then gradually incorporate them with the extract of jalap and a sufficient quantity of water to form a mass, to be divided into 1000 pills"—(*U. S. P.*). Often repeated, this pill will salivate. Dose, as a laxative, 1 pill (about 3 grains); as a brisk cathartic, 3 pills. Extensively used by members of the old school of practice as a laxative and cathartic. It is not employed in Eclectic medicine.

PILULÆ ANTIMONII COMPOSITÆ (*U. S. P.*), *Compound pills of antimony*, *Plummer's pills*, *Compound pills of subchloride of mercury*, *Compound calomel pills*.—"Sulphurated antimony, four grammes (4 Gm.) [62 grs.]; mild mercurous chloride, four grammes (4 Gm.) [62 grs.]; guaiac, in fine powder, eight grammes (8 Gm.) [123 grs.]; castor oil, a sufficient quantity to make 100 pills. Beat the powders together with castor oil, added a few drops at a time, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*). This pill is not employed by the Eclectic profession. It is used in old school practice for *rheumatic* and *cutaneous disorders of syphilitic origin*. Dose, 1 to 4 pills a day

PILULÆ CIMICIFUGÆ COMPOSITÆ.—COMPOUND PILLS OF BLACK COHOSH.

Preparation.—Take of the alcoholic extracts of black cohosh and scutellaria, each, 1 drachm; valerianate of quinine, $\frac{1}{2}$ drachm. Mix thoroughly together, form into a pill mass, and divide into 60 pills.

Action, Medical Uses, and Dosage.—These pills will be found very useful in *chorea* and other derangements of the nervous system, also in *fevers* or other diseases, attended with much *restlessness* or *wakefulness*, and in several *uterine affections*. The dose is 1 pill every 1, 2, or 3 hours, daily, according to the urgency of the symptoms (J. King).

PILULÆ COLOCYNTHIDIS COMPOSITÆ (N. F.)—COMPOUND PILLS OF COLOCYNTH.

SYNONYMS: *Pilulæ cocciæ*, *Cochia pills*.

Preparation.—"Extract of colocynth (*U. S. P.*), one and one-tenth grammes (1.1 Gm.) [17 grs.]; purified aloes (*U. S. P.*), thirteen grammes (13 Gm.) [200 grs.]; resin of scammony (*U. S. P.*), thirteen grammes (13 Gm.) [200 grs.]; oil of cloves, one and one-half cubic centimeters (1.5 Cc.) [25 ♏]. To make 100 pills. Each pill contains $\frac{1}{6}$ grain of extract of colocynth, 2 grains of aloes, 2 grains of scammony, and $\frac{1}{4}$ minim of oil of cloves (see *Pilulæ*, N. F.). *Note.*—The *Pilula Colocynthidis Composita* of the *British Pharmacopœia*, for which the above is an equivalent, is prepared with colocynth pulp, and contains potassium sulphate, which was originally added as an aid to reduce the ingredients to powder. With the use of extract of colocynth this becomes unnecessary. The *British Pharmacopœia* directs the above to be kept as a pill mass, to be made into pills of such weight as may be prescribed. When such specification is omitted, it is recommended to dispense pills containing the quantities above directed." Adapted from *Nat. Form.*

Action, Medical Uses, and Dosage.—This pill is employed as a purgative. Dose, 1 to 2 pills.

Related Pills.—PILULÆ COLOCYNTHIDIS ET HYOSCYAMI (N. F.), *Pills of colocynth and hyoscyamus*. "Extract of colocynth (*U. S. P.*), sixty-five centigrammes (0.65 Gm.) [10 grs.]; purified aloes (*U. S. P.*), nine and seven-tenths grammes (9.7 Gm.) [150 grs.]; resin of scammony (*U. S. P.*), nine and seven-tenths grammes (9.7 Gm.) [150 grs.]; oil of cloves, one cubic centimeter (1 Cc.) [17 ♏]; extract of hyoscyamus (*U. S. P.*), nine and seven-tenths grammes (9.7 Gm.) [150 grs.]. To make 100 pills. Each pill contains $\frac{1}{10}$ grain of extract of colocynth, $1\frac{1}{2}$ grains of aloes, $1\frac{1}{2}$ grains of scammony, $\frac{1}{6}$ minim of oil of cloves, and $1\frac{1}{2}$ grains of extract of hyoscyamus (see *Pilulæ*, N. F.). *Note.*—The *Pilula Colocynthidis et Hyoscyami* of the *British Pharmacopœia* is directed to be made by mixing 2 parts of compound pill of colocynth (F. 298), with 1 part of extract of hyoscyamus, and is directed to be kept as a pill mass, to be made into pills of such weight as may be directed. When such specification is omitted, it is recommended to dispense pills containing the quantities above directed." Adapted from *Nat. Form.*

PILULÆ COLOCYNTHIDIS ET PODOPHYLLI (N. F.), *Pills of colocynth and podophyllum.*—"Compound extract of colocynth (*U. S. P.*), sixteen and two-tenths grammes (16.2 Gm.) [250 grs.]; resin of podophyllum (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]. To make 100 pills. Each pill contains $2\frac{1}{2}$ grains of extract of colocynth, and $\frac{1}{4}$ grain of resin of podophyllum" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ COPAIBÆ.—PILLS OF COPAIBA.

Preparation.—Take of copaiba and white wax, of each, 1 drachm. Melt the wax, mix in the copaiba, and divide into 30 pills (compare *Massa Copaibæ*). These pills are frequently combined in other proportions, and with the addition of cubebs. Thus: take of copaiba 1 part; white wax, $1\frac{1}{2}$ parts; cubebs, in powder, 2 parts. Melt the wax, add the copaiba and cubebs, and divide into 4-grain pills. This combination is suitable to warm climates. Another combination is: take of copaiba, 1 part; white wax, 2 parts; cubebs, in powder, 3 parts. Prepare as above, and divide into 4-grain pills.

Copaiba is usually solidified into a pill mass by the use of the recently calcined magnesia. The magnesia absorbs the oil of copaiba, and at the same time forms with the acid of the copaiba a copaivate of magnesium. The time required to effect the solidification of the copaiba will be several hours, and the quantity of magnesia required will depend upon the amount of copaivic acid present. Ordinarily, 16 parts of magnesia to 1 of copaiba will effect the solidification; and the mass should not be allowed to harden too much before it is divided into pills. The addition of the magnesia does not materially increase the size of the pill.

Action, Medical Uses, and Dosage.—These pills are useful in *gonorrhœa*, and other affections where the medicinal agents are indicated. The dose is 2 to 4 pills, 3 times a day.

PILULÆ COPAIBÆ COMPOSITÆ.—COMPOUND PILLS OF COPAIBA.

Preparation.—Take of solidified copaiba, 1 drachm; ethereal extract of cubebs, ½ drachm; resin of podophyllum, 9 grains; gum myrrh, 1 drachm; alcoholic extract of nux vomica, 15 grains. Mix thoroughly, and divide into 3-grain pills.

Action, Medical Uses, and Dosage.—These pills are useful in *gonorrhœa, gleet, stricture*, and *chronic inflammation of the prostate*. The dose is from 2 to 4 pills, twice a day. For ordinary cases, the following preparation will be found beneficial: Take of solidified copaiba, 2 drachms; ethereal extract of cubebs, 1 drachm; oil of juniper, a sufficient quantity, not to impair the pilular consistency of the mass. Mix, and divide into pills of 4 grains each. The dose is the same as above.

PILULÆ FERRI CARBONATIS (U. S. P.)—PILLS OF FERROUS CARBONATE.

SYNONYMS: *Ferruginous pills, Chalybeate pills, Blaud's Pills, Pills of iron, Griffith's pills.*

Preparation.—"Ferrous sulphate, in clear crystals, sixteen grammes (16 Gm.) [247 grs.]; potassium carbonate, eight grammes (8 Gm.) [123 grs.]; sugar, four grammes (4 Gm.) [62 grs.]; tragacanth, in fine powder, one gramme (1 Gm.) [15 grs.]; althæa, in No. 60 powder, one gramme (1 Gm.) [15 grs.]; glycerin water, each, a sufficient quantity to make 100 pills. Rub the potassium carbonate, in a mortar, with a sufficient quantity (about 10 drops each) of glycerin and water, then add the ferrous sulphate and sugar, previously triturated together to a uniform powder, and beat the mass thoroughly, until it assumes a greenish color. When the reaction appears to have terminated, incorporate the tragacanth and althæa, and, if necessary, add a little more water, so as to obtain a mass of a pilular consistence. Divide this into 100 pills. These pills should be freshly prepared, when wanted"—(*U. S. P.*).

History.—This pill is the modified Blaud's pill, and has the official name formerly given to Vallet's mass (*Pilulæ Ferri Carbonatis*), and also differs much from the pill of similar name directed by the *British Pharmacopœia*. Hence, a confusion of names and the pills they represent will be likely to occur among physicians.

Action, Medical Uses, and Dosage.—Its uses are those of compound mixture of iron (see *Mistura Ferri Composita*). This pill is a ferruginous tonic, and may be employed in all cases where iron is required. It is especially valuable in *anæmia, atonic amenorrhœa, chlorosis*, and *hysterical affections;* also in the *hectic fever of phthisis* and *chronic mucous catarrhs*. It appears to have the usual effects of iron on the blood, increasing its coloring particles and rendering it of a more scarlet color. It may be divided into 3 or 5-grain pills, of which from 2 to 6 may be given 3 times a day, and continued for several weeks, particularly if their use is followed by an amelioration of the symptoms of disease.

Related Pills.—PILULÆ FERRI CARBONATIS (N. F.), *Pills of carbonate of iron, Ferruginous pills, Blaud's pills, Chalybeate pills*. "Sulphate of iron, in clear crystals, 240 grains; carbonate of potassium, 140 grains; sugar, 48 grains; tragacanth, in fine powder, 16 grains; glycerin, 10 minims; water, a sufficient quantity. Triturate the sulphate of iron with the sugar to a uniform powder. In another mortar triturate the carbonate of potassium with the glycerin and 10 minims of water. Add to this mixture the previously prepared powder, and beat the mass thoroughly until it assumes a greenish color. When the reaction appears to have terminated, incorporate the tragacanth, and, if necessary, add a little more water, so as to obtain a mass of a pilular consistence. Divide this into 96 pills. Each pill represents about 1 grain of carbonate of iron (ferrous). *Note.*—Sometimes so-called '3-grain' Blaud's pills (*Pilulæ Blaudii Minores*) are prescribed or demanded. These may be prepared by using the quantities given in the above formula, and dividing the mass into 168 pills"—(*Nat. Form.*, 1st ed.).

Pilulæ Metallorum (N. F.), *Metallic Pills, Pilulæ metallorum amaræ, Bitter metallic pills.*—"Reduced iron, six and one-half grammes (6.5 Gm.) [100 grs.]; quinine sulphate, six and one-half grammes (6.5 Gm.) [100 grs.]; strychnine, alkaloid, thirty-two centigrammes (0.32 Gm.) [5 grs.]; arsenous acid, thirty-two centigrammes (0.32 Gm.) [5 grs.]. To make 100 pills. Each pill contains 1 grain of reduced iron, 1 grain of quinine sulphate, $\frac{1}{20}$ grain of strychnine, and $\frac{1}{20}$ grain of arsenous acid (see *Pilulæ*, N. F.). *Note.*—A similar combination is known under the name of *Aitken's tonic pills:* "Reduced iron, four and one-half grammes (4.5 Gm.) [67 grs.]; quinine sulphate, six and one-half grammes (6.5 Gm.) [100 grs.]; strychnine, alkaloid, thirteen centigrammes (0.13 Gm.) [2 grs.]; arsenous acid, thirteen centigrammes (0.13 Gm.) [2 grs.]. To make 100 pills. Each pill contains $\frac{2}{3}$ grain of reduced iron, 1 grain of quinine sulphate, $\frac{1}{50}$ grain of strychnine, $\frac{1}{50}$ grain of arsenous acid" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

PILULÆ FERRI COMPOSITÆ.—COMPOUND PILLS OF IRON.

Synonym: *Emmenagogue pills.*

Preparation.—Take of Vallet's carbonate of iron, 1 drachm; resin of podophyllum, 15 grains; white turpentine, ½ drachm. Mix well together, and divide into 30 pills. This pill should not be confounded with *Pilulæ Ferri Compositæ* of the *U. S. P.* of 1880 (which see under *Pilulæ Aloes et Myrrhæ*).

Action, Medical Uses, and Dosage.—This pill is used chiefly as an emmenagogue. The dose is 1 pill every 3 or 4 hours.

PILULÆ FERRI FERROCYANIDI COMPOSITÆ.—COMPOUND PILLS OF FERROCYANIDE OF IRON.

Preparation.—Take of ferrocyanide of iron, sulphate of quinine, and alcoholic extract of black cohosh, each, 40 grains. Mix, and divide into 40 pills.

Action, Medical Uses, and Dosage.—These pills are tonic, alterative, and antiperiodic, and may be used in all diseases attended with periodicity, as *intermittent fever*, *chorea*, *epilepsy*, etc. They will be found an excellent remedial agent. The dose is 1 pill, 3 or 4 times a day, or oftener if required (J. King).

PILULÆ FERRI IODIDI (U. S. P.)—PILLS OF FERROUS IODIDE.

Synonym: *Pills of iodide of iron.*

Preparation.—"Reduced iron, four grammes (4 Gm.) [62 grs.]; iodine, five grammes (5 Gm.) [77 grs.]; glycyrrhiza, in No. 60 powder, four grammes (4 Gm.) [62 grs.]; sugar, in fine powder, four grammes (4 Gm.) [62 grs.]; extract of glycyrrhiza, in fine powder, one gramme (1 Gm.) [15.5 grs.]; acacia, in fine powder, one gramme (1 Gm.) [15.5 grs.]; water, balsam of tolu, ether, each, a sufficient quantity to make 100 pills. To the reduced iron, contained in a small mortar, add six cubic centimeters (6 Cc.) [97 ♏] of water, and then, gradually, the iodine, constantly triturating, until the mixture ceases to have a reddish tint. Then add the remaining powders, previously well mixed together, and mix the whole thoroughly. Transfer the mass to a porcelain capsule, and evaporate the excess of moisture, on a water-bath, with constant stirring, until the mass has acquired a pilular consistence. Then divide it into 100 pills. Dissolve ten grammes (10 Gm.) [154 grs.] of balsam of tolu in fifteen cubic centimeters (15 Cc.) [243 ♏] of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle"—(*U. S. P.*).

Tests.—"Pills of ferrous iodide should be devoid of the smell of iodine. If a few of the pills be triturated with water, the filtrate should not assume more than a light-blue tint on the addition of starch T.S. (absence of more than traces of free iodine)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This pill possesses the same medicinal properties as the solution of iodide of iron, and may be given in the same diseases. About 1½ grains of the iodide of iron enters into each pill, 1 of which may be given for a dose, and repeated 2 or 3 times a day. The *U. S. P.* pill contains about 1 grain of ferrous iodide.

PILULÆ GALBANI COMPOSITÆ (N. F.)—COMPOUND PILLS OF GALBANUM.

Preparation.—"Galbanum, nine and three-fourths grammes (9.75 Gm.) [150 grs.]; myrrh, nine and three-fourths grammes (9.75 Gm.) [150 grs.]; asafœtida, three and one-fourth grammes (3.25 Gm.) [50 grs.]; syrup, a sufficient quantity to make 100 pills. Each pill contains 1½ grains of galbanum, 1½ grains of myrrh, and ½ grain of asafœtida" (see *Pilulæ*, N.F.). Adapted from *Nat. Form.* This agrees with the *U. S. P.* (1880) formula.

Action, Medical Uses, and Dosage.—Formerly much employed in *hysterical manifestations*, and as a stimulant in *mucous profluvia*. Dose, 2 to 5 pills.

PILULÆ GLONOINI (N. F.)—PILLS OF GLONOIN.

SYNONYM: *Pills of nitroglycerin.*

Preparation.—"Spirit of glonoin (*U. S. P.*), six and one-half grammes (6.5 Gm.) [100 grs.]; althæa, in fine powder, six and one-half grammes (6.5 Gm.) [100 grs.]; confection of rose (*U. S. P.*), a sufficient quantity. Mix the spirit of glonoin intimately with the powdered althæa, expose the mixture for a short time to the air, so that the alcohol may evaporate, then make a pill mass by means of confection of rose, and divide it into 100 pills. Each pill contains $\frac{1}{100}$ grain of glonoin (nitroglycerin)"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—(See *Spiritus Glonoini.*)

PILULÆ HYOSCYAMI COMPOSITÆ.—COMPOUND PILLS OF HYOSCYAMUS.

Preparation.—Take of extract of hyoscyamus, extract of valerian, each, 2 drachms; extract of aconite, sulphate of quinine, of each, 1 drachm. Mix thoroughly together, and divide into pills of 3 grains each.

Action, Medical Uses, and Dosage.—These pills will be found advantageous in *neuralgia*, *rheumatism*, *chorea*, *dysmenorrhœa*, and many affections of a similar character. The dose is 1 pill every 2, 3, or 4 hours, according to circumstances. As the virtue of valerian resides in its oil, it is probable the extract is nearly useless, and one-half the quantity of the oil of valerian, or of valerianic acid, should be substituted for the extract, and forms a much more efficient pill (J. King).

PILULÆ LEONURI COMPOSITÆ.—COMPOUND PILLS OF MOTHERWORT.

Preparation.—Take of the alcoholic extracts of motherwort and unicorn-root, each, 2 drachms; extract of leptandra, resin of cimicifuga, each, 1 drachm. Mix thoroughly together, form a pill mass, and divide into 60 pills.

Action, Medical Uses, and Dosage.—These pills are useful in many *uterine affections*, acting as a uterine tonic and alterative. One pill may be given every 1, 2, or 4 hours, according to the urgency of the case (J. King).

PILULÆ LEPTANDRÆ COMPOSITÆ.—COMPOUND PILLS OF LEPTANDRA.

Preparation.—Take of extract of leptandra, 1 drachm; resin of podophyllum, ½ drachm; extract of rhubarb, a sufficient quantity. Mix together, and divide into 60 pills. Some prefer making these pills with extract of dandelion instead of rhubarb.

Action, Medical Uses, and Dosage.—This is a valuable cholagogue pill, very beneficial in *liver affections*, *obstinate constipation*, or wherever catharsis is required. It will likewise be found useful in *dysentery*. The dose is from 1 to 3 pills, once or twice a day. A very useful and effectual pill, that will not occasion gastro-intestinal irritation, may be made by thoroughly mixing together resin of podophyllum, 30 grains; extract of leptandra, 60 grains; extract of hyoscyamus, 45 grains; and dividing the mass into 60 pills. The *compound cathartic pill* of some of our practitioners is composed of resin of podophyllum, 15 grains; dry extract of leptandra, extract of hyoscyamus, each 1 drachm. Mix, and divide into 60 pills.

PILULÆ OLEORESINÆ EUPATORII COMPOSITÆ.—COMPOUND PILLS OF OLEORESIN OF QUEEN OF THE MEADOW.

Preparation.—Take of oleoresin of Eupatorium purpureum (eupurpurin), 40 grains; oleoresin of xanthoxylum, 20 grains; strychnine, 1 grain. Mix thoroughly together, and divide into 20 pills.

Action, Medical Uses, and Dosage.—This forms a stimulating diuretic, and will be found useful in *suppression of urine*, *torpor* or *paralysis of the kidneys or bladder*, *rheumatism*, *hepatic torpor*, *derangements of the digestive functions*, etc. The dose is 1 pill, to be repeated 3 or 4 times a day (J. King).

PILULÆ OPII (U. S. P.)—PILLS OF OPIUM.

Preparation.—"Powdered opium, six and one-half grammes (6.5 Gm.) [100 grs.]; soap, in fine powder, two grammes (2 Gm.) [31 grs.]; water, a sufficient quantity to make 100 pills. Beat the powders together with water, so as to form a mass, and divide it into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(Same as *Opium*.) Old pills of opium are better than fresh pills or liquid preparations of the same when a local action and prolonged contact of the drug is desired in *painful gastric* and other *visceral disorders*. By their slow solution they are effectual in *gastric ulcers*, *gastralgia*, etc. Dose, 1 pill, which contains 1 grain of opium.

Related Pills.—Pilula Saponis Composita (*U. S. P.*, 1870). Opium, in fine powder, 60 grains; soap, in fine powder, ½ troy ounce. Beat together with water so as to form a pilular mass.

PILULÆ OPII ET PLUMBI (N. F.)—PILLS OF OPIUM AND LEAD.

Preparation.—"Powdered opium, six and one-half grammes (6.5 Gm.) [100 grs.]; lead acetate, six and one-half grammes (6.5 Gm.) [100 grs.]; to make 100 pills. Each pill contains 1 grain of opium and 1 grain of lead acetate" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

Action, Medical Uses, and Dosage.—This agent is used chiefly by members of the old school as an astringent and anodyne in *bowel* and *bronchial disorders*. Dose, 3 to 5 grains.

PILULÆ PHOSPHORI (U. S. P.)—PILLS OF PHOSPHORUS.

Preparation.—Phosphorus, six centigrammes (0.06 Gm.) [1 gr.]; althæa, in No. 60 powder, six grammes (6 Gm.) [93 grs.]; acacia, in fine powder, six grammes (6 Gm.) [93 grs.]; chloroform, glycerin, water, balsam of tolu, ether, each, a sufficient quantity to make 100 pills. Dissolve the phosphorus in a test-tube in five cubic centimeters (5 Cc.) [81 ♏] of chloroform, with the aid of a very gentle heat, replacing from time to time any of the chloroform which may be lost by evaporation. Mix the althæa and acacia in a mortar, next add the solution of phosphorus, then immediately afterward a sufficient quantity (about four cubic centimeters [4 Cc., 65 ♏]) of a mixture of 2 volumes of glycerin and 1 volume of water, and quickly form a mass, to be divided into 100 pills. Dissolve ten grammes (10 Gm.) [154 grs.] of balsam of tolu in fifteen cubic centimeters (15 Cc.) [243 ♏] of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle.

The *U. S. P.* pill contains $\frac{1}{100}$ grain of phosphorus, that of the *British Pharmacopœia* (1898) $\frac{1}{50}$ grain of phosphorus, which is twice the strength of the phosphorus pill in *British Pharmacopœia*, 1885. It is necessary in handling phosphorus that its oxidation be prevented if possible, and this is accomplished by dissolving it in a closed tube in chloroform, the vapor of which prevents its oxidation. It may also be melted under water as is directed by the *British Pharmacopœia*, 1885. The present *British Pharmacopœia* employs a solution of phosphorus in carbon disulphide. Besides tolu balsam, rosin has been proposed as an excipient (A. W. Gerrard ; cacao butter (Walling) has also been successfully employed.

Action, Medical Uses, and Dosage.—Same as for *Phosphorus* (which see). Dose, 1 to 2 pills.

PILULÆ PHYTOLACCÆ COMPOSITÆ.—COMPOUND PILLS OF POKE.

Preparation.—Take of extract of poke, 2 drachms; alcoholic extract of stillingia, 1 drachm; extract of stramonium, 8 grains. Mix thoroughly together, form into a pill mass, and divide into 64 pills.

Action, Medical Uses, and Dosage.—These pills will be found of value in *osteocopus*, or *pains in the bones* of a mercurial or syphilitic character, and are also beneficial in *rheumatism*, *syphilis* and *scrofula*. The dose is one pill every 2, 3 or 4 hours, as the urgency of the case may require. The fluid extract of stillingia may be substituted for the alcoholic extract, and pulverized poke root added as an excipient (J. King).

PILULÆ PODOPHYLLI BELLADONNÆ ET CAPSICI (N. F.)

PILLS OF PODOPHYLLUM, BELLADONNA, AND CAPSICUM.

SYNONYM: *Squibb's podophyllum pills.*

Preparation.—"Resin of podophyllum (*U. S. P.*), one and six-tenths grammes (1.6 Gm.) [25 grs.]; alcoholic extract of belladonna leaves (*U. S. P.*), eight decigrammes (0.8 Gm.) [12.5 grs.]; capsicum, in moderately fine powder, three and two-tenths grammes (3.2 Gm.) [50 grs.]; sugar of milk, in fine powder, six and one-half grammes (6.5 Gm.) [100 grs.]; acacia, in fine powder, one and six-tenths grammes (1.6 Gm.) [25 grs.]; glycerin, syrup (*U. S. P.*), each, a sufficient quantity to make 100 pills. Each pill contains $\frac{1}{4}$ grain of resin of podophyllum, $\frac{1}{8}$ grain of extract of belladonna leaves, $\frac{1}{2}$ grain of capsicum, 1 grain of milk sugar, $\frac{1}{4}$ grain of acacia, glycerin, syrup, each, a sufficient quantity" (see *Pilulæ*, N. F.). Adapted from *Nat. Form.*

Action, Medical Uses, and Dosage.—Efficient laxative and cathartic. Dose, 1 to 2 pills.

PILULÆ POLYGONI COMPOSITÆ.—COMPOUND PILLS OF WATER-PEPPER.

Preparation.—Take of dried sulphate of iron, and resin of cimicifuga, each, 1 drachm; oleoresin of iris, 15 grains; extract of water-pepper, a sufficient quantity. Mix well together, and divide into 60 pills.

Action, Medical Uses, and Dosage. These pills are emmenagogue, and exert an especial influence on the female organs of generation. They have been used with advantage in *chlorosis*, *amenorrhœa*, *dysmenorrhœa*, *uterine leucorrhœa*, etc. The dose is 1 pill every 2 or 3 hours (J. King).

PILULÆ QUININÆ COMPOSITÆ.—COMPOUND PILLS OF QUININE.

Preparation.—Take of sulphate of quinine, extract of cornus, and tartaric acid, each, in powder, 1 drachm; alcoholic extract of black cohosh, a sufficient quantity. Mix together, and divide into 4-grain pills.

Action, Medical Uses, and Dosage.—These pills are tonic and antiperiodic, and may be employed in *intermittent and remittent fevers*, and in all diseases attended with symptoms of periodicity. The addition of the tartaric acid renders the quinine more readily soluble in the juices of the stomach. The dose is 1 pill every 1, 2, or 3 hours, according to the severity or urgency of the symptoms. A *compound quinine pill* is occasionally employed, which is composed as follows: Take of sulphate of quinine, hydrochlorate of berberine, each, 1 drachm; resin of podophyllum, 10 grains; extract of nux vomica, 8 grains. Mix, and divide into 60 pills (J. King).

PILULÆ QUININÆ SULPHATIS.—PILLS OF SULPHATE OF QUININE.

Preparation.—Take of sulphate of quinine, 1 drachm; aromatic sulphuric acid, 45 drops; drop the acid into the quinine on a tile or slab, and triturate with a spatula until it assumes a pilular consistence; then divide into 60 pills. The same can be effected much more readily by substituting a very small quantity of tartaric acid in solution for the aromatic sulphuric acid (J. King). This pill should be coated with either sugar or gelatin.

This method of forming quinine into a pill mass was made known by Mr. E. Parish. The ingredients, when mixed, form a fluid, which soon thickens into a paste, and finally becomes quite solid, and so adhesive as to be readily divided and rolled into pills; care must be taken not to allow the mass to become too dry and brittle before dividing it, as it is liable to do if allowed to remain too long. In this form, a portion of the neutral sulphate being converted into the soluble bisulphate, the preparation more nearly resembles the solutions in composition, and is believed to be more certain and rapid in its action. When it is desired to incorporate other substances in powder with the quinine thus prepared, as ferrocyanide of iron, etc., they should be added to the mass when it is just so soft that, upon their addition, it will immediately assume the proper consistence. It is not, however, advisable to employ this process when any considerable quantity of other ingredients are prescribed with the quinine, unless a little syrup or honey is also added to prevent the too rapid hardening and consequent crumbling of the mass.

Action, Medical Uses, and Dosage.—(For the uses of these pills, see *Quininæ Sulphas*.) Each pill contains 1 grain of sulphate of quinine, and 12 are equivalent to 1 ounce of good Peruvian bark. The above pill mass may be made into 2 or 5-grain pills if desired, which will not be found inconveniently large.

PILULÆ RESINÆ PODOPHYLLI COMPOSITÆ.—COMPOUND PILLS OF RESIN OF PODOPHYLLUM.

Preparation.—Take of resin of podophyllum, scammony, gamboge, each, in powder, 1 drachm; castile soap, ½ drachm. Triturate the powders thoroughly together for about half an hour, then add the soap. Mix, and beat the whole together until they are thoroughly incorporated. Divide the mass into 120 pills.

Action, Medical Uses, and Dosage.—This is a most valuable pill for all diseases where cathartics are required, and has cured many cases of *hepatic affections* by a continued use of them. The dose is 1 or 2 pills every night. They have no tendency toward producing constipation, but rather the reverse, and, after using them for several days in succession, they will generally be found so active that it will be necessary to omit them for a number of days before resuming their administration. They may be safely used in all ordinary cases where purgation is desired; they operate freely and thoroughly, and usually without causing nausea, griping, or debility.

In consequence of the difficulty with which pure scammony is obtained in this country, many practitioners substitute for it, in these pills, extract of apocynum, or extract of rhubarb, or oleoresin of iris, either of which will probably be found preferable to an impure or counterfeit scammony (J. King). A very useful pill for *saturnine constipation* is the following: Take of resin of podophyllum, 6 grains; extract of nux vomica, 7 grains; extract of belladonna, 4½ grains. Mix, and divide into 10 pills. Dose, 2 or 3 pills a day, accompanied with sulphurous baths (Van den Corput).

PILULÆ RHEI (U. S. P.)—PILLS OF RHUBARB.

Preparation.—"Rhubarb, in No. 60 powder, twenty grammes (20 Gm.) [309 grs.]; soap, in fine powder, six grammes (6 Gm.) [93 grs.]; water, a sufficient quantity to make 100 pills. Beat the powders together with water so as to form a mass, to be divided into 100 pills"—(*U. S. P.*). This pill contains 3 grains of rhubarb.

Action, Medical Uses, and Dosage.—Mildly laxative in 3-grain doses (1 pill). Of value in mild forms of *constipation* (see *Rheum*). Dose, 1 to 3 pills.

PILULÆ RHEI COMPOSITÆ (U. S. P.)—COMPOUND PILLS OF RHUBARB.

SYNONYM: *Compound rhubarb pills.*

Preparation.—"Rhubarb, in No. 60 powder, thirteen grammes (13 Gm.) [201 grs.]; purified aloes, in fine powder, ten grammes (10 Gm.) [154 grs.]; myrrh, in fine powder, six grammes (6 Gm.) [93 grs.]; oil of peppermint, one-half cubic centimeter (0.5 Cc.) [8 ♏]; water, a sufficient quantity to make 100 pills. Mix the oil of peppermint with the powders, then beat the mixture with water so as to form a mass, to be divided into 100 pills"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Tonic laxative (see *Myrrh*, *Aloes*, and *Rhubarb*). Useful in *chronic constipation* and *gastric* and *intestinal flatulence.* Dose, 1 to 4 pills.

PILULÆ SAPONIS COMPOSITÆ (ECLECTIC).—COMPOUND PILLS OF SOAP.

SYNONYM: *Diuretic pills.*

Preparation.—Take of oils of spearmint, juniper, and sassafras, each, 1 fluid drachm: castile soap, 1½ drachms. Beat the soap in an iron mortar, gradually adding the oils, and, when the ingredients are thoroughly incorporated, divide into 18 pills (Beach's *Amer. Prac.*). This is not the *Compound Pill of Soap* (*Pilula Saponis Composita*) of the *British Pharmacopœia* or the *U. S. P.*, 1870 (for which, see *Related Pills*, under *Pilulæ Opii*).

Action, Medical Uses, and Dosage.—These pills are stimulant and diuretic, and are very beneficial in *gravel* and *chronic urinary affections.* The dose is 3 pills, 3 times a day, or 1 pill every hour through the day. They were first recommended by the late Prof. T. V. Morrow, M. D.

PILULÆ SCAMMONII COMPOSITÆ.—COMPOUND SCAMMONY PILLS.

Preparation.—"Take of resin of scammony, 1 ounce; resin of jalap, 1 ounce; curd soap, in powder, 1 ounce; strong tincture of ginger, 1 fluid ounce; rectified spirit, 2 fluid ounces. Add the spirit and the tincture to the soap and resins, and dissolve with the aid of a little heat; then evaporate the spirit by the heat of a water-bath until the mass has acquired a suitable consistence for forming pills"—

(*Br. Pharm.*, 1885). The *British Pharmacopœia* (1898) replaces the rectified spirit with an equal quantity of tincture of ginger.

Action, Medical Uses, and Dosage.—(See *Scammonium.*) A drastic purgative. Dose, 5 to 15 grains.

PILULÆ TARAXACI COMPOSITÆ.—COMPOUND PILLS OF DANDELION.

Preparation.—Take of bloodroot, in powder, 1 drachm; resin of podophyllum, 10 grains; extract of dandelion, 1 drachm; oil of spearmint, 5 minims. Mix the powder with the extract, add the oil, beat up thoroughly together, and divide into 50 pills.

Action, Medical Uses, and Dosage.—Laxative, nauseant, and diuretic. They are of much efficacy in *jaundice*, *hepatic diseases*, and *affections of the kidneys*. The dose is 1 or 2 pills, 3 times a day, sufficient to produce a slight sensation of nausea. This pill is superior to the one made after the old formula (T. V. Morrow, M. D.).

PILULÆ VALERIANÆ COMPOSITÆ.—COMPOUND PILLS OF VALERIAN.

Preparation.—Take of the alcoholic extract of scullcap, and extract of chamomile, each, 2 drachms; extract of boneset, sulphate of quinine, of each, 1 drachm; capsicum, 20 grains; oil of valerian, ½ drachm, by weight. Mix the articles together, beat them until thoroughly incorporated, and divide into 90 pills.

Action, Medical Uses, and Dosage.—These pills are tonic and nervine, and may be used in all cases where such a combination of action is desired. The dose is 1 pill, every 2 or 3 hours.

PILULÆ VIBURNI COMPOSITÆ.—COMPOUND PILLS OF HIGH CRANBERRY.

Preparation.—Take of alcoholic extracts of high cranberry, blue cohosh, and unicorn root, each, ½ drachm; extract of partridge-berry, 1 drachm. Mix together, and divide into 40 pills.

Action, Medical Uses, and Dosage.—These pills are of superior efficacy in *uterine diseases*, as *amenorrhœa*, *dysmenorrhœa*, *leucorrhœa*, etc.; as a uterine tonic in *habitual miscarriages;* and may be given during *pregnancy* to relieve cramps and many other unpleasant sensations occurring at that period. The dose is 1 or 2 pills, 3 times a day (J. King.)

PIMENTA (U. S. P.)—PIMENTA.

"The nearly ripe fruit of *Pimenta officinalis*, Lindley"—(*U. S. P.*). (*Eugenia Pimenta*, De Candolle; *Myrtus Pimenta*, Linné; *Pimenta vulgaris*, Wight and Arnott.)

Nat. Ord.—Myrtaceæ.

COMMON NAMES: *Allspice, Pimenta, Pimento, Jamaica pepper.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 111.

Botanical Source.—This tree, the *Eugenia Pimenta* of De Candolle, is an evergreen, reaching to the height of 25 feet, or more. The trunk is erect, with many round branches toward the summit; twigs compressed, the younger and the pedicles downy. The leaves are opposite, entire, oblong or oval, with pellucid dots, and somewhat opaque and smooth. The flowers are small, in axillary and terminal, trichotomous panicles; some flowers are fourfid and subsessile in the forks of the panicle. Calyx-tube is nearly globose, the limb being divided down to the ovary into 4 roundish segments. Petals 4, greenish-white. Stamens numerous, distinct; ovary 2-celled. Berry globose, 1-seeded, black, the size of a pea. Embryo roundish, with the cotyledons consolidated (L.).

History.—The allspice, or pimento tree, is a native of South America and the West India Islands, especially Jamaica. The tree completes its growth in about seven years, though fruit may be had from it in its third year: it flourishes best in a limestone soil. The unripe berries are the official part, and are more generally known by the name of *Allspice*. Other names, as *Jamaica pepper*, *Bayberry*, etc., have been given to them. They are gathered just before maturity, thoroughly dried, and then packed for foreign markets. When these trees are in blossom they emit a most delicious fragrance. The pimento tree is not improved by cultivation. After the old groves, or *walks*, as they are called, are exhausted, a clearing is made in the forest near the old groves, and, through the agency of birds and the winds, seeds are scattered in this open area, and a new grove springs up. When the young trees are two or three years old the weaker ones are cut down. After thus thinning the grove, it requires no further attention. The fruit is gathered in July and August, the young fruit-laden tips of the branches being broken off (which benefits the trees) and thrown upon the ground, where they are stripped of the berries by women and children and placed in bags, carried to a sunny exposure and dried, either by solar or artificial heat, and again bagged for the market. The stems of young pimento trees at one time were exported from Jamaica to England and the United States, to be used for umbrella sticks. They came in bundles, containing from 500 to 800 sticks, each representing a young pimento tree (*Amer. Jour. Pharm.*, 1882, p. 11, from *Scient. Amer.*, 1881).

Description.—Pimento, or allspice, also known as *Piper Jamaicense*, and *Semen Amomi*, when dried, becomes brownish-black, round, wrinkled, and umbilicate at the apex. Its odor and taste combines that of cinnamon, nutmegs, and cloves; hence its name, *allspice*. Boiling water takes up the aroma, and alcohol all the active properties. The infusion is brown, and has an acid reaction on litmus paper. The *U. S. P.* describes pimenta as being "about 5 Mm. $\frac{1}{5}$ inch) in diameter, nearly globular, crowned with the short, 4-parted calyx or its remnants, and a short style; brownish or brownish-gray, granular and glandular, 2-celled; each cell containing 1 brown, plano-convex, roundish-reniform seed; odor and taste pungently aromatic, clove-like"—(*U. S. P.*).

Chemical Composition.—Two-thirds of the fruit consists of the shell, and one-third of the seeds. The berries contain a volatile oil (see *Oleum Pimentæ*), which may be obtained by distillation, a green, soft resin, of a burning aromatic taste, a concrete fatty substance, tannic acid, gum, sugar, malic and gallic acids, etc. (Bonastre). They also contain starch (Braconnot). Dragendorff (1871) found a minute portion of an alkaloid in the fruit. The latter, upon incineration, leaves 6 per cent of ash. W. W. Abell (*Amer. Jour. Pharm.*, 1886, p. 163) obtained from the leaves $\frac{1}{2}$ per cent of an essential oil bearing a close resemblance to oil of bay (*Myrcia acris*). The leaves also contain 0.4 per cent of tannin and 11.25 per cent of ash.

Action, Medical Uses, and Dosage.—Pimento is a hot, aromatic stimulant, and carminative, and may be used where such agents are indicated. It is seldom employed in medicine, but is used largely as a hot aromatic in cookery; and sometimes it is added to other medicines to render them more agreeable. A tincture has been advised as a local remedy in *chilblains*. Dose of the powder, from 10 to 30 grains; of the tincture, from 1 to 2 fluid drachms; of the oil, from 2 to 5 drops.

PIPER (U. S. P.)—PIPER.

"The unripe berries of *Piper nigrum*, Linné"—(*U. S. P.*).

Nat. Ord.—Piperaceæ.

Common Name: *Black pepper*.

Illustration: Bentley and Trimen, *Med. Plants*, 245.

Botanical Source.—Piper nigrum is a perennial vine with a trailing or climbing stem, round, smooth, shrubby, flexuose, dichotomously branched, jointed, swelling at the joints, and often throwing out radicles there which adhere to bodies like the roots of ivy, or become roots striking into the ground. The leaves are from 4 to 6 inches long, alternate, distichous, broad-ovate, acuminate, of a dark-green color, glossy above, paler beneath, 5 to 7 nerved, the nerves connected by lesser transverse ones or veins, and prominent beneath; the petioles are round, and from $\frac{1}{2}$ to 1 inch long. The flowers are whitish, small, not stalked, and borne in spikes opposite the leaves, chiefly near the upper ends of the branches, pedunculate, 3 to 6 inches long, slender, drooping, apparently some male, others female, while sometimes the flowers are furnished with both stamens and pistils. Stamens 3. The fruit ripens irregularly all the year round, is sessile, the size of a pea, at first green, then red, and afterward black, covered by pulp (*L.*).

History and Description.—Piper nigrum is a native of the East Indian continent, notably the Malabar coast, as well as of many islands in the Indian ocean, where it is extensively cultivated, as well as in the West Indies. Commercial grades are known as *Malabar*, *Singapore*, *Penang*, *Sumatra pepper*, etc. The berries are collected while red, before they have fully matured, and when dried, form the *black pepper* of commerce; when allowed to ripen, and then divested of their husks by being soaked in water, dried, rubbed and winnowed, they constitute *white pepper*, which is less pungent and aromatic than the black. Sumatra and Java furnish the principal portion of the black pepper met with in this country and Europe. The berries, which are about the size of a currant, are officially described as "globular, about 4 Mm. ($\frac{1}{6}$ inch) in diameter, reticulately wrinkled, brownish-black or grayish-black, internally lighter, hollow, with an undeveloped embryo; odor aromatic; taste pungently spicy"—(*U. S. P.*). Alcohol or ether extracts their virtues completely; water only partially.

Chemical Composition.—The sharp taste of pepper is due to the presence of about 6 to 8 per cent of the weak alkaloid *piperine* ($C_{17}H_{19}NO_3$) which in substance is almost tasteless, but develops its sharp taste when in solution. White pepper seems to contain even more piperine than black. Piperine, when boiled with alcoholic caustic potash, is decomposed into the potassium-salt of *piperic acid* ($C_{12}H_{10}O_4$), and into the powerfully basic *piperidine* ($C_5H_{11}N$) (see *Piperinum*). According to T. Weigle (*Chem. Zeitung*, 1893, p. 1365), the sharp taste of the fresh fruit is produced by the piperine being dissolved in the essential oil; old fruits taste less sharp owing to partial resinification of the essential oil and consequent partial crystallization of piperine. The odor of the fruit is due to the essential oil (*oil of pepper*) which is devoid of sharp taste. From 1 to 2.3 per cent may be obtained from the powdered fruit by distillation with water. It is colorless to yellowish green, slightly lævo-rotatory and has a specific gravity of 0.880 to 0.905 Its principal constituent is *lævo-phellandrene* (Schimmel & Co., 1890). The pepper fruit also contains cellulose, large quantities of starch (as much as 32 per cent), some coloring matter and a viscid, non-saponifiable, tasteless and almost odorless oil ($C_{10}H_{16}O_4$), probably formed from the essential oil by oxidation. It is soluble in alcohol of 90 per cent, in ether, and petroleum ether; piperine is hardly soluble in the latter solvent (Weigle). Pepper fruit dried at 100° C. (212° F.), leaves from 3.2 to 5.7 per cent of ash; its average is 4.5 per cent. Tannin is absent in the pepper fruit. Buchheim (1876) obtained from the pepper fruit, besides *piperine*, an amorphous alkaloid *chavicine* soluble in alcohol, ether and petroleum ether. Alcoholic caustic alkali decomposes it into the alkali salt of *chavicic acid*, and *piperidine* (compare *Piperinum*).

Adulterations and Tests.—Falsification of the whole pepper fruit is of rare occurrence. It may be found occasionally admixed with the fruit of cubebs, allspice, piper longum, etc. A globular iron ore (*bean-ore*) has been reported as an adulterant of whole pepper (*Chem. Zeitung*, 1889, p. 1030). Adulteration of powdered pepper may be recognized by the microscope and by chemical methods. The determination of ether extract, representing the piperine and resin, in conjunction with the determination of ash may be useful in deciding the purity of a given sample. Mr. J. E. S. Bell (*Amer. Jour. Pharm.*, 1888, p. 481) found sixteen out of twenty samples of pepper, mostly from American markets, to be pure. The ether extract in the four impure samples varied from 3.29 to 4.11 per cent, the ash from 7.25 to 8.59 per cent, while in pure pepper it varies from 3 to 5 per cent The highest yield of ether extract was 7.85 per cent. Genuine black pepper should yield 7.66 per cent piperine (Niederstadt). T. F. Hanausek (1884) mentions among adulterants of powdered pepper, crust of bread, flour, linseed cake, acorn meal, sawdust, powdered olive kernels; of late (1898), powdered exhausted coriander fruit, less frequently mineral matters, such as sand, gypsum, etc. Mr. F. A. Hennessy (*Amer. Jour. Pharm.*, 1890, p. 276) reports on the wholesale manufacture of "spice mixture" from a low grade of wheat flour. Also see an interesting article on "poivrette," an adulterant of powdered pepper made from olive kernels, in *Amer. Jour. Pharm.*, 1887, p. 146. (For a detailed consideration of the microscopical and chemical analysis of pepper, see J. König, *Die Menschl. Nahrungs- und Genussmittel*, 3d ed., 1893, p. 673; also see literature in Flückiger's *Pharmacognosie*, 3d ed., 1891, p. 914.)

Action, Medical Uses, and Dosage.—Pain and redness are the results of the local application of powdered pepper. Internally administered it excites in the mouth and fauces a burning sensation, warms the stomach and slightly quickens the circulation. Abdominal heat and burning, marked thirst, vomiting, fever, and sometimes convulsions follow an excessive dose. It may produce an urticaria, which, however, soon disappears. Large doses increase renal activity and irritate the urinary tract. Black pepper is a gastro-intestinal stimulant, and is much used as a condiment to improve the flavor of food, and to favor its digestion by stimulating the stomach. It has been advantageously used as a carminative to remove *flatulency*, and to correct the nauseating or griping quality of other drugs, and is sometimes added to quinine in cases where the stomach, from torpidity or other cause, is not acted upon by the quinine alone. It has been recommended as a remedy in *intermittents*, but very often fails, though it nearly always materially assists the action of quinine. As a gastric stimulant it is very valuable in *congestive chill*, *cholera morbus*, and associated with hydrastis, nux vomica, or other stomachic bitters is effectual in *atonic dyspepsia*. Combined with macrotys it has rendered good service in *atonic amenorrhœa* and *dysmenorrhœa*. The unbroken seeds of white pepper taken in teaspoonful doses 2 or 3 times a day, have been recommended to overcome the *obstinate constipation of dyspeptics;* they are, however, rarely used at present.

The dose of black pepper is from 1 to 15 grains. Prof. Scudder, with whom black pepper was a favorite drug, directs from 1 to 10 drops of the following tincture: Take finely ground black pepper, ℥viii; alcohol, 98 per cent, Oj. Pack the drug in a percolator, moisten with a portion of the alcohol, allow it to stand a day, and then pass through it the remaining portion of alcohol.

Specific Indications and Uses.—Gastric atony; congestive chills.

Related Peppers.—LONG PEPPER. This pepper is derived from two species of Piper, *Piper officinarum*, De Candolle (*Chavica officinarum*, Miquel), producing the Java long pepper, and *Piper longum*, Linné (*Chavica Roxburghii*, Miquel) producing the India long pepper. Both species grow in the islands of the Indian Ocean, the latter species also in the Philippine Islands, in southern India, Malabar, Bengal and Ceylon.

The *Java long pepper* grows in cylindrical aments consisting of a multitude of minute ovoid berries, each $\frac{1}{10}$ of an inch long, densely arranged in spiral form around a common axis, the whole spike being about $1\frac{1}{2}$ to 2 inches long and $\frac{1}{4}$ inch thick and of an ashen gray color. When washed they are reddish brown. The fruits are collected before maturity, dried in the sun, and have a mild aromatic odor but a pungent, aromatic taste.

India long pepper is of similar growth, but its spikes are shorter, only from 1 to $1\frac{1}{2}$ inch in length, and the fruits are less pungent. Its aromatic taste and odor are gradually developed upon drying. It is less esteemed than the Java variety. Long pepper contains piperine (Winkler, 1828; Flückiger, *Pharmacognosie*, 1891), and yields upon distillation with water, 1 per cent of a bland, thickish, yellow-green oil of specific gravity 0.861, and resembling ginger in odor. Long pepper is rarely used medicinally in the United States.

Piper Novæ-Hollandæ.—Australia. The berries of this pepper contain an essential oil reputed useful in *gonorrhœa* and related disorders.

PIPER METHYSTICUM.—KAVA-KAVA.

The root of *Piper methysticum*, Forster (*Macropiper methysticum*, Miquel).

Nat. Ord.—Piperaceæ.

COMMON NAMES: *Ava*, *Kava-kava*, *Intoxicating long pepper*, *Ava pepper shrub.*

Botanical Source and History.—This is a shrub about 6 feet high, somewhat resembling the bamboo in growth, a native of and common in cultivation in the South Sea Islands. It was discovered by James Cook, the celebrated explorer, in 1769, in the Tahiti Islands. The leaves (see illustration in *Pharm. Jour. Trans.*, 1876, p. 149) are alternate, cordate, with a wavy, entire margin, and an abrupt, acute point. The petiole is about an inch long, dilated at the base, and furnished with linear, erect stipules. The veins are prominent, about 12, diverging from the base of the leaf-blade. The flowers are small, apetalous, and arranged on slender spikes. Those bearing male flowers are axillary and solitary. The female spikes are numerous. This shrub is known in its native country under the names *Kava*, *Ava*, *Arwa*, *Ava-kava*, *Kava-kava*, etc., and is the "Intoxicating Long Pepper," from which a disgusting drink is prepared by the natives, and even by the whites, of these islands. This drink is invariably made by chewing the root of the plant to a pulp, covering this with water, macerating a short time, and then straining it through "fow," a fibrous material obtained from the bark of a certain native tree. The taste is said to resemble soap-suds and tannin. (For the methods of its preparation by the natives and its uses, see an interesting illustrated paper by Dr. R. H. True, in *Pharm. Review*, 1896, p. 28; also see T. R. N. Morson's abstract from Mariner's History of the Tonga Islands, in *Pharm. Jour. Trans.*, Vol. III, 1844, p. 474; and Dr. Seeman's Letters from the Fiji Islands, in the *Althenæum*, 1861.) The leaf is chewed with the betel-nut, and the dried root, under the name *pipula moola*, forms an article of commerce in India.

Description.—The root is the part recommended for use in medicine. Of the lot inspected by us, the main root seems to have grown horizontally beneath the surface of the ground, sending up stalks at intervals of from 2 to 4 inches. Each stalk is from ½ to 3 inches in diameter at the base, and is hollow. The cavity extends through the main root, thus giving to a longitudinal section of the root the appearance of several separate roots having grown together. Externally, the main root is brown, and covered with a thin bark. From the sides and lower part are secondary roots, about ½ to ¾ of an inch in diameter. These appear to be arranged about the bases of the stalks; in some cases they are quite long, and commence to send out rootlets at a distance of 6 inches from the main root. Internally, the large root is covered with a network of fibers beneath the bark. Coarse medullary rays compose the body. The root breaks with a fibrous fracture; it is frequently much worm-eaten internally, though, to an external examination, apparently sound. After chewing a little of it, a peculiar, acrid, benumbing sensation is imparted to the parts of the mouth with which the pulp comes in contact. This property is possessed in a much greater degree by the small rootlets.

Chemical Composition.—The chief constituent of kava-kava root, amounting to 49 per cent, is starch (Gobley, 1860). It also contains about 1 per cent of a neutral, tasteless, crystallizable principle called *kavahin* or *methysticin* (Morson, 1844; Cuzent, 1860). It is hardly soluble in cold water, easily soluble in alcohol and ether. C. Pomeranz (*Chem. Centralbl.*, 1890, p. 124) found *methysticin* ($C_{15}H_{14}O_5$) to be the methyl ester of *methysticic acid* ($C_{14}H_{12}O_5$) which stands in close relationship to *piperic acid* of Fittig and Mielck (see *Piperinum*). Dragendorff (*Heilpflanzen*, 1899) differentiates *methysticin* from *kavahin*, stating the latter to be *methylene protocatechuic aldehyde* (which is the chemical name for *heliotropin* or *piperonal*). An alkaloid, *kavaine*, was isolated in 1889 by Lavialle (*Amer. Jour. Pharm.*, 1889, p. 136). The active principle of kava-kava consists, however, in an acrid resin (2 per cent, Gobley, 1857) which was differentiated by Lewin (*Pharm. Centralhalle*, 1886, p. 72) into *alpha-resin*, which is a strong local anæsthetic, and the less active *beta-resin*.

Action, Medical Uses, and Dosage.—The root of Piper methysticum has a pleasant, somewhat lilac odor, and a slightly pungent, bitter and astringent taste, which augments the salivary discharge. It has marked general and local anæsthetic properties. It has been employed as a pleasant remedy in *bronchitis*, *rheumatism*, *gout*, *gonorrhœa*, and *gleet*, and has also been recommended as a powerful sudorific. It appears to exert its influence more especially upon diseased mucous membranes, and may be found useful in *chronic catarrhal affections* of various organs, and in *chronic inflammation of the neck of the bladder*. The action of the root varies, according to the amount taken; in small doses, it is tonic and stimulant; while in large doses it produces an intoxication, which, unlike that from alcohol, is of a reserved, drowsy character, and attended with confused dreams. The natives who use its infusion as an intoxicating beverage for a considerable length of time, are said to become affected with a dry, scaly, cracked, and ulcerated skin, and vision becomes more or less obscured. According to Kesteven, leprous ulcerations may be produced by its habitual use. M. Dupouy, who has given considerable attention to the therapeutical virtues of this drug, arrives at the following conclusions: Given in drink, kava is a sialagogue, but is not sudorific. In medicinal doses, it acts upon the stomach, similar to the bitter stimulants, increasing the appetite, without occasioning diarrhœa or constipation, and may prevent catarrhal affections of this portion of the digestive tube. It exerts a special stimulation upon the central nervous system, differing essentially from ethylic intoxication; and, as its taste is agreeable, one soon becomes a proselyte to it. It has a very powerful action upon aqueous diuresis, and may be classed among the most efficient diuretics. It does not occasion priapism, but, on the contrary, antagonizes it. It is endowed with remarkable and prompt blennostatic properties, augmenting the discharge previous to effecting its cure. It is of undoubted efficiency in *acute vaginitis* or *urethritis*, allaying the inflammation, causing the pain during micturition to disappear, when dysuria is present, and suppressing the mucopurulent catarrh from the vesico-urethral mucous membrane. It has, over other blennostatic agents, the marked advantages of being pleasant to take, of augmenting the appetite, of occasioning neither diarrhœa nor constipation, of alleviating or entirely subduing pain during urination, of completely changing the character of the discharge, and of effecting the cure in a very short time—10 or 12 days. He can not too highly recommend its employment, especially in the treatment of *gonorrhœa*. Ellingwood (*Mat. Med.*, 1898) declares it of great value in subacute and slow forms of gonorrhœa, and especially in *gleet*. It is a remedy for *nocturnal incontinence of urine* in the young and old, when due most largely to muscular weakness.

The anticatarrhal action is probably due to the resin present, and the diuretic effects to the neutral crystallizable principle, methysticin or kavain. There may likewise be present some other active principle, not yet detected, to account for certain other influences following its employment. Piper methysticum has been successfully employed in *atonic dyspepsia* and in *neuralgic* or *spasmodic dysmenorrhœa*. Prof. Webster (*Dynam. Therap.*) regards it as our most reliable remedy for *neuralgia*, particularly of the parts supplied by the fifth cranial nerve, as in *dental neuralgia* (when not due to exposure of the dental pulp), *neuralgic affections of the eyes*, *ears*, etc., and in *reflex neuralgias* in other parts of the body, as *gastric* and *intestinal neuralgia*, *abdominal neuroses*, from prostatic, urethral, or testicular disorders, and pectoral pain due reflexly to *nervous dyspepsia*. He also suggests its employment in *renal colic*. Piper methysticum has proved useful in *dropsy*, *intestinal catarrh*, and in *hemorrhoids*. Sixty or 70 grains of the scraped root, macerated for about 5 minutes in a quart of water, may be taken in the course of 24 hours, repeating this quantity daily, as long as required. The dose of the fluid extract of the root is from 15 to 90 minims, in a glass of water, repeating the dose every 3 or 4 hours; specific piper methysticum, 5 to 30 minims.

Specific Indications and Uses.—Neuralgia, particularly of the trifacial nerve; toothache; earache; ocular pain; reflex neuralgia; anorexia; dizziness and despondency; gonorrhœa; chronic catarrhal inflammations; vesical irritation; painful micturition; dysuria.

Related Species—*Piper Betle*, Linné. An indigenous East Indian creeper, the leaves of which, together with the areca nut (also called betel nut), and the addition of lime and sometimes catechu, constitute the celebrated masticatory of the Asiatics, the richer natives adding such aromatics as cloves, camphor, cardamoms, nutmegs, etc. Betel leaf, masticated, exerts a gently stimulant and exhilarant effect, and such is its power that, when deprived of it, its habitué experiences a sense of languor and fatigue. (See an interesting illustrated article, by Dr. Rodney H. True, on the subject of betel chewing, in *Pharm. Review*, 1896, pp. 130 and 177.) It has several medicinal applications among the natives, being especially used to harden the gums, preserve the teeth, and sweeten the breath. It is said to improve the voice, and is reputed aphrodisiac. (For Indian uses of the drug, see either Dymock's *Materia Medica of Western India*, or Dutt's *Hindu Materia Medica*.) Piper Betle leaves are about 5 inches long, broad-ovate, obliquely heart-shaped at base, acuminate, 5 to 7-nerved, and leathery. Their upper surface is glossy. They have an aromatic, bitter, burning taste. Betel leaves contain an essential oil, the composition of which differs according to the geographical source of the leaves. Eykman (1889) found the oil from Java leaves to contain a peculiar phenol which he called *chavicol* ($C_6H_4.C_3H_5.OH$, *para-allyl-phenol*). The characteristic constituent of all betel oils, however, is *betel phenol* (Bertram and Gildemeister, 1889), an isomer of *eugenol* (see *Oil of Cloves*). Siam betel oil also contains the sesquiterpene *cadinene* ($C_{15}H_{24}$). (For interesting details, see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 426; also see Dymock, *Mat. Med. of Western India;* and article under *Areca*).

PIPERAZINUM.—PIPERAZINE.

FORMULA: $C_4H_{10}N_2$. MOLECULAR WEIGHT: 85.9.

SYNONYMS: *Piperazidine*, *Diethylene-diamine*, *Ethylene-imine*, *Dispermine*, *Hexahydro-pyrazine*.

Preparation.—This substance, once thought to be identical, chemically, with spermine, may be produced when ethylene bromide (or chloride) is acted upon by ammonia, and the product of the reaction subjected to fractional distillation. The fraction, distilling between 130° and 180° C. (266° to 356° F.), deposits, on cooling, crystals of piperazine (A. W. Hofmann). (For the process of W. Majert and A. Schmidt, see *Amer. Jour. Pharm.*, 1893, p. 188.)

Description.—Piperazine, a patented preparation of R. Schering, forms crystalline, colorless masses; when crystallized from water, it forms lustrous, glass-like, tabular crystals. Exposed to the atmosphere, it rapidly absorbs carbon dioxide, and is very deliquescent. It fuses between 104° to 107° C. (219.2° to 224.6° F.), although the true melting point seems to be 112° C. (233.6° F.). It boils at about 145° C. (293° F.). Alcohol does not dissolve it as readily as water, in which it is very soluble. Its aqueous solution has a distinctly alkaline reaction. Chemically, it stands in close relation to *piperidine* (see *Piperinum*), as the two formulæ here given will show: $CH_2:(CH_2.CH_2)_2:NH$ (piperidine); $NH:(CH_2.CH_2)_2:NH$ (piperazine). It forms a characteristic, insoluble, red double salt with bismuth iodide. It unites with uric acid to form a compound soluble in 50 parts of water, hence is thought to be more valuable than lithium carbonate, for the removal of uric acid in excess from the body, on account of its greater solvent action. Its hydrochlorate forms lustrous, silky needles, and is likewise very soluble in water.

Action, Medical Uses, and Dosage.—Marked physiological effects are not produced by ordinary doses of piperazine. This agent appears to be a solvent of great power for uric acid, and is, therefore, a remedy for the conditions hinging upon a *uric acid diathesis*. It also dissolves *phosphatic* and *oxalic concretions*. The cases for its exhibition are those in which there is a persistent oversecretion of uric acid and urates, with dry skin, sickening backache and general muscular aching, and scanty secretion of urine of high specific gravity and with brick-dust deposits. With such conditions, it relieves *acute rheumatism*, *rheumatic pericarditis*, *gout*, and *chronic rheumatic arthritis*. It has recently been found of much value in *acute* and *chronic gonorrhœa*, and in *purulent cystitis*, daily doses of 10 grains having been employed in carbonated water (Tison and Attaix, *Gaz. Méd. de Strasbourg*, 1896). For ordinary use, about 3 grains every 3 hours, or 5 grains 3 times a day, in water or carbonated water, will be the proper dosage (Ellingwood).

Related Preparations.—LYCETOL, *Dimethylpiperazine tartrate*. A permanent white powder, melting at 243° C. (469.4° F.), and obtained by expelling the water of crystallization (3 molecules) from the well-crystallizable salt; it is readily soluble in water, with a pleasant acidulous taste (For its preparation and properties in detail, see *Pharm. Centralhalle*, 1894, p. 180.) This remedy, in doses of 15 to 30 grains, well diluted, daily, is praised as a decided uric acid solvent, and of therapeutic value in the various phases of *gout*, *lithæmia*, *chronic rheumatism*, *renal calculus*, and *renal colic*.

UROTROPIN, *Hexamethylene tetramine* ($C_6H_{12}N_4$).—This agent is produced by the action of ammonia upon formaldehyde. It forms white crystals, readily soluble in water, but difficultly soluble in alcohol. The aqueous solution has a pleasant, sweetish taste, and the drug is excreted by the kidneys unchanged. This agent, in doses of 15 to 30 grains, is said to be a very positive remedy in *phosphaturia*, and *purulent cystitis* and *pyelitis*. Sixty grains, well diluted with water, may be given in a day.

PIPERINUM (U. S. P.)—PIPERIN.

FORMULA: $C_{17}H_{19}NO_3$. MOLECULAR WEIGHT: 284.38.

"A neutral principle obtained from pepper, and obtainable also from other plants of the natural order *Piperaceæ*"—*U. S. P.*).

Source, History, and Preparation.—Piperin, the active principle of pepper (see *Piper*), exists in the black, white and long pepper, and in the berries of *Cubeba Clusii*, Miquel. It was first obtained by Oersted, of Copenhagen, in 1819, who believed it to be an organic base. Pelletier (1821) proved, however, that it is a non-basic principle. It may be isolated by various methods. According to Cazeneuve and Caillol (*Jahresb. der Pharm.*, 1877, p. 68), powdered pepper is mixed with milk of lime, the mixture evaporated to dryness on the water-bath, and extracted with ether. This solvent upon evaporation leaves piperin in the form of impure crystals, which are purified best by crystallization from acetone (Flückiger, 1891). Sumatra pepper yielded Cazeneuve, on an average, 8.10 per cent; Singapore white pepper, 9.15 per cent of piperin. T. Stevenson (see *Amer. Jour. Pharm.*, 1885, p. 513) prepares an extract from 50 grammes of pepper with methyl alcohol, dissolves out the resinous portion by means of potassium carbonate; the residual piperin is washed with water and recrystallized from alcohol.

Description and Chemical Composition.—*Piperin* ($C_{17}H_{19}NO_3$) is described by the *U. S. P.* as forming "colorless or pale yellowish, shining, prismatic crystals, odorless, and almost tasteless when first put in the mouth, but on prolonged contact producing a sharp and biting sensation. Permanent in the air. Almost insoluble in water; soluble in 30 parts of alcohol at 15° C. (59° F.), and in 1 part of boiling alcohol; very soluble in hot acetic acid; only slightly soluble in ether. When heated to 130° C. (266° F.) piperin melts; upon ignition it emits alkaline vapors, and is consumed, leaving no residue. The alcoholic solution of piperin is neutral to litmus paper. Concentrated sulphuric acid dissolves piperin with a dark blood-red color, which disappears on dilution with water. When treated with nitric acid, piperin turns rapidly first orange and then red, and the acid acquires a yellow color, deepening to reddish as the crystals dissolve. On adding to this solution an excess of potassium hydrate T.S., the color is at first yellow, but upon boiling it becomes blood-red"—(*U. S. P.*). Piperin is also soluble in chloroform, benzol, carbon disulphide, but almost insoluble in petroleum ether. Piperin has only weak basic properties, being hardly soluble in dilute acids. With hydrochloric acid and platinic chloride, however, it forms a well crystallizable double salt. Piperin is not decomposable even by boiling solution of caustic potash (Gerhardt); but prolonged heating with alcoholic solution of caustic potash decomposes it into *piperidine* and the *potassium salt of piperic acid* (v. Babo and Keller), according to the following equation: $C_{17}H_{19}NO_3+KOH = C_{12}H_9O_4K+C_5H_{11}N$. *Piperin*, reversedly, was synthetized from these constituents by L. Rügheimer (1882). *Piperic acid* ($C_{12}H_{10}O_4$), being nearly insoluble in water, may be precipitated from the solution of its potassium salt by the addition of hydrochloric acid, and recrystallized from alcohol. The acid forms yellow crystals, melting at 150° C. (302° F.). According to Fittig and Mielck (1869), it has the formula: $CH_2{:}O_2{:}C_6H_3.CH{:}CH.CH{:}CH.COOH$. The potassium salt by oxidation yields *piperonal* (which see). *Piperidine* ($C_5H_{11}N$) is a volatile, strong base, which may be separated in the above reaction by distillation with steam and collecting the vapors in dilute acid. It has the odor of ammonia and pepper, and forms well crystallizable salts with acids. Ladenburg, in 1885, succeeded in obtaining piperidine by synthesis, proving it to be *hexa-hydro-pyridine* ($C_5H_5N.H_6$, or $CH_2{:}[CH_2.CH_2]_2{:}NH$).

Action, Medical Uses, and Dosage.—Formerly this agent was frequently substituted for or used in conjunction with the cinchona alkaloids in the treatment of *malarial fevers*. Piperin is now occasionally employed in *intermittent fever*, but will be found less efficient than the alcoholic extract of black pepper. Its use has also been advised in *colic*, *diarrhœa*, *cholera*, *scarlatina*, *chronic gonorrhœa*, and in solution as a wash for *tinea capitis*. Piperin should not be administered with astringents, as it is thereby rendered nearly inert. The dose is 1 to 8 grains, 3 or 4 times a day (see *Piper*).

Derivative of Piperin.—PIPERONAL, or HELIOTROPIN ($C_8H_6O_3$). This compound is an aldehyde, the methylene ether of protocatchuic aldehyde, and has the formula: $CH_2{:}O_2{:}C_6H_3.CHO$. Its corresponding acid ($CH_2{:}O_2{:}C_6H_3.COOH$) is called *piperonylic acid*. Piperonal is obtained by oxidizing the potassium salt of *piperic acid* (see *Piperinum*; also see *Piper Methysticum*) with potassium permanganate in neutral solution. It forms small, white crystals, soluble in alcohol and ether, but sparingly soluble in cold water (1 in about 600). It resembles coumarin and vanillin in odor, and is now manufactured for purposes of perfumery; but it has also been given medicinally in 10 to 15-grain doses, every 3 hours, as an antipyretic and an antiseptic.

PISCIDIA.—JAMAICA DOGWOOD.

The bark of the root of *Piscidia Erythrina*, Jacquin.

Nat. Ord.—Leguminosæ.

COMMON NAME: *Jamaica dogwood.*

ILLUSTRATION: Nuttall's *North American Sylva*, Plate 52.

Botanical Source and History.—This is a small tree, native of the West Indies, and known as Jamaica dogwood. It is rarely found in southern Florida. The

Fig. 200.

Piscidia Erythrina.

flowers are in lateral clusters, appearing in profusion before the leaves. They have a broad, bell-shaped, 5-toothed calyx, and a papilionaceous corolla, of a dirty white color tinged with purple. The leaves are unequally pinnate, with entire, oval, acute leaflets, resembling those of the coffee-nut tree. The fruit is a 4-winged legume. The bark of the tree is very astringent, and is said to have been used in tanning. It is much employed in its native country as a fish poison (whence the generic name of the tree). It seems to act upon the lower animals as a poisonous narcotic.

Description.—Piscidia bark comes in quilled pieces, or in curved or flat sections. The corky layer is of a vivid orange (occasionally whitish) color, and is rugose, or appears fissured. Upon removal of the cork a deep ashen-gray surface appears, somewhat tinted with a brownish or blackish shade, and is marked with sinuous, longitudinal striæ, as well as by small ridges transversely arranged. Internally, it is smooth (sometimes fibrous) and of a brownish hue. The interior of the bark is bluish-green or brown-green, probably due to chlorophyll. It breaks with a fibrous, tough fracture, giving a narcotic, opium-like odor, and its taste, though slight at first, soon becomes acrid and bitter.

Chemical Composition.—The bark exhibits crystals of apparently oxalate of calcium, which, however, are phosphate of calcium (Berberich, 1898). According to Edward Hart (*Amer. Jour. Pharm.*, 1883, p. 369), the active principle is a neutral body, *piscidin* ($C_{29}H_{24}O_8$), which is neither a glucosid nor an alkaloid. It is produced by mixing 1 pound of the fluid extract of piscidia with 30 grammes of slaked lime, digesting for ½ hour, filtering, adding water in small amounts until the liquid becomes turbid; upon standing for 2 or 3 days the crystalline principle falls out, contaminated with some resin. They are finally recrystallized by means of alcohol. The principle occurs in prismatic, nearly colorless crystals, readily soluble in chloroform, boiling alcohol, and benzol, sparingly in cold alcohol and ether, insoluble in water. The crystals are also dissolved by strong acids, and from this solution are precipitated, apparently unchanged, by the addition of water. Its melting point is 192° C. (377.6° F.). These results were fully confirmed more recently by H. Berberich (*Amer. Jour. Pharm.*, 1898, p. 424), who made a complete analysis of the bark. Beside the active principle, *piscidia* (*piscidin*), some resin, caoutchouc, wax and fat, starch (1.34 per cent), were present; tannin was not found.

Action, Medical Uses, and Dosage.—Jamaica dogwood possesses active properties, its chief uses being to control pain and to produce sleep. Dr. Isaac Ott (see *Pharmacology of Newer Materia Medica*, p. 597), who made extensive experiments with the drug, declares its physiological effects to be essentially as follows: It increases the salivary and cutaneous secretions; slows the pulse, increases the arterial tension, succeeded by a fall of tension due to a weakening of the heart; dilates the pupils, except when passing into a state of asphyxia, when contraction takes place; it does not affect the irritability of the motor nerve fibers, nor does it attack the peripheral sensory nerve endings; it reduces reflex action by stimulating Setschenow's centers, and induces a tetanoid condition by stimulation of the spinal marrow; finally, he pronounces it narcotic to frogs, rabbits, and men. Piscidia destroys life by causing heart failure or by arresting respiratory action. Unpleasant results have been occasioned by even small doses of piscidia; among these are nausea, vomiting, headache, etc. Convulsions were provoked in the case of a woman who had been given a ½-drachm dose for hemicrania. The drug is recommended to replace opium, chloral, and similar narcotics. Dr. Hamilton (Burnett's *Outlines*, p. 684) states that a tincture of the bark of this tree is, the same as the bark itself, astringent and irritating. He also observes that it is most powerfully and remarkably narcotic and diaphoretic, and that its local application is a specific in removing *toothache*. For the latter purpose it has also been applied locally and given internally at the same time, in *irritation of the dental pulp, inflammation of the peridental membrane, alveolar abscess*, as well as in other painful affections of the mouth. *Burns, scalds* and *hemorrhoids* have been relieved by it, while a solution of it has been recommended as an injection in *gonorrhœa* (Fearn). Internally administered, it relieves pain, overcomes spasm, allays nervous excitability, and induces sleep. It is a favorite remedy in prolonged *insomnia*, particularly in the aged, and in those of an excessively nervous temperament. It should at least be given the preference over opiates until its utility or non-utility is established. It has rendered good service in *neuralgia*—particularly *sciatica, abdominal neuralgia, renal neuralgia, migraine*, and *tic-douloureux*. It allays the pain of *cholera morbus*, and the *gastro-enteralgia* sometimes following *enteric fever*. It also relieves *painful spasms of the muscles* and *acute articular* and other forms of *rheumatism*. In the disorders of women it has rendered excellent service in alleviating neuralgic and other forms of *dysmenorrhœa* and in various *pelvic neuroses*. With viburnum, it has been administered to check *false labor-pains* and *threatened abortion*. *Hysterical convulsions, delirium tremens* and the *insomnia of insanity* have yielded to it. In the pain of *carcinoma* and that attending *fractures*, it has been preferred by some to opium and other anodynes. It relieves the spasmodic element of *pertussis* and *asthma*, and has been lauded for *reflex coughs* and the cough of *spasmodic* and *chronic bronchitis*, and *pulmonary consumption*. Foltz (Webster's *Dynam. Therap.*, p. 595) praises it in *neuralgia of the eyeball* (where opium was not tolerated) and in *supraorbital neuralgia*, the dose given being from 10 to 20 drops of the fluid extract every 2 or 3 hours. He speaks lightly of it for the relief of pain in *acute catarrh of the tympanum*. Others speak highly of it in *acute abscess of the external auditory canal* and in *iritis, panophthalmitis*, and other inflammatory and painful affections of the eye. The dose of the fluid extract ranges from 10 drops to 2 fluid drachms; of specific Jamaica dogwood, 10 to 60 drops.

Specific Indications and Uses.—Insomnia and nervous unrest; to allay spasm, control pain and allay nervous excitability: migraine; neuralgia.

PIX BURGUNDICA (U. S. P.)—BURGUNDY PITCH.

"The prepared, resinous exudation of *Abies excelsa*, Poiret"—(*U. S. P.*). (*Abies excelsa*, De Candolle; *Pinus excelsa*, Lamarck; *Picea excelsa*, Link; *Pinus Picea*, Du Roi; *Pinus Abies*, Linné.)

Nat. Ord.—Coniferæ.

Common Names: *Norway pine, Spruce fir, Norway spruce fir.*

Illustrations: Bentley and Trimen, *Med. Plants*, 261; Woodville, *Med. Bot.*, 208.

Botanical Source.—This tree inhabits northern Germany, the Alps, Russia, Norway, and other northern parts of Europe, as well as of Asia, and also grows now in this country. It is a large tree, often having a diameter exceeding 4 feet, and attaining an altitude of 140 feet. The leaves are somewhat tetragonal, short, scattered, mucronate, dark-green, and glossy above. The male catkins are solitary, growing out of the axils, and purplish; the scales staminiferous at the apex. The female catkins are simple, purple, growing from the summit; the ovaries 2; the cones cylindrical, pendent, with oval, imbricated, slightly indented scales. The *Polyporus officinalis*, or *Larch agaric*, is a fungus nourished on this tree.

Though only the *Abies excelsa*, Poiret, is given as the official source of this drug, it is also prepared from the concretions formed upon *Abies Picea* (*Pinus Picea*, Linné; *Pinus pectinata*, De Candolle) (see below). The term Burgundy pitch is a misnomer, since no such substance has ever been produced in Burgundy. In France, resin is produced from *Pinus maritima*, Poiret (*P. Pinaster*, Aiton and Lambert). The bulk of true Burgundy pitch comes from Finland, and smaller quantities at one time came from the Black Forest in Germany, and from Vienna (see D. Hanbury, *Amer. Jour. Pharm.*, 1867, p. 547). The resin from which Burgundy pitch is prepared, is collected by making longitudinal incisions into the bark of the trees. The exudate is called *Abietis resina*, *Thus*, or *Frankincense* (a term also applied to *Olibanum*), and forms concrete tears, consisting of resin and volatile oil similar to oil of turpentine. An exudate, formerly collected in Alsatia from the same tree, and known under the name of *Strassburg turpentine*, is now obtained on a small scale only (see *Terebinthina*). Burgundy pitch proper is prepared from the exudate by boiling it in water and straining it. In composition, it largely consists of *abietic acid*.

Description.—Burgundy pitch is officially described as being "hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish-brown or yellowish-brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter. It is almost entirely soluble in glacial acetic acid, or in boiling alcohol, and partly soluble in cold alcohol"—(*U. S. P.*). Burgundy pitch softens by the warmth of the hand. Much of the article now found in commerce is a concoction. D. Hanbury (1867) believes it to be obtained by melting together common resin with palm oil or other fats, water being stirred in to produce an opaque appearance. The characteristic odor of true Burgundy pitch, and its nearly complete solubility in alcohol, and especially in glacial acetic acid, may aid in establishing some of its possible sophistications.

Action and Medical Uses.—Burgundy pitch is generally used externally for the purpose of producing a redness of the surface with a slight serous exhalation. Occasionally, it produces an eruption of pimples, sometimes minute blisters, and in some rare instances has been known to cause hardness, considerable suffering, and irritation, terminating in one or more ulcers. It has been principally employed as a counter-irritant in *chronic diseases*, especially of the lungs, stomach, intestines, etc., as well as in *local rheumatic affections*. It enters into the composition of several salves and plasters.

Related Species.—*Abies Picea* (*Pinus pectinata*, De Candolle; *Abies pectinata*, Lamarck; *Pinus Abies*, Du Roi; *Abies alba*, Miller; *Abies excelsa*, Link; *Pinus Picea*, Linné; *Pinus taxifolia* of *French Codex*), *European silver fir*, *Silver pine*. This tree grows in the mountains of Siberia, Germany, and Switzerland (L.). Branches horizontal; leaves copious, linear, either acute or emarginate, entire, spreading more or less perfectly in two rows, sometimes curved to one side; upper surface of a dark, shining, rather glaucous green; under glaucous white. Male flowers numerous, axillary, solitary, about as long as the leaves, yellow; their axis the length of the toothed involucre; anthers remarkable for their rounded, 2-lobed crest, crowned with a pair of divaricated horns. Female catkins lateral, erect, cylindrical, green; bracts, much narrower than the capillary scales, distinguished by a long, projecting, awl-shaped point, very conspicuous in the full-grown cones, which are also erect, 3 or 4 inches long, cylindrical, of a reddish-green, till they turn brown in drying (L.). According to Tingley, this species alone furnishes the true *Burgundy pitch*.

Retinol.—This product, obtained in 1838, as resin oil or resinol, from Burgundy pitch, by destructive distillation, is a yellowish, oleaginous fluid, boiling above 280° C. (536° F.). It is not soluble in water, but is itself a solvent for many substances, such as numerous alkaloids, phosphorus, phenol, iodol, cocaine, aristol, salol, etc. It is a non-irritating antiseptic, and in 8-grain doses, in capsule, it has been used in *gonorrhœa*. Besides being a vehicle for the application of the substances named above, it has been injected (5 to 10 per cent solution) in *cystitis*, and used locally in *vaginitis*.

PIX CANADENSIS.—CANADA PITCH.

The prepared juice or resinous exudation from *Abies canadensis*, Michaux (*Tsuga canadensis*, Carrière; *Pinus canadensis*, Linné; *Picea canadensis*, Link).

Nat. Ord.—Coniferæ.

Common Names: *Canada pitch*, *Hemlock pitch*, *Gum hemlock* (improperly).

Botanical Source and Preparation.—Canada pitch is obtained from the oleoresinous exudate of the hemlock spruce tree (see *Abies canadensis* for botanical source). It is sometimes improperly termed *gum hemlock*.

Mr. F. Stearns (1859) reports that the resin is collected by two methods—either by cutting a cup-like cavity in the tree, allowing the oleoresin to accumulate therein, from which it is then collected; the more common method of producing pitch, however, is that of removing the bark and wood around the pitch-laden knots and gnarled portions, putting the pieces together into boiling water, skimming the resinous product from the surface of the water, and purifying by melting and straining a second time.

Description and Chemical Composition.—Purified Canada pitch or gum hemlock, is at first whitish, but gradually becomes darker colored, changing to a yellow, brown, or blackish color. It is pulverable, almost insipid, of a faint characteristic odor, unlike that of turpentine, and has the specific gravity 1.033. A gentle heat renders it soft and tenacious, and, when elevated to nearly 93.3° C. (200° F.), liquefies it. It consists of resin, the composition of which has not been studied, with a small quantity of volatile oil. An essential oil is also obtained by distilling with water the branches and leaves of the tree, about 8 pounds of which yield an ounce of the oil. It is known as *oil of hemlock*, or *oil of spruce*. The oil, according to Bertram and Walbaum (1893), contains *lævo-pinene* and *lævo-bornyl-acetate*. This result was verified by C. G. Hunkel (*Pharm. Review*, 1896) on a genuine specimen of oil distilled by himself. About 51 per cent bornyl-acetate was present (also see *Abies canadensis*). The leaves and bark of the root and the trunk also contain notable amounts of tannin (see analyses and description of hemlock tannin by Prof. H. Trimble, in *Some North American Coniferæ*, 1897, pp. 111–118). An aqueous extract of the bark is used by tanners.

Action and Medical Uses.—Canada pitch is a mild stimulant, and, when in contact with the skin for a few hours, causes a slight degree of redness. It is frequently substituted for Burgundy pitch, as it possesses similar virtues. The tincture of hemlock pitch is diuretic and stimulant. It is not so eligible for plasters, however, on account of its softness.

PIX LIQUIDA (U. S. P.)—TAR.

"An empyreumatic oleoresin obtained by the destructive distillation of the wood of *Pinus palustris*, Miller, and of other species of *Pinus* (*Nat. Ord.—Coniferæ*)"—(*U. S. P.*).

SYNONYM: *Resina empyreumatica liquida*.

Source and Preparation.—The trees generally employed in producing tar are, besides the above-named *Pinus palustris*, Miller, the American species, *Pinus rigida*, Miller, *Pinus Tæda*, Linné; and also the European species, *Pinus sylvestris*, Linné; and *Larix sibirica*, Ledebour (see *Terebinthina*). Tar is made in several northern countries of Europe (*e. g.*, Stockholm tar), and in the United States, especially in North Carolina and Virginia, from the waste of pine or fir timber; it is usually prepared by making a conical cavity in the earth, communicating at the bottom with a reservoir. Logs or billets of wood are then placed, so as not only to fill the cavity, but to form a conical pile over it, which is covered with turf or earth, and kindled at the top. The admission of air is so regulated, that the wood burns from above downward, with a slow and smothered combustion. The wood itself is reduced to charcoal, and the smoke and vapors formed are obliged to descend into the excavation in the ground, where they are condensed, and pass along with the liquefied matters into the receivers. This mixture is termed tar, *Pix liquida*. By long boiling or distillation in retorts, tar is deprived of its volatile ingredients (*Oil of Tar;* see *Oleum Picis Liquidæ*), and converted into pitch, *Resina nigra*, or *Pix nigra*.

Description and Chemical Composition.—The *U. S. P.* describes tar as "thick, viscid, semifluid, blackish-brown, heavier than water, transparent in thin layers, becoming granular and opaque with age; odor empyreumatic, terebinthinate; taste sharp, empyreumatic. Tar is slightly soluble in water, soluble in alcohol, fixed or volatile oils, and solution of potassium or sodium hydrate.

Water agitated with tar acquires a pale yellowish-brown color and an acid reaction, yields with ferric chloride T.S. a transient green color, and is colored brownish-red by an equal volume of calcium hydrate T.S."—(*U. S. P.*). Upon prolonged standing, tar becomes granular from the deposition of pyrocatechin. Tar is a very complex substance and varies in composition according to the method of preparation and the kind of wood employed. The tar from leaf-trees, *e. g.*, the beech, is rich in phenols (see *Creosotum*) while pine-wood tar contains more resinous matters. Pine-wood tar also differs from beech-wood tar in being miscible with melted lard. Coal tar differs from wood tar principally in containing more basic substances, such as aniline and quinoline, while wood, upon dry distillation, yields more acid products, *e. g.*, pyroligneous acid. (For constituents of wood tar, see *Acetic Acid* and *Creosotum.*)

Action, Medical Uses, and Dosage.—Tar is stimulant, diuretic and diaphoretic. It has been advantageously used in *chronic coughs*, *chronic bronchial* and *laryngeal affections;* the inhalation of its vapor acts as a stimulant and irritant to the bronchial mucous membrane, promoting its secretion, but is seldom used. It is chiefly used externally as a local application to some cutaneous affections, as *porrigo*, *tinea capitis*, *lepra*, *psoriasis*, *prurigo*, *eczema*, and *herpes circinatus*. Excellent results sometimes follow its employment in *suppurating burns*, *excoriations*, *furuncles*, *cracked nipples*, and *piles*. Oakum, a dressing sometimes impregnated with tar forms a good antiseptic absorbent for pus-bathed surfaces, and also to *obstinate ulcers*. It is an excellent antipruritic and that is its specific use. A *tar-water* has been recommended in *cough* and *bronchial affections*, and to prevent the reproduction of *boils*. It is prepared as follows: To ½ gallon of boiling water, add 1 pint of tar and 1 pint of honey; stir the mixture, and when cold strain off the liquid. It is stimulant and diuretic, and may be taken 3 or 4 times a day, in doses of a wineglassful. It will also be found beneficial as a wash in some forms of cutaneous disease. B. J. Crew recommends the following: Rub 2 drachms of oil of tar with 40 grains of carbonate of magnesium, add a portion of 14 ounces of water, mix well; and then add the balance, filter, and add simple syrup, 2 ounces. The dose is a small wineglassful, 3 times a day (*Amer. Jour. Pharm.*, Vol. XXVII, p. 13). (See also *Aqua Picis.*) M. Adrian gives the following formula for a *glycerinated tar*, which has the consistence of an ointment, and the advantage of being soluble in water, and of not adhering to the skin: Take of tar, 15 parts; glycerin, 15 parts; water, 30 parts. Mix. The French employ emulsions, syrups, wine, and concentrated alkaline solutions of tar, which, however, have not been introduced into the medical practice of this country. Internally, the dose of tar is from 30 to 60 grains, 3 or 4 times a day, or even oftener, but it is commonly used in the form of tar-water, 1 pint of which may be taken in a day.

Specific Indications and Uses.—Locally to itching surfaces.

Related Product.—PIX NAVALIS, *Pix nigra*, *Resina nigra*, *Pix solida*, *Resina pini empyreumatica; Pitch*, or *Black pitch*. This substance is obtained by evaporating or distilling off the more volatile constituents of wood tar; in the second case, *oil of tar* (see *Oleum Picis Liquidæ*) distills over and pitch remains as residue. It is a black, firm substance, having a faint, tarry odor, a brilliant fracture, softening by the warmth of the hand, melting in boiling water. It is soluble in alcohol, and in alkaline solutions, and consists of empyreumatic resin and colophony (*rosin*).

Pix nigra has been used internally in *ichthyosis*, and certain *obstinate diseases of the skin;* its dose is from 10 to 60 grains, and may be made into pills with flour or other farinaceous substance. Pereira says it may be taken to a great extent, not only without injury, but with advantage to the general health. In *piles* it has been used with great advantage in the form of the following ointment: Take of pitch, wax, resin, each, 10 ounces; olive oil, 1 pint. Melt them together, and express through linen, and when nearly cool, stir in four ounces of Scotch snuff.

PLANTAGO.—PLANTAIN.

The root and tops of *Plantago major*, Linné.

Nat. Ord.—Plantaginaceæ.

COMMON NAMES: *Plantain*, *Rib grass*, *Ripple-grass*, *Ribwort*.

Botanical Source.—This is a perennial acaulescent plant with a round scape 1 to 3 feet in height, arising from a fibrous root. The leaves are ovate, smoothish, somewhat toothed, 5 to 7-nerved, each of which contains a strong fiber which may be pulled out, and abruptly narrowed into a long, channeled petiole. The flowers are white, very small, imbricated, numerous, and borne on a cylindrical spike 5 to 20 inches long. Small plants are frequently found with the spikes only ½ to 2 inches long, and the leaves and stalks proportionately small. The stamens and styles are long; the seeds numerous (G.—W.).

History and Chemical Composition.—Plantain is a well-known herb, growing in rich, moist places, in fields, by the roadsides, and in grass plats, and is common in Europe and America. It flowers from May to October. The root has a somewhat sweetish, salty taste; the leaves are bitterish and unsavory. The plant loses its medicinal activity by drying. All its preparations should be made from the freshly-gathered roots and tops. Water or alcohol extracts the virtues of the plant. The leaves contain chlorophyll, resin, wax, albumin, pectin, citric and oxalic acids (Th. Koller, *N. Jahrb. f. Pharm.*, 1868, p. 139). Upon incineration, they leave 12.8 per cent ash. Sugar is present, while alkaloids and glucosids are absent (D. Rosenbaum, *Amer. Jour. Pharm.*, 1886, p. 418). The root, according to Strawinsky (*ibid.*, 1898, p. 189), contains starch, wax, fatty matter, dextrose, saccharose, mucilage, traces of tannin, but no alkaloid or glucosid. The ash was 24.7 per cent, moisture 6.9 per cent.

Action, Medical Uses, and Dosage.—Plantain is alterative, diuretic, and antiseptic, once considered vulnerary. The tops and roots, in strong decoction, have been highly recommended in *syphilitic*, *mercurial*, and *scrofulous diseases*, in the dose of from 2 to 4 fluid ounces, 3 or 4 times a day. It is likewise reputed beneficial in *menorrhagia*, *leucorrhœa*, *hematuria*, *colic*, *cholera infantum*, *aphthæ*, *diarrhœa*, *dysentery*, *incipient phthisis*, *pulmonary hemorrhage*, *dysuria*, and *hemorrhoids*. The specific medicine may be employed in these disorders. The juice taken internally, in doses of 1 fluid ounce every hour, and also applied to the wound, is in high repute as an antidote to the *bites of venomous serpents*, *spiders*, and *insects*. It is a remedy for *toothache* from dental caries, the cavity being cleansed and specific plantago major applied on cotton to the sensitive pulp, renewing every half hour. Its internal use is said to control toothache through its effects upon the trifacial, *tic-douloureux* being benefited in the same manner. The same preparation, locally applied, often relieves *earache*. *Bedwetting* in children, due to relaxed vesical sphincter, with profuse colorless discharge of urine, is said to be relieved by plantago. Externally, the bruised leaves, or an ointment made with them, is useful in *wounds*, *ulcers*, *ophthalmia*, *eczema*, *erysipelas*, and some other cutaneous affections. The best forms of administration are the juice dissolved in diluted alcohol, and evaporated by gentle heat to the consistence of an extract; and specific plantago major, the dose of which is from 1 to 5 drops.

Specific Indications and Uses.—Locally, toothache and earache.

Related Species.—*Plantago lanceolata*, Linné; *Lance-leaved plantain*, has properties similar to common plantain. Its leaves contain much bitter matter. Locally applied, it has proved a hæmostatic for small *bleeding surfaces*.

Plantago cordata, Lamarck.—This is an indigenous perennial plant, known likewise as the *Heart-leaved plantain*. It is an acaulescent herb, with stout, naked scapes, 1 or 2 feet in height. Leaves radical, cordate-ovate, broad, smooth, somewhat toothed, thickish, about 6 inches long, 6 or 8-ribbed below, with a thick midrib, on long, stout petioles. Flowers small, whitish, somewhat imbricate, the lower one scattered, and on elongated spikes which are from 6 to 8 inches long; bracts ovate, obtuse. Calyx and corolla lobes very obtuse. Pyxis a third longer than the calyx, 2-celled, with 2 seeds in each cell (G.—W.). This plant grows in moist places, and along the banks of rivers, from New York and New Jersey to Tennessee, also from Ohio to Wisconsin, and flowers from April to August. The root is the part used, and it yields its properties to water. The root of Plantago cordata is astringent, anodyne, antispasmodic, and antiemetic. The decoction and extract have been successfully used in *Asiatic cholera*, checking the disease in a short time; they have likewise proved beneficial in *dysentery*. The plant is certainly deserving of more extended investigation, for it directly influences the nervous system, controlling irritation. A poultice of the roots is recommended as an application to old, indolent *ulcers*, *bruises*, *wounds*, etc. It allays inflammation and reduces swelling.

Plantago Psyllium, Linné; *Flea-wort*, *Flea-seed plant.*—South Europe and Barbary. The seeds of this species are flea-colored, boat shaped, and shining on the convex surface. They yield a mucilage, used in southern Europe as that of flaxseed, slippery elm, etc., is used in this country. The seeds, in tablespoonful doses, in a glass of water, before dinner, have been successfully employed to relieve *chronic constipation*. The *Plantago arenaria*, Waldstein and Kittaibel, and *Plantago Cynops*, Linné, also contain mucilage.

Plantago Ispaghula, Roxburgh (*Plantago decumbens*, Forskal), *Spogel* or *Ispaghul seed*.—This little plant is common throughout northwestern India, Arabia, and neighboring countries.

The seeds are the parts used. They are about ⅛ of an inch in length, and half as broad, concave on one side, convex upon the opposite, and according to the *Pharmacographia*, are so light as to require 100 to weigh a single grain. Spogel seed have long been employed in India, and, in 1868, were admitted to a position in the *Pharmacopœia* of that country. For an illustration of this plant, see *New Remedies*, 1878, p. 68.) Spogel seed are very mucilaginous, and form a thick jelly with water. They are employed, either in substance or in decoction, in India, for the treatment of *diarrhœa* and *dysentery*,. In chronic diarrhœa, they are often given whole, in doses of from 1 to 2 drachms, mixed with a little syrup, or powdered and mixed with sugar and water. When bruised and moistened with water, the seeds are often used by physicians, in India, as an emollient poultice.

Dr. O. S. Laws (*Calif. Med. Jour.*, 1899) calls attention to a plant of the Plantago family, growing in damp situations in southern California and Arizona, as a valuable local remedy for *nasal catarrh*. He applies equal parts of the tincture of the roots, water and glycerin, on cotton placed in the nasal fossæ. He calls it *Plantago aquatica;* it is probably *Alisma Plantago.*

PLASMÆ.—PLASMAS.

History.—In 1858, G. F. Schacht proposed *glycerin* as a substitute for oils and fats in ointments, the glycerin being heated with starch, and the compounds thus formed being termed "Plasmas." This term we propose to employ here for all solid or semisolid preparations for external use, excepting *glycerites*, in which glycerin forms an important basis. These preparations are more costly than the ordinary fatty ointments, but there are certain cases in which the latter irritate the parts to which they are applied, and, consequently, aggravate the disorders for which they are used, which is not the case with the plasmas, the glycerin being comparatively unirritating, not possessed of any rancidity, nor of any irritating fatty acids, etc. In addition to these advantages, it can be removed at any time without the use of soap and friction, and its application does not involve soiling and greasing the garments or bed-clothing (see *Glycerita*). The formula of Mr. Schacht is to take powdered starch, 70 grains; glycerin, 1 fluid ounce; mix the ingredients and heat to 115.5° C. (240° F.), constantly stirring. If a large quantity (6 or 8 pounds) is to be prepared, he advises that the starch be triturated with one-twelfth of the glycerin, placing the remainder on the fire, heating it to 126.6° C. (260° F.), and then stirring it thoroughly into the mixture previously made. By this means much time is saved, as well as labor, in stirring the mass. He states that the plasma does not mold by keeping.

Other formulæ besides that of Mr. Schacht's have, at various times, been offered to the profession, thus: Mr. H. Seymour has offered the following: (1) Take of Fuller's earth, ½ ounce; palm oil, 2 drachms. (2) Take of Fuller's earth, ½ ounce; oil of sweet almonds, 2 fluid drachms; water, 2 fluid drachms; glycerin, 1 fluid drachm. More recently, Mr. T. B. Groves has proposed a new basis for ointments, which he calls *Glycelæum*. It is made by triturating together almond meal (from oil-cake, or decorticated pressed sweet almonds), ½ ounce; glycerin, 1 ounce; olive oil, 3 ounces. Mix by trituration in a mortar. It forms a soft, semi-gelatinous paste, which, when mixed gradually with water or a watery fluid, readily forms an emulsion. As it remains unaffected by the ordinary temperatures of the body, its softness is not an objection to its use, which, in fact, is an advantage, as it leaves plenty of room for powdery admixtures of every kind (*Trans. Brit. Conf.*, 1867; *Chem. and Drug.*, Sept. 14).

PLASMA ACIDI CARBOLICI.—PLASMA OF CARBOLIC ACID.

Preparation.—Take of carbolic acid 6⅘ parts; glycerin, 27⅕ parts: prepared chalk, finely powdered, 94 parts. Mix together the carbolic acid and glycerin, and then add the chalk; mix thoroughly by kneading, and enclose in closely stopped jars (Thomas E. Jenkins, *Amer. Jour. Pharm.*, 1869, p. 292). This gives a preparation possessing the proper consistence, and preserving its properties unimpaired for a long time, when kept in closed jars. It is offered as a substitute for Dr. Lister's preparation made with putty, which dries very rapidly and become hard.

Action and Medical Uses.—This plasma is used as a surgical dressing to *wounds*, etc., effectually excluding the action of the air and other external agencies, and at the same time preventing any tendency to gangrene or putrefaction.

PLASMA CUPRI SULPHATIS.—PLASMA OF COPPER SULPHATE.

Preparation.—Take of finely powdered sulphate of copper, 20 grains; glycerin 1 fluid ounce; finely powdered starch, 70 grains. Dissolve the copper salt in the glycerin, then add the starch; heat the mixture to 115.5° C. (240° F.), constantly stirring, and continue the heat and stirring until the consistence of a soft ointment is acquired. Keep in closely stopped jars.

Action and Medical Uses.—This forms an excellent local application to *granulated lids*, and in other *ophthalmic affections;* also as a stimulant to *chancres*, *ulcers*, etc.

PLASMA PETROLEI.—PLASMA OF PETROLEUM.

Preparation.—Take of finely powdered starch, 70 grains; petroleum, 1 fluid drachm; glycerin, 1 fluid ounce. Triturate the starch and petroleum together until quite smooth, gradually add the glycerin, and heat to 115.5° C. (240° F.), constantly stirring (G. F. Schacht).

Action and Medical Uses.—This is very valuable as a local application in many *cutaneous diseases*, and in *hemorrhoids*.

PLASMA PICIS LIQUIDÆ.—PLASMA OF TAR.

Preparation.—Take of finely powdered starch, 2 drachms; glycerin, purified tar, each, 6 ounces. Add the glycerin, warm, to the starch, stir well together, heat to 115.5° C. (240° F.), gradually add the tar, and stir constantly until thoroughly incorporated (Brady).

Action and Medical Uses.—This will be found useful as a local application to *wounds*, *ulcers*, and in several forms of *cutaneous diseases*.

PLASMA POTASSII IODIDI.—PLASMA OF POTASSIUM IODIDE.

Preparation.—Take of finely powdered starch, 140 grains; glycerin, 2 fluid ounces; iodide of potassium, 2 drachms. Dissolve the iodide of potassium in the glycerin, then add the starch gradually with trituration, and heat to 115.5° C. (240° F.), constantly stirring until it is of the proper consistence.

Action and Medical Uses.—A local application to *scrofulous* and *other tumors*, several forms of *cutaneous diseases*, and wherever the external use of iodide of potassium is indicated.

PLASMA ZINCI OXIDI.—PLASMA OF ZINC OXIDE.

Preparation.—Take of finely powdered starch, 140 grains; glycerin, 2 fluid ounces; oxide of zinc, 1 drachm. Triturate the starch and oxide of zinc together, gradually add the glycerin, then heat to 115.5° C. (240° F.), constantly stirring until thoroughly incorporated.

Action and Medical Uses.—A local application for severe *burns*, and in *cutaneous diseases*, as, *herpes*, *eczema*, *pemphigus*, *chafes*, *chaps*, etc.

PLATINUM.—PLATINUM.

SYMBOL: Pt. ATOMIC WEIGHT: 194.3.

Source and History.—Platinum occurs in nature only in its elemental form, but is almost invariably contaminated with other metals, *e. g.*, iridium, osmium, rhodium, iron, copper, etc. It has probably been known for centuries in Mexico and other Central American countries. The Spanish gave it the name, "Platina del Pinto," from its silver-like appearance, and its occurrence in the gold-bearing sand of the River Pinto, in Brazil. In 1819 platinum was discovered in the Ural mountains, its present chief source. Platinum, in addition to the countries named, also occurs in Borneo, Australia, in Canada and in some parts of the United States, *e. g.*, North Carolina, California, and Oregon. Occasionally, though rarely, it is found in the form of cubical or octahedral crystals. Platinum is obtained pure from its ore in the same manner as spongy platinum (see below) is prepared. The metal obtained is melted down by means of the oxyhydrogen blow-pipe flame.

Description.—Platinum is a tin-white metal, somewhat darker than silver, ductile, malleable, unalterable in air or water, and has a specific gravity of 21.5 (Deville and Debray). It is only fusible by the highest heat that can be artificially produced. It may be drawn into wires of extreme thinness. Platinum utensils (crucibles, dishes, retorts) have become indispensable to analytical and technical chemists. Pure platinum is indifferent toward boiling sulphuric, hydrochloric or nitric acids. The presence of impurities, *e. g.*, nitrous acid in sulphuric acid or a concentration of the latter acid greater than 94 per cent are liable, in large operations, to cause notable quantities of platinum to be dissolved. The presence of iridium, though it renders the platinum brittle, causes it somewhat to resist the corrosive action of the acid (see in this connection an interesting paper by M. Scheurer-Kestner in *Pharm. Jour. Trans.*, Vol. VI., 1875–76, p. 505). Platinum is readily dissolved by a mixture of hydrochloric and nitric acids (*nitro-muriatic acid, aqua regia*), and is also attacked by free chlorine, bromine, and iodine. Platinum forms fusible alloys with lead, tin, etc.; hence, if platinum crucibles be heated with lead, etc., they become readily perforated.

H. Hager (*Handbuch der Pharm. Praxis*, 1886, p. 716) enumerates the following operations which should not be carried out in platinum vessels: (1) The fusion of alkali sulphides, or the reduction of sulphates with charcoal; (2) contact with liquids containing chlorine, bromine, iodine, aqua regia; (3) heating platinum to redness on a sand-bath, *i. e.*, in contact with silicic acid, which would cause the platinum to become brittle; (4) fusion of lithium salts and of alkali nitrates; (5) fusion of caustic alkalies or alkaline earths, oxides of calcium, barium, strontium, magnesium; (6) fusion of such metals as bismuth, lead, tin, cadmium, or the heating of reducing mixtures which, upon fusion, yield these metals; (7) exposure of the metal to a white heat in contact with metallic oxides giving off oxygen under this condition, *e. g.*, oxides of lead, bismuth, nickel, copper, etc.; (8) heating phosphoric acid and acid phosphates when mixed with carbon, owing to the liberation of phosphorus, which would form platinum phosphide; (9) boiling down such decomposable liquids as ferric chloride; (10) fusion of iodides and bromides; (11) the heating of all minerals, etc., yielding a volatile film (*Beschlag*), upon charcoal when heated by means of the blow-pipe. Nor should platinum utensils be heated in a sooty flame, owing to the possible formation of platinum carbide, which blisters the metal. Arsenic and melting potassium cyanide are likewise harmful.

Platinum in the form of wire, especially when warmed to about 50° C. (122° F.), has the property of condensing oxygen gas on its surface; this property is possessed to an even more remarkable degree by the two forms of platinum known as *spongy platinum* and *platinum black*. *Spongy platinum* is a soft, gray, porous mass of platinum, obtained by igniting ammonium platinic chloride ($PtCl_6[NH_4]_2$). It rapidly condenses oxygen on its surface. By directing a current of hydrogen upon spongy platinum, the oxygen contained in it causes the hydrogen to ignite. On this principle Doebereiner's lamp is based. Mixtures of oxygen with the vapors of alcohol or ether, or other inflammable vapors, may likewise be ignited by means of spongy platinum; or slow oxidation may be induced. *Platinum black* is an even more finely divided form of platinum, and may be obtained in various ways, *e. g.*, by reducing platinic chloride solution ($PtCl_6H_2$) with glycerin and caustic potash; or by treating an alloy of platinum and zinc or copper with nitric acid, whereby platinum remains undissolved in the form of platinum black. This substance, when washed out and thoroughly dried, absorbs 800 times its volume of oxygen, thereby becoming red-hot. In the form of platinum-asbestos (finely divided platinum deposited upon asbestos fibre), platinum black is being used with success in organic analysis in the place of oxide of copper; likewise in the manufacture of sulphuric acid by a new process, which consists in conducting an absolutely dust-free mixture of sulphur dioxide and oxygen over platinum asbestos at a *low* temperature (see Von Wartha, *Chem. Zeitung*, 1899, p. 977). Platinum black also has the property of oxidizing alcohol, forming acetic acid, a reaction that might be carried out on a larger scale.

Two oxides of platinum are known—the *monoxide* (PtO), forming with acids the brownish-green *platinous* salts, and the *dioxide* (PtO_2), which forms the yellow or brown *platinic* salts. Platinum dissolved in nitro-hydrochloric acid forms *platinic chloride*, supposed to be $PtCl_4$, but in reality a double compound ($PtCl_6H_2+6H_2O$). Platinic chloride causes insoluble crystalline precipitates in solutions of potassium, rubidium, cæsium or ammonium salts (*e. g.*, $PtCl_6K_2$, or $PtCl_6[NH_4]_2$), but not in sodium or lithium salts, which form water-soluble crystals (*e. g.*, $PtCl_6Na_2+6H_2O$). Precipitates are also produced with solutions of many alkaloids; in orde to test for these, the absence of potassium and ammonium salts must be pr viously established.

Salts of Platinum.—PLATINI CHLORIDUM, *Platinic chloride*, *Platinum tetrachloride*, *Platini bichloridum* ($PtCl_4$), *Nitromuriate of platinum*. The term *bichloridum* has reference to the old nomenclature of the salt and must not be confused with platinum bichloride ($PtCl_2$) as accepted to-day. The tetrachloride is prepared by dissolving platinum in nitro-hydrochloric acid, and cautiously evaporating the solution on the sand bath to drive off all excess of acid and the water of crystallization. The heat must not exceed 120° C. (248° F.). A dark, reddish-brown, deliquescent, saline mass is obtained, which is soluble in water, alcohol or ether. It is a powerful caustic poison. It was formerly often recommended, in doses of from ⅛ to ¼ of a grain, 3 or 4 times a day, in *secondary syphilis*. It may be administered in aqueous solution, or in pill form. An ointment, composed of 5 grains of the bichloride, 10 grains of extract of belladonna, and 160 grains of lard, has been applied to *indolent* and *syphilitic ulcers* (Hæfer).

By evaporation of the platinic chloride solution on the water-bath, brown-red deliquescent crystals of the composition ($PtCl_6H_2+6H_2O$) are obtained. By precipitating from this compound the excess of HCl by means of silver nitrate, and evaporating the supernatant liquid, non-deliquescent crystals of the composition ($PtCl_4+5H_2O$) result. The compound $PtCl_6H_2+6H_2O$ has action and uses similar to the bichloride, being employed in doses about one-half the size of those of the latter.

PLATINI ET SODII CHLORIDUM, *Sodii platino-bichloridum*, *Platino-bichloride of sodium*, *chloroplatinate of sodium*.—This salt may be procured by dissolving 170 parts of pure bichloride of platinum (platinum tetra-chloride, see above), and 58.5 of pure chloride of sodium, in separate portions of distilled water. Mix the solutions, and cautiously evaporate to crystallization. The crystals are red, soluble in water or alcohol, and have the formula, $PtCl_4.2NaCl+6H_2O$. When heated they lose their water of crystallization, and become anhydrous, forming a yellow powder. This is recommended in *syphilitic* and *scrofulous diseases*, in doses of ⅛ grain to ½ grain, 3 times a day, in powder with starch, pill, or a mucilaginous solution. It is milder in its action than the bichloride of platinum. Half a drachm of the sodium salt of platinum dissolved in ½ pint of decoction of poppies, has been used as an injection in *gonorrhœa*; or, 2 grains to 1 ounce of oil or fat has also been used.

PLATINI IODIDUM, *Platinic iodide* (PtI_4).—A blackish or brown-black non-crystalline tasteless powder, not soluble in water, but dissolving with a light-red color, in either potassium iodide, or carbonate.

PLATINI ET POTASSII CYANIDUM, *Potassium platino-cyanide* ($2KCN.Pt[CN]_2.3H_2O$).—In long acicular or prismatic crystals, yellow, with a handsome blue surface reflection. Exposed to air they become rose-colored and opaque. Hot water freely dissolves it. In solution it precipitates ferrous salts blue-white, cupric salts, green-blue, and mercurous nitrate, blue. Its barium compound ($BaPt[CN]_4+4H_2O$) is sensitive to the Roentgen rays, and is used in the preparation of the fluoroscope by means of which the effects of the rays are rendered visible.

None of the platinum compounds, which are said to resemble therapeutically the salts of gold, are employed in Eclectic practice. Platinum forms an excellent material for laboratory utensils.

PLUMBI ACETAS (U. S. P.)—LEAD ACETATE.

FORMULA: $Pb(C_2H_3O_2)_2+3H_2O$. MOLECULAR WEIGHT: 378.0.

SYNONYM: *Sugar of lead*, *Acetas plumbicus*, *Cerussa acetata*, *Saccharum saturni*.

"Lead acetate should be kept in well-stoppered bottles" (*U. S. P.*).

Preparation.—Acetate of lead is prepared in considerable quantities in this country, England, Holland and France, and may be obtained by several methods; either carbonate of lead (see *Plumbi Carbonas*) or litharge (*Plumbi Oxidum*) is dissolved in acetic acid, or the hot vapors of acetic acid are made to act upon lead oxide; the product is dissolved in water, and the solution obtained is evaporated to crystallization. In the latter operation a slight excess of acetic acid is always necessary (see directions in *Br. Pharm.*, 1885). As prepared for use in the arts, wood-vinegar and litharge being employed, the salt is impure and generally ranges in color from white to reddish or brown. Lead acetate is largely used in calico printing and dyeing as a mordant.

Description.—Lead acetate, as required by the *U. S. P.*, should form "colorless, shining, transparent, monoclinic prisms or plates, or heavy, white, crystalline masses, or granular crystals, having a faintly acetous odor, and a sweetish, astringent, afterward metallic taste. Efflorescent, and absorbing carbon dioxide, on exposure to the air. Soluble, at 15° C. (59° F.), in 2.3 parts of water, and in 21 parts of alcohol; in 0.5 part of boiling water, and in 1 part of boiling alcohol. When heated to 40° C. (104° F.), the salt loses its water of crystallization (14.25 per cent). It fuses at 200° C. (392° F.) with the loss of acetic acid, and when strongly heated it is completely decomposed, with the evolution of carbon dioxide and acetone, leaving a residue of finely divided metallic lead mixed with oxide and carbonate. On heating the salt with sulphuric acid, vapors of acetic acid are evolved. The aqueous solution of the salt has a slightly acid reaction, and yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid"—(*U. S. P.*). When lead acetate is dissolved in water, a small quantity of a white precipitate is usually formed, consisting of carbonate of lead, due to the carbonic acid, which is usually present in water, or to the action of the carbon dioxide contained in the air, if the salt has not been kept in well-stoppered vessels; a small quantity of acetic acid will redissolve this deposit, and render the solution clear. When exposed to a vacuum kept dry by sulphuric acid or quicklime, the acetate of lead falls into a white powder, which is completely anhydrous. Acetate of lead is incompatible with alkalies and alkaline earths, and especially with those acids or their soluble salts which form a precipitate with soluble lead salts, as sulphuric, phosphoric, hydrochloric, hydriodic, oxalic, malic acids, etc., and partially even by water containing carbonic acid.

Tests.—Acetate of lead dissolved in distilled water is precipitated as white carbonate of lead when treated with sodium carbonate. The above precipitate of lead sulphate, produced by the addition of sulphuric acid is quite characteristic for lead salts; it is soluble in basic ammonium tartrate (difference from barium sulphate). Lead sulphate also differs from barium sulphate by turning black in contact with ammonium sulphide. Complete solubility of lead acetate in distilled water acidulated with acetic acid, shows the absence of sulphates, and, to some extent, of chlorides. "A 10 per cent solution of the salt, prepared with water which has recently been boiled, should be clear, or only slightly opalescent (limit of carbonate), and should yield, with potassium ferrocyanide T.S., a pure white precipitate (absence of iron or copper). If to the aqueous solution hydrochloric acid be added until no further precipitate is produced, and the remainder of the lead removed from the filtrate by hydrogen sulphide, a portion of the new filtrate should not be affected by the addition of a slight excess of ammonia water (absence of zinc or iron). If another portion of the last filtrate be evaporated to dryness, it should leave no residue (absence of salts of the alkalies or of zinc)"—(*U. S. P.*). (For *Plumbi Subacetas*, see *Liquor Plumbi Subacetatis*.)

Action, Medical Uses, and Dosage.—I. LEAD. (For description, etc., see under *Plumbi Oxidum.*) Lead is a poison, though not specially active, and when taken internally it is absorbed, and may be detected in the fluids and solids. In acute lead poisoning there is a burning, prickling sensation in the fauces, thirst, dryness of tissues, gastric uneasiness and vomiting and severe intermittent colic relieved by pressure. Obstinate constipation is the rule. The abdomen is tense with the skin retracted and cold. The stools are dark, due to the formation of lead sulphide. If protracted, the nervous system is involved, giddiness, torpor, and coma sometimes being present, while numbness, cramps of calves of the leg and inner side of thighs, and paralysis may take place. A blue line may sometimes be observed upon the gums. For acute poisoning the soluble sulphates mentioned below, under *Lead Acetate*, are the proper antidotes. When the system is impregnated with lead (chronic lead poisoning) it is said to produce a leaden discoloration of the gums, teeth, and mucous membrane of the mouth, a peculiar lead taste and odor, jaundice, emaciation, and a feeble, irregular, state of the circulation, the pulse being often reduced to 40 or 45 beats per minute. In large doses, or when continued for some time in small doses, lead gives rise to certain abdominal pains, termed *lead colic;* sharp pains in the limbs, unaccompanied by either redness or swelling, and which are increased by motion, and diminished by pressure, and are frequently accompanied by hardness, and cramps in the affected parts, and which condition is termed *lead arthralgia; lead paralysis*, which attacks the extremities, more commonly the superior, and which appears to affect the extensor muscles principally, the hands being bent or dropped *wrist-drop*) and the arms dangling by the side. There may also be a paralysis of sensation. The brain may also become affected with what is termed *lead encephalopathy*, manifested by furious or tranquil delirium, more or less profound coma, or convulsions. *Painters' colic* (*colica pictonum*) is a peculiar affection attacking painters and other workers in lead. Its most characteristic symptoms are severe colic with a sense of sinking about the region of the navel, and a peculiar form of paralysis allowing the hands to drop (*wrist-drop*). General paralysis may occur, the skin becomes yellow, and on the abdomen retracted, constipation is obstinate, emaciation marked, the blue line is pronounced, and if severe enough epileptoid convulsions ending in death, may ensue. When convulsions occur death is very apt to follow. Painters and workers in lead are more commonly poisoned, but occasionally families are poisoned by drinking water from new lead pipes (allowing solutions of sulphuric acid or soluble sulphates to stand in the pipes will prevent this); typesetters are prone to lead-poisoning, and flour has been known to contain enough lead (from repairing holes in the mill stones with lead) to act as a poison. Lead chromate used to color pastry has produced serious results. In cases of chronic poisoning by lead, the antidotal treatment is, to place the patient in a bath made by dissolving sulphide of potassium, 4 ounces in 30 gallons of warm water, which converts the lead on the surface to a black sulphide, which must be removed by means of soap and water, and a good stiff brush, and which should be repeated every few days until the skin no longer becomes discolored by the sulphuretted bath. Internally, water acidulated with sulphuric acid should be drank; or solutions of the sulphates of sodium, magnesium, or alum. A decoction of ground ivy (*Nepeta Glechoma*) may be drank freely; or, water acidulated with the juice of preserved barberries. Iodide of potassium has been recommended, and is said to render the lead with which it comes in contact more soluble, so that it can be more readily passed from the system. The latter salt is by far the most common antidote now employed for *chronic* lead poisoning. The bowels must be kept regular by castor oil, to which croton oil may be added if necessary; opiates may be given to relieve pains and cramps; tonics to improve the strength when there is much debility; and nux vomica or strychnine, with electro-magnetism and frictions or shampooing, to overcome the paralysis. (For a record of wholesale poisoning through flour containing metallic lead, see *American Journal of Pharmacy*, 1888, p. 148.

II. Lead Acetate.—Acetate of lead, in doses of from 1 to 4 grains, every 1, 2, or 4 hours, is an efficient astringent and sedative. It is usually given in pill form. In large doses, it is an irritant; and in long-continued, small doses, it may induce the peculiar constitutional action of the preparations of lead. Its best antidote is sulphate of sodium, sulphate of magnesium, or phosphate of sodium, which should be followed by emetics, if necessary, and then by alternate purgatives and opium. Generally, an excess is followed by vomiting, which prevents any serious injury, and, as long as the bowels are kept regular, its effects upon the constitution are seldom experienced. Large doses have, at times, been taken, even to several drachms, without occasioning more than severe sickness, some pain in the stomach, vomiting, etc. Few fatal cases have been recorded. Some practitioners make extensive use of it in *active* or *passive hemorrhages from the lungs, bowels, womb*, etc., in which it is employed with the view of diminishing the caliber of the bleeding vessels, thereby checking the flow. It is generally given in connection with opium. It has also been exhibited in *colliquative diarrhœa*, *chronic dysentery*, to check excessive secretion in *bronchitis*, to remove obstinate *mercurial ptyalism*, and in *gastric irritability* attending certain forms of *fever*. In *passive hemorrhages*, the following has been found efficient: Take of acetate of lead, 2 grains; opium, ½ to 1 grain; capsicum, 2 grains; form into a pill with conserve of roses, and give 1 every hour or two, in urgent cases every 10 minutes. While administering this agent, the gums should be frequently examined, and as soon as a blue line is observed along their edge, indicative of its constitutional influence, its use should be stopped. Many practitioners, however, denounce its internal administration, and employ it occasionally, in solution, as an external application, in cases of *superficial inflammations*, as in *erythema*, *erysipelas*, spreading inflammation of the subcutaneous cellular tissue, and in many *cutaneous diseases*. The solution may be made by dissolving 1 drachm of the salt in 5 or 8 fluid ounces of distilled water, to which 1 fluid drachm of distilled vinegar may be added to prevent the oxide from being thrown down; 1 or 2 grains dissolved in 1 fluid ounce of pure water forms a common collyrium, but should not be used when the cornea is ulcerated, lest a deposit of lead leave an opacity after the parts are healed. In inflammations, opium is often conjoined with it, 4 grains of each being added to every fluid ounce of water. So much improvement has been recently made in American practice, that we believe even the external use of this agent can be, in a great measure, dispensed with. It forms a favorite injection among the laity for the cure of *gonorrhœa*, and is undoubtedly the most universally successful application, when used in alcoholic solution, for the relief of *poisoning by Rhus Toxicodendron*.

PLUMBI CARBONAS (U. S. P.)—LEAD CARBONATE.

FORMULA: $(PbCO_3)_2Pb(OH)_2$. MOLECULAR WEIGHT: 772.82.

SYNONYMS: *White lead*, *Cerussa*, *Flake white*, *Magistery of lead*, *Plumbum carbonicum*, *Carbonas plumbicus*, *Plumbum hydrico-carbonicum*.

Lead carbonate should be kept in well-closed vessels.

Preparation.—Lead carbonate is found in nature in the form of certain rare minerals, and may be prepared artificially by causing a current of carbonic acid gas to pass through a certain quantity of solution of subacetate of lead, prepared by boiling solution of acetate of lead with litharge. This is *Thénard's process*, of which *Benson's process* is a modification. Washed litharge, with a little acetate of lead, is made into a thin paste with water, and, with continual stirring, a current of carbon dioxide is conducted into the mixture until absorption ceases. The best mode of preparation, even at this day, and yielding a product of great "covering power" for the purposes of painting, is the old-time *Dutch process*. This consists in placing rows of earthenware pots under sheds, pouring into each pot a little acetic acid, placing above this, inside of each pot, a roll of sheet lead, and covering the entire arrangement with tan-bark. The heat of the decomposing bark causes evaporation of the vinegar, this unites with the lead to form basic acetate of lead, and the carbon dioxide supplied from the decomposing organic matter of the bark converts this into *white lead*.

Description and Tests.—Carbonate of lead is described by the *U. S. P.* as "a heavy, white, opaque powder, or a pulverulent mass, without odor or taste. Permanent in the air. Insoluble in water or alcohol, but soluble in acetic or diluted nitric acid, with effervescence. When strongly heated, the salt turns yellow without charring, and, if heated in contact with charcoal, it is reduced to metallic lead"—(*U. S. P.*). In the latter case, the metallic globule is surrounded by a volatile zone (*Beschlag*) of the yellow oxide. The salt parts with its combined water at 155° C. (311° F.), but does not lose weight at 100° C. (212° F.). The salt is somewhat soluble in water containing carbonic acid. It is blackened by sulphide of hydrogen, and by ammonium sulphide. The composition of white lead is variable, but should correspond to an oxycarbonate of lead $(PbCO_3)_2Pb(OH)_2$. This formula allows for a loss in weight of about 14 per cent upon igniting the salt, while the official requirements (see below) fixes the limit at 15 per cent. Barytes (barium sulphate) is a common adulterant of the white lead employed in the arts. A mixture of barytes (1 part) and white lead (1 part) is known as *Venetian white;* barytes (2 parts) and white lead (1 part), as *Hamburg white;* and barytes (3 parts) and white lead (1 part), as *Dutch white*. Barytes is easily detected by its insolubility in nitric acid. "If 2 Gm. of the salt be dissolved in a mixture of 2 Cc. of nitric acid and 10 Cc. of water, it should not leave more than 0.02 Gm. of residue (limit of insoluble foreign salts). This solution yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid. On completely precipitating the solution with hydrogen sulphide, the filtrate should not leave more than a trifling residue on evaporation (limit of salts of the alkalies, alkaline earths, or of zinc). If 1 Gm.

of the salt be strongly ignited, in a porcelain crucible, it should leave a residue of lead oxide weighing not less than 0.85 Gm."—(*U. S. P.*).

Action and Medical Uses.—Carbonate of lead is never used internally. It has been applied externally as an astringent and desiccative to *irritated surfaces*, *burns*, *scalds*, etc. It may be dusted over the parts. Applied in the form of ointment, 1 part to 8 of simple cerate; or, as a lotion, 1 part to 3 parts or more of linseed oil. Being a very poisonous compound, it should not, as it occasionally is, be applied to excoriated surfaces. It may be used on *local congestion of the skin*. Its absorption is said to be attended with considerable danger.

PLUMBI IODIDUM (U. S. P.)—LEAD IODIDE.

FORMULA: PbI_2. MOLECULAR WEIGHT: 459.46.

SYNONYMS: *Plumbum iodatum*, *Ioduretum plumbicum*.

"Lead iodide should be kept in well-stoppered bottles, protected from light"—(*U. S. P.*).

Preparation.—Iodide of lead is prepared by dissolving 4 ounces (av.) of nitrate of lead in 1½ pints of hot, distilled water, and then mixing with it a solution of 4 ounces (av.) of iodide of potassium in ½ pint of water; allow the precipitate to subside, throwing it on a filter, washing it well with cold water, and drying on bibulous paper, by exposure to the atmosphere. The reaction is as follows: $Pb(NO_3)_2 + 2KI \quad 2KNO_3 + PbI_2$. This equation represents equal parts, by weight, of the two salts employed. An excess of potassium iodide would hold some lead iodide in solution. The yield is about 133 parts of lead iodide from each 100 parts of nitrate employed. Acetate of lead should not be substituted for the nitrate, as the resulting acetate of potassium is a solvent of iodide of lead. Lead iodide may also be obtained by the action of hydriodic acid upon lead, which dissolves quite readily in this fluid.

Description.—Iodide of lead is officially described as "a heavy, bright-yellow powder, without odor or taste. Permanent in the air. Soluble in about 2000 parts of water at 15° C. (59° F.), and in about 200 parts of boiling water, separating from the latter solution in brilliant, golden-yellow spangles or crystalline laminæ. Very slightly soluble in alcohol, but soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the acetates of the alkalies, of potassium iodide, and of sodium hyposulphite, and in a hot solution of ammonium chloride. When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide"—(*U. S. P.*). Boiling ether decomposes lead iodide, the iodine dissolving in it, while pale-yellow lead oxyiodide is left behind (Vogel). Exposure to moisture and light tends to the decomposition of salt with liberation of iodine.

Tests.—"If 1 Gm. of the salt be triturated with 2 Gm. of ammonium chloride and 2 Cc. of water, a nearly white mixture will result. If this be transferred to a test-tube, and heated in a water-bath for a few minutes, a clear and almost colorless solution should be formed (absence of chromate and of other insoluble foreign salts). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals will be produced, and, on adding water or diluted sulphuric acid to this mass, yellow lead iodide will be separated. If 1 Gm. of the salt be boiled for a few minutes with 20 Cc. of water, the mixture then cooled and filtered, the lead removed from the filtrate by hydrogen sulphide, and the new filtrate somewhat concentrated by evaporation, a portion of this liquid when mixed with a little sulphuric acid, and tinted with a drop of indigo T.S., should not become decolorized on heating (absence of nitrate). If another portion of the liquid be carefully neutralized with ammonia water, it should not become colored red by a drop of ferric chloride T.S. (absence of acetate). If the remainder of the filtrate be evaporated to dryness, it should leave no residue (absence of soluble foreign salts)"—(*U. S. P.*). As to the chemistry of the reaction between lead iodide and ammonium chloride, see H. C. C. Maisch, *Amer. Jour. Pharm.*, 1884, p. 91.

Action, Medical Uses, and Dosage.—Lead iodide has been used both internally and externally in the treatment of *scrofulous* and *syphilitic tumors*, *indolent* *ulcers*, *periostitis*, etc. It is now seldom used internally, except by a few, who believe it efficient in reducing *splenic hypertrophy of malarial origin*. The dose internally is from $\frac{1}{5}$ to $\frac{1}{2}$ grain, cautiously increased to 3 or 4 grains, in pill form, with confection of roses. Externally, an ointment may be used, composed of 1 part of iodide of lead and 8 parts of lard; to be applied to the *tumors* by friction. The application of the ointment is reported to have cured a *dermoid cyst of the orbit* (Foltz, in Webster's *Dynam. Therap.*). It is liable to produce the ordinary effects of the lead preparations, in consequence of which, as an external application, iodide of cadmium has been preferred.

PLUMBI NITRAS (U. S. P.)—LEAD NITRATE.

FORMULA: $Pb(NO_3)_2$. MOLECULAR WEIGHT: 330.18.

SYNONYMS: *Normal lead nitrate*, *Plumbum nitricum*, *Nitras plumbicus*, *Azotas plumbicus*, *Lead saltpetre*.

Preparation.—This salt may be obtained by dissolving litharge (PbO), in fine powder, 4½ ounces, in diluted nitric acid, 1 pint, by the aid of a sand-bath heat. Filter, and set the liquor aside to crystallize, concentrate the residual liquid to obtain more crystals. Dry the crystals, on bibulous paper, in a warm atmosphere, and preserve in a well-closed bottle.

Description and Tests.—"Colorless, transparent, octahedral crystals, when obtained by the spontaneous evaporation of cold solutions, or white, nearly opaque crystals, when formed by the cooling of hot solutions; without odor, and having a sweetish, astringent, afterward metallic taste. Permanent in the air. Soluble in 2 parts of water at 15° C. (59° F.), and in 0.75 part of boiling water; almost insoluble in alcohol. When strongly heated, the salt decrepitates, emits nitrous vapors, and finally leaves a residue of lead oxide. The aqueous solution has an acid reaction, and yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid"—(*U. S. P.*). Lead nitrate is almost insoluble in strong nitric acid. Diluted alcoholic liquids dissolve it. Triturated with sulphur in a hot mortar, a feeble detonation is produced, and the lead is reduced to the metallic state. Trituration of this salt with oxidizable substances should, therefore, be avoided. Iron occasions no precipitate when kept in solution of nitrate of lead. It forms a precipitate with fibrin and albumen, also with sulphates, chlorides, and sulphides.

This compound is largely employed in the arts, in making *chrome yellow* and *chrome red* (neutral and basic lead chromate), in preparing mordants for dyeing purposes, and in the preparation of iodide of lead for medicinal use. "A 10 per cent aqueous solution of the salt should give, with potassium ferrocyanide T.S., a pure white precipitate (absence of iron or copper). If hydrochloric acid be added to the aqueous solution until no further precipitate is produced, and the remainder of the lead be removed from the filtrate by hydrogen sulphide, a portion of the new filtrate should not be affected by the addition of a slight excess of ammonia water (absence of zinc or iron). If another portion be evaporated to dryness, it should leave no residue (absence of the salts of the alkalies, or of zinc)"—(*U. S. P.*). The presence of copper would also be indicated by the blue solution produced by the addition of excess of aqua ammoniæ to the aqueous solution of the salt, after the white precipitate of lead hydroxide ($Pb[OH]_2$) has subsided.

Action, Medical Uses, and Dosage.—Lead nitrate produces the general effects of the soluble salts of lead. It is rarely used internally, though recommended, in doses of $\frac{1}{4}$ to 1 grain, in pill or solution, many years since, in *asthma*, *epilepsy*, and to check *hemorrhages*. Externally, a solution has been employed as a topical application to *wounds*, *ulcers*, *sore nipples*, *cancerous tumors*, *chapped hands*, *cutaneous affections*, and *phagedenic ulcers;* also as an injection in *offensive discharges from the vagina*, *urethra*, etc. It destroys the odor of *gangrenous affections*. The powder is a good application to destroy the *fungoid ulcerations*, with saneous discharges, arising from *onychia*, and is accredited with the cure of *epithelioma*. When applied to *sore nipples*, these should always be washed with warm water each time before the child is put to the breast. From 10 grains to 1 drachm of the nitrate, dissolved in 1 fluid ounce of distilled water, according to the strength desired, has been used. Nitrate of lead is likewise used as a disinfectant. It completely destroys the unpleasant odor of animal and vegetable substances which are evolving sulphide of hydrogen, or sulphide of ammonium. *Ledoyen's disinfecting fluid* is a solution of 8 drachms of nitrate of lead in ½ pint of distilled water.

PLUMBI OXIDUM (U. S. P.)—LEAD OXIDE.

FORMULA: PbO. MOLECULAR WEIGHT: 222.36.

SYNONYMS: *Litharge, Semivitrified oxide of lead.*

"Lead oxide should be kept in well-closed vessels"—(*U. S. P.*).

Preparation.—When lead is heated in the air so as to be converted into vapor, it burns with a white light and forms oxide of lead, which, when thus obtained, is termed *flowers of lead*. If melted lead be exposed to a current of air, it is rapidly oxidized on its surface; if the latter be renewed by continual stirring, the whole mass becomes converted into gray *lead ash*, this being a mixture of an amorphous yellow oxide (PbO), termed *massicot*, and gray particles of unoxidized metallic lead. Upon further oxidation, the latter also becomes converted into the oxide. If oxidation of the lead is carried out at a temperature above the melting point of the resultant oxide, the latter, upon cooling, solidifies in the form of a brick-red mass, called *litharge*, consisting of crystalline scales. It is largely obtained in the process of cupellation, *i. e.*, the obtaining of silver from argentiferous galena. Pure lead oxide may be obtained by igniting pure lead carbonate or oxalate to constant weight in a porcelain crucible.

Description.—The official requirements for lead oxide are: "A heavy, yellowish or reddish-yellow powder, or minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Almost insoluble in water, to which it, however, imparts a faintly alkaline reaction; insoluble in alcohol; but soluble in acetic or diluted nitric acid, and in warm solutions of the fixed alkalies. When heated, the oxide assumes a brownish-red color, becoming yellow again on cooling. It fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead"—(*U. S. P.*). It is likewise reduced to metallic lead at a dull-red heat by hydrogen and by carbon monoxide gas. Litharge is commercially distinguished by its color, as *yellow* or *silver litharge*, and *red* or *gold litharge*. Oxide of lead is soluble in water to the extent of only 1 in about 7000 parts (A. M. Comey, *Dict. Inorg. Solubilities*, 1892). Glycerin and sugar solutions also slightly dissolve it, and acquire the odor of caramel and a brownish color upon being digested with it. Lead oxide is also soluble in warm solution of lead acetate, basic lead acetate being formed (see *Liquor Plumbi Subacetatis*). Lead oxide dissolves in caustic alkali with formation of a *plumbite*, *e.g.*, PbO_2K_2. The specific gravity of oxide of lead is about 9.5.

Tests.—Litharge is liable to contain, among other impurities, the following: Metallic lead, minium (red lead), iron, copper, oxide of antimony, silicic and carbonic acids, etc. Brick dust and yellow ochre (an earthy iron silicate) have been used as adulterants. A pure article conforms to the following pharmacopœial requirements: "Lead oxide should be soluble in diluted nitric acid with but little effervescence (limit of carbonate), and without the development of the odor of nitrous acid, leaving not more than a trifling residue (absence of silicate, barium sulphate, etc.). The solution, which should be colorless, yields with hydrogen sulphide T.S. a black precipitate, with potassium iodide T.S. a yellow one, and with diluted sulphuric acid a white precipitate, the latter being soluble in a strong solution of sodium hydrate. If from the solution in diluted nitric acid the lead be precipitated by sulphuric acid, the filtrate, after the addition of an excess of ammonia water, should not assume more than a slight bluish tint (limit of copper), nor yield more than traces of a reddish-yellow precipitate (limit of iron). If 5 Gm. of the oxide contained in a small flask be shaken with 5 Cc. of water, then 20 Cc. of acetic acid added, and the mixture boiled for a few minutes and filtered, the insoluble residue, when well washed and dried, should not weigh more than 0.075 Gm. (absence of more than 1.5 per cent of insoluble impurities). When strongly heated, in a porcelain crucible, the oxide should not lose more than 2 per cent of its weight (limit of carbonate and of moisture)"—(*U. S. P.*). Mr. F. W. Haussmann (*Amer. Jour. Pharm.*, 1897, p. 572) found nearly all of 25 commercial specimens examined tolerably pure.

Action and Medical Uses.—Oxide of lead is used in the preparation of lead plaster and other compounds of lead. It is sometimes employed, sprinkled on *ulcers*, etc., as an astringent and desiccative, though, as a rule, care should be taken not to use it where the skin is broken. It enters into the composition of several plasters and ointments. A mixture of sweet oil and litharge may be applied to *burns*, provided the skin is intact, and a superficial caustic, prepared of litharge and caustic potash, is sometimes employed to destroy *genital warts*. When boiled with cream of lime, it forms a plumbite of calcium, which has been employed as a hair-dye.

Lead and Its Compounds.—Plumbum, *Lead*. Symbol: Pb. Atomic Weight: 206.4. This metal has been known from earliest antiqnity, and is frequently mentioned in the Bible. It exists in nature occasionally as an oxide; and in the form of normal lead carbonate (*white lead ore*) it constitutes the mineral *cerussite*. Its most common ore is, however, sulphide of lead, termed *galena* (*galenite*, PbS), from which it is extracted by roasting the sulphide in a reverberatory furnace, which drives off the greater part of the sulphur in the form of sulphurous acid (sulphur dioxide gas); it is then smelted with coal and lime, the lead collected and cast into large ingots, called "*pigs.*" By another method, galena is roasted so as to convert part of it into lead oxide (PbO), another into lead sulphate ($PbSO_4$). By now elevating the heat the remaining lead sulphide acts on these oxygenated ores, whereby sulphurous acid escapes and metallic lead melts out. The reaction is as follows: $2Pb+PbSO=Pb_3+SO_2$, and $PbSO_4+PbS=Pb_2+2SO_2$. When silver is present in galena it is separated by cupellation (see *Argentum*). Lead is of a bluish-white color, and when newly scraped is very bright, but soon tarnishes (oxidizes) when exposed to the air. It is almost tasteless, and emits a peculiar odor on friction. It is one of the softest of the metals, is malleable, but not very ductile, and has the specific gravity 11.35. It enters into alloys with other metals. It fuses at 334° C. (633.2° F.) and at a very strong heat boils and evaporates. The vapors ignite when in contact with air, lead oxide being formed. The fused metal crystallizes upon slowly cooling. The beautiful phenomenon known as the "lead tree" is produced by the action of zinc upon a solution of acetate of lead (for directions see, *e. g.*, Merck's *Report*, 1898, p. 17). Lead drawn across paper produces a gray streak, thus, by prior use, leading up to the term "lead pencil," although this is now made from graphite (see *Carbon*), not from lead. This metal forms several oxides: (1) Lead suboxide (Pb_2O); (2) lead oxide (PbO) (see *Plumbi Oxidum*); (3) lead sesquioxide (Ph_2O_3); (4) red lead or minium (Pb_3O_4); (5) lead dioxide or peroxide (PbO_2) (see *below*). Dilute acids and concentrated nitric acid scarcely affect lead; it is dissolved, however, by diluted nitric acid with evolution of nitrous vapors. It is also, though slowly, dissolved by strong sulphuric, hydrochloric and hydriodic acids when warm. Organic acids, *e. g.*, acetic, tartaric and citric acids, in a strength of about 6 per cent, at temperatures between 25° and 35° C. (77° and 95° F.), will dissolve lead sufficiently to make the use of lead utensils for cooking purposes dangerous to health (see experiments by F. P. Hall, *Amer. Jour. Pharm.*, 1884, p. 115). The corrosive action of water on lead pipes seems to depend on the simultaneous presence of oxygen and carbon dioxide. Small quantities of chlorides, nitrates, ammonia and organic matter in water free from these gases do not attack lead. A trace of sodium, or calcium bicarbonate added to distilled water, completely prevents the solution of lead, a protecting crust being formed on the metal. Likewise, a hard white crust (basic lead sulphate) is formed in solution of calcium sulphate, if free from an excess of carbon dioxide. No lead is then dissolved (see M. Müller, *Amer. Jour. Pharm.*, 1888, p. 250). The presence of ammonium nitrate especially induces corrosion of lead (see M. M. P. Muir, in Roscoe and Schorlemmer's *Chemistry*, p. 296). These and other experiments tend to show that for hard water, not liable to contain much free carbonic acid gas, lead pipes are a safe hydrant material for potable waters. Lead in solution may be detected by the black precipitate of lead sulphide, yielded in acid or neutral solution, by hydrogen sulphide gas; by the white, insoluble precipitate of lead sulphate produced when diluted sulphuric acid or a soluble sulphate is added; the precipitate is somewhat soluble in hydrochloric or nitric acids, and readily soluble in ammonium tartrate or acetate; from this solution yellow potassium chromate precipitates lead chromate ($PbCrO_4$). Lead sulphate is colored black by ammonium sulphide or hydrogen sulphide, which is not the case with barium sulphate. Iodide of potassium, with soluble lead salts, produces a yellow precipitate (see *Plumbi Iodidum*). Also, see methods for the detection of lead in potable water in *Jahresb. der Pharm.*, 1896, pp. 801–803). Medicinally, the preparations of lead are rarely used internally, except as sedatives and astringents in *hemorrhages* and *dysenteries*. The acetate is more generally employed. Their internal use is very apt to produce constipation, loss of appetite, indigestion, griping pains, etc. They are more commonly used as topical applications in *superficial inflammations*, *contusions*, *fractures*, *excoriations* (rarely), etc., and some forms of *cutaneous disease*. (For action of lead and lead poisoning see, *Plumbi Acetas*.)

Plumbi Oxidum Rubrum (Pb_2O_4), *Red oxide of lead.*—Red oxide of lead, also known by names of *Red lead*, *Minium*, etc., is prepared on a large scale from the oxide of lead (*yellow massicot*), by absorption of oxygen, *i. e.*, by exposing it, with the access of air, to a temperature just short of what is required to cause fusion, stirring it occasionally, for a day and a half or upward, and allowing the product to cool slowly. A fine grade of red lead is procured by calcining the oxide of lead obtained from the carbonate, and is known as *Paris red*. It is not so dense as the common red lead, and has a vivid, orange-red color. It is also known as *Sandix* and *Orange-red*.

Red lead is a tasteless powder, of an intense scarlet-red color, often inclining to orange, and very heavy, its specific gravity being 9.096. It does not sensibly lose weight at 400° F., but when heated to redness, it gives out oxygen gas, and gradually runs into a dark-brown glass of considerable hardness. Red lead is used in the manufacture of flint glass, which is a *silicate of lead*, and which is an exceedingly brilliant and fusible glass. Red lead is insoluble in water. Nitrous acid dissolves it entirely, forming nitrite of lead. Diluted acetic acid, or nitric acid, also a solution of lead acetate, instantly render it dark-brown, resolving it into two oxides, one of them, the lead oxide (PbO), which is dissolved, and the other, the peroxide or dioxide (PbO_2), which remains. Addition of oxalic acid or sugar will effect complete solution by these acids or lead acetate. Any insoluble foreign matter that may be present—*e.g.*, brick dust, oxide of iron, etc.—is thus left as residue. Diluted sulphuric acid does not affect minium. The only pharmaceutical purposes for which this article is used, is in plasters, as, for instance, the *Black plaster* or *Black salve*, a useful and efficient agent in *cuts, wounds, ulcers*, some *cutaneous affections*, etc. It is used in the arts for fine painting, for coating metals, cementing joints in metals, and, as stated above, in preparing flint glass.

Plumbi Dioxidum (PbO_2), *Lead dioxide, Lead peroxide, Puce oxide of lead.*—This is a dark or flea-brown, insoluble powder. When red lead is treated with diluted nitric acid, lead peroxide is left undissolved. It is also obtained by adding to solution of a lead salt solution of chlorinated soda or chlorinated lime. When a lead salt is acted upon by the electric current, lead dioxide, or rather its hydrate, *plumbic acid* (PbO_3H_2), is deposited at the positive pole. Lead dioxide is slowly decomposed in diffused light; oxygen is evolved, and red lead remains. If the dioxide is heated, litharge and oxygen are produced. Lead dioxide, warmed with hydrochloric acid, produces chlorine, and is converted into plumbic chloride ($PbCl_2$). The dioxide is insoluble in nitric acid, but becomes soluble in this acid upon addition of oxalic acid or sugar and warming. Lead dioxide is soluble in alkalies, forming therewith crystallizable *plumbates, e.g., potassium plumbate* ($PbO_3K_2+2H_2O$). Lead dioxide is employed in analytical chemistry as an oxidizing agent, also in the manufacture of matches.

Plumbi Chloridum ($PbCl_2$), *Chloride of lead, Horn lead.*—Lead chloride may be formed when lead is dissolved in concentrated, boiling hydrochloric acid, and the solution diluted with water. It is readily obtained by dissolving 4 parts of acetate of lead in 12 parts of distilled water, and then adding pure hydrochloric acid, as long as a precipitate is formed (about 3 parts). Throw the precipitate on a filter, wash it a few times with distilled water, and dry it with a gentle heat; the yield will be about 2⅔ parts. It is a white powder, consisting of fine needles, odorless, of a sweetish, astringent taste, and permanent in the air. Heated, it fuses, forming, when cold, a horny, semi-transparent mass (*plumbum corneum*); at a higher temperature, it is completely volatile without decomposition. The salt requires about 140 parts of cold, and not quite 30 parts of boiling water for solution. The solution has an acid reaction. It is completely soluble in strong hydrochloric acid, from which solution it is precipitated by the addition of water. Alcohol does not dissolve the salt. If it contains copper, it acquires a greenish tint on becoming moist in the air; and aqua ammoniæ causes a deep-blue solution. There are several oxychlorides (basic chlorides) of lead, the minerals *matlockite* (Pb_2OCl_2) and *mendipite* ($Pb_3O_2Cl_2$). Commercial preparations are known as *Turner's yellow, Paris, Verona*, or *Cassel yellow* ($PbCl_2.7PbO$). They are obtained by heating together lead oxide, or carbonate, or red lead, with chloride of lead in varying proportions, or ammonium chloride, or even sodium chloride may replace lead chloride. *Pattinson's white lead* (1849) is also an oxychloride of lead ($Pb[OH].Cl$) obtained by precipitating solution of chloride of lead with lime-water in definite proportions (Roscoe and Schorlemmer's *Chemistry*, Vol. II, Part I, p. 287).

Chloride of lead is employed externally, as an astringent and caustic application. It combines with fibrin and albumen forming insoluble compounds, and, when absorbed into the system, it produces the usual effects of the compounds of lead. When applied to *cancerous ulcerations*, and in *painful neuralgic affections*, it is said to allay pain and restrain morbid action, and also to allay inflammation. It may be used in the form of lotion, 1 drachm of the chloride dissolved in a pint of water; or, as an ointment, 1 part of the chloride to 8 parts of lard. It is also a disinfectant.

Plumbi Tannas, *Tannate of lead.*—This salt may be obtained by adding a solution of tannic acid, drop by drop, to a solution of acetate of lead, until a precipitate is no longer formed. Collect the precipitate on a filter, wash and dry it. The salt thus formed is a bitannate of lead, an almost white powder, which subsequently changes to a brown color. It has been recommended as an application in *excoriations, sloughing bed sores, chronic ulcers of the feet, sore nipples*, etc. It may be dusted on the parts, applied in the form of liniment, composed of 3 ounces of the salt moistened with 2 fluid drachms of alcohol, and applied while moist; or used in ointment, 2 parts of the tannate to 5 parts of lard.

The *German Pharmacopœia* directs the extemporaneous preparation of Unguentum Plumbi Tannici (*Cataplasma ad Decubitum*, or *Plumbum Tannicum Pultiforme*): Tannin (1 part), lead subacetate solution (2 parts), lard (17 parts).

Lead Chromate ($PbCrO_4$), *Chrome yellow, Lemon yellow, Paris yellow, Leipsic yellow, Chromate of lead, Lemon chrome.*—A neutral lead compound formed when a solution of lead salt, usually the nitrate, is precipitated with potassium chromate or bichromate. It is a beautiful canary or lemon-yellow powder. If digested with a weak potash solution, or with solution of potassium chromate, about half its chromic acid is taken up and a basic lead chromate (PbO,

$PbCrO_4$) results. This is a bright-red compound, which is used alone or mixed with varying quantities of neutral lead chromate (chrome yellow), producing the pigment known as *Chrome red*, *Chrome orange*, and *American vermilion*. *Chrome green* is a mixture of Prussian blue and chrome yellow. Chrome yellow must not be used for coloring food materials, because of its poisonous nature. Fatalities have resulted from its use by bakers to give color to cakes and pastries (see *Amer. Jour. Pharm.*, 1888, p. 151).

Naples Yellow.—A yellow pigment consisting of *lead stibiate*. It may be obtained by fusing a mixture of tartar emetic (1 part), nitrate of lead (2 parts), and sodium chloride (4 parts), or by roasting a mixture of litharge and antimony trioxide.

Mineral Yellow, *Patent yellow*.—A pigment containing principally lead oxychloride (see *Plumbi Chloridum*).

PODOPHYLLUM (U. S. P.)—PODOPHYLLUM.

"The rhizome and rootlets of *Podophyllum peltatum*, Linné"—(*U. S. P.*).

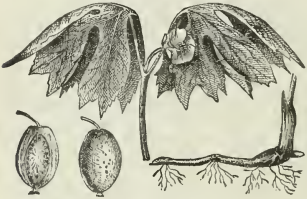
Nat. Ord.—Berberideæ.

Common Names: *May apple*, *Mandrake*, *Wild lemon*, *Raccoon-berry*. *Wild mandrake*, etc.

Illustrations: Bentley and Trimen. *Med. Plants*, 17; Johnson, *Med. Bot. of N. A.*, Plate I.

Botanical Source.—May apple is an indigenous, perennial herb, with a long, jointed, dark-brown rhizome or root, about half the size of the finger, spreading extensively in rich grounds in which it is introduced, and giving off fibers at the joints; internally, it is yellowish. The stem is simple, round, smooth, erect, dividing at top into 2 round petioles, from 3 to 6 inches long, each petiole supporting a leaf; is about a foot high, and invested at its base by the sheaths which covered it when in bud. The leaves are large, peltate-palmate, oftener cordate, in from 5 to 9 wedge-shaped lobes, each lobe 6 inches long from the insertion of the petiole, 2-lobed and dentate at the apex; smooth, yellowish-green on the upper surface, paler and slightly pubescent beneath. In barren stems which support but one leaf, the peltate character is the most perfect. The flower is solitary in the fork of the stem, on a round, nodding peduncle, 1 to 2 inches long, white, large, about 2 inches in diameter, and somewhat fragrant. The calyx consists of 3 oval, obtuse, concave, caducous sepals, which cohere in the bud by their scarious margins. The corolla is composed of from 6 to 9 white, obovate, obtuse, smooth, concave petals, curiously netted with slight, transparent veins. Stamens from 9 to 20, shorter than the petals, curving upward, with yellow, oblong anthers twice as long as the filaments, not opening by perfect uplifted valves. Ovary oval, compressed, and obscurely angular. Stigma subsessile, convex, its surface rendered irregular by numerous folds and convolutions. The fruit is fleshy, ovoid-oblong, 1-celled, 1 or 2 inches in length, of a lemon color, with brownish spots when ripe, and crowned with the large, persistent stigma; the flavor of the mucilaginous pulp is somewhat similar to that of a strawberry, and incloses 12 seeds in pulpy arils (L.—W.—G.). (For paper on microscopical structure of the rhizome of podophyllum, by Prof. E. S. Bastin, see *Amer. Jour. Pharm.*, 1894, p. 417.)

Fig. 201.



Podophyllum peltatum; with rhizome and fruit.

History.—Intimately associated with the progress of Eclecticism is the drug, *podophyllum* and its resin, *podophyllin*. The introduction of the latter to the medical profession by Prof. John King, who first prepared it and indicated its therapy at a time when improved and reliable pharmaceuticals were most urgently demanded, and when the introduction of indigenous remedies that could be administered in small doses, freed from extraneous and inert materials, with certain and definite results, was a necessity, marks an epoch in the history of Eclectic medicine. Podophyllum was one of the earliest favorites of our school of practice, and before the introduction of *podophyllin*, was much more extensively employed than at present. By many, in the treatment of certain disorders, its use is still preferred to that of its resin.

This plant, which grows abundantly from Canada to Florida, and throughout the middle and western states, is one of the most attractive of our medicinal plants. It is said to be scarce in the New England states. In the middle states, it is familarly known as Mandrake, and farther west as the May apple. It has also borne the names of Wild mandrake and Mayflower, and, on account of its fruit, Raccoon-berry, Indian apple, and Wild lemon. The name *podophyllum* is derived from two Greek terms—*poys*, foot; *phyllon*, leaf—either on account of its resemblance to the webbed foot of some aquatic bird, or in allusion to its long, firm stalk, which bears the leaves. Making their appearance in the early spring, the conical shoots may be seen piercing the ground in large patches, and, in a short time, expanding into wide-spread, umbrella-like leaves, which almost completely hide the ground beneath them. The plant is found growing in rich, moist soil, along the border of woodlands and on the banks of streams, as well as in low meadows and marshy situations. The rhizomes occur in great abundance, from 1 to 2 inches underneath the surface of the soil. May apple is hardy and will thrive in fence corners of cultivated fields, often resisting the advance of agricultural improvements, when other common fence-weeds have been exterminated. It is not, as is the case with many other valuable medicinal plants, likely to be very soon eradicated.

The creeping rhizome, which often attains a length of 1 to 6 feet, and is about one-fifth of an inch in thickness, sends up a stem to the height of about 1 foot. This stem then forks at the top and each petiole so created bears a single peltate leaf of palmate variety, having 6 or 7 lobes. Flowerless plants have only 1 leaf, generally centrally peltate, with from 7 to 9 lobes. In the fork of the stem the flower appears—a single, fragrant, beautiful, waxy-white blossom, about 2 inches wide. The flowers are eagerly sought for by the children of cities, and on account of their beauty and delightful fragrance, find ready purchasers among the lovers of "wild beauties." The bloom, which appears in May, hence the names May flower and May apple, is followed in August and September by a small, yellowish-green, lemon-like, succulent berry, about the size of a plum. Its flavor is agreeable to many persons, and its taste is sub-acid and sweetish. It may be eaten with impunity, though all other parts of the plant produce pronounced physiological effects. It is, however, slightly laxative, and possesses diuretic properties. The young shoots, it is said, were used by the aborigines for suicidal purposes. Like most drugs of the order Berberideæ, podophyllum has a bitter, acrid taste. Its therapeutic activity is due to a resinous principle of a compound nature, known as *podophyllin* (see *Resina Podophylli*). The root was well known to the Indians as an active cathartic; the proper time for collecting it is in the latter part of October, or early part of November, soon after the ripening of the fruit. The medicinal properties of the leaves are not satisfactorily determined, though by some deemed poisonous (see *Chemical Composition*).

Podophyllum has been extensively used in domestic practice, oftentimes to the detriment of the patient. The Cherokee Indians, according to Rafinesque, employed the "fresh juice of the root for deafness, putting a few drops of the juice in the ear." Settlers learned from the Wyandottes, that roasting the root deprived it somewhat of its drastic qualities. The famous "Indian Doctor" Hough recommended the "powdered root as an escharotic to cleanse foul and ill-conditioned ulcers, and to dispose them to heal and to promote the exfoliation or removal of carious or rotten bones." The powder was sprinkled on the parts once, and again, if necessary, in from 2 to 5 days. In domestic veterinary (?) practice, which often amounts to barbarity, the drug was employed to cure poll-evil in horses, the root being plunged into the sore and allowed to remain several days. Both Bigelow and Eberle praised the purgative qualities of this drug.

Description.—The *U. S. P.* thus describes the root: "Of horizontal growth, consisting of joints about 5 Cm. (2 inches) long, flattish, cylindrical, about 5 Mm. (¼ inch) thick, but somewhat enlarged at the end, which has a circular scar on the upper side, a tuft of about ten, nearly simple, fragile roots, on the lower side, and is sometimes branched latterly; smooth or somewhat wrinkled, orange-brown, internally white and mealy, with a circle of small wood-bundles; pith large; nearly inodorous; taste sweetish, somewhat bitter and acrid"—(*U. S. P.*). It is readily reduced to a grayish powder, having somewhat the odor of ipecacuanha, and breaks with a short fracture. Its active principles are readily taken up by alcohol, or ether; water takes up only a portion of its activity.

Chemical Composition.—The active principle of the root is a resinous body, soluble in alcohol and practically insoluble in cold water. It was discovered by Dr. John King, in 1844 (see historical notes, by J. U. Lloyd, *Amer. Jour. Pharm.*, 1890, p. 242), and named by him "*Resin of Podophyllum.*" It was afterward known as *podophyllin* (also see *Resina Podophylli*). Mr. John R. Lewis (*ibid.*, 1847, p. 165) found, in addition, gum, starch, albumen, gallic acid, fixed oil, etc. Prof. F. B. Power (*Proc. Amer. Pharm. Assoc.*, 1877, p. 420) disproved the statement of Prof. F. F. Mayer (1863) that berberine and saponine occur in the root. The resin of podophyllum was thoroughly investigated by Podwissotzky (see Prof. F. B. Power's abstract in *Amer. Jour. Pharm.*, 1882, pp. 102–115). According to this authority, the resin may be differentiated by ether into the insoluble, inert brown resin *podophyllic acid*, which is also insoluble in petroleum ether and water, soluble in alcohol and chloroform; and the soluble active principle, *podophyllotoxin*. This substance is a white, resinous, amorphous powder, very bitter, of slightly acid reaction, soluble in diluted alcohol and hot water, completely soluble in chloroform, also soluble in ether when free from the aforenamed podophyllic acid. It is insoluble in petroleum ether; hence pure podophyllotoxin may be obtained by treating a chloroformic extract of the rhizome with ether, and precipitating the ethereal solution with petroleum benzin, which keeps fatty matters dissolved. Both chloroform and ether must be alcohol-free, as far as possible, otherwise the podophyllotoxin will be contaminated with the yellow crystallizable coloring matter, *podophyllo-quercetin*, which is soluble in alcohol, ether and alkaline solutions, sparingly soluble in chloroform, insoluble in water. It produces a dark, greenish-brown coloration, with ferric chloride. R. Kürsten (*Archiv der Pharm.*, 1891, p. 220) obtained 0.2 per cent of *podophyllotoxin* in well-defined crystals melting at 93° to 95° C. (199.4° to 203° F.) and having the composition, $C_{23}H_{24}O_9+2H_2O$. *Podophyllotoxin*, according to Podwissotzky, is not a uniform body, but is a mixture of inert, resinous *picropodophyllic acid* and the cathartic, crystallizable, bitter principle *picropodophyllin*, the latter being held in solution by the former and falling out when the solvent is neutralized by an alkali. From the filtrate the acid is precipitated upon the addition of mineral acid. *Picropodophyllin*, the active principle, crystallizes in silky needles, and is a neutral body. It shares in general the solubilities of podophyllotoxin except that it is insoluble in water. For this reason Podwissotzky prefers the more soluble *podophyllotoxin* as a therapeutic agent. *Picropodophyllin* is soluble in 90 to 95 per cent alcohol, but hardly soluble in alcohol of 50 to 80 per cent. It also dissolves readily in glacial acetic acid. By warming its alcoholic solution or evaporating this solution with excess of ammonia, it is converted into an inert, amorphous, acid substance.

Podophyllotoxin was found by Dunstan and Henry (see *Amer. Jour. Pharm.*, 1898, p. 246) to be the active principle of both the Indian and American podophyllum, but these authors consider it to be a well-defined body of the composition $C_{15}H_{14}O_6$, which differs from the formula arrived at by Kürsten (1891). It is strongly lævo-rotatory, and acts as a powerful purgative and intestinal irritant. When heated with alkalies it takes water and is converted into the salt of an unstable gelatinous acid (*podophyllic acid*, $C_{15}H_{26}O_7$). This readily loses water again, being converted into the crystalline *picropodophyllin* of Podwissotzky, which, as Kürsten (*loc. cit.*) has ascertained, is an isomer of podophyllotoxin. Warming with aqueous alkalies again converts it into podophyllic acid. Picropodophyllin is claimed by Dunstan and Henry to be therapeutically inert. An uncrystallizable resin, *podophylloresin* was also isolated and found to be purgative.

The *leaves* of Podophyllum peltatum were analyzed by T. J. Husband (*Amer. Jour. Pharm.*, 1860, p. 200), who states that they are devoid of cathartic properties, and, when dried, are probably non-poisonous. B. F. Carter (*ibid.*, 1886, p. 449) collected leaves soon after flowering and found them to contain 6 per cent of a greenish-black bitter resin, all of which was soluble in alkali and alcohol, 90 per cent being soluble in ether, a hard resin remaining; 86 per cent in chloroform, 40 per cent in petroleum benzin, etc., and a considerable quantity being soluble in boiling water. This resin seems to exert a milder action than that from the rhizome.

Action, Medical Uses, and Dosage.—Physiologically, podophyllum acts as a certain, but slow cathartic. Small and repeated doses short of catharsis may induce ptyalism; on this account both podophyllum and podophyllin have been called "vegetable mercury" and "vegetable calomel." Under the influence of a cathartic dose, the intestinal and hepatic secretions are augmented and after a considerable time copious alvine evacuations result. Considerable pain and griping may attend its action, which, however, may be modified by such agents as leptandra, hyoscyamus and belladonna. Common salt increases its purgative power. Unlike other cathartics, its effects are permanent and leave the bowels in an improved condition. If the dose be too large, violent emeto-catharsis may result. Although the cholagogue value of this drug was asserted by our practitioners for years, it took extensive physiological investigations, conducted by Rutherford and Vignal, to convince our regular friends that it really possessed such a property. The green root internally administered, acts as an irritant poison, causing hypercatharsis, hyperemesis, gripings, and other unpleasant symptoms; even the recently dried root, in doses of from 30 to 60 grains, is a drastic cathartic and emetic; but the violence of its action is materially modified by age, or roasting. Either the green or the dried root continuously applied to the cutaneous structure, occasions irritation, followed by suppuration. Irritation of the mucous membrane is the result of contact with the powder, and workers in this drug and its resin are liable to conjunctival inflammation. Overdoses of podophyllum have produced death, and the drug, when contraindicated, may give rise to prolonged gastro-intestinal irritation and even inflammation. As a cathartic, very little tormina is produced by it when compared with the completeness of its purgative action. It acts somewhat like jalap, though more slowly. To render its hydragogue, it should be administered with potassium bitartrate on which account it has been found serviceable in *dropsical affections*.

Podophyllum may be used in nearly all cases in which podophyllin is useful, though there are some conditions where the former gives better results than the latter. These conditions we will briefly notice. It is conceded that as an alterative it is infinitely more decided in its action than the resin. It exerts a powerful influence upon the whole glandular system. Associated with proper hygienic measures and the indicated tonics and other alterative drugs, it will give good results in *constitutional syphilis*, *rheumatism* and *scrofula*. The dose should be small, not sufficient to produce any marked intestinal activity. In stomach troubles, podophyllum is superior to podophyllin. It acts as a gentle stimulant tonic, improves the appetite, and is particularly valuable in *atonic dyspepsia*, *gastric* and *intestinal catarrh*, and all *atonic forms of indigestion*, when the patient complains of dizziness, loss of appetite and heavy headache. There is indisposition to exertion, the movements being heavy and sluggish, the tongue is dirty and flabby, and the superficial veins, abdomen, and tissues in general, are characterized by *fullness*. Its action on the hepatic viscus renders it particularly serviceable where gastric disturbances are due to hepatic torpor. In stomach troubles, hydrastis, iris, lobelia, agrimonia and ipecac may also be indicated and associated with this drug. Podophyllum, iris, chionanthus and chelidonium are excellent agents for *chronic hepatitis*. By its slow and thorough action, yet permanent in its effects in restoring and maintaining the normal hepatic and intestinal secretions, podophyllum is one of the very best agents to overcome *habitual constipation*, and more especially if it be due to portal engorgement. The small dose should be given and continued until the evacuations become regular and normal. Formerly this drug was much employed in *bilious*, *remittent* and *intermittent fevers*. Cathartic and sometimes emeto-cathartic doses were employed with the result of producing so profound an impression on the hepatic function and on the portal circle and general glandular system that, it is asserted, the disease was often aborted, or at least rendered milder and of short duration. It is never so employed at the present day. As an emeto-cathartic it should be given in warm ginger tea. When a cathartic is needed, which, however, is not often, the specific podophyllum may be combined with compound syrup of rhubarb and potassa (neutralizing cordial), or to render it milder, lobelia, ipecac, leptandra, hyoscyamus or belladonna may be administered with it. As a cathartic in *dropsy* it has done good service, and should, in this disease, be given with cream of tartar. It has likewise been found very beneficial in *dysmenorrhœa*, *amenorrhœa*, *incontinence of urine*, *worms*, and some *affections of the bladder*. Further uses of this drug will be given when considering podophyllin. The usual medicinal dose of specific podophyllum ranges from 1 to 10 drops. Dose of the powdered root, as a cathartic, from 10 to 30 grains; of the tincture, from 10 to 60 drops; as a sialagogue and alterative, from 1 to 5 grains of the powder, or from 1 to 10 drops of the tincture.

Specific Indications and Uses.—Podophyllum is specifically indicated by *fullness* of tissues, and particularly by fullness of superficial veins; oppressed full pulse; dirty yellowish coating of tongue and dizziness. It is contraindicated by pinched features and tissues, contracted skin and tongue.

Related Species.—*Podophyllum Emodi*, Wallich. Dymock and Hooper report (*Pharm. Jour. Trans.*, 1889, Vol. XIX, p. 585) that this plant of the Kashmere valleys and other Himalayan points contains in its rhizome 12 per cent of a cathartic resin. It is altogether probable that the constituents of the latter are identical with those of our podophyllin. One-half grain of it purges. It was thought that the Indian drug might supplant *P. peltatum*, owing to its supposed superiority in active principle. John C. Umney, however, points out *Amer. Jour. Pharm.*, 1893, p. 24) that while *P. Emodi* yields 11.4 per cent and *P. peltatum* only 5.9 per cent of resin, the latter contains nearly twice as much of the active *podophyllotoxin* as the resin obtained from the Indian drug. The inferior medicinal action of the latter agrees with this result.

Podophyllum montanum of Rafinesque, having a slender, deeply furrowed stem; the leaves with sharp, bifid segments, palmate, not peltate, with narrow sinuses, and many unequal teeth; the petals 6 to 7, oblong, obtuse; stamens 7 to 9, and berry yellowish, oblong, is possessed of similar medicinal properties.

POLEMONIUM.—AMERICAN GREEK VALERIAN.

The root of *Polemonium reptans*, Linné.

Nat. Ord.—Polemoniaceæ.

COMMON NAMES: *American Greek valerian*, and sometimes called *Blue bells* and *Jacob's ladder*.

Botanical Source.—This indigenous perennial plant has a creeping root and a smooth, erect, weak, fleshy, diffusely-branched stem from 12 to 20 inches high. The leaves are alternate and pinnately divided; leaflets 7 to 11, ovate-lanceolate, acute, subopposite, smooth, entire, sessile, an inch long and half as wide; upper leaflets sometimes confluent. The flowers are numerous, terminal, rather large, nodding, on short petioles, blue, and nearly bractless. Calyx campanulate, 5-cleft; segments lanceolate-acute, persistent, much shorter than the tube of the corolla. Corolla rotate-campanulate, limb 5-lobed, erect, tube short, closed at the base by 5 staminiferous valves. The stamens are 5, equally inserted at the summit of the corolla tube; the filaments slender, declined, and hairy-appendaged at the base; the anthers introrse. The capsules are 3-celled and 3-valved; the cells from 2 to 3-seeded (W.—G.).

History.—This is a handsome plant, growing in woods, damp grounds, and along shady river banks, from New York to Wisconsin, bearing blue flowers in May. The root is the part used, and yields its virtues to water; it has not been analyzed.

Action, Medical Uses, and Dosage.—Alterative, diaphoretic, and astringent. A warm infusion of the root will, it is said, produce copious perspiration, and has been found serviceable in *pleurisy*, *febrile* and *inflammatory diseases*. The tincture, made of whiskey, in doses of from 1 to 2 fluid ounces, 2 or 3 times a day, has been found valuable in *scrofulous diseases*, and other chronic diseases where an alterative is indicated. The infusion is recommended in the *bites of venomous snakes and insects*, and in *bowel complaints* requiring the use of astringents. Reported to have cured *consumption*, but these cases were probably of severe *bronchorrhœa*. Useful in *bronchial and laryngeal affections*. The plant deserves investigation.

Related Species.—*Polemonium cœruleum*, or *Greek valerian*, is a native of England. It has been found in swamps in New York, Vermont, and New Jersey. It is larger and more numerously-flowered than the above, and is often found cultivated in gardens. Stems about 2 feet high, stout, hollow, several from the same root, each dividing at top into a corymbose panicle. Leaves mostly radical, on long, grooved petioles, pinnately 11 to 17 foliate; segments sessile, ovate-lanceolate, subopposite, acuminate, oblique, odd one lanceolate. Flowers blue, terminal, suberect. This plant, probably, possesses medicinal virtues similar to the one above (W.)

POLYGONUM.—WATER PEPPER.

The fresh herb of *Polygonum Hydropiper*, Linné.

Nat. Ord.—Polygonaceæ.

COMMON NAMES: *Smart weed, Water pepper.*

ILLUSTRATION: Britton and Brown, *Illustrated Flora of Northern United States, Canada, and the British Possessions*, Fig. 1333.

Botanical Source.—This is an annual, glabrous plant, with a simple or branched, erect stem, of a red, reddish, or sometimes greenish color, from 8 inches to 2 feet high. The lanceolate, or oblong-lanceolate, leaves are from 1 to 4 inches long, acute or acuminate at apex, ciliate, undulate, or slightly crisped, punctate, and very acrid. The ocreæ are cylindric, fringed with short bristles, or occasionally slightly pubescent, generally swollen at the base on account of the development of flowers within. The flowers are borne in a panicled raceme, which is narrow, drooping, interrupted, and from 1 to 3 inches long. The green calyx is usually 4-parted (3 to 5), and conspicuously punctate; stamens 4, occasionally 6; style 2 or 3-parted, short; fruit a lenticular achene, triangled, broad-oblong or ovoid, slightly gibbous, dull and granular (Britton and Brown).

History.—Polygonum Hydropiper is a well-known, intensely acrid plant, found growing in nearly all parts of the United States, in ditches, low grounds, among rubbish, and about brooks and water-courses, flowering in July, August, and September. That growing in our section of the country being naturalized from Europe; Britton and Brown state that it is perhaps indigenous in the far northwest. There are many species of Polygonum (at least 38), some of which, although possessing similar virtues, differ materially in medical potency. The whole plant (*P. Hydropiper*) is medicinal, and has a biting, pungent, acrid taste. and imparts its virtues to alcohol or water. Age renders it inert, and heat impairs its medicinal qualities. It should be collected and made into a tincture while fresh.

Chemical Composition.—According to analysis by H. Trimble and H. J. Schuchard (*Amer. Jour. Pharm.*, 1885, p. 21), the tops and leaves contain 3.46 per cent of tannin, 7.4 per cent of ash, and resin, wax, gum, sugar, etc. The active (pungent) principle was found to disappear upon heating; it was contained in the alcoholic extract of the drug, after successive treatment with petroleum spirit and ether. Dr. C. J. Rademaker, however, asserted (*ibid.*, 1871, p. 490; and 1886, pp. 279 and 373) that the active principle consists of crystallizable *polygonic acid*, which, when pure, differs in its reactions from those for tannic or gallic acids. It is soluble in water, less soluble in ether, and insoluble in petroleum spirit. The heat of the water-bath does not destroy any of its properties.

Action, Medical Uses, and Dosage.—Water pepper is stimulant, diuretic, emmenagogue, antiseptic, diaphoretic, and vesicant. Dr. Eberle found it very efficient in the dose of a teaspoonful of the saturated tincture, repeated 4 or 5 times a day, or from 2 to 5 grains of the aqueous extract, in *amenorrhœa;* probably, an alcoholic extract would be found more active. He states that the use of it caused an increase of the heat of the body with a kind of formication, with bearing down and sense of fullness in the pelvic region. The infusion, in cold water, has been found serviceable in *gravel*, *colds*, and *coughs*, and in *milk-sickness*, and, mixed with wheat-bran, in *bowel complaints*. In *Asiatic cholera*, the patients, wrapped in a sheet moistened with a hot decoction, are said to have been much benefited, and to have recovered. In combination with sulphate of iron and gum myrrh, it is said to have cured *epilepsy*—probably dependent on some uterine derangement. Externally used as fomentation (simmered in water and vinegar) in *gangrene*. The infusion, or a fomentation of the leaves, has been beneficially applied in *chronic ulcers* and *hemorrhoidal tumors*, also as a wash in *chronic erysipelas* and *inflammations*, and as a fomentation in *tympanites* and *flatulent colic*. The fresh leaves, bruised with the leaves of May-weed, and moistened with the oil of turpentine, and applied to the skin, will speedily vesicate. The ashes of the plant combined with the ashes of the garden thyme (*Thymus vulgaris*) are, it is said, used by many empiries, injected, in solution, into the bladder as a solvent for *gravel* and *stone;* hazardous and doubtful treatment. The infusion, in cold water, forms an excellent local application in the *sore mouth of nursing women*, and in *mercurial ptyalism*. The decoction or infusion, in hot water, is not so active as when prepared in cold or warm water. Dose, of the infusion, from 2 to 4 fluid ounces; of the saturated tincture, from 1 to 4 fluid drachms, 3 or 4 times a day: specific polygonum, 1 to 60 drops.

Related Species.—*Polygonum Persicaria*, Linné, called *Smart weed*, *Lady's thumb*, or *Spotted knotwood*, possesses similar but inferior medicinal properties, and may be distinguished from the above by the deeper-green or purplish color of the whole plant, a brownish, heart-shaped spot near the center of the leaf, and its rose-colored flowers, in short, dense, terminal spikes. It has a feebly astringent, saline taste, and, at one time, was considered antiseptic.

Polygonum arifolium, Linné, *Sickle grass*, *Halbert-leaved tear-thumb*, or *Hastate knot grass*.—This plant grows in low and wet grounds throughout the United States, flowering from June to September. An infusion, in cold water, is a powerful diuretic, useful in *uric acid* and *phosphatic gravel*, *strangury*, *gonorrhœa*, and all *urinary affections*; it must be drank freely. Also of service in *catarrh of the bladder*, and in muscular debility of this organ.

Fagopyrum esculentum, Mœnch (*Polygonum Fagopyrum*, Linné; *Fagopyrum Fagopyrum* [L.], Karsten), or *Common buckwheat*, may be used as follows, to recall the flow of milk in the breasts of nurses, where it has disappeared for several days. Stir into any amount of buckwheat flour, a sufficient quantity of buttermilk to form a poultice; warm it, but be careful not to boil or make it hot. Apply it thus warm, over the whole breast, and renew it every 4 or 6 hours. Sometimes it requires to be thus used for 3 or 4 days before its effect will be produced; usually, however, 24 hours will be sufficient. The seeds, deprived of their husks, contain about 70 per cent of starch and 13 per cent of gluten (Zenneck).

Polygonum erectum, *Erect knot grass*, *Bird knot grass*, *Goose grass*, *Bird weed*.—This is a perennial herb, common to the western and middle states and British America. It is found in abundance about country dooryards, roadsides, waste places, damp soils, etc., blossoming from June to October. This plant, in infusion, has been found highly efficient in the treatment of *diarrhœa*, and especially in *summer complaint of children*.

Polygonum amphibium, Linné, *Water persicaria*.—A variable plant growing in wet situations. It may be readily cultivated, and has been recommended for tanning purposes, as the dried stems yield over 17 and the root above 21 per cent of tannin.

Polygonum punctatum, Elliott (*Polygonum acre*, H. B. K., not of Lamarck , *Dotted* or *Water smart weed*.—A smooth annual or perennial, acrid species, found in swamps and other wet places throughout the most of North America. Has been used for similar purposes as smart weed.

Polygonum hydropiperoides, Michaux (*Polygonum mite*, Persoon), is *Mild water pepper*, found in wet soil and swamps throughout the United States, and flowering from June to September. It has decided stimulating properties. Eberle pronounces it a most active and certain emmenagogue (see *Amer. Jour. Pharm.*, 1883, p. 195).

Bistorta, *Bistort*.—The rhizome of *Polygonum Bistorta*, Linné, or *Snakeweed*. This plant is found in swampy places throughout the northern countries of the globe, being present in the United States northward from Colorado. The rhizome, which is recognized in some European pharmacopœias, is blackish-brown, peculiarly distorted, S-shaped, sub-annulate, reddish internally, and breaks with an almost smooth fracture. When broken it exhibits a large pithy center, surrounded by a single circle of many small, woody bundles, enveloped by a thicker bark. It is odorless, but powerfully astringent in taste, as it contains tannin to the extent of 21 per cent (Bowman, 1869). P. Krebs found tannin (15 per cent), resin (0.30 per cent), wax and fat, starch, dextrin, dextrose, mucilage, gallic acid, etc. (*Amer. Jour. Pharm.*, 1891. p. 476). It is employed where a vegetable astringent such as geranium, is indicated.

POLYMNIA.—UVEDALIA.

The root of *Polymnia Uvedalia*, Linné.

Nat. Ord.—Compositæ.

Common Names: *Bearsfoot*, *Leaf-cup*.

Botanical Source.—This is a large, perennial plant, from 3 to 6 feet in height, and found in ravines, on the edges of woods, etc., in the central states, from Illinois to Florida. The stems are erect, stout, branched, and covered with a rough, hoary pubescence. The leaves are large, thin, opposite, deltoid in outline, and abruptly contracted at the base to short dilated leaf-stalks. They are 3-lobed, with acute, sinuate-angled lobes, bright green on both surfaces, and studded below with numerous rough points. The flower heads appear late in summer, and are disposed in loose, corymbose clusters. The involucre is double; the outer consisting of about 5 ovate, obtuse, leaf-like scales, which are ciliate on the margin; and the inner, of the smaller thin bracts of the pistillate flowers. The flower heads are radiate, and the receptacle chaffy. The ray flowers are about 10, in a single row, each being nearly 1 inch in length; they are oblong, of a bright-yellow color, and equally 3-toothed at the apex. The ray flowers are pistillate, and alone fertile, as the disk-florets, although perfect, do not produce fruit. The fruit is an obovoid, black achenium, slightly flattened, and ribbed lengthwise.

History, Description, and Chemical Composition. Polymnia Uvedalia was introduced as a medicine, about 1870, by Dr. J. W. Pruitt, the root being the part employed. This, when dry, is from 6 to 12 inches in length, and from ¼ inch to ½ inch in diameter at the base of the plant. It extends downward into the ground, and running parallel with it several small roots springing from the base of the plant are often observed. The shape is somewhat like that of dandelion, but longer, not so tapering, and more flattened from the effect of drying. Toward he lower end it often divides into several fleshy rootlets, and secondary roots frequently spring from the main root. The outer surface is of a leather-color, and very much wrinkled longitudinally. Internally, it is white, or of a greenish cast, and soft, with the exception of a few woody fibers near the bark. It contains a large amount of resin, and exhales an unpleasant, animal-like odor when broken. Alcohol extracts from the root all its medicinal principles, the extractive matter mainly consisting of glucose in considerable proportion; a form of tannin which precipitates ferrous sulphate, black; an odorous principle, soluble in water and alcohol; and a mixture of two resins, which is present in greater amount than any other of its characteristic constituents; this resinous compound is heavier than water, of a brownish-yellow color, soft and sticky at ordinary temperatures, and possesses the odor of the root. It dissolves completely in chloroform, ether, and alcohol, imperfectly in benzin, which separates it into: (1) A dark-brown, hard resin, of an acrid taste, which remains undissolved; this is insoluble in carbon disulphide, but freely dissolves in chloroform, ether, and alcohol. (2) A light straw-colored, balsam-like, resinous body, heavier than water, rather thicker than Canada balsam, which it otherwise very nearly resembles; it readily dissolves in ether, alcohol, benzin, chloroform, and carbon disulphide, has the odor of polymnia root, and likewise an acrid taste. Undoubtedly, polymnia depends upon these resinous bodies for its medicinal virtues. The aqueous solution of the evaporated tincture yields a precipitate with phospho-molybdate of ammonium, but not with other alkaloidal reagents, and after precipitation of the tannin with either ferrous sulphate or gelatin, the filtrates give negative results with the phospho-molybdate of ammonium. Polymnia Uvedalia is used in medicine in form of tincture and ointment.

OINTMENT OF POLYMNIA.—Take of fresh polymnia root 8 troy ounces; lard or mutton suet 16 troy ounces; cut the root into small pieces, and, having added the lard, heat the mixture until water ceases to evaporate, and then strain while hot. The ointment is of a light-greenish color, and possesses the disagreeable odor of the root.

Action, Medical Uses, and Dosage.—Polymnia was introduced to the medical profession, in 1870, by Dr. J. W. Pruitt, although it had several years previously been highly lauded, under the name of *Bear's foot*, as a remedy in *rheumatism*. Dr. Pruitt recommended it in the form of ointment, as a local application in *mammary* and other *glandular tumors* or *abscesses*, in *splenic enlargement*, and, indeed, in all *painful swellings* and *local inflammations*. Subsequently, he employed a tincture of it internally, in connection with its external use, and found its efficacy to be thereby augmented. The tincture alone, was likewise found efficient in the treatment of *chronic intermittent fever*, *ozœna*, *scrofulous ophthalmia*, and similar affections. According to Dr. Pruitt, it may be considered a specific in *splenic enlargement* from malarial influence. Prof. J. M. Scudder, M. D., has used it with good effect in *chronic gastritis*, *chronic hepatic enlargement*, *hypertrophy of the cervix uteri*, *chronic metritis with hypertrophy*, *uterine subinvolution*, and *engorgement of the lower lobes of the lungs;* according to him the indications for its use are full, flabby, sallow tissues, impaired circulation, atonic impairment of function, and glandular enlargement. The efficacy of this drug in the effections named has been corroborated by many other practitioners who have tested it. It stands to-day at the head of spleen remedies, influencing not only the splenic circulation and reducing hypertrophies of that organ, but has more or less control over the other distributive branches of the cœliac axis. It is a remedy for *congestive* or *engorged states of the spleen* and other *ductless glands*. When *dyspepsia* depends upon a sluggish circulation in the gastric and hepatic arteries, and is attended with full, heavy, and burning sensations in the parts supplied by those branches, we have in uvedalia an efficient remedy. It even exerts a beneficial action in some cases of that intractable malady, *leucocythemia*, though it more often fails. The remedy to be of benefit in all glandular difficulties should be used for several weeks. For its influence in *splenic engorgement* (*ague cake*) the ointment should be applied warm over the spleen, while specific polymnia uvedalia should be given in from 5 to 10-drop doses every 3 or 4 hours. It is a remedy for imperfect blood-elaboration, with tumid, sodden abdomen, and for the removal of low inflammatory deposits. With Prof. Scudder the following was a favorite hair tonic: ℞ Specific uvedalia, ℥ii; bay rum, ℥vi. Mix. Rub thoroughly into the scalp once or twice a day. *White swelling* is stated to have been cured by the use of polymnia, both internally and as a local application, but we know of no authentic cases. The ointment appears to be a stimulating discutient. The dose of the tincture is from 10 to 60 minims, 2 or 3 times a day; of specific polymnia uvedalia from 2 to 20 drops.

Specific Indications and Uses.—Full, sodden, inelastic, flabby tissues; splenic and hepatic enlargements, fullness, weight and burning in the region of liver, stomach and spleen; congestive states and impaired functions of the parts supplied by the cœliac axis; impaired blood-making with tumid abdomen; low inflammatory deposits.

Related Species.—*Polymnia canadensis*, Linné, is a smaller plant than the preceding, and is found in similar localities. The stems are clammy, pubescent, and have long internodes. The lower leaves are pinnately-parted, the upper ovate, five-lobed, abrupt at the base, sub-regularly sinuate-toothed, and on slender, horizontal leaf-stalks. The flower-heads are smaller than those of the *P. Uvedalia*, and have acute involucral scales. The rays are of a pale, sulphur-yellow color, and are not longer than the involucre; they are three-toothed at the apex, the middle tooth being longer than the others. The two plants we have just described, are the only other indigenous species of Polymnia, and, together with a few South American species, constitute the genus.

POLYPODIUM.—COMMON POLYPODY.

The rhizome and tops of *Polypodium vulgare*, Linné.

Nat. Ord.—Filices.

Common Names: *Common polypody*, *Rock polypod*, *Fern-root*, *Rock-brake*, *Brake-root*, *Female fern*, etc.

Botanical Source.—Polypodium has a perennial, creeping, irregular, brown rhizome, with membranous scales extending to the caudex or base of the stipe. The fronds are 6 to 12 inches high, distiched, green, smooth, deeply pinnatifid, being divided into alternate segments, nearly to the mid-vein, which are linear-oblong, obtuse, crenulate, the upper ones gradually smaller, parallel, a little curved, about a quarter of an inch wide. The stipe is naked and smooth. The fruit is borne on the lower surface of the frond, in large, distinct, golden dots, sori, or capsules, without any indusium, round, in a double row, and becoming finally brownish (W.—Eaton).

History and Description.—Polypody is common on shady rocks, in woods, and mountains throughout the United States. The root and tops are used in medicine. The root is of some length, 2 to 4 lines in diameter, frequently crooked, with chaffy scales, which are readily removed, and having many delicate, knobby rootlets. It has a peculiar, rather unpleasant odor, and a saccharo-mucilaginous, somewhat sickening taste. Water extracts its properties. Its constituents, according to Hager (*Handbuch der Pharm. Praxis*), are fatty oil (about 8 per cent), resin, some tannin, mannit, dextrose, dextrin, starch, malic acid, and a sweet substance resembling glycyrrhizin.

Action, Medical Uses, and Dosage.—This plant is pectoral, demulcent, purgative, and anthelmintic. A decoction or syrup has been found very valuable in *pulmonary* and *hepatic diseases*, and a strong decoction is recommended as a purgative, and for the expulsion of *tænia* and other *worms*. Dose of the powdered plant, from 1 to 4 drachms; of the decoction or syrup, from 1 to 4 fluid ounces, 3 or 4 times a day.

Related Species.—*Polypodium adiantiforme*, a West Indian plant, is regarded by the natives as a pronounced antisyphilitic, and medical testimony seems to confirm its reputation in that direction. The Central American fern, *Polypodium friderichsthalianum*, is said to possess like virtues, and to be a remedy against the bite of the Mexican insect, *toboba* (*New Idea*, 1885; from Dragendorff's *Heilpflanzen*).

POLYTRICHUM.—HAIR-CAP MOSS.

The whole plant of *Polytrichum juniperum*.

Nat. Ord.—*Polytrichiaceæ*.

COMMON NAMES AND SYNONYMS: *Hair-cap moss*, *Bear's bed*, *Ground moss*, *Robin's rye*, *Herba adianthi aurei*.

Botanical Source.—This plant is indigenous and perennial, with a simple or divided stem, more generally simple, slender, of a reddish color, from 4 to 7 inches in height. The leaves are linear-lanceolate, awn-pointed, entire, flattish, appressed, somewhat spreading, with the margins inflexed. The capsule is oblong, 4-sided, and the angles acute; the calyptra densely hairy and white; the lid or operculum short-beaked from a convex base; and the apophysis depressed and discoidal. The peristome is single, of 64 teeth, adherent by their summits to the membranous-dilated apex of the columella. Inflorescence diœcious; sterile flowers terminal and cup-shaped (W.—G.).

History.—This is an evergreen plant, found on high, dry places, along the margins of dry woods, and exposed places, mostly on poor, sandy soil, and is of a darker-green color than the mosses in general. The leaves are closely set on the stem about one-half its length, above which the stem is naked, terminating in a capsule, covered with a white, hairy hood or calyptre. The whole plant is medicinal. It yields its properties to boiling water by infusion. It has not been analyzed, but is deserving of chemical investigation. The similar species, *P. formosum*, according to Reinsch, contains fatty oil, a crystalline substance, resins, a trace of tannin, etc. (Wittstein, *Handwörterbuch d. Pharmakogn. d. Pflanzenreichs*, Breslau, 1882).

Action, Medical Uses, and Dosage.—This is a very valuable and important, but somewhat neglected, remedial agent. It is a powerful diuretic in strong infusion. In doses of 2 fluid ounces of the infusion, every ½ hour, it has been known to remove from a dropsical patient from 20 to 40 pounds of water in the space of 24 hours. It possesses but very little smell or taste, and never produces any nausea or disagreeable sensation in the stomach. It may be used in connection with hydragogue cathartics, or even alone, in *dropsies*, with the most decided advantage; and is a very useful article in *uric acid* and *phosphatic gravel*, and other *urinary obstructions*, and especially *urinal suppression from cold*. Prof. Jones considered it worthy to be ranked among the first, if not at the head, of the class of diuretics. Notwithstanding the reputation of this plant, as a diuretic, I have known it frequently to fail in producing the slightest increase of the urinary discharge (J. King). A strong infusion of the fresh plant should be used when possible to obtain it; give specific polytrichum, 5 to 60 drops, every 1 to 3 hours.

POPULUS.—AMERICAN POPLAR.

The bark of the *Populus tremuloides*, Michaux.

Nat. Ord.—Salicaceæ.

COMMON NAMES: *American poplar*, *American aspen*, *Quaking aspen*, *White poplar*.

Botanical Source and History.—This tree attains the height of 20 to 50 feet, with a diameter of 8 to 12 inches. It is covered with a smooth, greenish-white bark, except on the trunks of very old trees. The leaves are orbicular-cordate, abruptly acuminate, dentate-serrate, smooth on both sides, pubescent at the margins, dark-green, 3-nerved, 2 to 2½ inches long, and 1½ as wide, on long, slender, and laterally compressed petioles, which accounts for the continual agitation of the leaves by the slightest breeze. The aments are plumed with silken hairs, and are about 2 inches long and pendulous, appearing in April, long before the leaves. The scales are cut into 3 or 4 deep, linear divisions, and fringed with long hairs (W.—G.). This tree is common in lower Canada and in the northern and middle states. The bark is the medicinal part, and should be collected in the spring, just as the sap begins to rise. Its virtues are imparted to alcohol, water, or acetic acid. There are several varieties of this tree, all of which possess similar properties, as the *Populus grandidentata*, Michaux; *P. candicans*, Aiton, etc.

Chemical Composition.—The glucosids, *populin* and *salicin*, are constituents common to the barks of nearly all species of Populus, as *P. tremuloides*, *P. tremula*, *P. alba* (for the latter, see analysis by M. F. Schaak, *Amer. Jour. Pharm.*, 1892, p. 226). The leaf-buds of *P. nigra*, *P. dilatata* (*P. pyramidalis*), and *P. balsamifera*, were found by Piccard (*Jahresb. der Pharm.*, 1865, p. 24; and 1873, p. 39) to contain a yellow coloring matter, *chrysin* (*acetyl-benzoyl-phloroglucin* [$C_{15}H_{20}O_8$]), *tectochrysin* ($C_{16}H_{12}O_4$), *salicin* and *populin*, resin and essential oil, which he believes (*ibid.*, 1875. p. 70) to contain *dipentene* ($C_{10}H_{16}$). The buds of the American aspen (*Populus tremuloides*), according to R. Glenk (*Amer. Jour. Pharm.*, 1889, p. 240), contain an acid resin of a hop-like odor, soluble in alcohol, caustic potash, glacial acetic acid, acetic ether, and amyl alcohol; slightly soluble in chloroform, ether, carbon disulphide, oil of turpentine, and benzol; insoluble in water. For description of the bitter glucosid, *salicin* ($C_{13}H_{18}O_7$, or $C_6H_4O.[C_6H_{11}O_5].CH_2OH$), see *Salicinum*.

Populin (*benzoyl-salicin*, $C_{20}H_{22}O_8.2H_2O$, or $C_{13}H_{17}.[C_7H_5O]O_7.2H_2O$) was discovered, in 1831, by Braconnot, and occurs, together with salicin, in the bark and the leaves of several species of Populus, The leaves of *P. tremula* contain more populin than the bark, and may be employed to advantage in its isolation. To prepare both, an aqueous decoction of the bark is precipitated by subacetate of lead, the filtrate freed from lead by carefully adding sulphuric acid, filtered again, treated with charcoal, and evaporated to a smaller bulk. The salicin, upon cooling, crystallizes out; the filtrate, upon the addition of potassium carbonate, yields a precipitate of populin, which is obtained pure by recrystallization from water. Populin is a very light substance, snow-white, with a sweetish taste not unlike that of liquorice. It requires about 2000 times its weight of cold and about 70 times its weight of boiling water to dissolve it. Alcohol, when boiling, dissolves it, depositing the populin on cooling in the form of a crystalline magma. It is soluble in acetic, nitric and phosphoric acids, from which solutions it is precipitated by alkalies. It is hardly soluble in ether. Boiling with diluted mineral acids decomposes it into dextrose, benzoic acid and *saligenin* ($C_6H_4OH.CH_2OH$), which is further converted into resinous *saliretin*. Concentrated sulphuric acid gives with populin a purple-red solution. When heated on platinum foil it burns with a strong flame, emitting an aromatic odor. By oxidation with a mixture of sulphuric acid and potassium bichromate, the odor of salicylic aldehyde ($C_6H_4.OH.CHO$), the principal constituent of the oil of *Spiræa Ulmaria*, is evolved.

Action, Medical Uses, and Dosage.—Poplar bark is tonic and febrifuge, and has been used in *intermittent fever* with advantage. An infusion of it is reputed a valuable remedy in *emaciation* and *debility*, after protracted fevers and reproductive disorders of the nervous and hysterical, *lumbricoid worms*, *impaired digestion*, *chronic diarrhœa*, *intermittent fevers*, etc. As a diuretic, it has been beneficially used in *urinary affections*, *gonorrhœa*, *gleet*, etc. Both populus and populin have a decided affinity for the genito-urinal tract. It is thought to aid the recuperative powers of the kidney when undergoing granular degeneration. In tenesmic vesical irritation and in tenesmus after urination it is decidedly effective. Minute doses—fraction of a drop—are most beneficial here. It is suggested by Prof. Webster for trial in stubborn *uterine congestion* and *prostatic hypertrophies*. The Large aspen, *P. grandidentata*, is said to be the most active and bitter. Dose of the powdered bark, 1 drachm, 2 or 3 times a day; of a saturated tincture of the fresh bark, from a fraction of a drop to 30 drops; of populin, 1 x trituration, 1 grain every 2 or 4 hours.

Specific Indications and Uses.—Marked debility with impairment of digestion; tenesmic vesical irritation; tenesmus *after* micturition.

Related Species.—Several species of Populus besides American poplar have been employed more or less in medicine, and probably most of them depend upon both salicin and populin for their virtues. Among those employed are *Populus nigra*, or *European black poplar*; *Populus tremula*, *European aspen*; *Populus alba*, *silver-leaf poplar*, etc. See the above-named species for chemical composition.)

Populus balsamifera, Linné, *Balsam poplar*.—This tree, also called *Tacamahac*, or *Tacamahac poplar*, attains the height of 50 to 70 feet, with a trunk about 18 inches in diameter. Branches smooth, round, deep-brown; buds acuminate, smooth, covered in the spring with an abundance of fragrant, viscid, balsamic juice. Leaves ovate, gradually tapering and pointed, smooth on both sides, with fine glandular serratures, deep-green above, whitish and reticulate-veined beneath, on long petioles; sometimes 2 glands at the apex of the petiole. Scales dilated, slightly hairy (L.—W.). This tree is found in Canada, the northern parts of the United States, and in Siberia. In this country it is in blossom in April. The leaf-buds are the medicinal parts, and should be collected in the spring; they are covered with a fragrant resinous matter, which may be separated in boiling water, and upon which their virtues depend. They have an agreeable, incense-like odor, and an unpleasant, bitterish taste. The balsamic juice is collected in Canada in shells, and sent to Europe, under the name of *tacamahaca*. Alcohol or spirits is the proper solvent. (For chemical composition, see Piccard, *loc cit.*.)

Populus candicans, Aiton.—The buds of the *Populus candicans*, Aiton, or *Balm of Gilead*, possess virtues similar to the above. The tree is of less stature than the *P. balsamifera*, the leaves are broader, and heart-shaped, with a distinct sinus at the base; the petioles are hairy and the branches terete (G.) Poplar buds are reputed stimulant, tonic, diuretic, and antiscorbutic. A tincture has been beneficially employed in *affections of the chest*, *stomach*, and *kidneys*, and in *rheumatism* and *scurvy*. With lard or oil they form a useful external application in *bruises*, *swellings*, *wounds*, some *cutaneous diseases*, *rheumatic pains*, etc. Added to ointments they prevent, in a great measure, their liability to become rancid, but in this respect are not equal to paraffin, which will wholly prevent rancidity in cerates and ointments prepared with it, as discovered by Prof. E. S. Wayne. The bark is said to be tonic and cathartic, and to have proved of service in *gout* and *rheumatism*. Dose of a tincture of the buds, from 1 to 4 fluid drachms; this is excellent for *colds* and *pain in the chest*. An extract of the bark made with diluted acid, in the dose of from 5 to 15 grains, 3 times a day, is a useful tonic in *debility*, *intermittent fever*, *rheumatism*, etc.

POTASSA (U. S. P.)—POTASSA.

FORMULA: KOH. MOLECULAR WEIGHT: 55.99.

SYNONYMS: *Caustic potash*, *Potassium hydrate*, *Potassium hydroxide*, *Potassa caustica*, *Potassii hydras*, *Potassæ hydras*, *Oxydum potassicum*, *Kali hydricum fusum*, *Lapis causticus chirurgorum*, *Caustic potassa*, *Kali purum*, *Vegetable alkali*, *Fixed alkali*.

"Potassa should be kept in well-stoppered bottles made of hard glass"—(*U. S. P.*).

Preparation.—Caustic potash is prepared by the interaction of potassium carbonate or bicarbonate and calcium hydroxide, the solution of caustic potash thus obtained (see *Liquor Potassæ*) being rapidly evaporated in a clean silver vessel until there remains a clear fluid of oily consistence, a drop of which, when removed on a warm glass rod, solidifies on cooling. The liquid is then poured into molds of proper shape and allowed to cool, care being taken to exclude the carbon dioxide of the air as much as possible. Evaporation should not be conducted in an iron vessel, because the concentrated liquid dissolves notable quantities of iron. This product is now hardly ever prepared by the pharmacist.

Description.—The officially recognized caustic potash is described as occurring in "dry, white, translucent pencils, or fused masses, hard and brittle, showing a crystalline fracture; odorless, or having a faint odor of lye, and a very acrid and caustic taste. Great caution is necessary in tasting and handling it, as it rapidly destroys organic tissues. Exposed to the air, it rapidly absorbs carbon dioxide and moisture, and deliquesces. Soluble, at 15° C. (59° F), in about 0.5 part of water, and in 2 parts of alcohol; very soluble in boiling water, and in boiling alcohol; slightly soluble in ether. When heated to about 530° C. (986° F.), potassa melts to a clear, oily liquid, and at a bright red heat it is volatilized unchanged. When introduced into a non-luminous flame, it imparts to it a violet color. A solution of potassa, even when greatly diluted, gives an intensely alkaline reaction with litmus paper"—(*U. S. P.*). It dissolves in water and combines with acids with evolution of much heat, and forms a number of crystallizable salts.

Impurities and Tests.—Commercial caustic potash is liable to contain as impurities: potassium chloride, potassium carbonate, alumina, lime, iron, sulphates, admixed common salt, etc. Prof. W. Dunstan (*Amer. Jour. Pharm.*, 1886, p. 173) found five specimens of commercial caustic potash in sticks to contain from 0.34 to 1 per cent of potassium nitrite, on account of which it liberated iodine from acidulated potassium iodide solution. The specimens contained from 78 to 79 per cent of total alkali. All the impurities mentioned are insoluble in alcohol, hence purified caustic potash ("potash by alcohol") may be obtained by dissolving the alkali in alcohol, decanting, evaporating the clear fluid to dryness and melting the dried mass. Mr. Carl E. Smith (*Amer. Jour. Pharm.*, 1898, p. 392) calls attention to a probably fraudulent substitution of commercial caustic potash by caustic soda. Both the present *U. S. P.* and that of 1880 demand caustic potash to contain 90 per cent of potassium hydroxide, the remainder to consist of carbonate, water and other impurities, the quantities of which are limited by the pharmacopœial tests subjoined. This standard, however, has never been attained on a manufacturing scale. E. Goebel (*Proc. Amer. Pharm. Assoc.*, 1885, p. 472) reports eight specimens of potassa in sticks to contain 75.5 to 79.5 per cent total and 63.3 to 72.3 caustic alkali. Prof. E. L. Patch (*ibid.*, p. 474) found in seven specimens from 57 to 86 per cent total and from 52 to 81 per cent caustic alkali One specimen of German origin, "purified by alcohol," gave 70 per cent of total alkali and 8.57 per cent of carbonate, with traces of sulphates, chlorides, silica and iron. As recently as 1892 Prof. J. U. Lloyd found the total alkali (calculated as hydroxide) in 30 casks of crude commercial American potash to vary from 16 to 84 per cent. By insisting in his purchases on a minimum amount of 70 per cent total alkali, Prof. Lloyd secured a marked improvement of the quality (see *Proc. Amer. Pharm. Assoc.*, 1892, p. 192). Mr. Carl E. Smith reports (*loc. cit.*) on a sample of the best crude potassa in sticks of the New York market, finding it to be not much below the pharmacopœial standard. It contained 86.4 per cent of potassium hydroxide (KOH), 4.85 per cent of potassium carbonate (K_2CO_3), 1.8 per cent of sodium hydroxide (NaOH), 1.4 per cent of potassium chloride (KCl), 0.1 per cent of potassium silicate ($K_2Si_4O_9$), and 5.55 per cent of water. The *U. S. P.* directs for caustic potash the following tests: "The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of organic matter). After acidulation with hydrochloric acid it yields bright yellow precipitates with platinic chloride T.S., and with sodium cobaltic nitrite T.S."—(*U. S. P.*). The precipitate with platinic chloride ($PtCl_4$) consists of octahedra having the composition $PtCl_6K_2$; they are insoluble in alcohol and nearly insoluble in water. The corresponding sodium compound is soluble in water and alcohol. The precipitate with sodium cobaltic nitrate has the composition $Co_2(NO_2)_{12}K_6$, combined with varying quantities of water. According to Mr. Carl E. Smith (*loc. cit.*), a dilution of 0.3 to 0.2 per cent of potassium hydroxide (KOH) is the approximate limit of the sensitiveness of this test. "A concentrated aqueous solution (1 in 10), when dropped into tartaric acid T.S., produces a white, crystalline precipitate, which redissolves when the potassa is added in excess"—(*U. S. P.*). This precipitate ($C_4H_4O_6KH$) is the well-known *cream of tartar* or acid potassium tartrate (see *Potassii Bitartras*). The added excess of potassa produces the soluble neutral tartrate ($C_4H_4O_6K_2$). "If 1 Gm. of potassa be dissolved in 10 Cc. of water, and slightly supersaturated with acetic acid, 10 Cc. of the solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, lead, etc.), nor by the subsequent addition of ammonia water in slight excess (absence of iron, aluminum, etc.). The remainder of the acidulated solution should not be rendered turbid by ammonium oxalate T.S. (absence of calcium). If a solution of 1.5 Gm. of potassa in 10 Cc. of water be slightly supersaturated with nitric acid, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the addition of more silver nitrate V.S. (limit of chloride). If to a solution of 3.5 Gm. of potassa in 10 Cc. of water, strongly supersaturated with hydrochloric acid, 0.1 Cc. of barium chloride T.S. be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate). If 1 Gm. of potassa be dissolved in 2 Cc. of water, and added to 10 Cc. of alcohol, not more than a slight, colorless precipitate should occur within 10 minutes (limit of silicate). After boiling this alcoholic solution with 5 Cc. of calcium hydrate T.S. and filtering, not the slightest effervescence should take place on adding the filtrate to an excess of diluted hydrochloric acid (limit of carbonate)"—(*U. S. P.*). Mr. Carl E. Smith (*loc. cit.*) justly points out that this test for silicate and carbonate is insufficient, because the precipitate produced by alcohol may largely consist of carbonate which may thus be mistaken for silicate and besides impair the test for carbonate. The author suggests that silica be tested for separately, by repeatedly evaporating on the water-bath an aqueous solution of the sample with excess of hydrochloric acid to perfect dryness, whereby silicic acid becomes insoluble and may be filtered, washed out, dried and weighed. The carbonate and total alkali may be determined in one operation by titrating a dilute solution of the sample (1 Gm. in 250 Cc. of water) with normal sulphuric or hydrochloric acids, employing phenolphtalein as indicator, adding the acid until the purple color disappears, then adding methyl orange and titrating until the color changes to red. The acid consumed with methyl orange as indicator is equivalent to half the quantity of carbonate present, while the quantity of acid consumed with phenolphtalein as indicator, minus that consumed with methyl orange, is equivalent to the caustic alkali present. This procedure is based on the fact that potassium carbonate (K_2CO_3) becomes neutral toward phenolphtalein at the point where it is converted into bicarbonate ($KHCO_3$), *i. e.*, when half of its potassium is converted into neutral sulphate or chloride. The bicarbonate, however, is still alkaline toward methyl orange; if this be added to the colorless liquid, the change to red takes place at the point where the remaining half, *i. e.*, all of the bicarbonate, is converted into the neutral salt. "If 0.2 Gm. of potassa be dissolved in 2 Cc. of water, and carefully mixed with 4 Cc. of pure sulphuric acid and 2 drops of indigo T.S., the blue color should not be discharged (limit of nitrate). To test for *soda*, dissolve 0.56 Gm. of potassa in 5 Cc. of water, add a few drops of phenolphtalein T.S., and then, from a burette, enough tartaric acid T.S. (3 Gm. in 20 Cc.) to accurately neutralize the solution. Next add another volume of the tartaric acid T.S., equal to that first used, and then enough absolute alcohol to completely precipitate the potassium bitartrate formed. Separate the precipitate by filtration and wash it with a little alcohol. The filtrate should not require more than 0.2 Cc. of normal potassium hydrate V.S. to restore the red color (absence of more than 1.5 per cent of soda). To neutralize 0.56 Gm. of potassa should require not less than 9 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 10 per cent of pure potassium hydrate), phenolphtalein being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Caustic potash is powerfully corrosive; when applied to soft animal textures, it first attracts their water, and then rapidly disorganizes them, producing with the fatty constituents, a soapy solution, after which extensive inflammation ensues around the part, previous to the separation of a deep slough. It has no action as a poison, except what depends directly on the local injury occasioned; no direct influence being exerted through the medium of absorption. The symptoms of poisoning from its ingestion are: Intense burning pain from mouth to stomach and bowels; acrid, caustic taste; vomiting of alkaline and bloody material, diarrhœa, delirium, convulsions, and cold, clammy surface. If the dose is large and not vomited, death quickly takes place; if death is not immediate, it may result later from laryngeal and gastro-intestinal inflammation and ulceration, or, after many months, death may be due to starvation, due to stricture of the œsophagus, produced by the healing of the lesions caused by the poison in passing through that tube. Acids, as vinegar, lemon-juice, etc., and the fixed oils, are antidotes to its injurious action, producing with it harmless salts of potassium or soapy solutions. The long-continued use of liquor potassæ may occasion a cachexia closely resembling scurvy.

It is administered internally only when in solution, as an antacid, antilithic, and diuretic (see *Liquor Potassæ*). Externally, it is used in its solid state for making caustic issues, opening *abscesses*, and destroying *tumors*, and is applied for the cure of *ingrown nails*, *paronychia*, *sinuses*, *callous ulcerations*, and to destroy *unhealthy granulations*, but from its extreme deliquescence, it is very apt to spread and act on parts not desired. To obviate this, the integuments around the parts to be acted on should be protected by 2 or 3 layers of cloth, spread with adhesive plaster, and perforated with a hole in the center, of the necessary size. Then a rod of potassa, slightly moistened at the end, is to be gently rubbed over that portion of the skin embraced in the perforation of the plaster. It must be rubbed until the skin becomes discolored, when an elm or bread-and-milk poultice must be applied. In a few days the eschar will be detached. After the slough separates, the retraction of the surrounding skin always makes the surface of the issue much larger than the circle originally cauterized, the extent of which must be regulated accordingly (C.). In applying the caustic, wrap it with paper. Occasionally this caustic is employed in the destruction of *tumors*, *cancers*, etc., and on the surface of unhealthy or malignant *ulcers*. A very unscientific application of a solution of this caustic, applied to the spine, has been recommended in the treatment of *tetanus*.

Potassium and Its Compounds.—Kalium, or Potassium. Symbol: K. Atomic Weight: 39.03. Metallic potassium was discovered, in 1807, by Sir Humphrey Davy, who obtained it by passing a powerful galvanic current through a small piece of caustic potash, the metal being liberated at the negative pole in the form of quicksilver-like globules. Subsequently, Gay-Lussac and Thénard obtained it by passing melted potassium hydroxide over iron-turnings, heated to whiteness in an iron tube. Potassium is now usually prepared by reduction of potassium carbonate with carbon at a white heat, according to the equation: $K_2CO_3+C_2=K_2+3CO$. An intimate mixture of both substances is first obtained by igniting cream of tartar in a covered crucible, which leaves a mixture, well known as *black flux*. This, while still warm, is mixed with a considerable proportion of charcoal, in coarse powder and small fragments recently ignited, and allowed to cool in a covered crucible. The whole is then introduced into an iron retort, which is then subjected to a white heat. The potassium distilling over is conducted into pure naphtha cooled by ice. In recent years, potassium is also obtained by the electrolytic decomposition of potassium salts, *e. g.*, the chloride.

Potassium is a solid, soft, bluish-white metal, of bright metallic luster when freshly cut, but becoming instantly tarnished and oxidized when exposed to the air, from which it absorbs oxygen. It should, therefore, be kept in purified naphtha or petroleum benzin, liquids which contain no oxygen. At the temperature of 10° C. (50° F.), it is soft and malleable like wax; at 58° C. (136.4° F.), it becomes perfectly fluid; and at 0° C. (32° F.), it is hard and brittle, exhibiting a crystalline structure. It is lighter than water, its specific gravity being 0.865, and is an excellent conductor of heat and electricity. Thrown upon the surface of water, it decomposes that liquid with rapidity, with evolution of an intense heat, the following reaction taking place: $K_2+H_2O=K_2O+H_2$; $K_2O+H_2O=2KOH$. The hydrogen gas evolved, carrying with it small particles of the metal, takes fire, and communicating the combustion to the potassium, the whole burns with a kind of explosion, emitting a purplish, violet, or rose-tinted light. Heated in oxygen gas it burns with a brilliant white light. Metals and metalloids, whose attraction for oxygen are too strong to be overcome by the usual means, are isolated by potassium. Thus, it decomposes the oxides or chlorides of aluminum, glucinum, yttrium, thorium, and zirconium, and the boracic and silicic oxides, in each case the element resulting. Potassium is found chiefly in the ashes of land plants, as oxide of potassium united to carbonic acid, and is also contained as chloride in the ashes of sea plants. Many rocks, minerals, and soils contain it; indeed, it is necessary to the growth of plants. It occurs as silicate in granite, feldspar (*orthoklase*), mica (*muscovite*), as chloride, near Stassfurt, Germany, in *sylvine* (KCl), *carnallite* ($MgCl_2+KCl+6H_2O$), and in the waters of the sea. In the form of nitrate it constitutes *saltpeter*. Potassium forms chiefly two compounds with oxygen—a dry, grayish-white *monoxide* (K_2O), and an orange-yellow *tetroxide* (K_2O_4), which is formed, *e. g.*, by combustion of metallic potassium in absolutely dry oxygen. Its monoxide unites with acids, forming salts of potassium, some of which are used in medicine. Potassium also combines with hydrogen, sulphur, and mercury, forming an amalgam with the latter. Potassium salts are generally colorless, unless the characteristic acid has a peculiar color. Nearly all potassium salts are readily soluble in water; the sulphate is less soluble; very little soluble are the bitartrate, the platinic hydrochloride (see *Potassa*), the silicofluoride ($SiFl_6K_2$, the picrate ($C_6H_2[NO_2]_3OK$), and the perchlorate ($KClO_4$). Among the compounds of potassium not mentioned in our main articles are the following:

Potassium Silicate ($K_2Si_4O_9$), or "*Soluble glass*," is prepared after the method of making the corresponding sodium salt, by fusing together potassium carbonate (10 parts , fine sand (15 parts), and charcoal (1 part). *Gout* and *rheumatism* have been treated with it, but without results to commend it. Its local surgical uses are those of sodium silicate which see .

Potassium Cobaltic Nitrite ($CO_2[NO_2]_{12}K_6+2H_2O$).—Upon adding to a solution of a cobaltous salt, previously acidulated with acetic acid, an excess of solution of potassium nitrate, nitrogen monoxide is liberated, and, after a time, a crystalline, yellow, double salt (cobaltic-potassium nitrite) is precipitated. The reaction takes place as follows: $Co_2Cl_4+4NO_2K+4NO_2H+6NO_2K=Co_2(NO_2)_6.6NO_2K+4ClK+2H_2O+2NO$. Solutions of acid hardly dissolve it. It has the therapeutic properties of the nitrites, and has been employed in *asthma*, *valvular heart diseases*, and in *renal disorders*, in which arterial tension is high, and dyspnœa marked (Roosevelt), being preferred to other nitrites on account of its limited solubility and more permanent character (Gibbs). Dose, ¼ to ½ grain every 2 hours.

Potassii Osmas ($K_2OsO_4.2H_2O$), *Potassium osmate.*—To a solution of osmium tetroxide in caustic potash add alcohol; the resulting red liquid, when concentrated, deposits potassium osmate as a crystalline powder. If slowly evaporated, dark-garnet crystals form. This salt is permanent in a dry, but deliquescent in a moist atmosphere, at the same time undergoing decomposition. Solutions in water are likewise unstable. It has an astringent and sweetish taste, and is used as a substitute for osmic acid. It is employed hypodermatically chiefly in the form of a 1 per cent solution, or it may be given by mouth in doses of $\frac{1}{35}$ to $\frac{1}{45}$ grain

Osmic Acid, or *Perosmic acid* ($OsO_4=254.14$) *Acidum osmicum*, or *perosmicum* , is the accepted name for *Osmium tetroxide*, from which potassium osmate may be prepared as stated above. Osmic acid proper (OsO_4H_2) is not known in the free state. The tetroxide is intensely poisonons. It is prepared by heating metallic and finely divided osmium to a temperature of near 400° C. (752° F.), in a current of air, or in the presence of oxygen. The metal then burns and the tetroxide, being vaporized, is collected in a cooled receiver. Thus sublimed, it forms exceedingly hygroscopic, yellow needles, which form neutral, colorless, acrid solutions with water. Osmium tetroxide boils at about the same temperature as water, and sublimes at somewhat above the ordinary temperature, giving off intensely poisonous vapors, which attack the lungs and the eyes most violently. Organic compounds are oxidized by it, and iodides are decomposed with liberation of iodine. Its solution in alcohol or ether deposits, upon standing for 1 day, all the osmium in the form of the tetrahydroxide (OsO_4H_4). Sulphurous acid produces with the aqueous solution a series of colors, changing from yellow to red, green, and blue. A freshly-made, 1 per cent solution is used hypodermatically (3 to 5 drops), or $\frac{1}{65}$ grain, internally, for the cure of *goitre, sarcoma, ancroid tumors, scrofulous ulcers, epilepsy*, and *lumbago*. It is a dangerous drug. It is used in microscopy for staining and hardening purposes.

Potassii Cantharidas ($C_{10}H_{12}K_2O_5.2H_2O$), *Potassium cantharidate.*—Cantharidin (1 part), potassium hydroxide (2 parts), water (100 parts). Heat together on a water-bath. By concentrating the clear solution, the salt may be obtained in the form of crystals. Twenty-five parts of cold water and 12 parts of boiling water dissolve the salt. Acid precipitates cantharidin from the solution (also compare *Cantharis*). This compound has, in recent years (1891), been proposed, by Liebreich, for some varieties of *tuberculosis*. It is injected hypodermatically in doses of a solution representing $\frac{1}{324}$ to $\frac{1}{216}$ grain of cantharidin.

Potassii Telluras ($K_2TeO_4+5H_2O$), *Potassium tellurate.* Neutralize a solution of pure crystallized telluric acid ($H_2TeO_4+2H_2O$) in water with potassium hydroxide. Evaporate to dryness, and wash with alcohol. It forms a crystalline, white powder, not soluble in alcohol, but freely so in water. This salt, in doses of from $\frac{1}{2}$ to $\frac{3}{4}$ grain, in pill or in alcoholic mint-julep, at bedtime, has been given in *pulmonary consumption* to control *colliquative sweating*. A similar sodium salt is prepared by substituting caustic soda for caustic potash. Both give to the breath a strong alliaceous odor.

POTASSA CUM CALCE (U. S. P.)—POTASSA WITH LIME.

Synonyms: *Vienna paste*, *Vienna caustic*, *Pulvis causticus Viennensis* (*or Londoninensis*), *Pulvis causticus cum calce*.

Preparation.—"Potassa, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; lime, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Rub them together, in a warm iron mortar, so as to form a powder, and keep it in a well-stoppered bottle"—(*U. S. P.*).

Description.—"A grayish-white powder, deliquescent, having a strongly alkaline reaction, and responding to the tests for calcium and potassium. It should be soluble in diluted hydrochloric acid without leaving more than a small residue"—(*U. S. P.*).

Action and Medical Uses.—This agent is used like potassa as a caustic, though it is slower and milder in action, and more readily controlled than the former. It is best applied as a paste prepared with a little alcohol. *Filho's caustic* is an improvement, being in sticks, and is in good form to treat disorders of the *uterine cervix*.

Related Preparations.—Causticum Commune Mitis, *Common milder caustic.* This is an old preparation. It is made by dissolving caustic potash in 3 parts (by weight) of water, and bringing it to the consistence of a paste by adding sufficient lime. Another method is that of mixing burned lime (powdered) with an equal part (by weight) of soft soap.

Soda cum Calce (N. F.), *Soda with lime, London paste.*—Soda, lime, each, equal parts. Reduce them to powder in a clean iron mortar, previously warmed, and mix them intimately. Keep the powder in small, well-stoppered vials.

Causticum cum Potassa et Calce, *Filho's caustic* (*Caustique de Filhos*).—This preparation is made by adding to fused caustic potash (100 parts) burned lime, in powder (10 parts), and molding in sticks by pouring the fused mass into leaden tubes. It is official in the *French Codex*.

POTASSA SULPHURATA (U. S. P.)—SULPHURATED POTASSA.

A mixture of essentially potassium trisulphide (K_2S_3) with potassium hyposulphite and some potassium sulphate.

Synonyms: *Liver of sulphur*, *Sulphuret of potassium*, *Hepar sulphuris*, *Potassii sulphuretum*, *Sulphide of potassium*.

History and Preparation.—This substance was known as early as the eighth century. The name "hepar sulphuris—liver of sulphur," was given it by the celebrated monk, Basil Valentine. To prepare it take of "sublimed sulphur, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; potassium carbonate, dried, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]. Mix the powdered and dried potassium carbonate thoroughly with the sublimed sulphur, and gradually heat the mixture, in a covered crucible, which should be only about half filled with it, until the mass ceases to foam and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a well-stoppered bottle"—(*U. S. P.*). The reaction is usually stated to take place according to the following equation: $3K_2CO_3$(414 parts)$+8S$ (256 parts)$=K_2S_2O_3+K_2S_3+3CO_2$. The pharmacopœial proportion of 2 parts of carbonate to 1 part of sulphur does not conform to this equation, unless, as was formerly the case, the carbonate is of 80 per cent or less. In the present *U. S. P.*, which demands a strength of 95 per cent, the quantity of sulphur directed is insufficient, and should be raised from 100 to at least 124 parts of sulphur. By the present formula, the pharmacopœial product necessarily contains a notable quantity of unacted-upon potassium carbonate (see B. Hirsch, *Pharm. Rundschau*, 1893, p. 281). The formation of sulphate takes place by oxidation of the hyposulphite when the crucible is opened too often for the purpose of watching the progress of the reaction. The latter may be judged by dissolving a sample of the mass in water; it should entirely dissolve (absence of free sulphur).

Description and Tests.—"When freshly prepared, sulphurated potassa forms irregular pieces of a liver-brown color, which, by exposure to the air, gradually absorb moisture, oxygen, and carbon dioxide, and change to a greenish-yellow and finally to a gray mass containing potassium carbonate, hyposulphite, and sulphate. The compound has a faint odor of hydrogen sulphide, and a bitter, alkaline taste. Soluble in 2 parts of water at 15° C. (59° F.), with the exception of a small residue. Alcohol dissolves only the potassium sulphide, leaving the other constituents (hyposulphite and sulphate) undissolved. The aqueous solution (1 in 10) is of an orange-yellow color, is strongly alkaline to litmus paper, and gives off the odor of hydrogen sulphide. On adding to it acetic acid in slight excess, an abundance of hydrogen sulphide is evolved, while sulphur is precipitated. In this liquid, after filtration, sodium bitartrate T.S. produces an abundant, white, crystalline precipitate. On triturating 1 Gm. of sulphurated potassa with 1 Gm. of crystallized copper sulphate and 10 Cc. of water, and filtering, the filtrate should remain unaffected by hydrogen sulphide T.S., corresponding to at least 12.85 per cent of sulphur combined with potassium to form sulphide"—(*U. S. P.*) A white deposit in the aqueous solution, unaltered by a large quantity of water, denotes the presence of silica or alumina; a black or gray one is probably iron; a yellow one free sulphur. Carbonate of potassium is detected by the addition of lime-water, which renders the solution turbid. If the liver of sulphur, when treated with diluted sulphuric acid, effervesces without evolving any hydrogen sulphide, it has become useless. A characteristic test for sulphides of alkalies and alkaline earths consists in the formation of a beautiful deep-violet coloration with solution of sodium nitroprusside ($Na_4Fe_2[CN]_{10}[NO]_2+4H_2O$).

Action, Medical Uses, and Dosage.—This is true "*hepar sulphur*" (*sulphuris*), and should not be confounded with the preparation (calcium sulphide) used by homœopaths under the same name. In large doses it is an energetic, narcotico-acrid poison, causing acrid taste, vomiting, mortal faintness, and convulsions, with an emission of the odor of sulphuretted hydrogen. In small doses, from 2 to 10 grains in solution, or in pill with soap or liquorice, and repeated 3 or 4 times a day, it acts as a general stimulant, increasing the frequency of the pulse as well as the heat of the body, and promoting the different secretions, especially those of the mucous membranes. It is likewise antacid, alterative, and antispasmodic, and has been used in *whooping-cough*, *chronic rheumatism*, *asthma*, *obstinate diseases of the skin*, *painters' colic*, *gout*, etc. (P.) Externally it has been very efficient in *chronic diseases of the skin*, as *eczema*, *scabies*, *lepra*, *pityriasis*, etc., in which it is used in the form of ointment, wash, or bath. Half a drachm of the sulphide to 1 ounce of lard forms an ointment; the same quantity to 1 fluid ounce of water, forms a wash or lotion. One part of the sulphide to 1000 parts of water, forms a bath. This bath is employed in *lead palsy*. It should not be used when there is fever or hemorrhages. By prolonged use vesicular or papular skin eruptions are apt to occur. Dose, 1 to 10 grains.

Related Compounds.—Potassii Sulphidum (K_2S), *Potassium monosulphide*, is formed by passing into a solution of caustic potash a stream of sulphuretted hydrogen, until it is saturated, and lastly adding to the product a like quantity of solution of potassa. The following reaction takes place: $KOH + H_2S = KSH + H_2O$; $KSH + KOH = K_2S + H_2O$. This alkaline, bitter solution, yields, by concentration *in vacuo*, prismatic crystals, colorless and deliquescent, and containing 5 molecules of water of crystallization. Alcohol partially dissolves it.

Potassii Sulphocarbonas (K_2CS_3), *Potassium sulphocarbonate (thiocarbonate)*, is produced by agitating potassium monosulphide in aqueous solution with carbon disulphide. The yellowish or red-brown fluid, carefully concentrated at 30° C. (86° F.) gives deliquescent, yellow, hydrated crystals, or if the red-brown fluid be treated with alcohol, a crystalline deposit. Soluble in alcohol, and of a sharp, cooling, sulphur-like taste. When carbon disulphide is shaken together with an alcoholic solution of caustic potash, a compound ($CS.OC_2H_5.SK$) is formed, called *potassium xanthogenate*. The crude compound was recommended by Dumas as a means to destroy the phylloxera on grapevines. In moist condition, it slowly evolves carbon disulphide. The above compound (K_2CS_3) is also a constituent of its solution.

POTASSII ACETAS (U. S. P.)—POTASSIUM ACETATE.

Formula: $KC_2H_3O_2$. Molecular Weight: 97.89.

Synonyms: *Acetas potassicus, Acetas kalicus, Acetate of potash, Acetate of potassium, Acetate of potassa, Terra foliata tartari, Sal diureticum, Diuretic salt.*

History and Preparation.—This salt in solution was known to Pliny, and was first obtained by Raymond Lully. Its properties were described in 1610 by Philip Müller, of Freiberg. The salt is prepared simply by dissolving carbonate or bicarbonate of potassium in solution of acetic acid, keeping the latter in slight excess, and evaporating the solution to dryness by carefully heating it on a sand-bath.

Description.—As met with in commerce, the salt often has a foliaceous appearance, not unlike spermaceti, which gave rise to its former name, *foliated earth of tartar*, acetic and tartaric acids having been at one time believed to be identical. The salt is officially described as "a white powder, or crystalline masses of a satiny lustre, odorless, and having a warming, saline taste. Very deliquescent on exposure to the air. Soluble at 15° C. (59° F.), in 0.36 part of water, and in 1.9 parts of alcohol; with increasing temperature it becomes much more soluble in both liquids. When heated to 292° C. (557.6° F.), the salt fuses. At a higher temperature it decomposes, blackens, and evolves vapors having an empyreumatic odor (an alliaceous odor would indicate the presence of arsenic), and finally leaves a white residue of potassium carbonate, which should be completely soluble in water"—(*U. S. P.*). Acetone is among the products of volatilization. Owing to its ready deliquescence, the salt should be kept in well-stoppered bottles. The aqueous solution of the salt soon becomes moldy, and the acetate is converted into carbonate. "The aqueous solution (1 in 20) colors litmus paper blue, but does not redden phenolphtalein T.S. Upon the addition of sodium cobaltic nitrite T.S., a copious yellow precipitate is formed. The addition of sodium bitartrate T.S. to the aqueous solution causes a white, crystalline precipitate. When the salt is heated with a small amount of sulphuric acid, vapors of acetic acid are evolved. The addition of a little ferric chloride T.S. to a solution of the salt produces a deep red color, and, upon the application of heat, a pale brown, flocculent precipitate of basic ferric acetate separates"—(*U. S. P.*). Potassium acetate is contained in many vegetable juices, and upon incineration is found in their ashes in the form of potassium carbonate. Potassium acetate is incompatible with the sulphates of sodium and magnesium, tartaric acid, the stronger acids, earths and their salts, bichloride of mercury, and some other metallic salts.

Impurities and Tests.—Impurities are rarely present; the most probable are carbonate of potassium, if this is left in excess during the preparation of the salt; sulphate of potassium, chloride of potassium, alumina, lime, magnesia, iron, lead, copper, tin, etc., which may respectively be detected by the pharmacopœial tests as given below. If lime is present, ammonium oxalate will produce, in the aqueous solution of the salt, a white precipitate, insoluble in diluted acetic acid. Magnesium is recognized by adding to the aqueous solution of the salt, ammonium chloride, aqua ammoniæ, and ammonium carbonate, filtering, and adding to the filtrate ammonium phosphate. A crystalline precipitate denotes the presence of magnesium. "Having prepared a solution of 2.5 Gm. of the salt in 50 Cc.

of water, use 10 Cc. of it for each of the following tests: After a portion has been acidulated with a few drops of hydrochloric acid, the addition of an equal volume of hydrogen sulphide T.S. should produce no precipitate (absence of arsenic, lead, etc.). In another portion, acidulated with hydrochloric acid, 1 Cc. of barium chloride T.S. should produce no visible change (absence of sulphate). If to a portion of the solution, acidulated with nitric acid, 0.1 Cc. of decinormal silver nitrate V.S. be added, the liquid should, after filtration, show no further change on the addition of more silver nitrate V.S. (limit of chloride). The addition of 0.3 Cc. of potassium ferrocyanide T.S. should effect no change in the solution within 15 minutes (limit of iron). No coloration or precipitate should be produced by adding 1 Cc. of ammonium sulphide T.S. (absence of iron, aluminum, etc.). Fragments of the salt sprinkled upon sulphuric acid, should produce no effervescence (absence of carbonate), nor impart any color (absence of readily carbonizable, organic impurities). If 1 Gm. of potassium acetate be, by thorough ignition, converted into carbonate, the residue should require, for complete neutralization, not less than 10 Cc. of normal sulphuric acid (corresponding to at least 98 per cent of pure potassium acetate), methyl orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Acetate of potassium is one of the most important of the salts employed in Eclectic medicine. In the dose of 2 or 3 drachms, it causes mild purging, which is occasionally attended with griping; and, in *dropsy*, it will often cause copious watery discharges by stool and urine. In doses of from 10 to 40 grains, it causes diuresis, to which effect is due its former name of *Sal Diureticum*. It is the ideal renal depurant, for it not only increases the watery constituents of the urine, but, by inducing retrograde metamorphosis, it augments the solid constituents as well. It acts not only upon the renal organs, but upon the remote parts of the body, serving to eliminate from the system much of the broken-down elements upon which diseased conditions depend. From the fact that it is decomposed before leaving the body, with the formation of potassium carbonate, it has been used in *dropsy*, to render the urine alkaline in *uric-acid diathesis*, and in other cases where diuresis is indicated. It is a remedy for *lithemia*. By its depurant action, it has cured *intermittent* and *remittent fevers*, when the usual treatment has failed. Not only does it remove the morbid products of fevers, but it also acts as a refrigerant. It should be well diluted, lest it irritate the gastric membranes. It should be remembered that all of the potassium salts act best when largely diluted, and the acetate is often given best in water to which a little vinegar has been added.

In *scrofulous conditions*, when old and broken-down tissues stand in the way of recovery, this salt acts as a true alterative in ridding the system of these obstructions, and the same is true in all inflammations marked by deposits of cacoplastic material. In *chronic diseases of the spleen* and *liver*, especially *hepatic congestion*, with limited secretion of bile, it is often the best remedy. In *chronic jaundice*, 30 or 40 grains of the salt should be given every 4 hours. It is a remedy for dropsies when the liver is inactive, or after scarlatina, but generally not otherwise, and, to increase its diuretic power, it may be given with parsley, spearmint, or queen of the meadow.

It has likewise been found beneficial in *acute* and *chronic rheumatism*, *acute vaginitis*, *gonorrhœa*, and in several obstinate cutaneous affections, when given in doses to increase the urinary discharge. It may be given with confidence in the early stages of *ovaritis*, *mastitis*, or *orchitis*. Prof. Locke recommends the following for *acute rheumatism*, with increase of temperature, swelling of the joints, and dirty tongue: ℞ Potassium acetate, ʒvj; salicylic acid, ʒii; aqua, fl℥iv. Mix. Sig. Dose, a teaspoonful in a wineglassful of water, every 3 or 4 hours. It should not be given when the tongue is pointed and red. With the special sedatives, it is often useful in *pneumonia*, and, given early, it may influence *phthisis* by preventing the deposition of tubercular matter. In *syphilis*, it may be administered awhile in alternation with the iodide of potassium. In *chronic ague*, it may be given to assist the antiperiodic. In *skin affections*, where the urinary secretion is imperfect, it aids other remedies, and is of itself often sufficient in *pimples*, *furunculous eruptions*, *scaly tetter*, and *psoriasis*. It should be borne in mind that to act properly the kidneys should be in good condition, otherwise too much should not be expected of the drug. It aids in curing *carbuncle*. Locally, it has been used to cure *acne*, the pimples being first emptied of their contents, and the parts touched with the deliquesced salt. The usual dose of potassium acetate ranges from 5 to 40 grains, well diluted; as a laxative, 4 drachms, though it is seldom used for this purpose. From 30 grains to 3 drachms may be taken in a day.

Specific Indications and Uses.—Retention of worn-out material in the body; imperfect renal excretions of the broken-down solids; deposits of cacoplastic material, giving rise to inflammations and fevers, especially malarial fever; tongue pallid, with light, pasty fur; scanty urine, with dull headache; sluggish lymphatic action; rheumatism, with swollen joints, dirty tongue, and fever; hepatic torpor and infarction.

POTASSII BICARBONAS (U. S. P.)—POTASSIUM BICARBONATE.

FORMULA: $KHCO_3$. MOLECULAR WEIGHT: 99.88.

SYNONYM: *Kali carbonicum acidulum, Acid potassium carbonate, Hydrogen potassium carbonate, Bicarbonas potassicus, Bicarbonas kalicus.*

"Potassium bicarbonate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation and History.—As originally prepared by Cartheuser, in 1757, this salt was produced by the interaction between caustic potash and ammonium carbonate. It is now frequently prepared by a method introduced by Cavendish, that is, by passing a current of carbon dioxide into a solution of potassium carbonate until saturated, then filtering from precipitated impurities (silicic acid), and evaporating to crystallization at a heat not to exceed 70° C. (158° F.). The reaction which takes place is as follows: $K_2CO_3+H_2O+CO_2=2KHCO_3$.

Another method of obtaining potassium bicarbonate consists in exposing a moistened magma of potassium carbonate, in shallow dishes, to the prolonged action of carbonic acid gas until a sample, diluted with water, produces a white precipitate with solution of corrosive sublimate, consisting of mercuric bicarbonate; a yellow precipitate would indicate unaltered carbonate. (For details regarding this method, as well as another, whereby solution of potassium carbonate is warmed with solution of ammonium carbonate to a temperature not exceeding 75° C. [167° F.], see Hager, *Handbuch der Pharm. Praxis*, Vol. II, 1886, p. 250.)

Description.—The *U. S. P.* describes the salt as in "colorless, transparent, monoclinic prisms, odorless, and having a saline and slightly alkaline taste. Permanent in the air. Soluble in 3.2 parts of water at 15° C. (59° F.), and in 1.9 parts at 50° C. (122° F.). At a higher temperature, the solution rapidly loses carbon dioxide, and, after being boiled, contains only potassium carbonate. Almost insoluble in alcohol. The dry salt begins to lose carbon dioxide at 100° C. (212° F), and this loss increases at a higher temperature, until, at a red heat, the salt has lost 30.97 per cent of its original weight, leaving a residue of carbonate"—(*U.S.P.*). The salt does not dissolve or disorganize animal textures. In contact with acids, it briskly effervesces. An impure bicarbonate of potassium, in powder form, known as *Sal æratus*, was once used extensively in baking.

Impurities and Tests.—Bicarbonate of potassium is liable to contain as impurities the sulphate or chloride of potassium, arising from an impure carbonate employed in its preparation. The sulphate and chloride may be detected by the use of chloride of barium or nitrate of silver, these causing a white precipitate in its solution acidulated with nitric acid. Carbonate of potassium may be known by adding a solution of corrosive sublimate, which will cause a brownish-red precipitate, if as little as 1 per cent of the carbonate be present (see *Preparation* above).

The *U. S. P.* gives the following identity-reactions and tests for purity: "The pure salt, when dissolved in water, is at first neutral to litmus paper and to phenolphtalein T.S., but the solution soon becomes feebly alkaline by partial conversion of the salt into carbonate. Sodium cobaltic nitrite T.S. produces in the aqueous solution a copious yellow precipitate. Tartaric acid T.S., added to the aqueous solution in excess, causes a white, crystalline precipitate. A solution of 0.5 Gm. of potassium bicarbonate in 10 Cc. of water, should not at once be colored red by 1 drop of phenolphtalein T.S. (limit of carbonate). Dissolve 2.5 Gm. of the salt in 30 Cc. of diluted acetic acid, and, having made up the volume to 50 Cc. with water, use 10 Cc. for each of the following tests: No visible change should occur in a portion of this solution upon the addition of an equal volume of hydrogen sulphide T.S. (absence of metallic impurities). The addition of 0.3 Cc. of potassium ferrocyanide T.S. to another portion should not produce a blue color within 15 minutes (limit of iron). After adding a few drops of nitric acid and 0.1 Cc. of decinormal silver nitrate V.S. to another portion, and filtering, the further addition of silver nitrate V.S. should not affect the filtrate (limit of chloride). To neutralize 1 Gm. of potassium bicarbonate should require 10 Cc. of normal sulphuric acid (corresponding to 100 per cent of pure salt), methyl orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Bicarbonate of potassium is antacid, antilithic, and diuretic, is less irritating and unpleasant than the carbonate and liquor potassæ, and may be used in larger doses. It is preferred, as a general rule, to the carbonate, for which it may, in nearly all cases, be used as a substitute. The indications for this salt are those for potash—"a leaden pallor of the tongue, and tremulous muscles." Following this indication, it is a good drug in *gout*, *fevers*, *syphilis*, *scrofula*, and *rheumatism*, with deposits of lithic acid in the urine. It may be given with mint water and syrup of stillingia. In *gonorrhœa*, it relieves the irritation produced by acid urine and other discharges. In combination with gentian, rhubarb, and mint water, it is a good remedy in *atonic dyspepsia*, with indications for an alkali, and in the form of neutralizing cordial with rhubarb and peppermint herb (Locke's formula), it is an excellent antacid in *infantile diarrhœa* with green, offensive discharges. It is of value in *cutaneous disorders*, depending upon a malarial cachexia and errors in diet. Dose, 10 to 30 grains, well diluted, as an antacid and antilithic; 1 to 2 drachms, as a diuretic. Potassium bicarbonate, in well-diluted solution, forms an excellent agent for softening and removing the scales formed upon the palpebral margins in *ciliary blepharitis*.

Specific Indications and Uses.—Leaden pallor of tongue and mucous membranes, and tremulous action of the voluntary muscles; fullness of muscles; debility out of proportion to diseased conditions.

Related Products.—POTASSII SESQUICARBONAS, *Sesquicarbonate of potassium*, *Mild vegetable caustic*. When a solution of potassium bicarbonate ($KHCO_3$) in water is evaporated by boiling, half of its carbonic acid is gradually given off and the normal carbonate (K_2CO_3) results. If evaporation is carried to the point where only one-fourth of its carbonic acid is given off, the solution contains potassium sesquicarbonate, which crystallizes out upon standing. It is claimed by some to be a crystallizable, deliquescent substance of definite composition, while others claim that the product is a mixture of mono- and bicarbonate of potassium. As prepared by the process mentioned, this mild caustic is sold in the form of a white powder, having an alkaline odor, a sharp, strongly alkaline taste, is permanent in dry air, very soluble in water, but insoluble in alcohol. Owing to the fact that carbonate of potassium is deliquescent, and that this preparation contains that salt, the bottle containing this salt must be well closed.

The above preparation differs materially from the original *Vegetable caustic*, which was prepared by making a strong lye of hickory or oak-wood ashes, and evaporating it in an iron kettle to dryness. This formed an impure caustic potash, of a dingy-gray or greenish color very caustic, but less so than the hydroxide of potassium, very deliquescent, and soluble in water. It is more severe in its action than the mild caustic, and has to be employed occasionally in cases where the latter exerts but little or no beneficial influence. As it rapidly extracts moisture from the atmosphere, it must, as soon as prepared, be placed in glass bottles with good corks or stoppers. Each of these preparations is escharotic, but they do not, like the hydroxide of potassium, destroy or decompose the healthy tissues; their action appears to be altogether exerted upon abnormal growths and conditions of parts. They are employed as local applications to *fistulas*, *cancers*, *fungous growths*, *indolent ulcers*, *unhealthy conditions of mucous tissues*, as in *ophthalmic affections*, *diseases of the Schneiderian membrane*, of the *mouth and throat*, *urethra*, *vaginal walls*, and *cervix uteri*. Prof. Scudder, who was very partial to this preparation, says (*Spec. Med.*): "In *chronic disease of bone*, and in *caries*, it exerts a most kindly influence upon the diseased tissues, promoting the removal of the dead bone, and at the same time stimulating the living. In *disease of the soft tissues* going on to suppuration, the same may be said, the local application promoting the removal of dying tissue in suppuration, yet strengthening the tissues adjoining. This may be noticed especially in the treatment of [illegible], as the thorough injection with a saturated solution of sesquicarbonate of potash arrests the progress of the disease, and establishes healthy suppuration." In solution, it has been injected into the uterus in *dysmenorrhœa*, *uterine leucorrhœa*, etc., without any unpleasant symptoms arising. In these latter cases the milder caustic should be used, commencing with a weak solution, and gradually increasing in strength until the maximum degree that can be used is obtained. Upon healthy tissues these agents exert but very feeble action; and in unhealthy conditions they bring about a normal action without exciting undue degree of inflammation. They are agents of great value.

POTASSII BICHROMAS (U. S. P.)—POTASSIUM BICHROMATE.

FORMULA: $K_2Cr_2O_7$. MOLECULAR WEIGHT: 293.78

SYNOYMS: *Potassium dichromate, Bichromas kalicus, Bichromate of potash, Red chromate of potash,* or *potassa, Kali chromicum rubrum, Kali bichromicum.*

Source and Preparation.—The chief source of all chromium compounds is the mineral *chrome iron ore* which is essentially *ferrous chromite, i.e.,* a compound of ferrous oxide and chromic oxide ($FeO.Cr_2O_3$). It occurs in Russia, Sweden, and many parts of the United States. Bichromate of potassium is made on the large scale by the decomposition and oxidation of chromic iron ore. The latter is mixed with lime, and roasted with free access of air in a reverberatory furnace until decomposition of the ore has taken place. Formerly nitrate of potassium was employed to oxidize the ore. The mass is then lixiviated with water, and the resultant solution of chromate of calcium (CrO_4Ca) decomposed by the addition of carbonate of potassium, and filtered from the calcium carbonate; the yellow, neutral chromate solution is then acidulated with sulphuric acid, and the bichromate solution evaporated to crystallization. Thus it is seen that the bichromate may be obtained from the neutral yellow chromate by acidulating the solution of the latter with sufficient sulphuric or acetic acids to convert half of the potassium of the neutral chromate into sulphate or acetate, as follows: $2K_2CrO_4+H_2SO_4=K_2SO_4+H_2O+K_2Cr_2O_7$. The solution upon sufficient evaporation yields large crystals of bichromate (see also *Related Compounds*).

Description and Tests.—"Large, orange-red, transparent, triclinic prisms, or 4 sided tables, odorless, and having a bitter, metallic taste. Permanent in the air. Soluble in 10 parts of water at 15° C. (59° F.), and in 1.5 parts of boiling water; insoluble in alcohol. The salt fuses below a red heat, without loss of weight, forming a dark brown liquid. At a white heat it evolves oxygen and leaves a residue of neutral potassium chromate and green chromic oxide. The aqueous solution (1 in 20) has an acid reaction upon litmus paper. On mixing 4 Cc. of the aqueous solution with 0.5 Cc. of alcohol, and then with 1 Cc. of sulphuric acid, the liquid will assume a green color and emit the odor of aldehyde. Sodium cobaltic nitrite T.S. produces in the aqueous solution a copious yellow precipitate"—(*U. S. P.*). Solutions of potassium bichromate form colored precipitates with salts of the various heavy metals, *e. g.*, salts of lead (*chrome yellow*), mercury, silver, barium, etc. These precipitates are soluble in diluted nitric acid; but silver chloride and barium sulphate are insoluble, hence the presence of chlorides or sulphates as impurities may be easily recognized by this test. The orange-red solution of potassium bichromate, especially when acidulated, is reduced to green by organic substances, *e. g.*, alcohol (see above), hydrogen sulphide, sulphurous acid, ferrous sulphate, etc. When heated with hydrochloric acid, chlorine is evolved. The chromate in these processes is reduced to salts of the chromic oxide (Cr_2O_3). The *British Pharmacopœia* (1898) directs the following quantitative test for the purity of potassium bichromate: "5.66 grammes of ferrous sulphate, dissolved in a little water and acidulated with sulphuric acid, should not cease to yield a blue color with solution of potassium ferricyanide until such a quantity of solution as contains 1 gramme of the potassium bichromate has been added"—(*Br. Pharm.*, 1898). This reaction takes place according to the equation $6(FeSO_4+7H_2O)+7H_2SO_4+K_2Cr_2O_7=3Fe_2(SO_4)_3+K_2SO_4+Cr_2(SO_4)_3+49H_2O$. The proportions directed by the *British Pharmacopœia* correspond to 99.7 per cent of the pure salt.

Potassium bichromate is extensively employed in the arts, being used in dyeing operations and tanning industries, as well as for other minor purposes.

Action, Medical Uses, and Dosage.—Internally, this salt is a poison, though it has been used as an alterative in *venereal* and *scrofulous affections*, in doses of $\frac{1}{12}$ to $\frac{1}{5}$ or $\frac{1}{6}$ of a grain, 3 or 4 times a day. In excessive doses this salt is a violent irritant and corrosive poison, and may quickly produce death. An ounce is said to have occasioned death in about half an hour, insensibility having occurred 5 minutes after its ingestion. The symptoms are vomiting, dark hemorrhagic mucus, purging, violent pain in the abdomen, excessive thirst, cold surface, cold breath, feebleness of speech, with quick, feeble pulse, hurried respiration, coma, cardiac failure, collapse, and death. If death does not occur, urinal suppression may last for many days. As small a dose as 2 drachms has produced death. Calico printers suffer from ulcers on the hands and the destruction of the nasal membranes and septum from inhalation of its dust. When this salt is applied in solution to the skin, habitually, it first produces an eruption of papulæ, which become pustular, and, provided the exposure be continued, forms deep sloughs under the pustules, of a peculiarly penetrating character. Externally it is a caustic, and one of its chief therapeutical uses is as an external application; it may be used in aqueous solution, from 30 to 60 grains to the ounce of fluid, or in the state of powder. Its solution possesses very powerful antiseptic properties, and will be found advantageous in cases of *gangrene, dry mortification*, etc. It is milder than chromic acid, and may be used for many of the purposes for which the acid is employed (see *Chromic Acid).* Bichromate of potassium in saturated solution has been recommended as a local application to *warts, excrescences*, and *tubercular elevations;* it causes but little pain, and often removes these growths by absorption without any slough; or if a slough has formed, it serves to expedite the cure, and it is not followed by deep, unmanageable ulcers. Internally, it is emetic and irritant in doses of $\frac{3}{4}$ of a grain. In doses of $\frac{1}{16}$ of a grain, repeated 3 times daily, it acts as an alterative, and occasionally as a sialagogue, and has been advantageously used in *syphilis;* gradually increasing the dose to $\frac{1}{3}$ of a grain. It should be used in pill form in combination with some tonic or alterative vegetable extract. It is much used in calico printing, and in preparing artificial valerianic acid from fusel oil. Paper impregnated with solution of it, and dried, forms excellent tinder. The alkaline carbonates, magnesia, soap, etc., are its antidotes. Of recent years potassium bichromate has been used for its specific action upon the throat and alimentary canal. Upon the former its specific effects are exerted upon the mucous membrane of the fauces, larynx, and trachea, seemingly not extending to the smaller bronchioles. *Hoarseness* and exudation, with *cough*, are the special guides to its selection. With these conditions, it may be used to relieve the hoarseness following *acute affections of the larynx* from cold, singing or speaking. In *diphtheria* and *pseudo-membranous croup* it may be added to the remedies employed, while in the latter stillingia liniment is to be externally applied. It acts also upon the bronchi and larger bronchioles, controlling irritation, and relieving hard, rasping cough of the subacute, bronchial type. It should be thought of in any inflammation with a tendency to low grades of deposit, and in *laryngeal irritation*, with hoarseness and dryness of the laryngeal tissues. It is a remedy for *croupous conjunctivitis* and *indolent corneal ulcers* with stringy secretions, and in granulated lids with tenacious discharges. Locally, a strong solution may be applied in *acute trachoma* with large granulations. Potassium bichromate is a remedy for muscular pain. In *non-inflammatory chronic rheumatism*, with deficient force to the circulation, this agent sometimes does good service, and is particularly valued by some practitioners in *syphilitic rheumatism.* It relieves the cramping, rheumatoid pains of *muco-enteritis* and *acute diarrhœa* occurring in cold weather (Webster). The recuperative power of the drug is shown in *chronic diarrhœa* and in *chronic dysentery*, with ulceration of the colon. *Chronic pharyngeal ulcers, syphilitic* or otherwise, *chronic gastritis*, and *round gastric ulcer*, are reputed cured by it. A yellow-coated tongue and *catarrh of the stomach* are the indications for it in dyspeptic troubles. The dose for specific purposes should be about 2 or 3 grains of the 3 x trituration, every 2 to 4 hours.

Specific Indications and Uses.—Respiratory irritation, with hoarseness, harsh or croupal cough, scanty expectoration, or thick, tenacious sputa, difficult respiration, and subacute inflammation; inflammations with low grade of deposits; muco-enteritis and irritative diarrhœa, with tenesmic rheumatoid pain; dyspepsia with gastric catarrh and yellow-coated tongue; corneal ulcers with stringy discharges; croupous conjunctivitis; trachoma with tenacious discharges; non-inflammatory, rheumatic or muscular pain; pseudo-membranous croup; laryngeal irritation and hoarseness from singing or speaking.

Related Compound.—*Potassium chromate* (K_2CrO_4). Molecular Weight: 193.9. To a hot solution of potassium dichromate add potassium carbonate until effervescence ceases. The solution becomes yellow, and, upon evaporation, yields canary-yellow, 6-sided crystals, which melt without decomposition. Two parts, or less, of water effect their solution. The salt in solution turns red litmus paper blue. It is employed as a laboratory reagent.

POTASSII BITARTRAS (U. S. P.)—POTASSIUM BITARTRATE.

FORMULA: $KHC_4H_4O_6$. MOLECULAR WEIGHT: 187.67.

SYNONYMS: *Cream of tartar*, *Crystals of tartar*, *Tartarus depuratus*, *Potassii tartras acida* (*Br.*), *Acid potassium tartrate*, *Supertartrate of potassa*, *Cremor tartari*, *Bitartras kalicus*, *Bitartras potassicus*, *Kali bitartaricum*.

Source, History, and Preparation.—This salt, commonly called *Cream of tartar*, was known to the ancient Greeks and Romans as a deposit from fermenting grape juice. Its chemical nature was cleared up by Scheele in 1769. It is obtained from the *crude tartar*, *argol*, or *winestone* of commerce, a constituent of many vegetable juices, especially of grape juice. When the sugar contained in the latter is converted into alcohol, in which the tartar is insoluble, it becomes deposited upon the sides of the fermenting casks in the form of a grayish or brownish, indistinctly crystalline substance. The tart wines deposit it in the largest quantity; it is composed of bitartrate of potassium (good commercial grades contain 80 to 85 per cent), tartrate of calcium (about 5 to 10 per cent), coloring matter, alumina, and other accidental impurities. The red wines give a *red tartar* (*Red argol*), and the white wines a *white tartar* (*White argol*), the first being brown-red in color, the second more gray. From the crude argol, purified cream of tartar (*tartarus depuratus*) is obtained by recrystallization from boiling water. In order to remove the coloring matter, a hot aqueous solution is agitated with charcoal, or aluminum hydroxide, or the white of egg, etc. If a hot, saturated solution of tartar be cooled, the surface of the liquid becomes coated by a layer of very fine crystals of bitartrate; hence this crust was called *cream of tartar*. An easy mode of purifying cream of tartar is to convert it into Rochelle salt by dissolving it in solution of sodium carbonate, the solution is then purified by animal charcoal, and the cream of tartar precipitated by means of hydrochloric acid.

Description.—As officially described potassium bitartrate forms "colorless or slightly opaque, rhombic crystals, or a white, somewhat gritty powder, odorless, and having a pleasant, acidulous taste. Permanent in the air. Soluble in about 201 parts of water at 15° C. (59° F.), and in about 16.7 parts of boiling water; very sparingly soluble in alcohol. When a small portion of the salt is heated on platinum foil, it chars and emits inflammable vapors having the odor of burning sugar. At a higher temperature, with free access of air, the carbon of the black residue is oxidized, and a white, fused mass of potassium carbonate remains, which has an alkaline reaction, and effervesces strongly with acids. The aqueous solution of the salt has an acid reaction upon litmus paper. With sodium cobaltic nitrite T.S. it yields a copious yellow precipitate. In the aqueous solution of the salt, rendered neutral by potassium or sodium hydrate T.S., silver nitrate T.S. produces a white precipitate which, on boiling, becomes black by the separation of metallic silver. If, before applying heat, enough ammonia water be added to dissolve the white precipitate, upon boiling the solution a mirror will be deposited on the sides of the test tube"—(*U. S. P.*). Cream of tartar is readily soluble in water to which borax or boracic acid has been added, forming a solution termed *soluble cream of tartar*, or *borotartrate of potassium*. It is incompatible with all alkaline substances, *e. g.*, ammonia water, carbonates of sodium or potassium, magnesium oxide, with all of which it forms soluble compounds; salts of heavy metals, *e. g.*, lead acetate, likewise decompose it, insoluble tartrates being formed.

Adulterations and Tests.—As found in commerce, bitartrate of potassium is always contaminated with from 3 to 10, or even 14 per cent of tartrate of calcium; also frequently with copper, which gives it a green tint. These impurities may be removed, without any great loss of material, by finely powdering the cream of tartar, and digesting it at a gentle heat, with very dilute hydrochloric acid. To detect the tartrate of calcium agitate the cream of tartar with a solution of aqua ammoniæ, then filter and add oxalate of ammonium, which causes a white precipitate if a calcium salt be present. If a large amount of tartrate of calcium be present, the ammonia will not dissolve all of the powder. If copper be present, ferrocyanide of potassium added to an aqueous solution will give a chocolate or reddish-brown precipitate. The latter is bluish-green when iron is present. Intentional adulterations of cream of tartar usually consist of starch, chalk, clay, or alum. Some samples have been found to consist for the greater part. or almost entirely, of calcium sulphate or phosphate. The presence of carbonate of calcium will cause an effervescence with weak acids; starch may be known by the blue color caused upon the addition of iodine; mineral substances, by their insolubility in boiling water; alum, by the white precipitate caused upon the addition of chloride of barium, and which is insoluble in nitric acid. The tests of the *U. S. P.*, in addition to the characteristics given under *Description*, are as follows: "If 1.5 Gm. of the salt be shaken with 30 Cc. of water and the mixture filtered, 10 Cc. of the filtrate, after being acidulated with nitric acid, should not be rendered turbid by 0.5 Cc. of silver nitrate T.S. (absence of chloride), nor by 0.5 Cc. of barium chloride T.S. (absence of sulphate). A solution of 0.5 Gm. of the salt in 3 Cc. of ammonia water should leave no insoluble residue (absence of insoluble matter), nor be affected by ammonium sulphide T.S. (absence of copper, lead, iron, etc.). If 1.2 Gm. of potassium bitartrate be repeatedly agitated, during half an hour, with a mixture of 5 Cc. of acetic acid and 1 Cc. of water, and the mixture be then diluted with 30 Cc. of water, and filtered, the clear filtrate should not be rendered turbid, within one minute, by the addition of 0.5 Cc. of ammonium oxalate T.S. (limit of calcium salt). The odor of ammonia should not be evolved on heating the salt with a slight excess of potassium or sodium hydrate T.S. If 1.88 Gm. of potassium bitartrate be thoroughly ignited at a red heat, it should require for complete neutralization not less than 9.9 Cc. of normal sulphuric acid (each Cc. corresponding to 10 per cent of the pure salt), phenolphtalein being used as indicator"—(*U. S. P.*). With regard to the last-mentioned test. Mr. Carl E. Smith (*Digest of Criticisms*, *U. S. P.*, Part II, 1898) points out that direct titration of the salt with caustic alkali is preferable to titration with acid after ignition, because in the latter case the presence of calcium tartrate affects the accuracy of the result, and because of the greater convenienc of the former method.

Action, Medical Uses, and Dosage.—Bitartrate of potassium is diuretic and laxative. Doses of about 20 grains generally act as a diuretic. In large doses it occasions severe and long-continued purging of watery discharges, seldom, however, griping, or producing subsequent debility; on this account, it forms an invaluable agent in *dropsy*. Excessive doses cause gripings and flatulence, with symptoms of gastro-enteritis. Its continued use deranges the digestive functions, and produces emaciation. A combination of sulphur, bitartrate of potassium, and confection of senna, is frequently used with advantage as a laxative in *piles*, *prolapsus ani*, etc., and in some diseases of the skin. Equal parts of sulphur and cream of tartar in teaspoonful doses are often employed for *piles with constipation*. It is frequently combined with jalap, the compound powder of jalap, resin of podophyllum, sulphur, etc. In solution, sweetened with sugar, or in lemonade, it forms an agreeable, cooling drink, very useful in many *fevers*. As a hydragogue in *post-scarlatinal dropsy*, Prof. Locke (*Syllab. of Mat. Med.*) recommends: ℞ Cream of tartar, ℥ss; juniper berries, ℥ss; boiling water, Oj. Mix. Filter after standing a couple of hours and give in wineglassful doses, 3 or 4 times a day. Equal parts of bitartrate of potassium, powdered rhatany root, and myrrh, form a good dentifrice. Two drachms of cream of tartar added to 1 pint of milk, form a *cream of tartar whey*, which, when diluted with water, is sometimes given in *dropsical* and *febrile complaints*. Dose, as a cathartic, from 4 to 6 drachms; as an aperient, 1 or 2 drachms; and in dropsy, it may be given in doses of from 1 to 3 drachms, in water, 4 or 5 times a day.

POTASSII BROMIDUM (U. S. P.)—POTASSIUM BROMIDE.

FORMULA: KBr. MOLECULAR WEIGHT: 118.79.

SYNONYMS: *Bromide of potash*, *Bromide of potassium*, *Bromuretum potassicum*, *Bromuretum kalicum*.

Preparation.—Bromide of potassium may be prepared by several methods. The *U. S. P.*, 1870, obtained it by double decomposition of pure potassium carbonate with solution of ferrous bromide previously prepared by the action of bromine upon iron filings in the presence of water. The reaction takes place with precipitation of insoluble ferrous carbonate as follows: $FeBr_2+K_2CO_3$ $FeCO_3+2KBr$. The resulting solution of potassium bromide is then evaporated to crystallization. The process of the *British Pharmacopœia* (1885) consists in the action of bromine upon caustic potash, whereby potassium bromide and bromate are formed, according to the equation: $6Br+6KOH = 5BrK+BrO_3K+3H_2O$. The solution is evaporated to dryness, the salts mixed with charcoal and exposed to a red heat; the bromate is thus reduced to bromide, carbonic oxide being evolved. The fused mass, when cold, is dissolved in water, filtered and evaporated to crystallization. Potassium bromide may also be prepared by neutralizing hydrobromic acid with caustic potash.

Description.—Bromide of potassium is officially described as occurring in "colorless or white, cubical crystals, or granules, odorless, and having a pungent saline taste. Permanent in the air. Soluble, at 15° C. (59° F.), in about 1.6 parts of water, and in 200 parts of alcohol; in less than 1 part of boiling water, and in 16 parts of boiling alcohol; also soluble in 4 parts of glycerin. On heating the salt upon platinum foil, it decrepitates; near 700° C. (1290° F.) it fuses without decomposing, and at a bright red heat it volatilizes, communicating a violet color to the flame. The aqueous solution (1 in 20) is neutral, or has, at most, only a scarcely perceptible alkaline reaction upon litmus paper. The addition of tartaric acid T.S., or sodium bitartrate T.S., produces in it, after some time, a white crystalline precipitate. Sodium cobaltic nitrite T.S. produces in it at once a copious yellow precipitate. If to 10 Cc. of the aqueous solution of the salt a few drops of chloroform be added, then 1 Cc. of chlorine water, and the mixture be agitated, the liberated bromine will dissolve in the chloroform, imparting to it a yellow or brownish-yellow color without a violet tint"—(*U. S. P.*). A violet tint would denote the presence of iodine. Potassium bromide is precipitated also by acetate of lead and by mercurous and mercuric salts.

Impurities and Tests.—The commercial article frequently contains iodide of potassium, and the chloride is a regular constituent for which the *U. S. P.*, by the test given below, fixes an upper limit of 3 per cent. Commercial samples have been found to contain as much as 7 or 8 per cent of chloride. The alkaline reaction of bromide of potassium is due to adhering carbonate of potassium; if it is present in an appreciable quantity the salt becomes moist in the air, and effervesces with acid. If bromate of potassium is present, the addition of hydrochloric acid will liberate both bromic and hydrobromic acids, which at once act upon each other with liberation of bromine; hence a brown color is developed upon the addition of the acid. The reaction takes place as follows: $5BrH+BrO_3H = Br_6+3H_2O$. Of eight samples of commercial potassium bromide analyzed by Mr. G. H. Charles Klie (*Amer. Jour. Pharm.*, 1894, p. 382) none contained bromate, but five failed in the test for chlorides, as given below, and one contained appreciable quantities of sulphate. The *U. S. P.* directs the following tests for impurities: "If 1 Gm. of the salt be dissolved in 10 Cc. of a mixture of 100 Cc. of water and 0.2 Cc. of normal sulphuric acid, no red tint should be imparted to the solution by the addition of a few drops of phenolphtalein T.S. (limit of potassium carbonate)"—(*U. S. P.*). These proportions correspond to about 0.138 per cent of carbonate. Prof. V. Coblentz (*Amer. Jour. Pharm.*, 1884, p. 543) found the carbonate to vary from 0.01 to 3.10 per cent. "If a little of the salt be held in a non-luminous flame on a perfectly clean platinum wire, the flame should be colored violet at once, without any appearance of yellow (absence of sodium). If diluted sulphuric acid be dropped upon crushed crystals of the salt, they should not at once assume a yellow color (absence of bromate). If 10 Cc. of the aqueous solution (1 in 20) of the salt be mixed with a little starch T.S., the addition of a few drops of chlorine water should not produce a blue color (absence of iodine). Ten Cc. of the aqueous solution (1 in 12) should not be rendered turbid by the addition of 0.5 Cc. of ammonia water and of 0.5 Cc. of ammonium sulphide T.S. (absence of iron, aluminum, etc.); nor should 10 Cc., after being slightly acidulated with acetic acid, be rendered turbid by an equal volume of hydrogen sulphide T.S. (absence of arsenic, lead, copper, etc.); nor by 0.5 Cc. of ammonium oxalate T.S. (calcium); nor by 0.5 Cc. of potassium sulphate T.S. (barium); nor by 0.5 Cc. of barium chloride T.S. (sulphate); nor be colored blue by 0.5 Cc. of potassium ferrocyanide T.S. (iron). If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should not require more than 42.85 Cc. of decinormal silver nitrate V.S. to produce a permanent red color of silver chromate (absence of more than 3 per cent of chloride)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt, whose therapeutic properties were discovered by accident while the drug was being tried as a substitute for the iodide, is the most important and most powerful of the bromides. The bromides as a rule have a bitterish and sharply saline taste, and when ingested are rapidly diffused throughout the system, and are eliminated by the kidneys, skin, salivary and intestinal glands and bronchial membranes. When the kidneys are inactive the effects of the bromides are much more pronounced. The effects of bromide of potassium on the system appear to be slightly similar to those of iodide of potassium, with the addition of a sedative influence upon irritable or excited conditions of the nervous system. When given in small doses and continued daily for several months it does not exert any injurious effect, and may be detected in the urine by the application of starch, and a few drops of chlorine, which impart a yellow color. If the alimentary canal is in an irritable condition its use is apt to produce diarrhœa. The same effect is produced by concentrated doses, and gastric catarrh is one of the untoward results of the long-continued administration of large doses of the bromides. It generally produces diuresis. The bromides derive their therapeutical efficiency from several effects, the chief of which probably is their sedative influence upon the sympathetic system of nerves. They are known to slow the action of the heart, and in the case of the potassium salt the base undoubtedly adds to the heart-depression; they diminish the supply of blood to the tissues, and reduce temperature. Two drachms of the potassium salt have reduced the temperature a half degree in a healthy adult; the tension of the arterioles is diminished and breathing is depressed by the bromides. The long-continued use of the bromides induces a diminished sensibility of the fauces, which is also produced by a solution locally applied, and a disturbed action of the muscles of deglutition. This action, as well as the impaired tactile sensation of all parts of the mucous tissues, the skin, and the palmar and plantar surfaces is thought to be due to the local action of the salt in being eliminated by these parts. Sexual desire and the power of erection are diminished by the bromides in large doses, the potassium salt being the most active in this respect. The protracted use of the salt in doses of from ½ to 2 drachms a day intensify the hypnotic effects which are produced by a few doses and a continual drowsiness is experienced. The breath becomes bromous and fetid, the fauces red and swollen and a condition known as *bromism* becomes established. This condition differs from the effects stated only in intensity, and among the chief symptoms are the following: Fetid breath, acneiform and other cutaneous eruptions, including boils, pustules and ulcers, diminished sensibility of the fauces, base of tongue, epiglottis and skin; slow, feeble heart-action, marked pallidity, anemia, cold extremities, general sense of coolness, breathlessness and quickened heart-action on the slightest exertion, tremulous and uncertain locomotion, suppression or repression of sexual desire; complete genital relaxation, disordered menstruation and a general inertia and heaviness of movement; drowsiness, generally with natural sleep, sometimes, however, lethargic; weakness of intellect, enfeebled memory, silly or meaningless laughter, headaches, mental confusion, and occasionally insanity, are among its effects. Pulmonary and gastric catarrh, with diarrhœa, or sometimes constipation, are common. Finally death, preceded by fever and coma, relieves the wreck of humanity of all his sufferings.

Of the bromides, the sodium salt is least, and the potassium compound the most toxic; lithium bromide is most active as a hypnotic, sodium bromide next, and potassium bromide least in hypnotic power (Bartholow). Ammonium bromide is the quickest to produce its effects.

Bromide of potassium is a very valuable therapeutical agent, but, in many respects, it has been greatly overrated. It is a very powerful nervo-sanguine sedative (Locke). As an alterative, for which it was first used, it is very inferior to the iodide. For this purpose, it has been successfully used in *enlarged spleen* and *liver*, *swelling of the lymphatic glands*, *scrofula*, *ovarian enlargements*, *goitre*, *catarrhal affections*, and *hypertrophy of the cardiac ventricles*. Potassium bromide is not a remedy in anemia and debility, but is efficient and applicable only in plethoric and sthenic conditions. Owing to its decided control over the genital organs, it is one of the best of remedies for *nocturnal emissions*, when the patient is full-blooded or plethoric, and there is excitation of the nervous system and the circulation. It does not benefit, and may even harm the pale, bloodless individual. The remedy acts best when the person is in fairly good health, but who, from lascivious dreams, and vascular excitement, and nervous irritability of the ejaculatory ducts, is an easy victim to *spermatorrhœa*. Often the venereal excitation is so pronounced as to more nearly resemble *satyriasis*. It is, therefore, a remedy for *sexual hyperæthesia*, with determination of blood to the genitalia.

If administered in proper cases, in *gonorrhœa*, it will prevent *chordee*, and may be given when that condition has already supervened. *Priapism*, due to various causes, in infants and young men, is relieved by this drug. *Hysteria*, bordering upon *nymphomania*, or when associated with sexual irritation, regular twitchings of the facial muscles, and abdominal or uterine throbbing, is signally relieved by this drug. It is equally efficient in many of the *nervous disorders of the menopause*, when plethora is prominent. In actual *nymphomania*, it is one of our best agents. For genital troubles, large doses are required—20 to 40 or 60 grains in plenty of water, 3 or 4 times a day; in nervous disturbances of females, 10 to 20 grains, 3 or 4 times a day. Bromide of potassium is not employed as an antipyretic by members of our school. It is, however, valued by some in *urethral fever*, caused by the introduction of instruments into the urethra, and by operations upon that canal. It may be used in the *delirium of fevers*, and in *cerebral*, *spinal*, or *cerebro-spinal inflammations*, when these conditions are sthenic. A very important property of the drug is its control over certain *spasmodic affections*. Thus it is frequently of value in *puerperal* and *infantile convulsions*, from teething or nervous irritation. After infantile convulsions have been controlled by chloroform, their return may be prevented by grain doses for each year of the child's age, every 1 or 2 hours. It has proved successful in *pertussis;* and also in *spasmodic asthma*, in doses of 20 or 30 grains, repeated 2 or 3 times a day.

It is useful in *nervous palpitation of the heart*, especially when there is cerebral fullness. It controls the *vomiting of pregnancy*, when not due to gastric wrongs; also acting well in *sea-sickness* and the *vomiting of congestion of the brain*. Furious *puerperal mania*, the *night terrors* of children, with *somnambulism*, reflex irritations in infantile complaints, and *headache*, from congestion, are conditions in which it has rendered very effectual service. The headache relieved by it, is associated with a flushed face, throbbing and fullness of the cerebral vessels, and great mental agitation. *Sthenic insomnia*, with the same symptoms without the headache, is promptly overcome by the drug. It is often combined with chloral and the other bromides in such disorders, and it may be used where opium would do harm. As a rule, cold applications to the head assist its action in headache. The dose should be about 25 grains to start with, followed every ½ hour by 10-grain doses. In *acute mania*, with violent manifestations, from 20 to 40 grains may be given every hour with excellent calmative effect, and in *delirium tremens*, with great excitation of the nervous and vascular systems, from 10 to 20 grains, each, of bromide of potassium and chloral hydrate, form an excellent treatment. It has cured in *tetanus* and *tetanus neonatorum*, and is antagonistic to strychnine. The *amblyopia* of the intemperate, and the *tinnitus* from the effects of quinine, are often relieved by it. Elixir of bromide of potassium is a favorite agent in some quarters to quickly overcome the effects of *drunkenness*. *Enteralgia* of children, with intense colicky pain and contraction or knotting of the intestines, purely nervous in character, and *spasmodic œsophageal stricture*, are relieved by this salt. Headache, due to *eye-strain*, is relieved by 10 to 15-grain doses of this drug, every 3 hours, but its protracted use is charged with causing recurrent corneal ulcers (Foltz).

Bromide of potassium is generally conceded to be the best-known remedy for *epilepsy*. It appears to protract the frequency, and render lighter attacks of epilepsy from any cause, but a cure can not be expected when the malady depends upon organic lesions or tumors, or upon sexual disorders, remediable only by operative procedures, as phimosis, or when congenital. It does, however, act better than any other agent when the trouble depends upon genital irritation, or irritation of the cerebellum, or fright. In the cases to which it is especially applicable, there is extreme susceptibility to external impressions and plethora. It must be given in from 15 to 40-grain doses, well diluted, 4 times a day, and continued until a complete saturation of the system is acquired, as evidenced by the acneiform eruptions. These cutaneous blemishes are said to be diminished or prevented by administering Fowler's solution with the salt. In cases of epilepsy, apparently cured, the drug should be continued for some time afterward.

Owing to its power of blunting the sensibility of the mucous tissues, it has been used to prepare the way for the passage of urethral bougies, and the use of the laryngoscope. Twenty to forty grains of the salt, mixed with an ounce of lard, forms an ointment useful in *bronchocele*, *enlarged spleen*, and *scrofulous tumors*; and this should be conjoined with the internal use of iodine, or the bromide. Solutions, ointments, or suppositories containing this salt, and introduced into the rectum, relieve *cystic irritability*, and are said to reduce *prostatic hypertrophy*. The dose of bromide of potassium ranges from 1 to 60 grains, 3 or 4 times a day.

Specific Indications and Uses.—Plethoric conditions, with vascular and nervous excitation; headache or insomnia, with throbbing pain and fullness in the cerebral vessels, and great mental excitation; spasmodic muscular contractions; restlessness and nervousness from sthenic conditions; violent mania; spermatorrhœa in the plethoric; nymphomania; satyriasis; epilepsy from sexual irritation or irritation of the cerebellum; strong sexual excitement; disorders associated with a vigorous circulation, without fever; extreme susceptibility to external impressions.

Related Compound.—BROMIDIA. A specialty of Battle & Co., of St. Louis, Mo. containing chloral hydrate, potassium bromide, and extracts of cannabis indica and hyoscyamus. The conditions in which it is used are *insomnia*, *nervousness*, *headache*, *neuralgia*, *nervous irritability*, *colic*, *mania*, *convulsions*, and *epilepsy*. As a sleep producer, the dose is from ½ to 1 fluid drachm, in water or syrup, every hour until sleep is induced.

Cæsium and Rubidium Salts.—These salts closely resemble the salts of potassium. Some of them are occasionally employed in medicine.

CÆSIUM AND AMMONIUM BROMIDE ($CsBr.3NH_4Br$).—Crystalline, white powder. Dissolves in water.

CÆSIUM HYDROXIDE ($CsOH$).—A somewhat deliquescent, grayish-white mass. With water, or alcohol, its behavior is similar to that of caustic potash.

CÆSIUM CARBONATE (Cs_2CO_3).—Very hygroscopic, white, sand-like compound, soluble in alcohol, and easily so in water.

CÆSIUM SULPHATE (Cs_2SO_4).—Colorless, permanent, anhydrous prisms, insoluble in alcohol, but very soluble in water.

CÆSIUM CHLORIDE ($CsCl$).—According to Botkin, this salt retards cardiac movements and increases the arterial pressure.

CÆSIUM BROMIDE ($CsBr$).—Prof. Laufenauer claims for this compound better results in *epilepsy* than from the other bromides.

RUBIDIUM AND AMMONIUM BROMIDE ($RbBr.3NH_4Br$).—A crystalline powder, white or yellowish-white, having a cooling, sharply saline taste, and easily dissolving in water. Rubidium has been found to exert medicinal actions similar to cæsium, and Laufenauer has used the above salt in doses of 1 to 2 drachms.

POTASSII CARBONAS (U. S. P.)—POTASSIUM CARBONATE.

FORMULA: K_2CO_3. MOLECULAR WEIGHT: 137.91.

SYNONYMS: *Salt of tartar*, *Carbonate of potassium*, *Carbonate of potash*, *Carbonate of potassa*, *Sal tartari*, *Potassii carbonas purus*, *Carbonas potassicus*, *Carbonas kalicus*, *Kali carbonicum*.

Source, History, and Preparation.—Potassium carbonate is a natural constituent of the waters of certain mineral springs. It is also one of the chief inorganic constituents of *ashes*, from inland plants, while plants growing near the sea yield more sodium carbonate. Other constituents of ashes are sodium, potassium, magnesium, and calcium, in the form of chlorides, sulphates, silicates, and phosphates. Ferric oxide, alumina, manganese, etc., are often present.

In former years, much potash was produced in the United States and Canada, but owing to the destruction of the woods, the manufacture has gradually declined; thus, the Canadian exports, in 1850, were more than twenty times those of the present day. (In this connection, see an interesting article on Canadian potash, by Dr. T. D. Reed, in *Proc. Amer. Pharm. Assoc.*, 1893, p. 126.) Russia and other countries around the Baltic Sea and of Europe furnish much of the present supply. Large quantities of potassium carbonate are now obtained as a by-product in the manufacture of sugar from sugar beets, these being rich in various potassium salts, which are accumulated in the uncrystallizable molasses. Another source of potassium carbonate is *suint*, the dried sweat of sheep contained in their wool. By evaporating the washings of the wool to dryness, and distilling the residue in iron retorts, an illuminating gas is obtained, and the charred residue in the retort yields to water carbonate of potassium (Clarke). The Stassfurt salt deposits are an indirect source of potassium carbonate. The chloride and sulphate of potassium there obtained are converted into carbonate by a process analogous to that of LeBlanc, for the manufacture of sodium carbonate (which see).

POTASH, or POTASHES or *Crude Potash*, is the brown mass obtained by lixiviating wood-ashes and evaporating to dryness, or to crystallization, in iron pots. The product is often melted in reverberatory furnaces in order to burn out carbonaceous matter. The resultant mass is yellow, brown, or greenish; the latter color is due to the presence of manganate. The American potash is often made by the use of lime, hence contains large quantities of caustic potash (see article on *Potassa*, for Prof. Lloyd's report on American potash).

PEARL ASH is purified crude potash, and is obtained by lixiviating the mass, allowing impurities (potassium sulphate) to crystallize out, boiling down to crystallization, freeing the crystals from adhering mother liquor (containing chlorides and silicates) by washing with a small amount of cold water, and finally heating the salt to redness. Pearl ash is the POTASSII CARBONAS IMPURA of the *U. S. P.*, 1870. According to its directions, it contained about 75 per cent of anhydrous potassium carbonate.

POTASSII CARBONAS (*U. S. P.*, 1890).—The potassium carbonate of the *U. S. P.*, 1880, was directed to be the compound $(K_2CO_3)_2.3H_2O$, which contains 83.7 per cent of the anhydrous salt; a minimum amount of 81 per cent was permitted, corresponding to a purity of 96.7 per cent. The present *U. S. P.* demands the salt K_2CO_3, and allows for an impurity of 5 per cent (see *Tests* below). The purest potassium carbonate may be obtained in several ways—by heating crystallized bicarbonate of potassium to redness, or by heating recrystallized potassium bitartrate to redness, until fumes are no longer disengaged, dissolving the carbonate in water, filtering from the charcoal formed, and evaporating the filtrate to crystallization. From this mode of preparation, potassium carbonate has received the name *salt of tartar*.

Description and Tests.—Carbonate of potassium, when exposed to the air, attracts moisture, speedily deliquesces, and forms an oleaginous fluid, termed by the earlier chemists *oleum tartari per deliquium*. Owing to its deliquescence, the *U. S. P.* directs that potassium carbonate should be kept in well-stoppered bottles. The official salt is "a white, granular powder, odorless, and having a strongly alkaline taste; very deliquescent. Soluble in 1.1 parts of water at 15° C. (59° F.), and in about 0.65 part of boiling water; insoluble in alcohol. When heated to 130° C. (266° F.), the salt loses all the water which it may have retained or absorbed; at a bright-red heat it melts, and at a white heat it volatilizes, communicating to the flame a pure violet color. Its aqueous solution (1 in 20) has a strongly alkaline reaction upon litmus paper, and effervesces with acids"—(*U. S. P.*). The effervescing gas is characterized as carbonic acid by the turbidity it will cause in a drop of lime-water held into it at the end of a glass rod. The potassium in the above solution may be recognized by the precipitate yielded with solution of platinic chloride, as well as by the following *U. S. P.* tests: "With excess of tartaric acid T. S. it slowly yields a white, crystalline precipitate; with sodium cobaltic nitrite T.S., a copious yellow precipitate is formed at once"—(*U. S. P.*).

Impurities in potassium carbonate are recognized by the following *U. S. P.* tests: "When a small portion of the salt, treated with a drop of hydrochloric acid, is introduced into a non-luminous flame on a perfectly clean platinum wire, the flame should be colored violet at once, without any appearance of yellow (absence of sodium). No residue should be left on dissolving 1 Gm. of the salt in 20 Cc. of water (absence of earthy impurities). No precipitate or coloration should be produced in the aqueous solution (1 in 20) by an equal volume of hydrogen sulphide T.S. (absence of metallic impurities). On neutralizing the solution with hydrochloric acid, no odor of burning sulphur, nor any white precipitate, should appear (absence of hyposulphite). If 2 Cc. of the aqueous solution (1 in 20) be carefully mixed with an equal volume of concentrated sulphuric acid, and, after cooling, 1 Cc. of ferrous sulphate T.S. be poured upon it so as to form a separate layer, no brown color should appear at the line of contact (absence of nitrate). If 0.5 Gm. of potassium carbonate be dissolved in 5 Cc. of diluted hydrochloric acid and 5 Cc. of water, the addition of 1 Cc. of barium chloride T.S. should not produce any turbidity (absence of sulphate). A solution of 0.5 Gm. of the salt in 5 Cc. of diluted hydrochloric acid mixed with 5 Cc. of water, should not be colored blue within 15 minutes by 0.3 Cc. of potassium ferrocyanide T.S. (limit of iron). If 0.5 Gm. of the salt be dissolved in 6 Cc. of diluted nitric acid and 4 Cc. of water, then 0.1 Cc. of decinormal silver nitrate V.S. be added, and the mixture filtered, no change should be produced in the filtrate by the further addition of silver nitrate V.S. (limit of chloride). If 10 Cc. of the aqueous solution (1 in 20) be mixed with 2 drops, each, of ferrous sulphate T.S. and ferric chloride T.S., and the mixture heated, and slightly supersaturated with hydrochloric acid, no blue color should appear (absence of cyanide)"—(*U. S. P.*). This important test is based on the conversion of potassium cyanide into potassium ferrocyanide when in contact with ferrous sulphate, as follows: $2FeSO_4+12CNK=Fe_2(CN)_{12}K_8+2H_2SO_4$. The potassium ferrocyanide then reacts in acid solution with ferric chloride, forming Prussian blue (see *Ferri Ferrocyanidum*). "The addition of a few drops of lead acetate T.S. to the aqueous solution should produce a pure white precipitate (absence of sulphide). To neutralize 0.69 Gm. of potassium carbonate should require not less than 9.5 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 10 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*). (For a convenient method of determining potassium carbonate and potassium hydroxide in one operation, see *Potassa*.)

Action, Medical Uses, and Dosage.—All the carbonates of potassium are sufficiently corrosive to be energetic poisons. They occasion destruction of the mucous membranes of the fauces, œsophagus, stomach, and sometimes of the intestines—indicated at first by violent burning pain, prostration and vomiting, which is sometimes bloody, and if death does not ensue in consequence, in a few days, excessive emaciation follows, and constant irritation of the stomach and bowels. The proper antidotes to them are vinegar, lemon juice, or fixed oil.

Medicinally, carbonate of potassium is antacid, antilithic, and diuretic. Useful in *urinary affections*, where the morbid secretion consists of lithic acid, and the lithates, for which about 35 grains, in divided doses, should be given in the course of a day. Some prefer the potassium carbonates to the corresponding sodium salts, for antilithic purposes, on the supposition that they are the more energetic solvents. It is sometimes used in solution as an injection into the bladder for *calculus*. It has also been employed to remove *acidity of stomach*, and to increase the urinary discharge in *dropsical affections*. It has also been found occasionally available in *jaundice*. Mascagni has used it in *pneumonia* and other *inflammatory diseases*, with benefit, especially in those forms where there is a tendency to the deposition of false membranes. Combined with cochineal, it has considerable reputation in the treatment of *pertussis*. The *Cochineal mixture* is made as follows: Dissolve carbonate of potassium, 20 grains, in a gill of water, and add to it 10 grains of powdered cochineal, sweeten with loaf sugar, and give to an infant a teaspoonful 4 times a day; to a child 2 or 3 years old, 2 teaspoonfuls; 4 years and upwards, a tablespoonful or more. To this preparation 5 to 15 drops of tincture of belladonna is sometimes added. Externally, it has been used in the form of a solution to *wounds*, as a collyrium in some *affections of the cornea*, as an injection in *gonorrhœa*, and as an application to some *obstinate cutaneous eruptions*. Dose, of the powder, in solution, from 5 to 30 grains. For external use, ½ to 1 pound is usually employed for a bath; from 6 to 12 grains to the fluid ounce of water, for a lotion; and from 10 to 60 grains to an ounce of lard, for an ointment.

Carbonate of potassium, free from impurities, is used in making the common effervescent draught, or citrate of potassium. *Liquor Potassæ Carbonatis* (*Solution of carbonate of potassium*) is made by dissolving 20 ounces of carbonate of potassium in distilled water, 1 pint (Imp. meas.), and then filtering the solution. The dose is from 10 to 60 drops, in a sufficient quantity of water or mucilaginous fluid.

Specific Indications and Uses.—Leaden pallor of the tongue and mucous surfaces; muscular tremors; debility, all out of proportion to the diseased condition; articular pains.

POTASSII CHLORAS (U. S. P.)—POTASSIUM CHLORATE.

FORMULA: $KClO_3$. MOLECULAR WEIGHT: 122.28.

SYNONYMS: *Chlorate of potash, Chloras potassicus, Chloras kalicus, Kali muriaticum oxygenatum, Kali oxymuriaticum, Hyperoxymuriate of potassa.*

History and Preparation.—This salt was prepared as early as 1786 by Higgins, but its chemical character was distinctly pointed out in the same year by Berthollet. This author prepared it by the action of chlorine gas upon caustic potash, the following reaction taking place: $6KOH+6Cl=5KCl+KClO_3+3H_2O$. The present methods are modifications of this process, intended to improve the yield, because, as the formula shows, only one-sixth of the potassium is converted into chlorate. According to Liebig's proposition, an aqueous solution of chlorinated lime is evaporated to dryness. The calcium hypochlorite which it contains is thereby converted into calcium chlorate as follows: $3Ca(OCl)_2=Ca(ClO_3)_2+2CaCl_2$. The calcium chlorate is then dissolved in water and treated with potassium chloride; by double decomposition, potassium chlorate results, according to the equation $Ca(ClO_3)_2+2KCl=CaCl_2+2KClO_3$. The present methods of making potassium chlorate, on a large scale, are based on these reactions. Chlorine gas is conducted into milk of lime to saturation, the solution is evaporated to a certain bulk, treated with potassium chloride, and allowed to crystallize.

Description and Tests.—As officially described, potassium chlorate forms "colorless, lustrous, monoclinic prisms or plates, or a white powder, odorless, and having a cooling, saline taste. Permanent in the air. Soluble in 16.7 parts of water at 15° C. (59° F.), and in 1.7 parts of boiling water; insoluble in absolute alcohol, and but slightly soluble in mixtures of alcohol and water. At 234° C. (453.2° F.), the salt fuses, and above 352° C. (665.6° F.), it is decomposed into oxygen and potassium perchlorate; above 400° C. (752° F.), all its oxygen is liberated, and a white residue of potassium chloride remains, amounting to 60.8 per cent of the chlorate employed. The residue is readily soluble in water, and the solution yields a white, curdy precipitate with silver nitrate T.S. The aqueous solution (1 in 20) of the salt is neutral to litmus paper. With excess of tartaric acid T.S., the solution slowly yields a scant, white, crystalline precipitate; with sodium cobaltic nitrite T.S., or with platinic chloride T.S., a copious yellow precipitate is produced at once. When introduced into a non-luminous flame on a clean platinum wire, potassium chlorate communicates to the flame a pure violet color without admixture of yellow (absence of sodium). When heated with hydrochloric acid, the aqueous solution assumes a greenish-yellow color, and evolves chlorine"—(*U. S. P.*). Triturated with combustible substances, chlorate of potassium is highly dangerous, even in small quantities, hence the pharmacopœial caution: "Potassium chlorate should be kept in glass-stoppered bottles, and *great caution should be observed* in handling the salt, as dangerous explosions are liable to occur, when it is mixed with organic matters (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and either heated directly, or subjected to trituration or concussion"—(*U. S. P.*). Mr. Charles Bullock reports (*Amer. Jour. Pharm.*, 1890, p. 385) that a mixture of chlorate of potassium and chloride of ammonium gradually undergoes decomposition with evolution of chlorine compounds. In one instance, some tablets, composed of the two salts mentioned, and more than one year old, underwent a sudden explosion, probably due to the formation of the highly explosive chloride of nitrogen. Concentrated sulphuric acid, when acting upon potassium chlorate, evolves free chloric acid, which at once yields the highly explosive *chlorine dioxide* (ClO_2). At a comparatively low temperature it decomposes, with explosion, into chlorine and oxygen. The chlorine evolved when potassium chlorate is mixed with hydrochloric acid, contains some chlorine dioxide, and was believed by Sir Humphrey Davy to be a new oxide of chlorine, which he named *euchlorine*. In reducing chlorate of potassium to powder by trituration, a little water should be added, enough to cover the salt, in order to prevent an explosion. Strain, and dry the powder. In order to test potassium chlorate for impurities, the *U. S. P.* directs as follows: "Separate portions, each of 5 Cc., of the aqueous solution (1 in 20) should not be rendered turbid by 0.5 Cc. of barium chloride T.S. (absence of sulphate); nor by 0.5 Cc. of ammonium oxalate T.S. (calcium); nor by 0.5 Cc. of silver nitrate T.S. (chloride); nor should an equal volume of hydrogen sulphide T.S., produce either a precipitate or a coloration (absence of metals). If a mixture of 1 Gm. of the salt with 0.5 Gm., each of iron and of zinc, in coarse powder or filings, be heated with 5 Cc. of potassium hydrate T.S., no evolution of ammonia should be perceptible either by moistened red litmus paper or by odor (absence of nitrate or nitrite)"—(*U. S. P.*). (For Jorisen's test for nitrate, see *Amer. Jour. Pharm.*, 1888, p. 489.)

Action, Medical Uses, and Dosage.—The theory, formerly entertained, that chlorate of potassium acted by giving to the blood oxygen, and thereby imparting to it a florid color, has been disproved, as it is now known that the salt is eliminated unchanged from the system, and that largely by the salivary glands. In very large doses, it is extremely poisonous, producing, besides the effects of potash, violent local inflammation. Gastro-intestinal inflammation, with violent pain and vomiting, and finally ending in death, was produced by 300 grains of the salt. Death, when caused by it, is believed to be due to the disorganization of the corpuscles, rendering them incapable of carrying oxygen, and from the obstruction of the renal emunctories with these broken-down discs, and the presence of crystals of the salt. The blood, though remaining fluid, is changed to a chocolate color, due to the transformation of oxyhæmoglobin into methæmoglobin. The organs containing blood also show this discoloration. Splenic and hepatic enlargements may ensue. Autopsies have revealed the following results of poisoning with this salt: The changes, besides the hypertrophies referred to above, were found chiefly in the gastro-intestinal tube and the kidneys. In the former were hyperemic, or inflamed, or eroded tracts, and, in the latter, the organs were found greatly enlarged, with adherent capsule and œdematous infiltration, overdistension of the renal vessels, and brownish plugs with adherent epithelial detachments in the uriniferous tubules. A physician, who took an ounce, died after 7 days of suffering from gastro-enteritis. At first diuresis was free, but finally suppressed. Daily doses of 160 grains have produced hot skin, headache, quick hard, and full pulse, white tongue, and increase of urine.

A typical case of poisoning by the drug may present the following symptoms: Faintness, great thirst, vomiting, hypochondrial and renal pain, headache, constipation or diarrhœa, chills, lowering of temperature, anemic skin, slight jaundice, and cyanosis. The urine is almost or quite suppressed, and, when voided at all, is very albuminous, and deposits tube-casts and a sediment of brown, altered blood discs. These, filtered out, leave the urine cherry-red in color. The chief lesions then are gastro-intestinal inflammation and acute nephritis, death being chiefly due to the blood destruction, producing profound anemia, and the plugging of the renal tubules, causing nephritis. The treatment of chlorate of potassium poisoning recommended, consists in the use of hot baths, saline cathartics and diuretics, and the transfusion of blood.

Chlorate of potassium is a very important remedy, particularly where there is a tendency to septicæmia. Besides its marked antiputrefactive properties, it seems to hold a position between chloride of ammonium and nitrate of potassium, and has been used in *malignant febrile diseases*, and in *cholera*. It is diuretic, and is recognized in the urine of those to whom it has been administered. The keynote to its selection is a cadaverous fetor of the secretions and breath. Under such circumstances, it is very useful in the affections named herein. It has been efficiently employed in *scorbutus*, *hepatic affections*, in *aphthous ulcerations of the mouth*, *cancrum oris*, *mercurial salivation*, *abscesses*, *boils*, *eruptions*, *ulcers*, *purpura hemorrhagica*, etc. In *ulcerative stomatitis*, where the ulcers spread to the tongue, gums, and lips, smell badly, and the gums are spongy and bleed easily, it is especially applicable. In these cases, there are pseudo-membranous deposits, and the lesions show very little disposition to recovery. Here a wash of the chlorate, with the drug taken internally, will promptly effect a cure. Associated with stillingia, it is a good agent in *syphilis* and *syphilitic ulcerations* of the mouth with cadaveric fetor. It is a useful agent in *diphtheria*, with the special indication referred to, but the kidneys should be carefully watched, and, if affected, the drug should be withdrawn. Chlorate of potassium is a much abused, but excellent agent. It has long been in domestic repute as a remedy for *ordinary sore throat*, and its indiscriminate and misapplied use has often failed in curing the trouble, but has, at times, led to serious renal disturbances. When indicated by the cadaverous odor of the breath, and bluish, pallid membranes, or ulcerated, foul discharging mucous surfaces, it is an excellent therapeutic agent in respiratory lesions. Under these conditions, it may be used locally in *influenza*, *ozæna*, and in the various forms of *pharyngitis*. Applied early, it often aborts *tonsillitis*. In *pneumonia*, with hot, pungent skin, putrid odor of breath, and increased secretion, it may be given in 5 or 10-grain doses, every 3 hours. It is also useful in *fetid purulent bronchitis*. As a remedy for *cough*, it is serviceable if the indications are followed, but should not be used when the mucous surfaces are dry, or when the urinary secretion is scanty. In *membranous croup*, it tends to prevent the formation of the membrane, and to favor its detachment when formed. For the *aphthous condition of the mouth*, with extensive tissue destruction, in *phthisis*, and where the patient can not take food, Prof. Locke recommends (Locke's *Syllabus*) the following: ℞ Saturated solution of potassium chlorate, ℥iv; colorless hydrastis, glycerin, syrup of morphine and simple syrup, aa, ℥i. Mix. Sig. Dose, 1 teaspoonful every 3 hours. In *scrofula*, it may be given with chloride of iron and syrup; in *chronic cystitis*, with putrid urine, it may be given in infusion of buchu. Use the drug in *erysipelas*, threatening *gangrene*. When large doses are administered, they should be given at meal-time, and in a large quantity of broth or other fluid. M. Isambert considers it a sedative to the nervous system, and to the circulation; a stimulant to the digestive organs and kidneys; and a stimulant and alterative to mucous tissues. It certainly proves very useful in *leucorrhœa*, *excoriations of the os uteri*, *chronic dysentery*, *nursing sore mouth*, some forms of *chronic ophthalmia*, and *gleet*. Its solution, used in injection, has effected cures of *leucorrhœa*, *erosion of the os uteri*, and *gonorrhœa*. It controls salivation. Perhaps its most important use is in obstetric practice, to correct the tendency to *septic conditions*, where there is *offensive lochia* and fetid discharges from retained clots and fragments of placenta. The better practice is to remove these disturbers by curetting and douching, but when this has not been done, the chlorate serves the purposes of controlling the tendency to putrescency. The offensive odor, reminding one of the dissecting room, here plainly points to the use of it, as in other conditions. It may be used both locally and internally, well diluted. As a rule, its use should be avoided in scarlatina, lest a nephritic complication should occur, and it is contraindicated when the mucous tissues are dry and secretion scanty. Applied in the form of powder with starch, or oxide of bismuth, it causes but little pain. In *gangrene* and *ulceration of the mouth*, it removes the offensive odor, lessens the discharge of saliva, and favors granulation. Daily applied, the powder has cured small *epithelial growths of the eyelids* (Foltz). Externally, it may be applied in solution as a wash or injection; from 6 to 15 grains being dissolved in a fluid ounce of water. It answers thus, in affections of the mouth, aided by its internal administration. The dose ranges from 1 to 30 grains, well diluted with water.

Specific Indications and Uses.—The puerperal antiseptic; troubles arising from decomposition of fragments of placenta, blood-clots, and absorption of lochia; fetid lochia; fetid breath; the fetor, as of decaying animal tissues; pallid tongue, pale or bluish membranes; ulcerated, foul-discharging mucous surfaces; tender mouth and gums, with fetid salivation; tongue coated, dirty, and thick; cough, with purulent expectoration; hot, pungent skin; cadaverous odor of discharges.

Related Salts.—POTASSII PERCHLORAS ($KClO_4$=138.24), *Potassium perchlorate*, *Hyperchlorate of potassium*. Melt potassium chlorate, and continue heating until the evolution of oxygen nearly ceases, and the mass becomes solid. The following reaction takes place: $2KClO_3 = KClO_4 + KCl + O_2$. Decomposition of the chlorate is nearly complete when a sample, treated with strong hydrochloric acid, produces only a light-yellow color. Remove the chloride formed by washing with cold water, the perchlorate being not easily soluble. The last traces of chlorate are removed by warming with hydrochloric acid. When crystallized, potassium perchlorate forms colorless, rhombic crystals, feebly saline to the taste, insoluble in alcohol, freely soluble in hot water, but not easily soluble in cold water. At a high heat (400° C. [752° F.]) it splits into potassium chloride and oxygen. It is employed in the preparation of perchloric acid, and as a medicine. According to Rabuteau (*Bull. de Thérap.*, 1869), it is useful as a diuretic and sedative in cases where quinine and potassium nitrate are applicable. It has been given in *pernicious fevers*, and in *intermittents*.

POTASSII CHLORIDUM (KCl = 74.40), *Potassium chloride*, *Sal digestivum sylvii*, *Kalium chloridum* or *chloratum*, *Chloruretum potassicum*.—This salt is used to a considerable extent in the preparation of potassium compounds. It occurs native abundantly as *sylvine* (KCl) and *carnallite* (KCl–$MgCl_2+6H_2O$), in the Stassfurt deposits, in the form of colorless or white cubes, without odor, but resembling sodium chloride in taste. It is but little soluble in alcohol, and freely so in 2 parts of hot and 3 parts of cold water. Care should be taken, on account of its obsolete name, *Kalium chloratum*, not to confuse this salt with *Potassium chlorate*. It is said to be a nervous and arterial sedative, and, in large doses, is poisonous. Such doses produce a jaundiced or a slate-hued skin, suppress the urine, which is dark in color and sometimes contains albumen, and also diarrhœa and vomiting. One hundred and fifty grains, in divided doses, killed a strong individual. It is employed as a medicine much as common salt is. It is inoperate in *epilepsy*, for which it has been tried. Potassium chloride is one of the Schuessler tissue salts, and is valued by Schuessler's followers to prevent the deposition of plastic exudates in acute disorders, as *pneumonia*, and in *chronic hepatic affections*, where fibrous changes are anticipated. It is claimed that it reduces *congestion of the liver*, and, if given early, will prevent suppuration in *acute hepatitis*. It has been overestimated as a remedy to prevent *diphtheritic deposits*. It is also given in *boils, pimples, carbuncles*, etc. Five grains of the 3x trituration are added to 4 fluid ounces of water, and the solution administered in teaspoonful doses, every 2 to 4 hours.

POTASSII CITRAS (U. S. P.)—POTASSIUM CITRATE.

FORMULA: $K_3C_6H_5O_7+H_2O$. MOLECULAR WEIGHT: 323.59.

SYNONYMS: *Citrate of potassium, Citrate of potash, Potassæ citras, Kali citricum, Citras kalicus, Citras potassicus, Kalium citricum.*

Preparation.—"Take of carbonate of potassium, 8 ounces (av.), or a sufficiency; citric acid, in crystals, 6 ounces, or a sufficiency; distilled water, 2 pints (Imp.). Dissolve the citric acid in the water, add the carbonate of potassium gradually, and, if the solution be not neutral, make it so by the cautious addition of the acid or the carbonate of potassium. Then filter, and evaporate to dryness, stirring constantly after a pellicle has begun to form, till the salt granulates. Triturate in a dry mortar, and preserve the powder in stoppered bottles"—(*Br. Pharm.*, 1885). The process is one of simple neutralization, as follows: $3K_2CO_3+2H_3C_6H_5O_7=2K_3C_6H_5O_7+3H_2O+3CO_2$. If evaporation is conducted on a sand-bath, care should be taken not to burn the salt.

Description and Tests.—"Transparent, prismatic crystals, or a white, granular powder, odorless, and having a cooling, saline taste. Deliquescent on exposure to air. Soluble in 0.6 part of water at 15° C. (59° F.), and very soluble in boiling water; sparingly soluble in alcohol. When heated above 100° C. (212° F.), the salt begins to lose water; at 200° C. (392° F.), the water of crystallization (5.55 per cent) is completely lost. At 230° C. (446° F.), the salt begins to decompose, turns brown, and, at a higher temperature, carbonizes and emits inflammable gases, which have a very pungent, acid odor. At a red heat, a blackened mass of potassium carbonate and carbon is left, which has an alkaline reaction, and strongly effervesces with acids. The aqueous solution of the salt is neutral to litmus paper. The salt yields a white, crystalline precipitate with sodium bitartrate T.S. With sodium cobaltic nitrite T.S., a yellow precipitate is formed. On mixing 10 Cc. of the aqueous solution (1 in 20) with 2.5 Cc. of calcium chloride T.S., the liquid remains clear until it is boiled, when a white, granular precipitate is produced"—(*U. S. P.*). This precipitate consists of neutral calcium citrate ($[C_6H_5O_7]_2Ca_3+4H_2O$), and is distinguished from the corresponding tartrate by being insoluble in excess of caustic potash. It is soluble in acetic acid (difference from calcium oxalate and racemate) (see *Tartaric Acid*).

The *U. S. P.* directs the following tests: "The aqueous solution (1 in 20) should not be colored red by a drop of phenolphtalein T.S., nor effervesce on the addition of an acid (absence of carbonate). Separate portions of this solution acidulated with nitric acid should not be affected by barium chloride T.S. (absence of sulphate), nor by silver nitrate T.S. (absence of chloride). A solution of 1 Gm. of potassium citrate in 1 Cc. of water should not deposit any precipitate on the addition of 1 Cc. of acetic acid (absence of tartrate)"—(*U. S. P.*). This test is based on the formation of cream of tartar (potassium bitartrate) upon the addition of acetic acid. "If 1.08 (1.079) Gm. of potassium citrate be thoroughly ignited at a red heat, it should require for complete neutralization not less than 10 Cc. of normal sulphuric acid (corresponding to 100 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(See *Liquor Potassii Citratis.*) Dose, 20 to 40 grains, well diluted with water.

POTASSII CITRAS EFFERVESCENS (U. S. P.)—EFFERVESCENT POTASSIUM CITRATE.

Preparation.—"Citric acid, sixty-three grammes (63 Gm.) [2 ozs. av., 97 grs.]; potassium bicarbonate, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; sugar, forty-seven grammes (47 Gm.) [1 oz. av., 288 grs.]. Powder the ingredients separately, and mix them thoroughly in a warm mortar. Dry the resulting, uniform paste rapidly at a temperature not exceeding 120° C. (248° F.), and, when it is perfectly dry, reduce it to a powder of the desired degree of fineness. Keep the product in well-stoppered bottles"—(*U. S. P.*).

This effervescing salt, when made into solution, is pleasantly acidulous. Lest decomposition take place, the temperature above directed should not be exceeded, for, under such circumstances, fusion and discoloration of the salt takes place, and an unpleasant, bitter taste develops.

Action, Medical Uses, and Dosage.—A pleasant form of administering potassium citrate. As a laxative, 100 grains may be dissolved in a glass of water.

POTASSII CYANIDUM (U. S. P.)—POTASSIUM CYANIDE.

FORMULA: KCN. MOLECULAR WEIGHT: 65.01.

SYNONYMS: *Cyanide of potash, Potassii cyanuretum, Cyanuret of potassium, Potassii cyanidum, Kalium cyanatum, Cyanuretum kalicum, Cyanuretum potassicum.*

Preparation.—Chemically pure potassium cyanide may be prepared by conducting the vapors of hydrocyanic acid into an alcoholic solution of potassium hydroxide. The cyanide, being nearly insoluble in alcohol, is precipitated in the form of a crystalline powder. The hydrocyanic acid is obtained by the action of diluted sulphuric acid upon potassium ferrocyanide (yellow prussiate of potash) (see *U. S. P.* process under *Acidum Hydrocyanicum Dilutum*). Usually potassium cyanide is prepared by Liebig's method, which consists in melting together previously dried potassium ferrocyanide (yellow prussiate of potash) 8 parts, with pure potassium carbonate (dried), 3 parts. The *U. S. P.* (1870) directs as follows: "Mix the salts intimately, and throw the mixture into a deep, iron crucible, previously heated to redness. Maintain the temperature until effervescence ceases, and a portion of the fused mass, of a pure white color, concretes upon a warm glass rod dipped into it. Then pour the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt becomes contaminated with the precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stoppered bottle"—(*U. S. P.*, 1870).

The reaction takes place with formation of potassium cyanate (KOCN) and liberation of carbonic acid gas and iron, as follows: $Fe_2(CN)_{12}K_8+2K_2CO_3=10KCN+2KOCN+CO_2+Fe_2$. The formation of the cyanate may be prevented by adding charcoal, or the potassium cyanate may be dissolved out by means of alcohol. The *French Codex* prepares a purer potassium cyanide by strongly heating potassium ferrocyanide alone, whereby nitrogen is evolved and iron carbide formed, as follows: $Fe_2(CN)_{12}K_8=8KCN+2FeC_2+N_4$. The *U. S. P.* demands an article of 90 per cent strength.

Description and Tests.—As officially demanded, it forms "white, opaque, amorphous pieces, or a white, granular powder, odorless when perfectly dry, but, in moist air, exhaling the odor of hydrocyanic acid. The taste is sharp, and somewhat alkaline, but should be ascertained with great care, as the salt is very poisonous. In moist air the salt deliquesces. Soluble in about 2 parts of water at 15° C. (59° F.). Boiling water dissolves its own weight of the salt, but rapidly decomposes it. In alcohol it is but sparingly soluble. At a low red heat the salt fuses. Its aqueous solution (1 in 20) has a strongly alkaline reaction, and emits the odor of hydrocyanic acid. With an equal volume of sodium bitartrate T.S., it yields a white, crystalline precipitate. With sodium cobaltic nitrite T.S., a copious yellow precipitate is produced"—(*U. S. P.*). With soluble salts of heavy metals, potassium cyanide forms precipitates of metallic cyanides, soluble, as a rule, in excess of potassium cyanide, with the formation of double salts (see *Potassium Ferrocyanide*). The salt, when fused with access of air, attracts oxygen, and forms potassium cyanate. The salt is decomposed by the weakest acids, even carbonic acid, hence its odor of hydrocyanic acid. "Potassium cyanide should be kept in well-stoppered bottles"—(*U. S. P.*). Possible impurities in potassium cyanide consist in unchanged carbonate, ferrocyanide, potassium cyanate, etc., which are detected by the following official tests: A few drops of an aqueous solution (1 in 20) "give with silver nitrate T.S., a white precipitate, which is soluble in an excess of the solution of potassium cyanide, also in ammonia water, and in concentrated nitric acid (distinction from silver chloride). If 5 Cc. of the solution be shaken with a few drops of ferrous sulphate T.S., and a slight excess of hydrochloric acid then added, a blue precipitate (Prussian blue) will be produced. The aqueous solution (1 in 20) should not produce more than a slight effervescence on the addition of diluted hydrochloric acid (limit of carbonate). After the acid has been added in slight excess, a drop of ferric chloride T.S. should produce neither a blue (absence of ferrocyanide) nor a red color (sulphocyanate). A solution of 0.65 Gm. of potassium cyanide in 12 Cc. of water should require the addition of at least 45 Cc. of decinormal silver nitrate V.S. before the precipitate, which at first redissolves on agitation, becomes permanent (each cubic centimeter of the volumetric solution indicating 2 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt ranks in activity as a poison next to hydrocyanic acid (see *Acidum Hydrocyanicum* for action). Medicinally, it has been preferred to hydrocyanic acid, on account of its not so readily becoming decomposed, and being more constant in its strength. It is used in all instances where hydrocyanic acid is indicated, in the dose of about ⅛ of a grain, or less, and should be given in a tablespoonful of pure water, or diluted aromatic syrup. Great care must be employed in using it, if, indeed, it should be used at all. It adds to the efficiency of some *cough remedies*. Externally, it has been efficiently used in *sick headache*, *neuralgia*, *sciatica*, *rheumatism*, etc., being applied to the part on lint or linen, in the proportion of 8 grains of the cyanide to 2 fluid ounces of distilled water, keeping the part constantly moistened with it. This solution is one of the promptest agents for the removal of silver nitrate stains. The dark spots produced by nitrate of silver on the conjunctiva, are obliterated by dropping the solution of the cyanide into the eye on each alternate day (Guthrie). As this salt is extensively used in photography, silver plating, etc., numberless cases of poisoning have occurred from its use. Three grains internally have produced death. The treatment is the same as for hydrocyanic acid (which see). Atropine may be employed to antagonize its effects.

Specific Indications and Uses.—Same as for *Hydrocyanic Acid* (which see).

POTASSII ET SODII TARTRAS (U. S. P.)—POTASSIUM AND SODIUM TARTRATE.

FORMULA: $KNaC_4H_4O_6+4H_2O$. MOLECULAR WEIGHT: 281.51.

SYNONYMS: *Rochelle salt, Tartarated soda, Soda tartarata, Natrokali tartaricum, Tartras potassico-sodicus, Sal polychrestum Seignetti, Seignette's salt, Sodæ et potassæ tartras.*

History and Preparation.—This salt was introduced as a secret medicine, in 1672, by Seignette, an apothecary of Rochelle, France. Its composition and preparation was made known, in 1731, by Boulduc and Geoffroy. It is a double salt, tartrate of potassium and sodium ($C_4H_4O_6KNa+4H_2O$), and is prepared by neutralizing acid potassium tartrate (see *Potassii Bitartras*) with sodium carbonate. The following process agrees with that of the formula of the *British Pharmacopœia* (1898): Take of bitartrate of potassium, in powder, 16 ounces; carbonate of sodium, 12 ounces; boiling water, 4 pints (Imp. meas.). Dissolve the carbonate in the water, add the bitartrate to neutralization; boil and filter. Concentrate the liquor till a pellicle forms on its surface, and then set it aside to cool and crystallize. The residual liquor will yield more crystals by further concentration and cooling (*Ed.*). The *U. S. P.* (1870) employed the same weights (troy) and 5 pints of water; in other respects the process is the same.

Description and Tests.—Tartrate of potassium and sodium often forms crystals of a considerable size. The *U. S. P.* describes the salt as in "colorless, transparent, rhombic prisms, or a white powder, odorless, and having a cooling, saline taste. The crystals slightly effloresce in dry air. Soluble in 1.4 parts of water at 15° C. (59° F.), and in less than 1 part of boiling water; almost insoluble in alcohol. When heated to 74° C. (165.2° F.), the salt fuses to a colorless liquid, which, at a higher temperature, froths, becomes brown, and gradually carbonizes, while inflammable vapors are emitted, having the odor of burning sugar. Finally, a black residue is left, consisting of alkaline carbonate mixed with carbon. The aqueous solution of the salt is neutral to litmus paper. A 10 per cent aqueous solution yields, with an equal volume of acetic acid, a white, crystalline precipitate. With sodium cobaltic nitrite T.S., the solution yields a copious yellow precipitate. With silver nitrate T.S., it produces a white precipitate, which becomes black on boiling. To a non-luminous flame it communicates a yellow color (sodium), which, when viewed through a blue glass, appears violet-red (potassium)"—(*U. S. P.*). Sulphuric acid, added to the aqueous solution, combines with the sodium, and replacing it by hydrogen, causes a precipitate of small crystals of bitartrate of potassium; perchloric acid precipitates perchlorate of potassium; platinum tetrachloride gives a yellow precipitate. The solution of the salt is incompatible with acetate of lead, soluble barium and calcium salts, many acids, and salts containing excess of acid.

To test for impurities, the *U. S. P.* directs: "The aqueous solution (1 in 20) should not be rendered turbid by the addition of a small amount of ammonium oxalate T.S. (absence of calcium), nor by an equal volume of hydrogen sulphide T.S., either before or after acidulation with diluted hydrochloric acid (absence of arsenic, lead, copper, etc.). When heated with potassium hydrate T.S., the solution should not give off the odor of ammonia. If 10 Cc. of the solution (1 in 20) be mixed with 1 Cc. of hydrochloric acid, the addition of 1 Cc. of barium chloride T.S. should produce no turbidity (absence of sulphate). If 0.36 Gm. of the salt be dissolved in 9 Cc. of water, and then 1 Cc. of nitric acid and 0.2 Cc. of decinormal silver nitrate V.S. be added, and the mixture filtered, the filtrate should remain clear upon the further addition of silver nitrate V.S. (limit of chloride). If 1.41 Gm. of potassium and sodium tartrate be completely decomposed by ignition, the alkaline residue should require for complete neutralization not less than 10 Cc. of normal sulphuric acid (corresponding to 100 per cent of the pure salt), methyl orange being used as indicator"—(*U. S. P.*). Mr. F. W. Haussmann (*Amer. Jour. Pharm.*, 1894, p. 296), reporting on about 10 samples of commercial Rochelle salt, both in crystals and powder form, found them to be of a high degree of purity, especially free from lead.

Action, Medical Uses, and Dosage.—Tartrate of potassium and sodium is a mild, laxative, cooling salt, rather more agreeable than most neutral salts, and adapted for irritable or fastidious stomachs. Its dose is from 2 drachms to an ounce, dissolved in 8 to 10 parts of water. When given in the form of dilute solution, and so as not to excite purging, it becomes absorbed, and produces alkalinity of the urine; consequently, its use should be avoided in phosphatic urine, but is of advantage in *excessive acidity of the urine*, and has been employed with success in *acute rheumatism*, with acidity of the urine. Two drachms of tartrate of potassium and sodium added to 40 grains of bicarbonate of sodium, and put up in one (blue) paper, and 35 grains of tartaric acid, placed in the other (white) paper, form the gentle laxative known as *Seidlitz powder*. Dissolve the contents of each paper, separately, in half a tumbler of water, mix the two solutions, and drink immediately, while it is effervescing. The necessity for using two papers may be obviated, and a very satisfactory preparation obtained, by mixing 2 parts of bitartrate of sodium with 1 part of bicarbonate of sodium. The mixture keeps well even in paper, and effervesces briskly when mixed with water.

Related Salts. SODII CITRAS, *Sodium citrate* ($2C_6H_5Na_3O_7.11H_2O$). Saturate a solution of citric acid with sodium bicarbonate, evaporate, and set aside for crystallization. Forms white, rhombic pyramids of a non-bitter, saline taste. A pleasant cathartic in doses of from 1 to 1½ ounces.

SODII TARTRAS, *Sodium tartrate* ($Na_2C_4H_4O_6.2H_2O$). A white, crystalline salt, nearly tasteless, and acting as a pleasant purgative. Dose, 8 to 10 drachms.

POTASSII FERROCYANIDUM (U. S. P.)—POTASSIUM FERROCYANIDE.

FORMULA: $K_4Fe(CN)_6+3H_2O$. MOLECULAR WEIGHT: 421.76.

SYNONYMS: *Yellow prussiate of potash, Kalium ferrocyanatum, Cyanuretum ferroso-potassicum, Potassæ prussias flava, Kalium borussicum, Prussiate of potassa, Prussiate of potash, Ferrocyanuret of potassium, Ferroprussiate of potassa.*

History and Preparation.—Macquer, in 1752, by boiling Prussian blue with caustic potash, was the first to obtain this salt, and Berthollet, in 1787, qualitatively established its composition, stating it to contain iron, alkali, and prussic acid. Potassium ferrocyanide may be obtained by several methods. Ferrous salts, treated with excess of potassium cyanide, first yield a light-brown precipitate ($Fe_2[CN]_5K$), formerly thought to be ferrous cyanide ($Fe_2[CN]_4$). The precipitate is soluble in excess of potassium cyanide, with yellow color, potassium ferrocyanide resulting as follows: $Fe_2(CN)_5K+7CNK=Fe_2(CN)_{12}K_8$ (compare tests under *Potassii Carbonas*). Until within recent years, the following old method has been exclusively employed on a large scale. It consisted in exposing a mixture of pearl ash (impure potassium carbonate) and organic matter, such as hoofs, horns, and other nitrogenous animal matters to a cherry-red heat, in an iron crucible, and constantly stirring the mass. The calcined product is then cooled, lixiviated with water, and concentrated by evaporation; upon standing, crystallization takes place. The crystals are purified by repeated crystallization. This method, within recent years, is being largely supplanted by the manufacture of yellow prussiate of potash from waste products in the purification of illuminating gas. This salt was formerly very popular as a medicine.

Description and Tests.—Potassium ferrocyanide, as officially described, occurs in "large, soft, transparent, yellow, 4-sided, monoclinic tables, odorless, and having a mild, saline taste. Slightly efflorescent on exposure to dry air. Soluble in 4 parts of water at 15° C. (59° F.), and in 2 parts of boiling water; insoluble in alcohol. When heated to 60° C. (140° F.), the salt begins to turn white from loss of water, and when heated to 100° C. (212° F.), it is rendered anhydrous. The aqueous solution is neutral to litmus paper"—(*U. S. P.*). A low, red heat decomposes the salt, converting it into cyanide of potassium, carbide of iron, and other compounds, while distillation with diluted sulphuric acid yields vapors of hydrocyanic acid (see *Potassii Cyanidum*). "With sodium bitartrate T.S., the aqueous solution yields a white, crystalline precipitate. Sodium cobaltic nitrite T.S. produces a copious yellow precipitate. The color of the precipitate produced by ferric chloride T.S. is dark blue; that produced by copper sulphate T.S. is reddish-brown; while lead acetate T.S. or silver nitrate T.S. throws down a pure white precipitate"—(*U. S. P.*). These precipitates are salts of the crystallizable water- and alcohol-soluble *ferrocyanic acid* ($Fe_2[CN]_{12}H_8$), which may be obtained in the form of a precipitate by adding solution of hydrochloric acid to a concentrated solution of potassium ferrocyanide. The iron salt is the well-known Prussian blue (see *Ferri Ferrocyanidum*). The copper precipitate is characteristic for this metal. The aforenamed ferrocyanides of heavy metals are insoluble in diluted mineral acids, but decomposable by caustic alkalies. The precipitate formed in silver nitrate solution with potassium *ferricyanide* is orange-red.

The *U. S. P.* directs the following tests for impurities: "No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt (absence of carbonate). The aqueous solution (1 in 20), acidulated with hydrochloric acid, should, upon the addition of barium chloride T.S., remain clear, or at most show but a trifling turbidity (limit of sulphate). If a mixture of 0.5 Gm. of the salt with 1.5 Gm. of pure potassium nitrate and 0.5 Gm. of pure, anhydrous sodium carbonate be heated to redness in a porcelain crucible, the residue dissolved in water, the filtered solution supersaturated with nitric acid, mixed with 0.1 Cc. of decinormal silver nitrate V.S., and again filtered, no turbidity should be produced in the filtrate by the further addition of silver nitrate V.S. (limit of chloride). The precipitate produced in the aqueous solution, acidulated with nitric acid, by silver nitrate T.S. should be of a pure white color, without a tinge of red (absence of ferricyanide)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Ferrocyanide of potassium is not poisonous, being absorbed and carried off quickly with the urine. Large doses are said to cause giddiness, debility, occasional non-fetid salivation, and ulceration of the mouth. From 5 to 12 grains, dissolved in water, and repeated 2 or 3 times a day, have been found efficient as a sedative and calmative in *febrile diseases*, *pertussis*, *tic-douloureux*, etc. It has also proved advantageous in *chronic bronchitis* and *night-sweats*. Its special place in therapeutics is to act as a sedative to the circulation, and to lessen nervous irritation, and it is indicated in chronic diseases with excitation, frequent pulse, marked nervous irritability, with impairment of the nerve centers. This agent is reputed useful in *genital hyperæsthesia* at the menopause, and in *ovarian irritation*. It relieves the manifestations of *hypochondria* of the male, and *hysteria* in chronic female disorders. Another indication for its use is a pale, lax condition of the mucous tissue, with over-secretion of mucus, as of *chronic vaginitis*, *intestinal catarrh*, and *catarrhal affections of the nose, throat*, and *bronchiæ*. Dose, 5 to 15 grains, every 3 hours. It is much used in the preparation of hydrocyanic acid, and as a reagent for detecting iron in solution. A mere trace of iron in solution occasions a blue precipitate with it.

Specific Indications and Uses.—Nervous irritability, with excited circulation; impairment of nerve centers; hysteria or hypochondriasis, with slow, imperfect waste and nutrition; ovarian irritation; genital hyperæsthesia; lax, pale mucous tissues, with mucorrhœa.

Related Compounds.—Potassii Ferricyanidum ($K_6Fe_2[CN]_{12}$), *Potassium ferricyanide, Potassium ferridcyanide, Red potassium prussiate, Red prussiate of potash*. This salt is obtained from the foregoing salt by oxidation. Into a cold solution of ferrocyanide of potassium, pass a current of chlorine gas until the liquid ceases to form a blue precipitate or a blue color with ferric chloride. Evaporate and allow to crystallize. The reaction is as follows: $Fe_2(CN)_{12}K_8 + Cl_2 = Fe_2(CN)_{12}K_6 + 2KCl$. It forms large, dark-red, or hyacinth-red prisms, transparent, anhydrous, saline and feebly astringent to the taste. Four parts of water effect its solution. Exposure to light causes it to be reduced again to potassium ferrocyanide, at the same time a blue precipitate being formed. Lead and mercuric salts produce no precipitates with it. It is the prominent test for *ferrous* salts, with which it strikes a deep-blue color, forming ferrous ferricyanide or *Turnbull's blue*, while *ferric* salts produce only a brown coloration. Silver salts form with it an orange, cupric salts a greenish-yellow, and mercurous compounds, a red-brown precipitate. This salt was first obtained by Gmelin.

Sodium Nitro-prusside ($Na_4Fe_2[CN]_{10}[NO]_2.4H_2O$).—The salts of *hydrogen-nitro-prusside*, or *nitro-prussic acid* ($H_4Fe_2[CN]_{10}[NO]_2$), are characterized by the beautiful violet coloration they yield when in contact with solutions of alkali sulphides. The sodium salt is obtained by dissolving powdered potassium ferrocyanide in diluted nitric acid, and warming on the water-bath. The reaction is accompanied by evolution of much gas, consisting especially of carbon dioxide and hydrocyanic acid. When the reaction is completed, nitrate of potassium falls out upon cooling. The mother liquor is then neutralized with sodium carbonate, and after filtration and further crystallization of nitrate, the salt is allowed to crystallize. *Sodium nitro-prusside* forms permanent, ruby-red prisms, soluble in 2½ parts of water. Exposure to light decomposes the solution, Prussian blue being precipitated, and nitric oxide evolved. The violet-blue color produced with soluble sulphides, as mentioned above, is a delicate test for the latter.

Potassium Sulphocyanate (or *Sulphocyanide*, as it was formerly called), *Potassium thiocyanate, Potassium rhodanate* ($KSCN=96.99$).—Melt together, at a low red heat, anhydrous potassium ferrocyanide (46 parts), sulphur (32 parts), and potassium carbonate (17 parts). Cool and treat the mass with boiling alcohol, in which the salt dissolves, crystallizing out upon cooling; it forms colorless prisms of a biting, saline, cooling taste. The salt deliquesces on exposure, and is easily dissolved by water or alcohol. This substance is a test for ferric salts, with which it produces a blood-red color, soluble in ether. The color is not readily affected by hydrochloric acid, but is dissipated by mercuric chloride (compare ferric chloride tests for *Meconic Acid*, under *Opium*). This reaction also serves as a test for cyanides. By melting potassium cyanide with sulphur, combination takes place with formation of potassium thiocyanate, which may be recognized by the above test. Likewise, sulphur may be tested for by this reaction. Potassium sulphocyanate has been suggested (Sommering) as a substitute for cyanide of potassium and prussic acid in therapy, on the ground that it is fully as effective without the inconveniences attending those drugs.

POTASSII HYPOPHOSPHIS (U. S. P.)—POTASSIUM HYPOPHOSPHITE.

Formula: KPH_2O_2. Molecular Weight: 103.91.

Synonyms: *Potassæ hypophosphis, Hypophosphite of potassium, Hypophosphite of potash, Hypophosphis kalicus, Hypophosphis potassicus, Kalium hypophosphorosum.*

Preparation.—This salt may be produced by neutralizing hypophosphorous acid (which see) with potassium carbonate, and carefully evaporating the solution to dryness, or it may be prepared by double decomposition of solutions of potassium carbonate and calcium hypophosphite, whereby potassium hypophosphite goes into solution, while calcium carbonate precipitates as follows: $K_2CO_3+Ca(PO_2H_2)_2=2KPO_2H_2+CaCO_3$. The salt may also be obtained by the action of phosphorus upon a warm, concentrated solution of caustic potash, the following reaction taking place with evolution of inflammable hydrogen phosphide gas: $P_8+6KOH+6H_2O=2PH_3+6PO_2H_2K$. When evaporating a solution of this salt, the temperature should be far below boiling, lest an explosion occur.

Description and Tests.—Potassium hypophosphite forms "white, opaque, hexagonal plates, or crystalline masses, or a granular powder, odorless, and having a pungent, saline taste; very deliquescent. Soluble at 15° C. (59° F.), in 0.6 part of water, and in 7.3 parts of alcohol; in 0.3 part of boiling water, and in 3.6 parts of boiling alcohol; insoluble in ether. When heated in a dry test-tube, the salt at first loses moisture, and then evolves spontaneously inflammable hydrogen phosphide gas, which burns with a bright-yellow flame. On triturating or heating the salt with nitrates, chlorates, or other oxidizing agents, it detonates violently. The aqueous solution (1 in 20) is neutral to litmus paper, and yields, with sodium bitartrate T.S., a white, crystalline precipitate. With silver nitrate T.S. a white precipitate is formed, which rapidly turns brown and black, owing to the separation of metallic silver. If a small quantity of an aqueous solution of the salt be acidulated with hydrochloric acid, and mercuric chloride T.S. added, so that the latter remain in excess, a white precipitate of mercurous chloride will at first be produced, which, upon further addition of the acidulated solution, is reduced to metallic mercury"—(*U. S. P.*). The latter two reactions are in consequence of the reducing qualities of potassium hypophosphite. The second reaction takes place, with the formation of phosphoric acid, as follows: $4HgCl_2+HPO_2H_2+2H_2O=4HgCl+4HCl+H_3PO_4$ and $4HgCl+HPO_2H_2+2H_2O=2Hg_2+4HCl+H_3PO_4$. The salt should be kept in close-stoppered bottles, and, owing to the danger involved in mixing it with oxidizers, should not be used in combination with the latter class of bodies.

The *U. S. P.* directs the following tests for this salt: "The aqueous solution of the salt (1 in 20) should not effervesce on the addition of an acid (absence of carbonate), nor should it be rendered turbid by ammonium oxalate T.S. (absence of calcium). Separate portions of 5 Cc. of the aqueous solution (1 in 20), heated with 1 Cc. of nitric acid, should remain clear upon the addition of silver nitrate T.S. (absence of chloride), or of barium chloride T.S. (absence of sulphate). Not more than a slight cloudiness should be produced in the aqueous solution of the salt by the addition of magnesia mixture (limit of phosphate). If 0.1 Gm. of dry potassium hypophosphite be dissolved in 10 Cc. of water, then mixed with 7.5 Cc. of sulphuric acid and 40 Cc. of decinormal potassium permanganate V.S., and the mixture be boiled for 15 minutes, it should not require more than 2 Cc. of decinormal oxalic acid V.S. to discharge the red color (corresponding to at least 98.7 per cent of the pure salt)"—(*U. S. P.*). Mr. Frank X. Moerk found one of two samples of potassium hypophosphite to contain over 13 per cent of potassium phosphite (PO_3HK_2) (*Amer. Jour. Pharm.*, 1889, p. 391).

Action, Medical Uses, and Dosage.—This salt is usually prescribed in the combination known as the compound syrup of the hypophosphites. The hypophosphites are particularly useful in allaying *pulmonary irritation* in atonic subjects, and in controlling *cough* and giving increased freedom of respiration. At the same time, the digestion, blood-making, and the nutrition of the body are improved by it. They are useful in *phthisis*, *bronchitis*, convalescence from debilitating diseases, the disorders produced by *mental strains*, *sexual excesses*, etc. The salt under consideration is especially useful in *chronic cough*, with thoracic pain, and in the *neuralgia* following *pleurodynia*, *rheumatism*, *muscular cramps*, etc. The indications are soreness or lameness, with pain and tenderness in the muscles. Dose, 1 to 25 grains.

Specific Indications and Uses.—Atony, with pallid tongue and membranes; muscular soreness, tenderness, pain, or lameness; chronic cough, with irritation and pain in the chest, pulse weak and rapid; emaciation.

Related Salt.—POTASSII PHOSPHAS (K_2HPO_4), *Potassium phosphate, Dipotassic orthophosphate*. This salt may be prepared by saturating solution of orthophosphoric acid with potassium carbonate until effervescence ceases, filtering, and allowing to crystallize. It forms a white, deliquescent powder, which crystallizes with difficulty. Potassium phosphate, from 10 to 30 grains, in water, 3 times a day, is employed in *phthisical* and *scrofulous diseases* as an alterative. According to the Schuessler treatment, it is a remedy for *mental depression, nerve exhaustion*, and in *brain* and *cord lesions*. Excessive prostration, morbid fear, and rapid blood-decay, are guides to its selection. The usual method of prescribing it is to add 5 grains of the 3 x trituration to 4 ounces of water, the dose of which is a teaspoonful every 2 hours in acute troubles, and every 4 hours in chronic affections.

POTASSII IODIDUM (U. S. P.)—POTASSIUM IODIDE.

FORMULA: KI. MOLECULAR WEIGHT: 165.56.

SYNONYMS: *Iodide of potassium, Iodide of potash, Kalium iodatum, Kali hydriodicum, Ioduretum kalicum, Ioduretum potassicum.*

Preparation.—Potassium iodide is obtained either by neutralization of hydriodic acid with caustic potash, or potassium carbonate, or by the action of potassium carbonate upon ferrous iodide, previously prepared by the action of iron filings upon iodine in the presence of water; or iodine is allowed to act upon caustic potash, whereby potassium iodide and iodate are formed, according to the equation: $3I_2+6KOH=5IK+IO_3K+3H_2O$. The iodate is then reduced to iodide by mixing the salts with charcoal and exposing to a dull-red heat (compare *Potassii Bromidum*).

Description.—"Colorless, transparent, or translucent, cubical crystals (the white, opaque, commercial variety being crystallized from an alkaline solution, and less pure), or a white, granular powder, having a peculiar, faint, iodine-like odor, and a pungent, saline, afterward bitter taste. Permanent in dry air, and but slightly deliquescent in moist air"—(*U. S. P.*). If it contain a small portion of carbonate of potassium or sodium iodide, it gradually attracts moisture from the air, becoming entirely liquid and yellowish from the liberation of iodine. "Soluble, at 15° C. (59° F.), in 0.75 part of water, and in 18 parts of alcohol; in 0.5 part of boiling water, and in 6 parts of boiling alcohol; also soluble in 2.5 parts of glycerin. When heated, the salt decrepitates. At a low, red heat it fuses, and at a bright-red heat it is volatilized without decomposition. Its aqueous solution is neutral, or has, at most, a scarcely perceptible alkaline reaction upon litmus paper. The salt yields a white, crystalline precipitate with sodium bitartrate T.S. If to 5 Cc. of the aqueous solution (1 in 20) of the salt, 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a yellow color. On agitating the mixture with a few drops of chloroform, this will acquire a violet color"—(*U. S. P.*). Other substances liberating iodine from potassium iodide are concentrated sulphuric acid, nitrous acid, ferric chloride, etc. The aqueous solution of potassium iodide readily dissolves iodine, forming a dark, reddish-brown fluid (see *Decinormal Iodine Volumetric Solution*). Potassium iodide forms characteristic compounds with the salts of heavy metals. With mercuric chloride, a vermilion-red precipitate of mercuric iodide is formed, soluble in excess of potassium iodide. The solution, containing the double salt, mercuric potassium iodide ($HgI_2.2IK$), is known as *Mayer's solution*, the well-known test-reagent for alkaloids. *Nessler's solution*, the delicate test-reagent for ammonia, is the same fluid rendered alkaline by the addition of caustic potash (see *Aqua Ammoniæ* and *U. S. P. Test Solutions*). Soluble mercurous salts produce with small amounts of potassium iodide a green precipitate of mercurous iodide (Hg_2I_2), soluble in excess of potassium iodide as mercuric potassium iodide, with precipitation of mercury, as follows: $Hg_2I_2+2IK=Hg+HgI_2.2IK$. From cupric salts, potassium iodide precipitates white, cuprous iodide, with liberation of iodine, as follows: $2CuSO_4+4KI=Cu_2I_2+I_2+2K_2SO_4$. Acetate of lead produces, with potassium iodide, a yellow precipitate of iodide of lead (which see). Nitrate of silver precipitates pale-yellow iodide of silver, which is almost insoluble in aqua ammoniæ (difference from silver chloride); insoluble in diluted nitric acid.

Tests.—Iodide of potassium is often rendered impure by the presence of foreign substances. Carbonate of potassium may be detected by lime-water, which would render the solution milky, or by alcohol, which does not dissolve the carbonate, but dissolves the pure iodide. Other impurities liable to be present are sulphate of potassium, iodate of potassium, chlorides of potassium or sodium, nitrates, metallic impurities, etc. The crystallized salt is naturally purer than the granulated (see analyses by G. H. Charles Klie, *Amer. Jour. Pharm.*, 1894, p. 380). The *U. S. P.* directs the following tests for potassium iodide: "No residue should be left when 1 Gm. of the salt is dissolved in 2 Cc. of diluted alcohol of specific gravity 0.928 (absence of less soluble salts)"—(*U. S. P.*). The strength of this alcohol is about 52.5 per cent by volume. "If 1 Gm. of the salt be dissolved in water and 0.05 Cc. (1 drop) of decinormal oxalic acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphtalein T.S., even after heating (limit of alkali). When a fragment of the salt is brought into a non-luminous flame on a clean platinum wire, a violet color should appear at once (absence of sodium). If to a solution of the salt (1 in 20) in distilled water, from which all gases have been expelled by boiling, a little starch T.S. be added, and then a few drops of pure diluted sulphuric acid T.S., no blue color should appear at once (absence of iodate)"—(*U. S. P.*). This test is based upon the action of hydriodic acid upon iodic acid, which takes place according to the equation: $5IH + IO_3H = 3I_2 + 3H_2O$. "The aqueous solution (1 in 20) should not be colored or precipitated by the addition of an equal volume of hydrogen sulphide T.S., either before or after acidulation with hydrochloric acid (absence of arsenic, lead, copper, etc.). The aqueous solution should remain clear after the addition of barium chloride T.S. (absence of sulphate)"—(*U. S. P.*). Mr. L. F. Kebler points out that in the latter test the addition of hydrochloric acid should be directed, because the *U. S. P.* allows a trace of carbonate to be present, which causes turbidity with barium chloride (*Amer. Jour. Pharm.*, 1896, p. 197). "If 1 Gm. of the salt be mixed with 0.5 Gm., each, of iron and of zinc, in coarse powder or filings, and heated in a test-tube with 5 Cc. of sodium hydrate T.S., no ammoniacal vapors should be evolved (absence of nitrate or nitrite). No blue color should be communicated to 5 Cc. of the aqueous solution (1 in 20) by 0.1 Cc. (2 drops) of potassium ferrocyanide T.S. (absence of iron). If 5 Cc. of the aqueous solution be gently heated with 1 drop of ferrous sulphate T.S. and 0.5 Cc. of potassium hydrate T.S., no blue color should appear after acidulating the mixture with hydrochloric acid (absence of cyanide). If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require not more than 30.25 Cc. nor less than 30 Cc. of decinormal silver nitrate V.S. to produce a permanent red color of silver chromate (corresponding to at least 90.5 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—In very large doses, iodide of potassium is an irritant, though Dr. Elliotson states that 6 drachms may be given daily and continued for many weeks without inconvenience. In small doses, it is diuretic and alterative. Iodine has been detected in the urine a few minutes after the exhibition of the iodide. (Iodide of potassium, or iodine, may be detected in urine, by first adding starch to the suspected urine, then a few drops of nitric acid, or solution of chlorine; the blue iodide of starch will be precipitated.) A drachm of the iodide, taken in divided doses, has caused vomiting, colicky pains, slight diarrhœa, frequency of pulse, and slight exhaustion, and Dr. Laurie has known small doses to produce serious and even fatal results in certain constitutions. Mercurial salivation is frequently occasioned by the administration of this salt to persons who had been subject to mercurial treatment at some prior time. In some constitutions iodide of potassium produces certain symptoms termed *iodism*, as "violent vomiting and purging, with fever; great thirst; palpitation; rapid and extreme emaciation; cramps, and small, frequent pulse, occasionally with a dry cough, and terminating in death" (P.) (see also *Iodine*). Usually, the unpleasant symptoms occasioned by the use of iodide of potassium gradually pass away upon ceasing its use. A common result from the administration of this salt, is the condition produced simulating "summer catarrh." Being excreted partially by the air passages, it sets up a severe coryza, with bronchorrhœa, and swelling, congestion or even inflammation of the pharyngeal, laryngeal, and conjunctival membranes. The skin and kidneys are also more or less irritated. The action may be so severe as to inflame the antrum of Highmore and the frontal sinus, to cause hoarseness, dyspnœa, œdema of the larynx, impairment of sight and speech, and a paresis of the organs of speech. Even very small doses, in susceptible individuals, have produced symptoms of iodism. It is not uncommon for the iodide to produce an indurated form of acne, and, less commonly, urticaria, watery or bloody blisters, and iodic purpura. The latter consists of purple spots, chiefly upon the legs, which disappear after a short time. Rarely, large blebs form, which are extremely painful to the touch, and are filled with watery or bloody serum. These are termed *hydroa*, and have produced death. The iodides pass with exceeding rapidity into the blood, and are eliminated by the faucial, salivary, and broncho-pulmonary glands, but chiefly by the renal organs, the urine having been known to contain at least 90 per cent of the amount ingested. That it contaminates the milk of nursing mothers, is proven by its emaciating effects upon suckling infants. Iodide of potassium is more likely to do mischief when the kidneys are inactive; it should be very cautiously used, if at all, when the kidneys are diseased. As small a dose as 5 grains have produced decided iodic symptoms, while, as above stated, very large doses have been taken without apparent harm. It should always be given largely diluted with water, and the initial doses of the salt should always be small lest laryngeal œdema should result.

As a therapeutical agent, iodide of potassium has been widely and variously used. Properly employed, it is an agent capable of great good, but if improperly administered, may do irreparable harm. It increases retrograde metamorphosis, and the detritus is eliminated with the salt. If given beyond this action, it attacks the healthy tissues. Prof. Scudder has laid down the indication for its selection as "a broad, pallid, leaden-colored tongue, rather full. With this indication, it is a very certain antisyphilitic, whilst, with a red and contracted tongue, it is pretty sure to do the patient injury" (*Spec. Med.*, 159).

Iodide of potassium is usually given in all cases where iodine is indicated, being less irritating in its action. It appears to be more especially useful in *goitre*, *strumous enlargement of the glands*, *strumous sores* and *eruptions*, *strumous ophthalmia*, *syphilitic affections*, *mammary tumors*, *enlargement of the liver*, *amenorrhœa*, *leucorrhœa*, *mercurio-syphilitic sore throat*, *mercurial cachexia*, and *tubercular affections of serous tissues.* It is extensively employed in the above forms of disease, alone, or in combination with the compound syrup of stillingia, in the proportion of 4 drachms of the salt to a pint of the syrup.

Owing to its chemical action, it is the remedy relied upon in *chronic lead*, *mercurial*, and *arsenical poisoning.* It must, however, be very cautiously used, lest in its union with these minerals it aggravates so as to renew the poisonous effects of the original poisons. Not more than 20 grains should be given during the day. It is regarded as a singular fact that some cases of *mercurial sore-mouth* are relieved by it, while others are not; but, in the light of specific indications, this is not at all surprising. As an agent for *syphilis*, it is one of the most important remedies for the tertiary stage. It does harm, and is never indicated in the primary stage. Good hygienic and dietetic care are required in the first stage; small doses of the iodide in syrup of stillingia, as mentioned above, may be given in the second stage; but in the third stage, when the ulcerative processes, and the periosteal and bone complications ensue, the drug may be given in heavy doses with the greatest of benefit. Its efficiency in *ulcerative syphilitic destruction*, *caries*, *periostitis*, *nocturnal bone-pains*, *nocturnal tri-facial neuralgia*, all due to the syphilitic infection, is promptly and thoroughly declared. While large doses may here be exhibited, care should be taken not to produce iodism, lest a worse than the syphilitic condition be provoked. The vegetable alteratives, as phytolacca, berberis aquifolium, etc., are sometimes given with it. Potassium iodide has a marked action in reducing enlargements, and especially when due to *hyperemia* of the part. *Bronchocele* has been cured by it. A *syphilitic* or *scrofulous cachexia* is usually behind these troubles when so relieved, for it does not affect solid growths unaccompanied with a cachectic state. The many nervous disorders experienced by those affected by syphilis at the time or some remote period, are benefited by the iodide. Thus *epilepsy*, *severe neuralgia*, *headache*, *arthritic pains*, *chronic rheumatism*, and *gout* are relieved by it. *Lumbago*, *paraplegia*, and *sciatica* have been cured by it, when due to syphilis or chronic mineral poisoning. In *scrofulous conditions*, give it with cod-liver oil. The *eye disorders of syphilis*, *rheumatism*, and *scrofula*, such as *scrofulous* *corneal ulceration* and *opacity*, *scrofulous conjunctivitis*, and *rheumatic* or *syphilitic iritis*, are well treated with 5-grain doses after each meal. The lacteal secretions are dried by this salt, and though in health not a pronounced diuretic, and ordinarily harmful, where the kidneys are diseased it appears to relieve the *dropsy of Bright's disease* by acting efficiently as a diuretic, washing away the morbid products, though it does not cure or lessen the amount of albumen excreted. Owing to its action upon the mucous tissues in increasing secretion, it is of value in *dry asthma*, *dry cough*, and *chronic bronchitis* of a congestive or purulent type. As soon as its effect of increasing secretion is observed, it should be lessened in dose or withdrawn, so that it will not prove too debilitating. It has been thought of value to prevent the formation of the *diphtheritic membrane*, where there is marked dryness of the membranes. It has been used successfully in curing *aneurism*, by inducing thrombosis in the aneurismal sac. As a remedy for *skin diseases*, it is useful, when dependent upon a scrofulous or syphilitic taint. Upon a like cachexia probably depend those fibrous thickenings and deposits, inflammatory in character, which take place about joints, upon nerve-trunks and tendons, and the periosteal membranes, which are also relieved by the drug. *Syphilitic gummata* of the brain and elsewhere are often promptly dissipated by its use. It should be remembered that, when taken for a length of time, and especially if used in rather large doses, it will excite ptyalism, and frequently an affection of the mucous membranes of the air passages, very much resembling a cold in the head. The dose of it is from 2 to 30 grains, 3 times a day; the larger doses being employed in ulcerative syphilitic disorders. It should always be given in solution (water or milk) and well diluted, and should also be prescribed in the simplest possible form, on account of its numerous chemical relations with other bodies, many of which decompose it, and form insoluble iodides.

Specific Indications and Uses.—Pale, leaden-colored, rather full tongue; dryness of mucous membranes; nocturnal pains; scrofulous and syphilitic (tertiary) manifestations, with the above-mentioned tongue; blue line on the gums (chronic lead poisoning).

Related Compounds.—POTASSII IODAS (KIO_3=213.44), *Potassium iodate*. There are several methods of preparing this salt. Iodine is allowed to react with caustic potash, and the resulting mixture of iodide and iodate is treated with alcohol, which leaves potassium iodate undissolved; or it may be prepared by the action of iodine (in the form of its chlorine compound, ICl) upon potassium chlorate, as follows: $ICl+KClO_3=Cl_2+KIO_3$. The salt forms translucent or porcelain-like, cubical crystals, soluble in cold (13 parts) and boiling (3.1 parts water. Alcohol does not dissolve it, but it is freely soluble in solution of potassium iodide: This solution, acidulated, sets iodine free (see *Potassii Iodidum*). The salt is fusible, and when strongly heated, gives off oxygen, while potassium iodide remains. This agent has been substituted for potassium chlorate in *ulcerated conditions of the mouth and fauces*. *Gangrenous stomatitis*, *salivation*, and *diphtheria* have been treated with it, the usual dose being 4 to 8 grains. It appears to restrain the secretions of the mucous surfaces.

IODIA.—A combination of the active constituents of the green roots of stillingia, helonias, saxifraga, and menispermum; iodide of potassium, phosphate of iron, and aromatics. Employed in *uterine debility* and *menstrual derangements*, and in *syphilitic*, *cutaneous*, and *scrofulous diseases*. Dose, 1 to 2 fluid drachms, 3 times a day, before meals. Iodia is a specialty of Battle & Co., of St. Louis, Mo.

ELIXIR SALICYLIC COMPOUND.—A specialty of Wm. R. Warner & Co. (Philadelphia and New York), containing salicylic acid, gelsemium, sodium bicarbonate, and potassium iodide. It is designed for use in *rheumatism*, *lumbago*, *gout*, and like diseases. Dose, 1 to 2 teaspoonfuls.

POTASSII NITRAS (U. S. P.)—POTASSIUM NITRATE.

FORMULA: KNO_3. MOLECULAR WEIGHT: 100.92.

SYNONYMS: *Saltpetre*, *Saltpeter*, *Niter*, *Nitre*, *Nitrate of potash*, *Nitras kalicus*, *Nitras potassicus*, *Nitrum depuratum*, *Sal petræ*, *Sal nitri*, and *Sal prunelle* (when fused).

Source, History, and Preparation. Nitrate of potassium is a salt which was known to the ancients, though probably not sharply distinguished from other salts formed on the surface of soils by efflorescence. It is found in various parts of the globe, as in Europe, Egypt, South America, India, and in several parts of the United States. The greater part of the commercial article was at one time obtained from India, but is now largely supplanted by the artificial product Potassium nitrate is also found in several plants, as tobacco, crawley root, sunflower, nettle, etc. The process of obtaining it from the soil, or from heaps of earth containing decaying animal matter, consists in lixiviating the soil in an apparatus containing wood ashes. The resulting solution of nitrate of calcium is made to pass through the wood ashes, and reacts on the carbonate of potassium, producing nitrate of potassium and carbonate of calcium. The fluid thus obtained is evaporated and crystallized, and the crystals purified by recrystallization. The nitrification of soils is now known to be due to the presence of ferments and bacteria, which convert ammonium salts into nitrites and nitrates in the presence of sufficient alkali and the oxygen of the air.

Large amounts of nitrate of potassium are now produced by treating the chloride of potassium obtained from the mines at Stassfurt, Germany, with Chili saltpetre (sodium nitrate). By double decomposition, sodium chloride (common salt) and potassium nitrate (saltpetre) are formed as follows: $KCl + NaNO_3 = KNO_3 + NaCl$. Saltpetre from this source is called *conversion saltpetre*. It is an almost absolutely pure potassium nitrate. During the American war with England (1812), large quantities of saltpetre were prepared from the deposits in the Mammoth Cave of Kentucky. The wooden vats employed are still to be seen in that cavern. The salt erroneously termed *South American saltpetre*, is a nitrate of sodium (*Chili saltpetre*) (see *Sodii Nitras*).

Description.—Potassium nitrate occurs in the form of "colorless, transparent, 6-sided, rhombic prisms, or a crystalline powder, odorless, and having a cooling, saline, and pungent taste. Permanent in the air. Soluble in 3.8 parts of water at 15° C. (59° F.), and in 0.4 part of boiling water; very sparingly soluble in alcohol. When heated to 353° C. 667.4° F.), the salt melts. At a higher temperature it is decomposed, giving off oxygen at first, and then some of its nitrogen, leaving a residue of potassium nitrate, nitrite, and oxide. Thrown upon red-hot coals, the salt deflagrates. The aqueous solution is neutral to litmus paper"—(*U. S. P.*).

Cold is generated during solution of the salt in temperate or cold water. Alcohol, of specific gravity 0.878, dissolves about 1 per cent of this salt; it is not soluble in pure alcohol. When held in the non-luminous Bunsen flame, on a platinum wire, it imparts to it a violet color. When allowed to cool from a state of fusion, it concretes into a hard, fibrous, opaque, white mass, known in commerce by the name of *Sal prunelle* or *Crystal mineral*. Saltpetre, obtained by agitating the solution from which it crystallizes, occurs in the form of fine crystals, and is called *saltpetre flour*. Saltpetre, being a powerful oxidizer, should not be triturated together with easily combustible substances. Its most important use is in the manufacture of gunpowder, and of nitric acid.

Tests.—The presence of chloride of sodium or common salt renders nitre unfit as a constituent of gunpowder, owing to its tendency to absorb moisture from the air. When nitre is fused and allowed to cool, it assumes a radiated texture; the broader these radii, the purer the salt. If mixed with $\frac{1}{30}$ part of common salt, the radiated appearance is completely destroyed. Commercial samples of saltpetre have been found to contain, occasionally, as much as 75 per cent of sodium chloride (see *Amer. Jour. Pharm.*, 1886, p. 288).

The *U. S. P.* gives the following tests for potassium nitrate: "With sodium bitartrate T.S., the aqueous solution (1 in 20) yields a white, crystalline precipitate; with sodium cobaltic nitrite T.S., a yellow precipitate. If a small crystal of ferrous sulphate be dissolved in the aqueous solution (1 in 20), and then concentrated sulphuric acid be poured in, so as to form a separate layer, a dark-brown color will appear at the line of contact"—(*U. S. P.*). This is a general test for nitric acid and its salts, and is based upon the reduction of nitric acid by ferrous sulphate with evolution of nitric oxide, which dissolves in unattacked ferrous sulphate solution with brown color. The reaction takes place as follows: $6FeSO_4 + 3H_2SO_4 + 2HNO_3 \quad 3Fe_2(SO_4)_3 + H_2O + 2NO$. "If a drop of diphenylamine T.S. be mixed with the aqueous solution, and concentrated sulphuric acid be poured in, as in the preceding test, a deep-blue color will appear at the line of contact"—(*U. S. P.*). This test is based upon the formation of *diphenylamine blue*. "The aqueous solution (1 in 20) should remain unaffected by the addition of a few drops of potassium ferrocyanide T.S. (absence of iron); or of barium chloride T.S. (sulphate), or of silver nitrate T.S. (chloride); or of ammonium carbonate T.S., ammonium oxalate T.S., or ammonium sulphide T.S. (absence of calcium, zinc, etc.); or by the addition of an equal volume of hydrogen sulphide T.S., either before or after acidulation with hydrochloric acid (absence of arsenic, lead, copper, etc.). If to 5 Cc. of the aqueous solution of the salt, 1 Cc. of chlorine water and a few drops of starch T.S. be added, no blue color should appear (absence of iodine). No yellow color should appear when 1 Cc. of pure, concentrated sulphuric acid is added to 0.1 Gm. of the dry salt (absence of chlorate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Nitrate of potassium is irritant, cathartic, refrigerant, and diuretic. If the body be kept cool, it acts chiefly as a diuretic; if warm, as a diaphoretic. In doses of from ½ to 2 ounces, in solution, it occasions heat and pain in the stomach, vomiting, excessive nervous depression, and sinking of the pulse, and has proved fatal in a few hours; some of the effects being purging, bloody stools, cold extremities, and convulsions. On account of the uncertainty of its cathartic effects, it is seldom used for that purpose. Its most common actions are to increase the cutaneous and renal secretions; to diminish the temperature of the system, and the frequency of the pulse; to keep the bowels gently open, and, in consequence of these influences, to lessen febrile and inflammatory action.

In the *Amer. Jour. Med. Sci.*, Vol. XVIII, p. 204, an account is given of experiments by five students on their own persons while in health. The salt was taken in solution, with the addition of a little mucilage, in quantities increasing gradually from 1 to 5 drachms daily; the proportion for each day being divided into 5 doses. After from 8 to 12 days' use of it in this manner, it was found to produce general weakness, indisposition to mental or physical exertion, fatigue from the least exertion, low spirits, a bruised sensation of the muscles and joints, constant disposition to sleep, slow and weak pulse. The appetite continued good, and digestion was not disordered; occasionally pain in the bowels, with purging. Blood drawn from the veins at this time had the color and density of cherry-juice, the white blood-corpuscles were increased in number and size, the blood-globules were paler, and the blood coagulated very quickly. There was an increase of the water, and a decrease of the solids of the blood, with a dimunition of its fat and an increased proportion of ash in the serum. The pulse did not assume its natural strength and frequency for several days after the discontinuance of the medicine. Potassium nitrate is extensively employed as a diuretic, and especially in *dropsical affections*. It has also been found beneficial in *acute rheumatism* and in *active hemorrhages;* and in these cases it may be given to the amount of 1 or 2 ounces in the course of 24 hours, dissolved in 2 quarts of cold water, and flavored with lemon-peel, and which must be divided into several doses. In *acute inflammatory rheumatism*, with excessive tenderness, from 5 to 20 grains, well diluted, may be given 4 times a day. In some cases of *acute dysentery*, given in association with resin of podophyllum and leptandra, it will be found very valuable in facilitating the cure. From 3 to 5 grains of nitre, dissolved in a little water, and this dose repeated 3 times a day, I have found very efficient in removing the *aching pain in the testicles*, complained of by onanists and persons who commit excessive venery. I am not aware that this action is named in any other medical work (J. King). In *sore throat*, nitre mixed with white sugar, and gradually swallowed, has given great relief; it also forms a useful addition to gargles in *quinsy*, and, in 3-grain doses, well diluted, it sometimes aborts this trouble. A mixture of nitre and gum Arabic lessens the scalding of *gonorrhœa*. Urinal incontinence is relieved by nitre. The fumes produced by the deflagration of nitrate of potassium with paper, have been inhaled with benefit in *spasmodic asthma*. To obtain them, blotting paper must be moistened with a saturated solution of the salt, and then dried; by burning the paper or smoking it in a pipe, the fumes may be inhaled; relief usually follows in about 15 minutes. It is frequently substituted for the bitartrate of potassium in our powder of ipecacuanha and opium. Sal prunelle (fused nitrate of potassium) has been found useful as an application to *cracked lips*. The dose of nitre as a sedative refrigerant, is from 10 to 20 grains, well diluted; as a diuretic, from 20 to 60 grains. There is no certain antidote known to the more serious influences of nitre. The treatment generally pursued is to evacuate the stomach by free emesis, giving water freely, and to combat gastric irritation by external counter-irritants, mucilage and opiates internally, and stimulants to overcome any tendency to prostration. When used as a medicine, nitre should be largely diluted with water. Large doses, or a continued use of it for some time, will cause gastro-intestinal pain. A paste of the powder, prepared with a little water, is said to remove *freckles*, if applied to the face twice a day.

Specific Indications and Uses.—Renal atony; scanty urine, with difficult breathing; dysphagia, as if from paralysis of the throat muscles; acute inflammatory rheumatism, with excessive tenderness; spasmodic asthma (vapor); tonsillar hypertrophy; aching testicular pain.

Related Preparations.—GUNPOWDER (*Pulvis pyrius*, *Pulvis nitratis*). Gunpowder is prepared by combining together, 5 or 6 parts of nitre, with 1 part, each, of charcoal and sulphur. However, these proportions vary with the different manufacturers of the article, so that there is no regular or official method for its preparation. The uses of gunpowder, aside from medicine, are too well known to require description. Recommended as a detergent and alterative in *chlorosis* and *dyspepsia*, also as a corrective of morbid secretions of the gastro-mucous membrane, dependent on, or accompanied with *subacute inflammation*. Dose, 10 grains, 3 or 4 times a day, gradually increased, occasionally using a mild laxative. Externally, applied in powder or ointment to *indolent ulcers*, and several forms of *cutaneous diseases*. Gunpowder, dissolved in water, and the solution taken in teaspoonful doses, 3 or 4 times in 24 hours, and continued daily, has cured *gonorrhœa*. Dr. Bone and Dr. Henry, two celebrated botanic practitioners of the earlier part of this century, made considerable use of this article in the treatment of some forms of *cutaneous disease*, *indolent ulcers*, and even *cancers*. For the formula they employed, see previous editions of *American Dispensatory*.) The ointment applied twice a day, was reputed to destroy *cancer*.

POTASSII NITRIS (KNO_2=84.96), *Potassium nitrite*.—This salt is obtained by heating potassium nitrate, either alone, or with addition of lead, copper, or iron ($NO_3K = NO_4K + O$). When lead is used, the liberated oxygen oxidizes the metal, forming litharge. It is amorphous and fusible, and often is put on the market in the form of white sticks, resembling those of caustic potash; also in crystalline, granular form. Besides being exceedingly deliquescent, it also absorbs carbonic acid gas from the atmosphere. It is readily soluble in water, insoluble in alcohol. The salt is used in the testing for potassium or cobalt by the formation of potassium cobaltic nitrite (see *Potassa*), also in the preparation of *diazo compounds* (see *Anilinum*). Its physiological and therapeutical effects are those common to the nitrites, particularly those of amyl nitrite. The usual dose is 3 grains, doses of 10 grains having produced dangerous toxic symptoms.

POTASSII PERMANGANAS (U. S. P.)—POTASSIUM PERMANGANATE.

FORMULA: $KMnO_4$. MOLECULAR WEIGHT: 157.67.

SYNONYMS: *Permanganate of potash*, *Potassæ permanganas*, *Kali hypermanganicum crystallizatum*, *Hyperpermanganas kalicus*, *Hyperpermanganas potassicus*.

History and Preparation.—As early as 1659, this salt was produced by Glauber, while fusing together caustic potash and black oxide of manganese. The *British Pharmacopœia* (1898) gives it the formula $K_2Mn_2O_8$, and states that it may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide. (For this process, full directions are given in the *Br. Pharm.*, 1885.) Accordingly, an evaporated mixture of 4 parts of black oxide of manganese, 3½ parts of potassium chlorate, and 5 parts of caustic potash, previously dissolved in 4 parts of water, is exposed to a dull-red heat in a covered crucible, the fused, dark-green mass, boiled out with water, and the solution, decanted from insoluble manganese dioxide, is saturated with carbonic acid gas, and evaporated to crystallization. Purify by recrystallization.

In this process, potassium manganate (K_2MnO_4) is first formed, according to the equation: $3MnO_2+6KOH+KClO_3+3K_2MnO_4+KCl+3H_2O$. This compound, upon boiling with water, is decomposed into potassium permanganate and hydrated manganese dioxide, as follows: $3K_2MnO_4+3H_2O \quad K_2MnO_8+MnO_3H_2+4KOH$. The free caustic potash formed is neutralized by carbonic acid gas.

Description and Tests.—The *U. S. P.* describes potassium permanganate as "slender, monoclinic prisms, of a dark-purple color, almost opaque by transmitted, and of a blue, metallic lustre by reflected light, odorless, and having a taste at first sweet, but afterward disagreeable and astringent. Permanent in the air. Soluble in 16 parts of water at 15° C. (59° F.), and in 3 parts of boiling water. In contact with alcohol, it is decomposed. When heated, the salt decrepitates, and at 240° C. (464° F.), it decomposes, yielding oxygen, potassium manganate, and manganese dioxide. The aqueous solution of the salt is of a deep, violet-red color when concentrated, and of a rose color when much diluted, and this color is discharged by hydrogen sulphide, ferrous sulphate, oxalic acid, alcohol, and many other readily oxidizable substances, especially if the solution be first rendered acid by sulphuric acid. The solution is neutral to litmus paper"—(*U. S. P.*).

Potassium permanganate is one of the most energetic oxidizing agents known. It is readily decomposed when in contact with organic and oxidizable inorganic bodies, especially the substances before mentioned. By oxidation in acid solution, 5 atoms of oxygen, from each 2 molecules of the salt, become available, according to the following equation: $Mn_2O_8K_2+3H_2SO_4+2MnSO_4+K_2SO_4+3H_2O+O_5$. The available oxygen oxidizes ferrous to ferric salts, oxalic acid to carbonic acid, hydrochloric acid to chlorine, etc. On account of the definiteness of these reactions, potassium permanganate finds a most important application in volumetric analysis (see *U. S. P. Volumetric Solutions*). When its solution is warmed with strong alkali it turns green, oxygen being evolved and potassium manganate formed as follows: $2MnO_4K+2KOH=2MnO_4K_2+H_2O+O$. Permanganate of potassium should be kept in well-closed bottles, and secure from impure air and light. Its solution, not being permanent, should be made as required and should not be allowed to come in contact with caoutchouc, upon which it acts, being at the same time decomposed by it. On account of its action on organic bodies, a writer in the *British Medical Journal* (1862) has recommended it as calculated in an eminent degree to meet every case of poisoning by organic poisons, as, by aconite, strychnine, veratrine, cyanide of potassium, etc. Recently, this view has been revived and put into practice, but probably without any satisfactory results. In this manner, it is reputed an antidote for morphine poisoning.

The *U. S. P.* directs the following tests for potassium permanganate: "If 0.5 Gm. of the salt be boiled with 10 Cc. of ammonia water and 10 Cc. of water (or with 20 Cc. of water and 4 Cc. of alcohol) until it is completely decomposed, and the liquid then filtered, the clear, colorless filtrate will serve for the following tests: If to 5 Cc. of the filtrate, acidulated with nitric acid, barium chloride T.S. be added, not more than very slight turbidity should be produced (limit of sulphate). In another portion of 5 Cc., acidulated with nitric acid, silver nitrate T.S. should produce no precipitate or cloudiness (absence of chloride). If to another portion of 5 Cc. of the filtrate 1 drop of diphenylamine T.S. be added, and then 1 Cc. of pure, concentrated sulphuric acid be poured in, so as to form a layer beneath, no blue color should appear at the line of contact (absence of nitrate or chlorate). If 0.1 Gm. of the salt be dissolved in 10 Cc. of boiling distilled water, and 1 Cc. of sulphuric acid be cautiously added, the solution should require for complete decoloration not less than 31.3 Cc. of decinormal oxalic acid V.S. (corresponding to at least 98.7 per cent of the pure salt)"—(*U. S. P.*). A delicate test for manganous salts (except when chlorides are present) is based on the formation of a purple-colored solution of permanganic acid (MnO_4H), when warming a small quantity of the manganous salt with lead dioxide and nitric acid. The following reaction takes place: $2MnSO_4+5PbO_2+6HNO_3=2PbSO_4+3Pb(NO_3)_2+2H_2O+2MnO_4H$.

Action, Medical Uses, and Dosage.—Locally, permanganate of potassium imparts a brown stain. Unbroken mucous surfaces are unaffected by its application, but a hot, smarting pain is felt when the surface is denuded. Internally, it produces a disagreeable form of heartburn and gastric uneasiness, and a sense of pressure beneath the sternum. Irritant poisoning has resulted from as small a dose as 2 grains when concentrated, while 4 or 5 times that quantity have been taken, well diluted, without apparent injury.

Permanganate of potassium, in powder or a concentrated solution, is a caustic, stimulant, and disinfectant. In weak solutions, it is a stimulant and disinfectant. It has proved very useful in the treatment of various offensive and infectious diseases, as in foul, indolent, and gangrenous *ulcers*, or *abscesses*, *leucorrhœa*, *otorrhœa*, *cancerous ulcers*, *nasal catarrh*, *ozœna*, etc., destroying the fetid odor in these cases, checking exuberant granulations when present, and inducing a healthy appearance of ulcerated surfaces. It has likewise been found a very efficient local application in *phlegmonous erysipelas*, *hospital gangrene*, and *carbuncle*. In these affections it may be applied locally, as a wash, by injection, or by means of spray, and of different strengths, varying from 10 grains to 2 drachms or more to a pint of water, according to circumstances. In *carbuncle* and *felon*, these must first be incised slightly, and then the solution be applied, having the strength of 1 part of the salt to 2 of water, or the fluid may be injected without incision. One part of the salt dissolved in 9 parts of distilled water, has been suggested as a standard solution; of this from ½ to 2 parts may be added to 16 parts of water, as required, though it is always better to commence with the weaker solution. The standard solution of full strength may be used in *indolent ulcers*, *gangrene*, *cancer*, and commencing *diphtheria*. As it becomes more or less decomposed by contact with organic bodies, the solution is best applied by means of a glass brush or syringe. In *stomatitis*, *diphtheritic affections*, *croup*, and other fetid or unhealthy conditions of the mouth, throat, and fauces, *diphtheroid* and *malignant sore throat*, *ulcerated fauces*, *catarrhal hypersecretion*, *pharyngitis*, *laryngitis*, *tonsillitis*, and *ulcerated catarrhal conditions of the broncho-pulmonary tracts*, it may be used in spray or as a gargle, 1 part of the standard solution to 16 parts of distilled water. No other water should be employed in forming its solutions, on account of the organic matters they contain. This fluid may also be used to correct the odor of decayed teeth, to free the hands from any bad smell contracted during post-mortem examinations, and to correct any bad odor from the feet or axillæ. From the fact that serpent poison is destroyed by this drug, it has been recommended as a local agent in *bites of serpents*. It must be in direct contact with the poison to be of any service. It has been proposed for dog-bites, to prevent *rabies*.

The indications for the local use of permanganate of potassium are clearly defined by Prof. Scudder (*Spec. Med.*, p. 209) as follows: "The indications for its use are where the tissues are swollen from infiltration into the connective tissue. In cases of *wounds*, we will notice that the edges are swollen, and the process of repair stops. The infiltration continuing, the pus becomes watery and ichorous, granulations pale and flabby; the parts separate, and finally slough. In inflammation we have very nearly the same indications for its use—the inflammation always being of a low grade, and showing infiltration of cellular tissue." Prof. Locke (*Mat. Med.*, p. 413) tersely puts the indications as "fetid surfaces with granulations half rotten and half alive." A drachm of the permanganate in half a fluid ounce of water, and placed in a saucer under a table, bed, or other convenient place, destroys all odor, and has this great advantage over other deodorants, that it has no odor of its own. Six grains of permanganate of potassium dissolved in a fluid ounce of water, and used as an injection 3 times a day, has proved very successful in the treatment of *gonorrhœa*, to destroy the infective material, after which a weak solution (2 grains to 1 ounce of water) should be employed until a cure is effected. The stains of potassium permanganate may be removed with diluted hydrochloric, sulphurous, or oxalic acids, or solution of ferrous sulphate.

Internally, it has been recommended in *diabetes*, in doses of about 3 grains, given in 3 or 4 tablespoonfuls of water, 3 times a day, a little before meals; but its results have not been very encouraging. Its internal use in *diphtheria*, *scarlatina*, and *zymotic diseases*, generally has been found serviceable, though but seldom employed at the present day. One part of the salt to 10 of water, has been extolled as a remedy against *cholera*. One or 2 parts to 500 of water has been termed *ozonized water*, the dose of which is a fluid drachm in 2 fluid ounces of water, to be repeated 4 or 5 times a day; as an oxidizing agent in the blood, transforming lactic acid into carbonic acid. Administered in ½-grain doses, permanganate of potassium, dissolved in water and raspberry syrup, and repeated 3 times a day, has cured *acute rheumatism*. Within a very few years, the agent, in doses of 1 to 2 grains, 4 times a day, near the menstrual period, has been lauded as an efficient emmenagogue in *atonic amenorrhœa* from cold and other causes. Some declare it useless. Certain it is, that very uncomfortable and even painful gastric symptoms often overbalance the good it may do in this direction. The dose of this salt is from 1 to 2 grains, in pill, every 4 or 6 hours. Solutions for topical use range in strength from 1 in 500 to 1 in 10 parts of water, accordingly, as a stimulant antiseptic or a caustic is required. This salt is claimed to be an antidote for *poisoning by morphine*.

Specific Indications and Uses.—Flabby, pale, unhealthy, half-rotten granulations; fetid surfaces; swollen, infiltrated tissues, with lack of reparative force; low inflammations, with infiltration of connective tissues; phlegmonous erysipelas; inflammations, with low vitality and inclined to slough; early in boils and felons (to abort); watery, ichorous pus; atonic amenorrhœa, from cold, mental strain, or following sea-sickness, with mental depression and pelvic weight and dragging (?).

POTASSII SULPHAS (U. S. P.)—POTASSIUM SULPHATE.

FORMULA: K_2SO_4. MOLECULAR WEIGHT: 173.88.

SYNONYMS: *Sulphate of potash*, *Sulfas potassicus*, *Sulfas kalicus*, *Tartarus vitriolatus*, *Arcanum duplicatum*, *Neutral sulphate of potassium.*

Source and Preparation.—Potassium sulphate occurs in volcanic lava, in sea-water, and the water of mineral springs, and in the ashes of plants. In combination with magnesium salts, it forms the mineral *kainite* in the Stassfurt salt deposits. The salt has, at different times, been known as *Vitriolated tartar*, *Sal polychrestum*, *Sal de duobus*, etc. The medicinal salt may be prepared in different ways, either by neutralizing diluted sulphuric acid with caustic potash or potassium carbonate, and evaporating to crystallization, or by exposing to a red heat potassium bisulphate ($KHSO_4$), obtained as a by-product in the manufacture of nitric acid (see *Acidum Nitricum*). Sulphuric acid is expelled, and neutral sulphate remains, as follows: $2KHSO_4 = K_2SO_4 + H_2SO_4$. Potassium sulphate may also be prepared on a large scale from *kainite* ($K_2SO_4.MgSO_4.MgCl_2 + 6H_2O$) by several methods, one of which consists in boiling a solution of this salt with a calculated quantity of potassium chloride, whereby potassium sulphate crystallizes upon cooling, and *carnallite* ($MgCl_2.KCl + 6H_2O$) remains in solution.

Description and Tests.—Potassium sulphate forms "hard, colorless, transparent, 6-sided, rhombic prisms, terminated by pyramids, or a white powder, odorless, and having a somewhat bitter, saline taste. Permanent in the air. Soluble in about 9.5 parts of water at 15° C. (59° F.), and in 4 parts of boiling water; insoluble in alcohol. When heated, the crystals decrepitate. At a bright-red heat they fuse, and at a white heat the salt suffers partial decomposition. The aqueous solution is neutral to litmus paper. The aqueous solution of the salt yields a copious yellow precipitate with sodium cobaltic nitrite T.S., and a white, crystalline precipitate with excess of tartaric acid T.S."—(*U. S. P.*). Heated with carbonaceous matter, the salt is deoxidized, and sulphide of potassium is formed. A solution of sulphate of potassium, slightly acidulated with nitric acid, yields a white precipitate with chloride of barium, consisting of barium sulphate, insoluble in water and acids. Potassium sulphate is seldom adulterated, though it may contain impurities from carelessness in preparation.

The *U. S. P.* directs the following tests: "When held in a non-luminous flame on a clean platinum wire, the salt should at once impart to the flame a violet color (absence of sodium). The aqueous solution (1 in 20) should remain unaffected by the addition of an equal volume of hydrogen sulphide T.S., either before or after acidulation with hydrochloric acid (absence of arsenic, lead, copper, etc.); or by the addition of a small amount of ammonium sulphide T.S. (absence of zinc, iron, aluminum, etc.). Other portions of the aqueous solution should not be rendered turbid by the addition of ammonium oxalate T.S. (absence of calcium); or of sodium phosphate T.S. and ammonia water (magnesium); or of silver nitrate T.S. (chloride). The addition of potassium ferrocyanide T.S. should produce neither a blue (absence of iron) nor a red color (copper)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sulphate of potassium is a mild, unirritating cathartic, in doses of 15 to 30 grains, when sufficiently diluted with water. In 1 or 2-ounce doses, it acts as a powerful irritant, and has given rise to fatal accidents. It has been used as an aperient after delivery, in *puerperal fever*, to remove intestinal accumulations in children, in *dyspepsia*, and in *jaundice*. Combined with 5 or 10 grains of rhubarb, it is useful in *hepatic disorders* and *hemorrhoids*. Given according to the Schuessler plan, the **3 x** trituration is reputed a good application in fugitive shifting *pains in the muscles* and in *chronic muscular rheumatism*, with debility and muscular soreness. Five grains of the triturate are added to 4 fluid ounces of water, the dose of which is a teaspoonful every 2 or 3 hours.

Specific Indications and Uses.—Dr. Scudder recommended this salt in doses of 5 to 10 grains, 3 times a day in a glass of water when the skin is dirty, tissues full and sodden, and skin scaly; wounds heal slowly, inflame, and suppurate.

Related Salts.—POTASSII BISULPHAS, *Potassium bisulphate, Potassæ bisulphas, Bisulphate of potassa, Bisulphate of potassium, Acid potassium sulphate.* Formula: $KHSO_4$. Molecular Weight: 135.85. This salt may be prepared as follows: Take of sulphate of potassium, in powder, 3 ounces; pure sulphuric acid, 1 fluid ounce. Place the acid and the salt in a small porcelain capsule, and to this apply a heat capable of liquefying its contents; the heat should be continued until acid vapors cease to be given off. The bisulphate, which concretes as it cools, should be reduced to a fine powder, and preserved in a well-stoppered bottle. The salt may also be obtained by recrystallizing from water the residue of potassium bisulphate which remains in the preparation of nitric acid. Precaution must be taken, however, to acidulate the solution with sulphuric acid, because otherwise the neutral salt will crystallize, a corresponding quantity of sulphuric acid passing into solution. According to the quantity of free sulphuric acid present, the following series of crystallizable double salts may be obtained: K_2SO_4; $K_2SO_4+KHSO_4$; $KHSO_4$; $KHSO_4+H_2SO_4$.

Bisulphate of potassium, formerly called *Sal enixum*, forms a white, crystalline powder, or small, oblique, tabular, 4-sided prisms; or, when obtained by extreme concentration and cooling, it forms an apparently firm, fibrous mass. It is odorless, of a very acid taste, is permanent in the air (but the concreted, fibrous mass effloresces), and is soluble in 2 parts of cold and ½ part of boiling water. Alcohol decomposes it into the neutral salt, which is insoluble, and sulphuric acid, which is soluble in alcohol. Exposed to a moderate heat the salt fuses; at a red heat it loses half its acid, and neutral sulphate of potassium remains (which see). It is incompatible with caustic soda and ammonia, the carbonates of these bases, earths and earthy salts, and most metals and their oxides. Bisulphate of potassium is laxative and tonic, and is very useful to keep the bowels regular during recovery from acute attacks, as well as to improve the appetite. Conjoined with rhubarb, it covers the bitter taste of the latter without injuring its medicinal properties. Seventy-two grains, each, of the bisulphate of potassium and carbonate of sodium, separately dissolved in 2 fluid ounces of water, form, when combined, a cheap effervescing purgative. Bisulphate of potassium may be taken in doses of from 20 grains to 2 drachms, properly diluted.

POTASSII SULPHAS CUM SULPHURE, *Sulphate of potassium with sulphur.*—Take of nitrate of potassium, in powder, and of sublimed sulphur, equal weights. Mix them well together, and throw the mixture, by small portions at a time, into a red-hot crucible. When the deflagration is over, allow the salt to cool and place it in a glass vessel, well stopped (*Ed.*). In this process the sulphur burns with a blue flame, and becomes oxidized at the expense of the oxygen of the nitre (nitric acid); the resulting grayish-white compound consists principally of sulphate of potassium, mixed probably with some sulphite. It is claimed to be much more soluble than the sulphate of potassium, and it crystallizes from solution in rhombic prisms. Both the substance itself and its yellowish solution have a sulphurous odor, and an acid reaction. Hydrogen sulphide is not obtained on the addition of an acid to it, nor is sulphide of lead thrown down by the salts of that metal. Eight parts of cold water dissolve one of this compound. It was formerly called *Sal polychrestum Glaseri, Glaser's sal polychrest* (C. P.). This preparation is considered a mild cathartic, resembling very much in its action, that of the sulphate of potassium. It was formerly much in vogue as a purgative in *dyspepsia, chronic cutaneous eruptions*, etc. The dose is from ½ to 1 drachm, and generally given with some other gentle laxative, as bitartrate of potassium.

POTASSII SULPHIS, *Potassium sulphite.*—Formula: $K_2SO_3.2H_2O$. Molecular Weight: 193.84. This salt is prepared by allowing sulphur dioxide to pass into a solution of potassium carbonate until all the carbon dioxide is driven off; upon slowly evaporating, potassium sulphite crystallizes; or the acid salt ($KHSO_3$) is prepared by continuing the current of sulphur dioxide to saturation; an equal quantity of potassium carbonate is then added, which produces the neutral salt, the solution of which is then carefully evaporated. Sulphite of potassium was official in the *U. S. P.*, 1880, which describes it as forming "white, opaque, obliquely-rhombic, octahedral crystals, or a crystalline powder, somewhat deliquescent, odorless, having a bitter, saline, and sulphurous taste, and a neutral or feebly alkaline reaction. Soluble in 4 parts of water at 15° C. (59° F.), and in 5 parts of boiling water; only sparingly soluble in alcohol. When gently heated, the salt loses its water of crystallization (18.5 per cent); at a red heat it is decomposed, and leaves a residue of an alkaline reaction. The aqueous solution of the salt yields a white, crystalline precipitate on the addition of a saturated solution of bitartrate of sodium. Addition of diluted hydrochloric acid to the aqueous solution, gives rise to the odor of burning sulphur, and this solution does not become cloudy (difference from hyposulphite)" (*U. S. P.*, 1880). This salt should be kept in well-stoppered bottles, as it slowly absorbs oxygen, being converted into potassium sulphate. To establish the absence of the latter, or its presence in small amounts, the *U. S. P.*, 1880, directs that a few drops of barium chloride T.S. should cause no precipitate, or produce but a white turbidity in a 1 per cent solution of the salt made strongly acid with hydrochloric acid. The *U. S. P.*, 1880, demanded for this salt a minimum strength of 90 per cent of the pure salt ($K_2SO_3+2H_2O$), which was to be ascertained by the following test: "If 0.485 Gm. of the salt be dissolved in 25 Cc. of water, and a little gelatinized starch added, at least 45 Cc. of the volumetric solution of iodine should be required until a permanent blue tint appears after stirring (corresponding to at least 90 per cent of pure sulphite of potassium)"—(*U. S. P.*, 1880). This agent is reputed to possess the same antifermentative and antiputrefactive qualities as the corresponding salts of sodium and magnesium (which see). From ʒi to ℥ss may be given, well diluted, in 24 hours.

Potassium Bisulphite ($KHSO_3$=119.89).—Pass an excess of sulphurous acid gas into a strong solution of potassium carbonate, and add strong alcohol, which causes this salt to be precipitated. It forms white needles of neutral reaction, yet with a sulphurous taste. It slowly evolves sulphur dioxide when exposed to the air. Its properties and uses are similar to those of potassium sulphite.

Potassium Pyrosulphite ($K_2[SO_2]_2O$).—Forms smooth, hard, glossy plates, having a saline taste. When heated, both sulphur dioxide and sulphur are evolved, the residue being sulphate of potassium. It is produced by passing into a hot and saturated solution of salt of tartar a stream of sulphur dioxide. Its uses are similar to those of potassium sulphite.

POTASSII TARTRAS.—POTASSIUM TARTRATE.

Formula: $K_2C_4H_4O_6.H_2O$. Molecular Weight: 243.66.

Synonyms: *Tartarus solubilis*, *Tartrate of potash*, *Soluble tartar*, *Tartras kalicus*, *Tartras potassicus*, *Potassæ tartras*.

History and Preparation.—Tartrate of potassium, also known by the names of *Soluble tartar*, *Sal vegetabile*, and *Tartarized kali*, was known as early as the seventeenth century. Boerhaave, in 1742, called it *Tartarus tartarisatus*, obtaining it by the action of potassium carbonate (*salt of tartar*) upon potassium bitartrate (*cream of tartar*), which is the method now usually employed. The reaction takes place with formation of the readily soluble, neutral tartrate, as follows: $2KHC_4H_4O_6+K_2CO_3=CO_2+H_2O+2K_2C_4H_4O_6$. In order to obtain a purer product, the bicarbonate is often employed. (For detailed directions, see preceding edition of this *Dispensatory*.)

Description.—Neutral tartrate of potassium forms fine, white, or transparent crystals, consisting of 4 or 6-sided prisms, or a white powder, odorless, somewhat deliquescent, and of a saline, slightly bitter taste, and a neutral reaction to litmus. It is soluble in 0.7 part of water at 15° C. (59° F.), and in 0.5 part of boiling water; almost insoluble in cold alcohol. Its aqueous solution decomposes upon keeping. When heated, the salt melts, becomes black, and evolves inflammable vapors, having the odor of burnt sugar. On moderate ignition, it leaves a blackened residue of an alkaline reaction, strongly effervescing with acids, on account of the formation of carbonate. Diluted acids precipitate crystals of cream of tartar from solutions of the salt, as follows: $K_2C_4H_4O_6+HCl=KHC_4H_4O_6+KCl$. Hence, the neutral potassium tartrate is incompatible with acids, or acid fruit juices; also with the salts of barium, magnesium, calcium, etc., owing to the formation of insoluble tartrates of these elements. A concentrated solution yields with test solution of silver nitrate a white precipitate, which becomes black upon boiling.

Tests.—Potassium tartrate is probably very seldom adulterated, but may contain accidental impurities. Mr. Haussmann (*Amer. Jour. Pharm.*, 1894, p. 297) found several commercial specimens to contain appreciable quantities of lead. If the salt does not yield a perfectly clear solution with water, tartrate of calcium is to be suspected; the filtered liquid, which will still retain a portion of the calcium salt, gives in this case a precipitate with oxalate of ammonium; if, when filtered from this, a fresh precipitate is caused by phosphate of ammonium, magnesium salts are present. If the residue, after dissolving the salt in water, is not entirely soluble in hydrochloric acid, silica is probably present. The presence of heavy metals, such as lead and copper, may be detected by the brown or black coloration or precipitate produced with hydrogen sulphide T.S. in an aqueous solution of the salt. Copper gives a reddish-brown, iron a blue precipitate or color with ferrocyanide of potassium; alumina may be detected by carbonizing the salt, boiling the residue with excess of diluted sulphuric acid, filtering, and then supersaturing with ammonia, when a white, flocculent precipitate occurs, which, being washed, dried, and heated with solution of cobaltous nitrate, on charcoal, acquires a blue color (*Thénard's blue*). Sulphuric and hydrochloric acids are also liable to be present in the form of salts.

The *U. S. P.*, 1880, directed for this salt the following tests: "A 10 per cent aqueous solution should yield no precipitate with test solution of oxalate of ammonium (absence of calcium). On adding nitric acid to a 1 per cent solution of the salt, until the precipitate first formed is redissolved, the resulting solution should yield no precipitate with test solution of chloride of barium (sulphate), and, at most, only a cloudiness with test solution of nitrate of silver (limit of chloride). If 2.938 Gm. of tartrate of potassium are ignited, until gases cease to be evolved, the alkaline residue should require, for complete neutralization, not less than 25 Cc. of the volumetric solution of oxalic acid (corresponding to 100 per cent of pure tartrate of potassium)"—(*U. S. P.*, 1880).

Action, Medical Uses, and Dosage.—This salt is a gentle purgative and diuretic, communicating alkaline properties to the urine, owing to the fact that it is eliminated as a carbonate. It has been employed in *dyspepsia*, *diarrhœa*, *liver complaint*, in *uric acid deposits*, and sometimes as an adjunct to other more active purgatives, as infusion of senna. It may be given in doses varying from 1 or 2 drachms to ½ ounce, or even an ounce, in sufficient water.

PRIMULA.—PRIMROSE

Primula officinalis, Jacquin (*Primula veris*, Linné).

Nat. Ord.—Primulaceæ.

COMMON NAME: *Primrose*.

Botanical Source.—The primrose is a perennial, stemless plant, having a short, upright, scaly root-stalk, of a brownish color, and giving off numerous fleshy roots, which contain a yellow meditullium and are covered with a thick and mealy bark. The pendulous flowers (*flores primulæ*) are borne in umbels of 10 or 12 upon scapes, which are either short or long. The 5-angled calyx is pale-yellow, while the corolla is of a lemon-yellow hue, and is marked in the throat with 5 blotches of a saffron color. The fresh root is slightly sweet in odor, while the taste, at first sweetish, is afterward acrid and bitterish. The flowers, when fresh, have a sweetish taste, and an odor suggestive of honey. When dry they have a deep-greenish color. Primrose is well known as a garden plant, and is native to the grassy and wooded lands of Europe and north Asia.

Chemical Composition.—The root of *Primula veris*, according to Saladin (1830), contains an acrid, neutral principle, which he called *arthanitin*, and which he had previously discovered in the root of *Cyclamen europæum*, Linné. Buchner and Herberger (*Repert. f. d. Pharm.*, Vol. XXXVI, 1831, p. 36) named it *cyclamin* ($C_{20}H_{34}O_{10}$, Hilger and Mutschler). It is a white, crystallizable powder, soluble in alcohol, insoluble in ether, chloroform, and oils; soluble, with difficulty, in water. The aqueous solution foams upon shaking. Upon drying the root, cyclamin decomposes to some extent. De Luca and Hilger found this substance to be a glucosid. By boiling with diluted acids, it splits into sugar and *cyclamiretin* ($C_{15}H_{22}O_2$). Saladin also found the root to contain a semisolid, yellowish essential oil, having the odor of fennel. It deposits *primula camphor* ($C_{11}H_{12}O_5$, Hilger and Mutschler), melting at 49° C. (120.2° F.), soluble in alcohol, ether, benzol, soluble with difficulty in water, and producing a violet color with ferric chloride.

Action, Medical Uses, and Dosage.—This plant constituted an important remedy in the early days of medicine. Under the names *Radix paralyseos* and *Radix arthritica*, it was formerly in great repute in *paralysis* and *gout*, and the plant was valued as a remedy in *muscular rheumatism*, *neuralgic headache* (*hemicrania*), *dysmenorrhœa*, *toothache*, *gravel*, and *insomnia*. Primula possesses sternutatory, astringent, vermifuge, antispasmodic, and pain-relieving properties. It is now seldom employed in medicine. Prof. J. M. Scudder (*Spec. Med.*, p. 212) suggests a tincture of the fresh plant in bloom (℥viij to alcohol, 98 per cent, Oj), the dose of which should range from the fraction of a drop to 10 drops. He gives the following indications: "Extreme sensitiveness, pain from slight impressions, restlessness, and insomnia." Infusion may be made of 5 to 10 per cent strength, the dose being ½ fluid ounce; dose of the flowers, 5 to 15 grains.

Related Species.—*Primula auricula*, Linné. Europe, in the mountains and cultivated. Fragrant lemon-yellow flowers. The aqueous distillate of the root deposits fragrant *auricula camphor* (Hunefeld). This species has, for ages, been used in certain parts of Germany as a remedy for *phthisis pulmonalis*. Other plants related to primrose are:

Primula elatior, Jacquin.—Europe. Large odorless flowers.

Lysimachia quadrifolia, Linné, *Crosswort.*—North America. Flowers yellow.

Lysimachia nummularia, Linné, *Moneywort.*—Europe, and naturalized in North America. Flower large and bright-yellow.

Primula obconica, England, is said to produce an eruption similar to that produced by poison ivy (*Rhus Toxicodendron*). Dr. J. H. Neale (see *Amer. Homœopathist*, Dec., 1897, p. 429) reports an interesting severe case of poisoning by this plant. Lotions of glycerin and alcohol (containing tincture of belladonna) gave relief.

PRINOS.—BLACK ALDER.

The bark and berries of *Prinos verticillatus*, Linné (*Ilex verticillata*, Gray).

Nat. Ord.—Aquifoliaceæ.

Common Names: *Black alder, Winterberry, Feverbush.*

Botanical Source.—This is an indigenous shrub of irregular growth, sometimes known as winterberry, having a stem 6 or 8 feet in height, with a grayish bark, and alternate branches. The leaves are alternate or scattered, on short petioles, oval, acute at the base, pointed, sharply serrate, of an olive-green color, smooth above, and downy beneath, particularly on the veins. The flowers are small, white, diœcious, on very short peduncles; the fertile ones somewhat clustered or solitary; the sterile ones sub-umbellate, and sometimes the flowers are monœcious. Calyx small, 6-cleft, and persistent. Corolla monopetalous, spreading, without a tube, the border divided into 6 obtuse segments. Stamens equal in number to the segments of the corolla, erect, with oblong anthers; in the fertile flowers they are shorter than the corolla, in the sterile they are equal in length to it. The ovary is large, green, and roundish, with a short style and obtuse stigma. The fruit consists of bright-scarlet, globular berries, about the size of a pea, supported by the persistent calyx, and crowned with the stigma. They are 6-celled, containing 6 long seeds, which are convex outwardly, and sharp-edged within. The berries are in scattered groups on the stem, forming small, apparently verticillate bunches (L.—W.).

History, Description, and Chemical Composition.—Black alder is common throughout the United States, growing in moist woods, swamps, edges of streams, etc., flowering from May to July, and maturing its fruit in the latter part of autumn. The bark and berries are medicinal. The dried bark of commerce is in pieces, either flat or slightly quilled, thin, white, with a greenish tint within, brownish-gray externally, readily pulverizable, inodorous, but of a bitterish, subastringent taste. It yields its properties to water by infusion or decoction. The berries have a saccharine, bitterish taste, and yield their virtues to water or alcohol. They should not be substituted, in practice, for the bark. They have not been analyzed. The bark contains, according to L. C. Collier (*Amer. Jour. Pharm.*, 1880, p. 437), resin, wax, tannin, chlorophyll, starch, sugar, albumen, and a yellow, amorphous, bitter principle. (For a quantitative analysis of the bark of this shrub, by J. Stewart Smith, see *Amer. Jour. Pharm.*, 1890, p. 275.)

Action, Medical Uses, and Dosage.—Black alder is tonic, alterative, and astringent. It strengthens the circulation, improves nutrition, and aids in the removal of waste material, thus effectually aiding the vegetative processes. It has been used with good effect in *jaundice*, *diarrhœa*, *gangrene*, and all diseases attended with great weakness. It has also been of service in *dropsy*. Two drachms of the powdered bark and 1 drachm of golden-seal, infused in a pint of boiling water, and, when cold, taken in the course of a day, in doses of a wineglassful, and repeated daily, has proved very valuable in *dyspepsia*. Externally, the decoction forms an excellent local application to *gangrene*, to *indolent ulcers*, some *affections of the skin*, etc. The berries are cathartic and vermifuge, and form, with cedar-apples, a pleasant and effectual worm medicine for children (see *Juniperus Virginiana*). Dose, of the powdered bark, from ½ to 1 drachm; of the decoction, 4 fluid ounces, 3 or 4 times a day. A tincture of the recent bark (℥viii to alcohol, 76 per cent, Oj) may be given in doses of from 5 to 30 drops. Black alder bark is an ingredient of several alterative syrups.

Related Species.—*Prinos glaber*, Linné (*Ilex glabra*, Gray), *Inkberry*. This species grows along the Atlantic seaboard, from Massachusetts south, being most abundant in the southern states. Its berries are black.

Prinos lævigatus, Pursh (*Ilex lævigatus*, Gray).—In northern states, in marshes and southward, and in the Allegheny Mountains.

PRUNUM (U. S. P.)—PRUNE.

"The fruit of *Prunus domestica*, Linné"—(*U. S. P.*).

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Prune tree, Plum tree.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 96.

Botanical Source, History, and Description.—This tree is about 20 feet in height, thornless, and has serrate, oval-elliptic leaves, and pedunculated, whitish flowers, appearing singly or paired. A great number of varieties have been produced so that the fruits differ in size, shape, and color. Its native country is western Asia, but it is now cultivated in most temperate countries.

The dried or prepared fruit is the only official part, and furnishes the *prunes* of commerce. The best prunes come from Bordeaux; an inferior grade is received from Germany. California prunes are of superior quality. Prunes are prepared in warm countries by placing them on hurdles and drying them by solar heat; in colder climates, artificial heat is employed. They have a faint, peculiar odor, and a sweetish, slightly acidulous, and viscid taste. The official prunes are "oblong or subglobular, about 3 Cm. (1¼ inches) long, shrivelled, blackish-blue, glaucous; the sarcocarp brownish-yellow, sweet, and acidulous; putamen hard, smooth, or irregularly ridged; the seeds almond-like in shape, but smaller, and of a bitter-almond taste"—(*U. S. P.*).

Chemical Composition.—The fresh fruits contain about 80 or 85 per cent of water. Dried prunes, analyzed by Bertram (*Jahresb. der Pharm.*, 1878, p. 184), had the following composition: Kernels, 13.7; pulp, 86.3 per cent. The latter contained water (30.03), albumen (1.31), crude fiber (1.34), ash (1.18), nitrogen-free extractive matter (52.44); the latter consisting of grape sugar (42.28), cane sugar (0.22), starch (0.22), free acid (1.74), pectin matter (4.22), undetermined substance (3.76). The acid occurring in prunes, according to Scheele and later observers, is malic acid. The crushed seeds yield upon maceration and subsequent distillation with water, an essential oil containing hydrocyanic acid; this is due to the presence of *amygdalin* (about 1 per cent) and the ferment, *emulsin*, in the seeds (see *Amygdala*). They also contain a brown-yellow, non-drying, fixed oil. Gum sometimes exudes from the ripe fruits.

Action, Medical Uses, and Dosage.—In Germany, a sort of brandy is made from this fruit. Dried prunes are mildly laxative, and are frequently employed in decoction, or the fruit eaten stewed, in convalescence from acute diseases, forming a nourishing and agreeable diet. They are often added to cathartic decoctions, to improve the flavor, and promote the purgative effect. They enter into the composition of the confection of senna. In large quantities, and with some dyspeptics, they are apt to disorder the bowels. The following preparation has been administered with much success in *leucorrhœa*, *irregular menstruation*, and in *debility* from frequent *abortions*: Take of small raisins, or dried currants, 2 ounces, aniseseed, mace, and cinnamon, of each, ½ ounce; and 1 nutmeg, in powder. To these add 1 quart of prune brandy, and let them macerate for 2 weeks, frequently agitating. This is the formula as originally given. Of the clear tincture thus made, 1 fluid ounce may be given previous to a meal, and repeated 3 times daily.

PRUNUS VIRGINIANA (U. S. P.)—WILD CHERRY.

"The bark of *Prunus serotina*, Ehrhart," * * * "collected in autumn"—(*U. S. P.*). (*Cerasus serotina*, De Candolle; *Cerasus virginiana*, Michaux; *Prunus virginiana*, Miller.).

Nat. Ord.—Rosaceæ.

COMMON NAME: *Wild cherry.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 97.

Botanical Source.—The wild cherry is a large tree, generally from 50 to 80 feet high, from 2 to 4 feet in diameter, being of uniform size, and undivided to the height of 20 or 30 feet. The bark is black, rough, and separates naturally from the trunk in thick, slender laminæ. The wood is compact, fine-grained, receives a fine polish, and is extensively employed by cabinet manufacturers. The leaves are deciduous, oval-oblong, acuminate, finely and unequally serrate, with incurved, short, and callous teeth, thickish, smooth, no hairs on the under side, shining above, 3 to 5 inches long, half as wide, and borne on petioles which are furnished with 1 or 2 pairs of reddish glands. The flowers are white, in long, erect, terminal racemes, with a small, solitary flower now and then in the axil of the leaves next to the raceme. Bracts inconspicuous. Calyx with sharp, shallow segments. The fruit is a globular drupe, about as large as a pea, of a purplish black color, edible, but having a bitter taste (L.—W.—G.).

History and Description.—This tree is the *Cerasus serotina* of De Candolle, and the *Cerasus virginiana* of Michaux. It was long confused with and went by the name of *Prunus virginiana*, which properly belongs to the *Choke cherry*, as given by Linnæus (see *Related Species*).

The wild cherry tree is found in many parts of the United States, but is most abundant, and attains the greatest magnitude, in the southwestern states. Its flowers appear in May, and the fruit ripens in August and September. The official portion is the bark, and that of the root should be preferred to that of the trunk and branches. It should be renewed annually, as its properties are much impaired by age. As officially described, wild cherry bark is "in curved pieces or irregular fragments, 2 Mm. ($\frac{1}{12}$ inch) or more thick, outer surface greenish-brown, or yellowish-brown, smooth and somewhat glossy, marked with transverse scars; if the bark is collected from old wood, and deprived of the corky layer, the outer surface is nut-brown and uneven; inner surface somewhat striate or fissured. Upon maceration in water it develops a distinct bitter-almond odor. Its taste is astringent, aromatic, and bitter. The bark of the very large and of the very small branches is to be rejected"—(*U. S. P.*). Water and alcohol take up its virtues; boiling impairs its medicinal properties, by driving off the hydrocyanic acid. That gathered in the fall of the year is the best, inasmuch as it yields more hydrocyanic acid than that collected at any other season; the bark collected in the spring being the least desirable. In order to establish whether a given specimen of bark was collected in autumn, Grace E. Cooley (*Journal of Pharmacology*, 1897, p. 167) recommended to test it for starch and tannin. The starch contained in bark reaches a maximum in spring (April) and in autumn (October), and disappears almost entirely in summer and in winter. Tannin occurs in spring bark in a notably greater quantity than in bark collected in autumn. The distinction is recognizable by means of the ferric chloride test for tannin (for details, see the original paper). Hence, the bark collected in autumn is characterized chemically by containing much starch and little tannin, and yielding the largest amount of hydrocyanic acid.

Chemical Composition.—Dr. Stephen Procter (*Amer. Jour. Pharm.*, Vol. VI, 1834, p. 8), made the first detailed analysis of this bark, and found it to contain starch, resin, tannin, gallic acid, fatty matter, etc., and a straw-colored, volatile oil, analogous to that from bitter almonds, and, like the latter, containing prussic acid. Prof. W. Procter (*ibid.*, Vol. X, 1838, p. 197) showed that the volatile oil is the decomposition product of *amygdalin* (see *Amygdala*), which he isolated from the bark. A ferment, analogous to emulsin, is probably present. The yield in essential oil, according to Schimmel & Co. (*Report*, April, 1890), is 0.2 per cent. Prof. F. B. Power and Mr. Henry Weimar (*Pharm. Rundschau*, 1887, p. 203) state that wild cherry bark does not contain crystallizable amygdalin, but an analogous substance, obtainable only in an extract-like form, and probably more closely related to *laurocerasin* (see *Laurocerasi Folia*). According to the same authors, the fluorescent principle contained in the bark, is a crystallizable glucosid, which is probably also the cause of the peculiar bitterness of the bark (compare R. Rother, *Amer. Jour. Pharm.*, 1887, p. 286). The amount of hydrocyanic acid obtainable from the bark varies from 0.05 per cent, in April, to 0.14 per cent in October (J. S. Perot, *Amer. Jour. Pharm.*, 1852, p. 111). More recently, A. B. Stevens and J. N. Judy (*Proc. Amer. Pharm. Assoc.*, 1895, p. 226) found notably higher results—viz.: 0.32 to 0.34 per cent for thick bark, and 0.24 to 0.27 per cent for thin bark, the higher results being probably due to a more perfect exhaustion of the bark, owing to repeated distillation. The same authors found 4.12 per cent of amygdalin-like substance in thick bark. and 3.16 per cent in thin bark. (For an admirable review of the earlier chemical and the botanical history of wild cherry bark, see R. Bentley, *Pharm. Jour. Trans.*, Vol. V, 1863, p. 97.)

Action, Medical Uses, and Dosage.—Wild cherry bark has a tonic and stimulating influence on the digestive apparatus, and a simultaneous sedative action on the nervous system and circulation. It is, therefore, valuable in all those cases where it is desirable to give tone and strength to the system, without, at the same time, causing too great an action of the heart and blood vessels, as, during convalescence from *pleurisy, pneumonia, acute hepatitis,* and other *inflammatory* and *febrile diseases.* Its chief property is its power of relieving irritation of the mucous surfaces, making it an admirable remedy in many *gastro-intestinal, pulmonic,* and *urinary troubles.* Like lycopus, it lessens vascular excitement, though it does not control hemorrhages like that agent. It is best adapted to chronic troubles. It is also useful in *hectic fever, cough, colliquative diarrhœa,* some forms of *irritative dyspepsia, whooping-cough, irritability of the nervous system,* etc., and has been found an excellent palliative in *phthisis,* the syrup being employed to moderate the cough, lessen the fever, and sustain the patient's strength. It has likewise been of service in *scrofula* and other diseases attended with much debility and hectic fever. Wild cherry is an excellent sedative in *cardiac palpitation,* not due to structural wrongs. It is particularly useful in this disorder when there is nervous fever, *tuberculosis,* or the debility consequent upon *irritative dyspepsia, anemia, chlorosis,* or *nervous diseases.* Externally, it has been found useful, in decoction, as a wash to *ill-conditioned ulcers* and *acute ophthalmia.* Dose of the powdered bark, 1 or 2 drachms; of the infusion, 1 ounce of bark to 1 pint of cold water, and allowed to stand a few hours, from 1 to 4 fluid ounces, 4 or 5 times a day, and which is the best mode of using it; syrup of wild cherry, 1 fluid drachm. This agent may be used as a vehicle for Fowler's solution and other medicines. Specific prunus, 1 to 20 drops.

Specific Indications and Uses.—Rapid, weak circulation; continual irritative cough, with profuse muco-purulent expectoration; cardiac palpitation, from debility; dyspnœa; pyrexia; loss of appetite; and cardiac pain.

Related Species.—*Prunus virginiana* of Linné and Marshall (*Prunus obovata,* Bigelow; *Cerasus virginiana,* De Candolle; *Prunus demissa,* Walters), *Choke cherry.* Common in the United States and Canada, and, according to Prof. Sargent, "the most widely distributed of any American species of tree" (Prof. E. S. Bastin, *Amer. Jour. Pharm.*, 1895, p. 595). A small shrub, sometimes arborescent, usually from 6 to 10 feet high, having thin, oval, or obovate, sharply-serrate leaves, terminating in an abrupt point. The flowers are white, and borne in short, dense racemes. The fruit is a red, or purplish-red, bitterish, and exceedingly astringent berry. The latter is often employed, in combination with cider, in domestic medication.

Related Preparation.—*Elixir Pinus Compositus.* This is a *cough* mixture, representing the combined virtues of white pine (fresh bark), balm of gilead buds, spikenard, cherry bark, ipecac, sanguinarine nitrate, chloroform, morphine acetate, and ammonium chloride. It is an excellent preparation, was introduced under this name, and is prepared only by the Wm. S. Merrell Chemical Co., of Cincinnati, O.

The dried and powdered alcoholic extract known as the "concentration," "*prunin,*" or "*cerasin,*" prepared from both wild cherry and choke cherry, is an inefficient agent, seldom now used.

PSORALEA.—PSORALEA.

The root and leaves of *Psoralea melilotoides,* Michaux.

Nat. Ord.—Leguminosæ.

Botanical Source and History.—The genus Psoralea comprises an extensive family of plants, mostly found in America, and in the neighborhood of Cape of Good Hope. It consists, generally, of glandular-dotted herbs, with from 3 to 5 foliate leaves, and short, thick, indehiscent, 1-seeded legumes. The flowers, which are white or blue, are disposed, in all our indigenous species, in axillary spikes or racemes. The tubular calyx is 5-parted, with the lowest lobe longest.

Psoralea melilotoides, Michaux (*P. eglandulosa,* Elliott), is the most common native species, found in open woods from Ohio and Kentucky, southward. The plant is pubescent and nearly glandless. The pale-blue flowers are borne on peduncles about 4 inches long. The leaves are trifoliate, with entire lanceolate leaflets. The root is variously known as *Bob's root*, *Samson snake-root*, and *Congo root*. The fresh root has an agreeable, aromatic odor, and a bitterish, spicy, even acrid taste. Odor and taste are weaker after drying the root. It contains about 2 per cent of a volatile oil, starch, and a bitter principle, probably also a substance resembling tannin.

Psoralea esculenta, Pursh, is indigenous to the elevated plains of the northwest. It has 5 leaflets and capitate spikes of blue flowers. The root is bulbous, and is said to act as a diuretic, although, when boiled, it is used as food by the natives. It is called *Bread root*, *Prairie turnip*, and sometimes (erroneously) *Indian turnip*. According to Mr. Clifford Richardson, the root of this species contains nearly 70 per cent of starch (see Prof. J. M. Maisch's interesting report on useful plants of the genus Psoralea, in *Amer. Jour. Pharm.*, 1889, pp. 345–352).

Besides these, there are several other species of Psoralea, among them the following: *P. bituminosa*, Linné, of the south of Europe, a tonic emmenagogue; *P. glandulosa*, Linné, to which, at one time Paraguay tea or Yerva mate was erroneously referred (see J. M. Maisch, *loc. cit.*, and analysis by Lenoble, *Jour. d. Pharm.*, 1850); *P. pentaphylla*, Linné, of Mexico, the root of which is sometimes called *White contrayerva* (see analysis by Mariano Lozano y Castro, in Prof. Maisch's report, *loc. cit.*); and *P. corylifolia*, Linné, of India and Arabia. The seeds of this species (*bauchee seeds*) are employed as a tonic in cutaneous affections.

Action, Medical Uses, and Dosage.—The root and leaves of these plants appear to possess the properties of a mild, stimulating, bitter tonic, and have been advantageously employed in cases of languor or feebleness from mental or physical exertion, in certain forms of *chronic dyspepsia*, to relieve anorexia, and as a stimulating tonic in *strumous affections of the mesentery*, accompanied with *diarrhœa*, tumid abdomen, etc. The *Psoralea melilotoides* is the plant employed in this country, in infusion, or made into a tincture.

PTELEA.—WAFER ASH.

The bark of the root of *Ptelea trifoliata*, Linné.

Nat. Ord.—Rutaceæ.

Common Names: *Wafer ash*, *Shrubby trefoil*, *Hop tree*, *Swamp dogwood*, *Wingseed*.

Botanical Source.—This plant is a shrub from 6 to 8 feet in height, leaves trifoliate, marked with pellucid dots; leaflets sessile, ovate, short, acuminate, downy beneath when young, crenulate, or obscurely toothed; lateral ones inequilateral, terminal ones cuneate at the base, 3 to 4½ inches long by 1¼ to 1¾ inches wide. The flowers are polygamous, greenish-white, nearly ½ inch in diameter, of a disagreeable odor, and borne in terminal corymbose cymes. Stamens mostly 4; style short. The fruit is a 2-celled samara, nearly 1 inch in diameter, winged all around, and nearly orbicular (G.—W.).

Fig. 202.

Ptelea trifoliata.

History and Description.—Wafer ash, or ptelea, is a shrub common to this country, growing more abundantly west of the Alleghanies, in shady, moist hedges, and edges of woods, and in rocky places; it flowers in June. The bark of the root is medicinal, and yields its properties to boiling water, but alcohol is its best solvent. It is when dried, of a light, brownish-yellow color externally, in cylindrical rolls or quills, 1 or 2 lines in thickness, and from 1 to several inches in length, irregularly wrinkled and furrowed externally, with broad, transverse lines or rings at short but irregular intervals, and is covered with a thin epidermis; internally it is yellowish-white, but becomes darker on exposure, and is wrinkled longitudinally.

It is brittle, with an almost smooth, resinous fracture; granular under the microscope, resembling wax. It has a peculiar smell, somewhat similar to that of liquorice root, and a peculiar, bitter, resinous, pungent, acrid, and rather disagreeable taste, speedily and powerfully acting upon the mouth and fauces, and of persistent pungency, which is probably owing to its oleoresin. The leaves and fruit have also been used in medicine. A related species, *Ptelea angustifolia*, Bentham, is indigenous to Colorado.

Chemical Composition.—Mr. George M. Smyzer (*Amer. Jour. Pharm.*, 1862, p. 200) found the bark of the root to contain gum, albumen, starch, volatile oil, of disagreeable taste and odor, fixed oil, and probably potassium nitrate. No tannin was present. The active properties of the root he believes to be due both to the volatile oil and an acrid, soft resin, soluble in alcohol and ether; another brittle resin, soluble in ether, but insoluble in alcohol, is inert. The leaves yield to water a bitter infusion, resembling in taste that of hops, and containing tannic and gallic acids. The fruit is likewise bitter, and yields the same resins as the root. Justin Steer (*ibid.*, 1867, p. 337) believes the bitterness of the root-bark and its virtues, as a tonic, to be due to *berberine*. More recently (*Jahresb. der Pharm.*, 1896, p. 510). E. Schulze found the root of *Ptelea trifoliata*, to contain the base *arginine* ($C_6H_{14}N_4O_2$), a constituent of germinating *Lupinus luteus*, and other plants, and one of the decomposition products of horn, obtained when treating it with hydrochloric acid and stannous chloride (S. G. Hedin, *Chem. Centralblatt*, Vol. II, 1894, p. 993; and Vol. I, 1896, p. 118). It is characterized by a dark-blue crystallizable compound with copper nitrate ($[C_6H_{14}N_4O_2]_2.Cu[NO_3]_2.3H_2O$).

Action, Medical Uses, and Dosage.—Ptelea is tonic, and surpassed in this line only by hydrastis. Used after *intermittent fevers*, *remittent fevers*, and all cases of *debility* where tonics are indicated. Said also to be anthelmintic. Equal parts of ptelea and Euonymus atropurpureus, have been found very useful in *pulmonary affections*. A tincture of ptelea, made in whiskey, is reputed to have cured several cases of *asthma*, and is said to cause, in many instances where it has been used, a troublesome external *erysipelatous inflammation*, either general or local, but which, if the use of the tincture be persisted in, finally disappears, and the patient becomes, at the same time, permanently cured of the disease for which he was treated. This would certainly indicate other valuable properties in this plant, than those with which we are acquainted, which deserve a further and thorough investigation. Prof. I. G. Jones stated that this bark is a pure, unirritating tonic, having rather a soothing influence when applied to irritated mucous membranes. He has employed it advantageously in convalescence after fevers, and in debility connected with gastro-enteric irritation. It promotes the appetite, enables the stomach to endure suitable nourishment, favors the early reestablishment of digestion, and will be tolerated by the stomach when other tonics are rejected. He employed it in cold infusion, of which ½ fluid ounce may be given every 2, 3, or 4 hours, according to circumstances. It is also said to cure intermittent fever, and is considered by some to be equal to quinine. It may be used in powder, tincture, or extract. Dose of the powder, 10 to 30 grains, 3 or 4 times a day; of the tincture, 1 or 2 fluid drachms; of the extract, 5 to 10 grains; specific ptelea, 1 to 20 drops.

Specific Indications and Uses.—Asthmatic breathing; chronic diseases, with sense of constriction in the chest, and short breathing.

PTERIS.—PTERIS.

The whole plants of *Pteris atropurpurea*, Linné, and other species of *Pteris*.

Nat. Ord.—Filices.

COMMON NAMES: (1) *Rockbrake;* (2) *Common brake.*

Botanical Source.—Rockbrake is an indigenous perennial fern, with a frond 6 to 10 inches in height, twice as long as wide, of a grayish hue, pinnate, the two lower divisions consisting of 1 to 3 pairs of leaflets, with a large terminal segment. The stipe and rachis are dark-purple, shining, with dense, paleaceous hairs at base. The lower leaflets are ternate or pinnate, lanceolate, obtuse, distinct, obliquely truncate or subcordate at the base, with margins conspicuously revolute. The involucre is rather broad, and formed of the inflected margin of the frond, opening inwardly. The sori are in a broad, continuous line along the margin of the frond. The several varieties of this species possess similar properties, as the *Pteris venosa*, with the stipe angled, and the leaflets veined beneath; *P. punctata*, with the stipe terete, and the leaflets punctate beneath (W.—G.).

The *Pteris aquilina*, Linné, or *Common brake*, likewise possesses analogous virtues. It is a fern 2 to 5 feet in height, upon a smooth, dark-purple, erect stipe. The frond is pinnate, 3-parted, broad-triangular in outline; the branches bipinnate; the leaflets linear-lanceolate; the lower ones pinnatifid, upper ones entire; the segments oblong and obtuse. The sori are covered by the folding back of the margins of the segments (W.).

History, Description, and Chemical Composition.—Rockbrake is common to the United States, usually growing on limestone rocks; the common brake is found in great abundance in woods, pastures, waste grounds, and stony hills. The whole plant is used in medicine, and imparts its virtues to water. As found in commerce, the dried root consists of a long cylindrical caudex, of a dark-brown color externally, and a light brownish-red internally, of an astringent, leathery taste, and around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leaf-stalks or stipes, which are 1 or 2 inches in length, from 2 to 4 lines thick, somewhat curved and directed upward, angular, dark-brown, furrowed longitudinally, and from between which emerge numerous small, radical fibers. The dried leaves are of a light-grayish or greenish-yellow color, of an odor resembling that of sole-leather, and a leathery, astringent, not disagreeable taste. As sold, it is usually in broken fragments. According to Wackenroder, the root of the common brake contains a bitter substance, fatty oil, mucilage, starch (33.5 per cent), tannin, etc. It also contains volatile oil and *filicin*, a derivative of the phenol *phloroglucin* ($C_6H_3[OH]_3$).

Action, Medical Uses, and Dosage.—Rockbrake is astringent and anthelmintic. A decoction of it, taken moderately, has proved efficient in *diarrhœa*, *dysentery*, *night-sweats*, and *hemorrhages;* and, used as a local application, it is beneficial in obstinate and ill-conditioned *ulcers*, *ulcerations of the mouth and fauces*, and as a vaginal injection in *leucorrhœa*. A strong decoction is in repute as a remedy for *worms*. A powerful astringent infusion may be made by adding 4 drachms of the plant to 1 pint of boiling water, and which has been used in diarrhœa and dysentery, in ½ fluid ounce doses, repeated every 2 or 3 hours, with success. A tincture of the fresh entire plant (℥viii to alcohol, 76 per cent, Oj) is suggested in from 1 to 10-drop doses (Scudder). *Pteris aquilina* is sometimes called *Female fern*, and has been used to expel *tapeworm*.

A plant called *Winter fern*, or *Brake*, is much employed in *amenorrhœa* and in *suppression of the lochia;* it is used in infusion and taken freely. By some it is supposed to be the *Pteris atropurpurea*, but of this I am not positive, not having been able to obtain a perfect specimen of the plant for examination. Both the roots and tops are used, and are worthy the attention of the practitioner in the above-named derangements (J. King).

PULSATILLA (U. S. P.)—PULSATILLA.

"The herb of *Anemone Pulsatilla* and *Anemone pratensis*, Linné, collected soon after flowering. It should be carefully preserved, and not be kept longer than 1 year"—(*U. S. P.*).

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Pasque flower*, *Passe flower*, *Wind flower*, *Meadow anemone.*

ILLUSTRATION: Meehan, *Native Flowers and Ferns*, Vol. I, 49.

Botanical Source.—ANEMONE PRATENSIS (*Pulsatilla nigricans*, *Pulsatilla pratensis*, Miller), *True* or *Small meadow anemone.* This is a handsome species of this genus of perennial plants, with simple, erect, rounded stems, from 3 to 5 inches high. The leaves are radical, pinnatifid, and downy; the segments many-parted, with linear lobes. The flowers are solitary, terminal, pendulous, deep-purple or violet-brown, having 6 sepals, somewhat narrow, pointed, reflexed at the point, erect and converging at the base. Stalked glands or sterile stamens are found between the fertile stamens and sepals (L.). The proximity of the involucre is such that it has a calyx like appearance.

ANEMONE PULSATILLA (*Pulsatilla vulgaris*, Miller).—This plant differs from the preceding by having the involucre more remote from the flower, at least in the mature plant, in being more hairy, and in possessing a scape curved above and more shaggy than that of the preceding plants. Its flower is but half the size and of a deeper color than that of *Anemone pratensis*.

Fig. 203.

Anemone Pulsatilla.

History.—Pulsatilla or Pasque flower grows in Turkey, in Russia, and in other parts of Europe, as in Germany, France, Denmark, Sweden, and southern England. It also grows in Asia, in open fields, plains, hills, sandy pasture grounds, and open pine woods, exposed to the sun, flowering early in the spring, and, according to some writers, again in the latter part of summer or early in the fall. Owing to its early blooming period, at about Eastertide, it has been named by the French *Pasque flower*, having reference to the Passover and Paschal ceremonies. The plant has a very slight odor, and an acrid, pungent taste. The leaves are not fully matured at the early flowering period. The whole plant is covered with soft, silky, white hairs, giving to it a lax, shaggy, woolly appearance. All species of Anemone wilt very quickly. An acrid, volatile constituent is emitted when the fresh plant is bruised, sufficiently powerful to produce lachrymation and even vesication. To give its best therapeutic action, the plant should be put into alcohol before being allowed to dry. Alcohol appears to be its best menstruum. The tincture may be prepared by macerating 2 pounds of the fresh plant in 4 pints of strong alcohol, then expressing and filtering. It has a brownish-green color, and an acrid, pungent taste. Even fluid preparations of pulsatilla become altered with age, consequently the physician should frequently renew his stock.

Description.—The *U. S. P.* thus describes the drug: "Leaves radical, petiolate, silky-villous, twice or thrice deeply 3-parted, or pinnately-cleft, with linear, acute lobes, appearing after the large, purple flowers; inodorous, very acrid"—(*U. S. P.*).

Chemical Composition.—Pulsatilla, in fresh condition, yields upon distillation with water, a colorless to yellow, acrid oil, from which chloroform abstracts crystallizable, acrid, vesicating *anemone camphor*. It is an unstable body and readily decomposes into *anemonin* and *isoanemonic acid*, especially when in moist condition. (For further details, see *Anemone patens* var. *Nuttalliana*.) The formula ($C_{10}H_8O_4$) given to *anemonin* by Beckurts (1892) was confirmed by Hans Meyer (*Jahresb. der Pharm.*, 1896, p. 509), who believes it to be related to *cantharidin* ($C_{10}H_{12}O_4$). Pulsatilla also contains iron-greening tannin.

Action, Medical Uses, and Dosage.—Topically applied, the fresh plant of pulsatilla is irritant, and, if kept long in contact with the skin, may produce vesication. When chewed, it produces a benumbing sensation and tingling formication, somewhat like that produced by aconite or prickly ash. Taken internally in overdoses, it acts as a gastric irritant, producing a sense of rawness, burning, pain in stomach, with endeavors to vomit, all accompanied with marked prostration. A case of poisoning with these symptoms is on record in the *Medical Gleaner*, Vol. IV, p. 173. A sense of constriction and tightness of the chest, with chilliness, marked weakness, and some congestion, has been produced by large doses. Full doses depress the action of the heart, lower arterial tension, and reduce temperature. Sensory and motor paralyses have followed large doses of pulsatilla, while toxic doses may produce mydriasis, stupor, coma, and convulsions. In medicinal doses, pulsatilla increases the power and regulates the action of the heart, and gives a better character to the pulse rate, particularly slowing the irritable, rapid and feeble pulse due to nervous depression. It improves the sympathetic system and cerebral functions, and especially strengthens sympathetic innervation, this action being very marked in troubles of the reproductive organs of male and female.

Pulsatilla forms an important remedy with the Eclectic physicians as well as with the Homœopaths, who make extensive use of it. According to the late Prof. J. M. Scudder, M. D., who used it largely in his practice, its most important use is to allay irritation of the nervous system in persons of feeble health, thus giving sleep and rest, preventing unnecessary expenditure of nerve force, and, by this means, facilitating the action of tonics and restoratives. In feeble women, and men who have become nervous from sedentary habits or mental over-exertion, as well as in the nervousness and restlessness of masturbators, or persons addicted to the excessive use of tobacco, he has found it very certain in its action. It is *the* remedy for nervous women, when there is debility and faulty nutrition of the nerve centers.

Pulsatilla is a remedy of wide applicability, but more particularly for those conditions in which the mind is a prominent factor. A gloomy mentality, a state of nerve depression and unrest, a disposition to brood over real or imagined trouble, a tendency to look on the dark side of life, sadness, mild restlessness, and a state of mental unrest generally denominated in broad terms "nervousness," are factors in the condition of the patient requiring pulsatilla. A pulsatilla patient weeps easily, and the mind is inclined to wander—to be unsettled. The pulse requiring pulsatilla is weak, soft, and open, and the tissues have a tendency to dryness (except when the mucous tissues are discharging a thick, bland material), and, about the orbits the parts appear contracted, sunken, and dark in color. The whole countenance and movements of the body depict sadness, moroseness, despondency, and lack of tone. Hysteria of the mild and weeping form may be a symptom. The whole condition is one of nervous depression, the nutrition of the nerve centers are at fault. With such symptoms, pulsatilla may be confidently prescribed in the conditions and disorders enumerated in this article. Pulsatilla may be given to produce sleep, when there is great exhaustion and opiates are inadmissible. If the insomnia depends upon determination of blood to the brain, pulsatilla will not relieve, but when due to nervous exhaustion it is a prompt remedy to give rest, after which sleep obtains. Where sleep is disturbed by unpleasant dreams, and the patient awakens sad and languid, pulsatilla should be given. Pulsatilla has a large field in troubles incident to the reproductive organs of both sexes. As an emmenagogue, it serves a useful purpose in *amenorrhœa* in nervous and anemic subjects, with chilliness a prominent symptom. When menstruation is suppressed, tardy or scanty from taking cold, or from emotional causes, pulsatilla is the remedy. In *dysmenorrhœa*, not due to mechanical causes, and with the above-named nervous symptoms, no remedy is more effective. *Leucorrhœa*, with a free, thick, milky, or yellow, bland discharge and pain in the loins, and particularly in scrofulous individuals, calls for pulsatilla. It is a remedy for mild forms of *hysteria*, where the patient is weak and weeps easily, has fears of impending danger, and passes large quantities of clear, limpid urine, and menstruation is suppressed.

The long-continued use of pulsatilla as an intercurrent remedy, is accredited with curative effects in *uterine colic*, but it is of no value during an attack. Pulsatilla frequently proves a good remedy in *ovaritis* and *ovaralgia* with tensive, tearing pain. Sluggish, ineffectual, and weak labor-pains are sometimes remedied by this drug. It is frequently a remedy for *pain*, when dependent on or associated with debility, and sometimes when due to acute inflammation. It is a leading remedy in *epididymitis* and *orchitis*, whether due to gonorrhœal infection or to metastasis from mumps. The dark-red, congested, enlarged, and sensitive testicle indicates it. It relieves the pains of *orchialgia*, and subdues *mammary swelling* from the metastasis of mumps. Pulsatilla increases sexual power, but lessens *morbid sexual excitement*. It is especially valuable in relieving urethral irritation and consequent *spermatorrhœa* and *prostatorrhœa*. In these troubles it overcomes the nervous apprehensions so frequently a troublesome feature. It also alleviates the nervous irritability accompanying or produced by *varicocele*. In *gonorrhœa*, particularly of the chronic type, pulsatilla is of value, when the urethral membrane is swollen. Pulsatilla has been used by some for the relief of *hydrocele*, but for this affection we possess better remedies. Many unpleasant conditions of the urinary apparatus are relieved by pulsatilla, as frequent but ineffectual attempts at urination, the bladder giving a sensation as if bloated; dribbling of urine from movement, the *dysuria of pregnancy*, and in involuntary micturition from colds or from nervous debility.

Pulsatilla frequently proves a useful remedy in *headache* of various types. It relieves the *frontal headache* from *nasal catarrh*, *nervous headache*, particularly when due to gastric disturbances, with greasy taste, *menstrual headache*, with chilliness and suppressed menses, *bilious* and *gastric headaches*, of a dull and heavy character, with greasy taste and nausea, and headaches due to uterine irregularities or to a rheumatic diathesis. These headaches are all of anemic character—the opposite of those relieved by gelsemium. Though ordinarily not a remedy for acute inflammations (contraindicated in gastro-intestinal inflammation), there are some conditions where small doses of pulsatilla are beneficial when the usual symptoms calling for the drug are present. These conditions are *acute inflammation of the nose, fauces, larynx*, or *bronchiæ*. It is especially effective in the secondary stage of *acute nasal catarrh*, when the naso-pharynx is affected and there is a sense of rawness and moisture, and an abundant discharge of thick, yellow, bland, inoffensive mucus or muco-pus. Pulsatilla frequently serves a good purpose in *asthma* superinduced by pregnancy, or by suppressed menses, and it favorably influences *whooping-cough* in properly selected cases. So-called "*stomach cough*" is frequently cured by pulsatilla.

Pulsatilla should be remembered as a remedy of much value to control the catarrhal symptoms of the *exanthemata;* it also controls the irritability frequently accompanying these disorders. In *measles*, it has done good service in checking the coryza and profuse lachrymation, as well as the dry, tight, painful cough, and when retrocession of the eruption has taken place, it has reversed this unpleasant condition. It relieves the irritable condition in *varicella*. Pulsatilla is very efficient in real and imaginary *cardiac affections*. It has proved useful in *cardiac hypertrophy* and in *dilatation of the venous heart*. It is especially effective in *functional heart disorders* with giddiness, imperfect voluntary motion, impaired vision, and with a symptom described as a sense of pressure over the larynx and trachea, with imperfect respiratory movement, and sense of impending danger; the symptoms just preceding are those not unfrequently associated with functional heart disease, dyspepsia, uterine disease, or over-excitation of the sexual system, and are generally very unpleasant and annoying. It often relieves that form of *venous congestion* which stops short of inflammation, as in threatened *ovaritis, orchitis, varicocele*, and *crural phlebitis. Varicocele* and other *varicoses* are frequently improved by its administration with other indicated remedies. Its chief advantage, outside of some control over the venous structure, is its relief of the nervous complications. It has been used to good advantage for the relief of *hemorrhoids*.

Constipation in the hysterical female yields to nux vomica and pulsatilla, and the latter has a pleasing action in some forms of *indigestion* and *dyspepsia*. These cases are those in which there is a thick, creamy paste upon the tongue and a greasy taste. Such troubles are frequently brought about by indulgence in pastries and fatty food. Pain is not marked, but there is pyrosis and greasy eructations, gastric distension, uneasy gnawing sensations in the stomach, and chilliness may be a pronounced symptom. The patient is nervous, sad, and may have a soft, yellow diarrhœa. For such cases pulsatilla is an excellent remedy. It is also said to relieve alternating *constipation* and *diarrhœa* with venous congestion. Pulsatilla is a prompt and decisive agent in *earache*, brought on by cold, wet, and exposure to winds. There is an absence of fever, the pulse is open and soft, the child sobs, the face is pale, the tissues full and waxen, the pain is intense and frequently paroxysmal and tearing in character—evidently a neuralgic condition, for physical signs of local disturbance are seldom observed. In *purulent otitis media*, with thick, yellow, bland discharge, and impaired hearing, and tinnitus aurium, pulsatilla is the indicated remedy.

One of the earliest uses of this plant was for the relief of "*amaurosis, cataract*, and *opacity of the cornea*," conditions in which the reputed value of pulsatilla is very much overrated. There is a condition, sometimes known as "*nervous blindness*," which has been benefited by pulsatilla, and this is probably the condition formerly referred to under the elastic term amaurosis. Pulsatilla stands out prominently as a remedy for *hordeolum* or "*stye*." It is also a prompt remedy when the conjunctiva is hyperemic and the vision weakened, especially after reading, or from sexual abuse or sexual excesses, and in *profuse lachrymation* from exposure to winds or when in the wind. It should be used locally (gtt. x to aqua ℥ij) and also given internally in small doses. In *chronic conjunctivitis*, with bland, yellow discharges, in scrofulous individuals, or due to the exanthemata, and in *ophthalmia* *neonatorum*, with like discharge, pulsatilla has been used with signal success. It relieves deep-seated, heavy pain in the globe of the eye, and has been recommended in *inflammation of the lachrymal sac*. Störck, who was one of the first to use pulsatilla, considered it useful in *secondary syphilis*, and in some forms of *cutaneous diseases*, as well as in amaurosis and other ocular affections.

This drug has been used with much success in *rheumatism*, when the pains were shifting and relieved by cold and aggravated by warmth. Depression of spirits is here a prominent feature. It has also aided in restoring the flow of milk in *agalactia* in nervous and fear-depressed women, whose breasts were painful and swollen. Prof. W. E. Bloyer emphasizes its value in "*jerking*" or "*jumping*" *toothache*, usually due to the formation of a pus cavity near the nerve. He applied the full strength specific pulsatilla, or diluted one-half with water, besides giving the drug internally. He also recommends this treatment as "especially useful in *inflammations* caused by dead teeth, and the inflammatory, painful, and unpleasant conditions of the pulp cavity in those in which the nerve has been destroyed" (*Ec. Med. Jour.*, 1895, p. 248). The dose of specific pulsatilla is from a fraction of a drop to 10 drops, administered in water; of the fluid extract, from 1 to 15 drops; of the extract, from $\frac{1}{6}$ to 1 grain; of anemonin, $\frac{1}{20}$ to $\frac{1}{4}$ grain.

Specific Indications and Uses.—Nervousness and despondency, sadness, unnatural fear, tendency to weep, morbid mental excitement, marked depression of spirits; pain, with debility, nervousness, headache, not dependent on determination of blood to the head; insomnia, from nervous exhaustion; neuralgia in anemic, debilitated subjects; pasty, white, or creamy, thick coating upon the tongue, with greasy taste; stomach disorders from indulgence in fats and pastries; thick, bland, inoffensive discharges from mucous surfaces; alternating diarrhœa and constipation, with venous congestion; amenorrhœa and dysmenorrhœa, with gloomy mentality and chilliness; severe pains in the ear, non-inflammatory and evidently neuralgic; pain from exposure to wind; jumping toothache, from abscess near the dental pulp; styes.

PULVERES.—POWDERS.

Medicines which have no nauseous or unpleasant taste, no acrid or destructive action, which are not deliquescent, and which can be given in not too bulky doses, are usually more advantageously administered in fine powder. When an article is reduced to powder, it has a much greater surface exposed to the influence of light and of the atmosphere than when in the crude, aggregate mass; and as most, if not all vegetable powders, are injured by the action of these agents, it is always better to keep them in well-closed tin cans, or in well-stoppered bottles, which are covered externally with a coat of black paint, varnish, or black paper. Some agents become damp or lose their virtues rapidly when in the state of powder; such should be pulverized in small quantities at a time, and only as they are required. As a general rule, the finer the powder, or the longer it is triturated, the more active it becomes.

M. Dorvault thinks that the operation of pulverization effects an actual change in the chemical and therapeutical properties of many agents. Sugar is less soluble in water, and less sweet, when long pulverized or triturated, and, he inquires, is this to be referred to an altered electrical condition of the sugar, as the phosphorescence developed during the act of pulverization in the dark would lead us to suppose? Gum Arabic, powdered, has not the same taste, nor the same solubility as when in the entire state. If a given quantity of water may be made to dissolve 40 parts of arsenous acid in the vitreous state, the same quantity of water can be made to dissolve only 14 parts after pulverization (*Annals of Pharmacy*, May, 1852). Changes of this kind may ensue from the action of light, the oxygen of the atmosphere, its nitrogen, or its electricity, etc., upon matter reduced to a state of great fineness.

When but one article is reduced to powder, it is termed a *simple powder*, when several articles in powder are rubbed together, the mixture is termed a *compound powder*. As the substances entering into the formation of a compound powder may be of various textures and densities, it is generally preferable to reduce each, separately, to a powder, and then mix and triturate them thoroughly together.

Some articles, however, require the intervention of another before they can be reduced to powder, as camphor, which is pulverized by the addition of a few drops of alcohol; others, again, are powdered with facility by the aid of a harder substance. Medicines that contain considerable fixed oil, or which are deliquescent, should never be prescribed in the form of powders, more especially when they are to be retained for any length of time, as the former may injure the powder in consequence of rancidity, while the latter may render it damp, moldy, and inert. Articles which are *incompatible* should never be united together, unless the decomposition product is required. When volatile or deliquescent substances are prescribed in powders, as camphor, carbonate of ammonium, or carbonate of potassium, they should be wrapped in wax papers, and enclosed in tin-foil, a tin box, or a wide-mouth vial. The paper used for powders of ordinary character, should be very smooth, or glazed, to prevent the powder from adhering to it, and sufficiently soft and yielding to be opened and closed readily, without springing, so as to throw out any portion of the powder. Some apothecaries fold their powders in foolscap paper, and these, when opened by the patient, in consequence of their stiffness, spill or throw out a very material proportion of the medicine. When a powder is prescribed in bulk, leaving it to the patient to apportion the dose, unless otherwise desired, it should always be put into a wide-mouthed vial.

The old absurd and unscientific style of combining eight or ten articles in one preparation is fortunately becoming unpopular, and, though a few preparations of the kind are retained, yet the major amount of our present compounds consist of but two or three, and rarely exceeding four substances. In the former the articles were too frequently thrown together without any guide or rule, or any regard to compatibilities, and, though benefit might have been, haphazardly, derived from these heterogeneous mixtures, it was always difficult to ascertain upon which article or articles the effect depended, or whether it was owing to a third agent, the result of decomposition.

In preparing powders, it will be best to dry the article, beat it in an iron or brass mortar for a time, then sift it through a fine sieve; again beat the coarser parts in a mortar for a short time, sift again; and so continue alternately pulverizing and sifting until the whole is reduced to fine powder, the product being well mixed. When very active articles, such as strychnine, chloride of gold, atropine, etc., are to be given in the form of powders, gum, sugar, sugar of milk, starch, or marsh-mallow should be triturated with them, in order to facilitate their reduction to minute division. Milk sugar is the most desirable diluent.

The usual vehicle for taking the lighter powders is an agreeable, thin liquid, as water, gruel, milk, etc. Heavy powders require a more consistent vehicle, as syrup, molasses, thick mucilage, etc.; always bearing in mind whether the vehicle be compatible with the active ingredients of the powder. Small amounts of powders of a disagreeable taste, may be conveniently administered in gelatin capsules. An elegant form of administration is that proposed, in 1862, by Limousin. This is by means of *wafer capsules*, or *Cachets de Pain*. These are wafers of unleavened bread, into which has been pressed a concavity. One wafer is filled with the powder, and the second wafer, wetted upon the inner surface, is pressed down upon the first with sufficient force to cause them to adhere. To administer, wet the capsule, place it upon the tongue posteriorly, and wash it down with a drink of water or other desired fluid. Similar receptacles are also made of rice flour.

Granular Powders.—Many methods have been suggested for the preparation of granular powders. Granules of vegetable and like powders were introduced by Dr. Thomas Skinner, in 1862. They were prepared by rubbing the desired powder with mucilage to form a non-adhesive, crummy mass, which, after drying and bruising, could be passed through sieves of any desired size. These granules were sometimes coated. *Granular effervescent powders*, now popular, may be prepared by pulverizing separately the acids, alkaline compounds, and sugar, mixing, and passing them through sieves, moistening with a little alcohol, to cause the particles to adhere, and then passing them with slight pressure through a sieve having suitable sized meshes. After drying, the granules are again passed through sieves of different sizes, to obtain the various sized granules.

General Formulas.—*Formula A* (*Fine powder*). "Medicinal agent, in fine powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; saccharated sodium bicarbonate

(F. 341), four hundred and seventy-five grammes (475 Gm.) [1 lb. av., 334 grs.]: saccharated tartaric acid (F. 8), four hundred and seventy-five grammes (475 Gm. [1 lb. av., 330 grs.]. Triturate the ingredients, previously well-dried, until a uniformly mixed powder is obtained.

Formula B (*Granular powder*).—"Medicinal agent, in fine powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; saccharated sodium bicarbonate (F. 341), four hundred and seventy-five grammes (475 Gm.) [1 lb. av., 330 grs.]; saccharated tartaric acid (F. 8), two hundred and thirty-seven and one-half grammes (237.5 Gm.) [8 ozs. av., 165 grs.]; saccharated citric acid (F. 5), two hundred and and thirty-seven and one-half grammes (237.5 Gm.) [8 ozs. av., 165 grs.]. Mix the ingredients in a mortar, transfer them to an evaporating dish, and heat upon a water-bath, keep at 60° to 71° C. (140° to 160° F.), under constant stirring with a wooden spatula, until dry and uniformly granular. The saccharated citric acid, being made from crystallized citric acid containing 1 molecule of water of crystallization, supplies the moisture necessary to cause the powder, when heated, to cake and adhere together. If the somewhat pasty mass is then stirred with the spatula, small granules are readily formed, and these become firm when completely dried. Throughout the process the contact of the powder with metals should be carefully avoided. Effervescent powders should be preserved in well-stoppered, wide-mouthed vials. *Note.*—To make these effervescent compounds it is not necessary to have the saccharated alkali and saccharated acids in stock. The quantities of sodium bicarbonate, of tartaric acid, of citric acid, and of sugar, required for each formula, are readily ascertained by simple calculation, according to the following rule: Multiply the number of grammes of the saccharate prescribed by the figures indicating the percentage of alkali or acid it contains, and divide the sum of this by 100. The quotient is the quantity of alkali or acid, expressed in grammes, and by deducting this quantity from the total quantity of the saccharate, the quantity of sugar necessary is ascertained. Applying this rule, by way of example, to *General Formula B*, we have the following result: (1 475 Gm. of saccharated sodium bicarbonate, containing 75 per cent, require 356.25 Gm. of sodium bicarbonate and 118.75 Gm. of sugar. (2) 237.5 Gm. of saccharated tartaric acid, containing 67.5 per cent, require 160.3 Gm. of tartaric acid and 77.2 Gm. of sugar. (3) 237.5 Gm. of saccharated citric acid, containing 62.5 per cent, require 148.4 Gm. of citric acid and 89.1 Gm. of sugar. And the formula would then be: Medicinal agent, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium bicarbonate, three hundred and fifty-six and one-fourth grammes (356.25 Gm.) [12 ozs. av., 248 grs.]; tartaric acid, one hundred and sixty and three-tenths grammes (160.3 Gm.) [5 ozs. av., 286 grs.]; citric acid, one hundred and forty-eight and four-tenths grammes (148.4 Gm.) [5 ozs. av., 102 grs.]; sugar, two hundred and eighty-five and five one-hundredths grammes (285.05 Gm.) [10 ozs. av., 24 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]"—(*Nat. Form.*).

The *National Formulary* directs the preparation of *Effervescent Powders* as follows:

PULVERES EFFERVESCENTES, *Effervescent Powders.*—"The effervescent powders for which formulas are given in the Formulary, are most conveniently and efficiently dispensed in the form of *fine powders*, because in this condition they can be made extemporaneously and with assurance of their freshness and efficiency. The popular demand, however, seems to be for granular effervescent powders, the preparation of which requires certain modifications of the formulas, important only in so far as they enable the dispenser to granulate the powder in a convenient and expeditious manner.

GENERAL OBSERVATIONS AND DIRECTIONS.—"Effervescent powders are composed of the medicinal agent in admixture with an alkaline bicarbonate, an organic acid, and sugar. The proportion of the medicinal agent is dependent upon its dose, that of the alkaline bicarbonate and of the organic acid is dependent upon their molecular relation to each other, while the proportion of sugar is dependent upon the quantity necessary as a sweetening agent and diluent. The ingredients for making the *fine pulverulent form* of effervescent powders are: The medicinal agent, sodium bicarbonate, tartaric acid, and sugar, and it is necessary that these be well dried before mixing them. To make the *granular form* of effervescent powders the ingredients need not be dried, unless specially directed, and the ingredients are the same as for the pulverulent form, with the single *exception that one-half the molecule of tartaric acid is replaced by one-half a molecule of crystallized citric acid.* With the view to simplifying the formulas of effervescent powders, three new preparations have been embodied in this Formulary, viz.: *Acidum Citricum Saccharatum* (Saccharated Citric Acid), Formula No. 5; *Acidum Tartaricum Saccharatum* (Saccharated Tartaric Acid), Formula No. 8; *Sodii Bicarbonas Saccharatus* (Saccharated Sodium Bicarbonate), Formula No. 341. The proportion of sugar in these new saccharates is so adjusted that when either of the acid saccharates is mixed with an equal weight of the alkaline saccharate, the acid and alkali are in molecular relation to each other, and, when dissolved in water, will form the neutral tartrate and citrate of sodium respectively. With these three saccharates in stock, it becomes possible to make effervescent powders quickly with any medicinal agent that may be prescribed, while they simplify the formulas for the effervescent preparations now in the Formulary, their use being exemplified by the following *General Formulas:*"

Effervescent Powders of the National Formulary.—PULVIS FERRI ET QUININÆ CITRATIS EFFERVESCENS (N. F.), *Effervescent powder of citrate of iron and quinine, Effervescent citrate of iron and quinine.* "Soluble citrate of iron and quinine (*U. S. P.*), in very fine powder, ten grammes (10 Gm.) [154 grs.]; saccharated sodium bicarbonate (F. 341), four hundred and ninety-five grammes (495 Gm.) [17 ozs. av., 202 grs.]; saccharated tartaric acid (F. 8), four hundred and ninety-five grammes (495 Gm.) [17 ozs. av., 202 grs.]. Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained. To make *Granular Effervescent Citrate of Iron and Quinine*, substitute saccharated citric acid (F. 5), not dried, two hundred and forty-seven and one-half grammes (247.5 Gm.) [8 ozs. av., 320 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). Ninety (90) grains (or about a heaped teaspoonful) of this preparation represent about one (1) grain of citrate of iron and quinine"—(*Nat. Form.*).

PULVIS FERRI PHOSPHATIS EFFERVESCENS (N. F.), *Effervescent powder of phosphate of iron, Effervescent phosphate of iron.*—"Phosphate of iron (*U. S. P.*), in very fine powder, twenty-four grammes (24 Gm.) [370 grs.]; saccharated sodium bicarbonate (F. 341), four hundred and eighty-eight grammes (488 Gm.) [17 ozs. av., 93 grs.]; saccharated tartaric acid (F. 8), four hundred and eighty-eight grammes (488 Gm.) [17 ozs. av., 93 grs.]. Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained. To make *Granular Effervescent Phosphate of Iron*, substitute saccharated citric acid (F. 5), not dried, two hundred and forty-four grammes (244 Gm.) [8 ozs. av., 266 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). Ninety (90) grains (or about a heaped teaspoonful) of this preparation represent about two (2) grains of phosphate of iron"—(*Nat. Form.*).

PULVIS POTASSII BROMIDI EFFERVESCENS (N. F.), *Effervescent powder of potassium bromide, Effervescent potassium bromide.*—"Potassium bromide, in very fine powder, one hundred and ten grammes (110 Gm.) [3 ozs. av., 385 grs.]; saccharated sodium bicarbonate (F. 341), four hundred and forty-five grammes (445 Gm.) [15 ozs. av., 305 grs.]; saccharated tartaric acid (F. 8), four hundred and forty-five grammes (445 Gm.) [15 ozs. av., 305 grs.]. Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained. To make *Granular Effervescent Potassium Bromide*, substitute saccharated citric acid (F. 5), not dried, two hundred and twenty-two and one-half grammes (222.5 Gm.) [7 ozs. av., 370 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319 B.). Ninety (90) grains (or about a heaped teaspoonful) of this preparation represent about ten (10) grains of potassium bromide"—(*Nat. Form.*).

PULVIS POTASSII BROMIDI EFFERVESCENS CUM CAFFEINA (N. F.), *Effervescent powder of potassium bromide with caffeine, Effervescent potassium bromide with caffeine.*—"Potassium bromide, in very fine powder, one hundred and ten grammes (110 Gm.) [3 ozs. av., 385 grs.]; caffeine, in very fine powder, eleven grammes (11 Gm.) [170 grs.]; saccharated sodium bicarbonate (F. 341), four hundred and forty grammes (440 Gm.) [15 ozs. av., 228 grs.]; saccharated tartaric acid (F. 8), four hundred and forty grammes (440 Gm.) [15 ozs. av., 228 grs.]. Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained. To make *Granular Effervescent Potassium Bromide with Caffeine*, substitute saccharated citric acid (F. 5), not dried, two hundred and twenty grammes (220 Gm.) [7 ozs. av., 333 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). Ninety (90) grains (or about a heaped teaspoonful) of this preparation represent about ten (10) grains of potassium bromide and one (1) grain of caffeine"—(*Nat. Form.*). (See also under *Aquæ Minerales.*)

Other Powders.—The following powders are not employed in Eclectic medicine:

PULVIS HYDRARGYRI CHLORIDI MITIS ET JALAPÆ (N. F.), *Powder of mild chloride of mercury and jalap, Calomel and jalap.* "Mild chloride of mercury, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; jalap, in fine powder, sixty-six grammes (66 Gm.) [2 ozs. av., 143 grs.]. Mix them intimately. *Note.*—When 'Calomel and Jalap' is prescribed for an adult, without any specification of quantities, it is recommended that about 30 grains be dispensed as a dose"—(*Nat. Form.*).

Pulvis Antimonialis (*U. S. P.*), *Antimonial powder, James' powder, Pulvis Jacobi, Pulvis antimonii compositus, James' pulver.*—"Antimony oxide, thirty-three grammes (33 Gm. [1 oz. av., 72 grs.]; precipitated calcium phosphate, sixty-seven grammes (67 Gm.) [2 ozs. av., 159 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix them intimately"—(*U. S. P.*). The foregoing is the official substitute for a nostrum first prepared by Dr. James, of England, who died in 1776. The original secret powder, upon being analyzed, revealed its constituents sufficiently to lead Dr. Pearson, of London, to recommend to the *London College* the following formula: It is prepared by calcining, in an iron crucible, 1 part of tersulphide of antimony, and 2 parts of horn shavings, stirring constantly until vapors cease to rise. Then rub the residue to powder, put it in a crucible with a perforated cover, and raise it gradually to red heat, which must be maintained for 2 hours. Reduce the product, when cold, to fine powder. It forms a white, gritty, odorless, tasteless powder, partially soluble in boiling water, and which solution gives an orange-yellow precipitate with sulphuretted hydrogen. It possesses the general properties of the antimonials according to the doses in which it is administered, and, like them, is very uncertain in its operation. It was principally used as a sedative and diaphoretic in *febrile diseases*, in doses of from 1 to 4 grains, in powder or bolus, repeating them every 3 or 4 hours, as required. It is not employed in Eclectic practice.

PULVIS ACETANILIDI COMPOSITUS (N. F.)—COMPOUND POWDER OF ACETANILID.

Preparation.—"Acetanilid, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; caffeine, two grammes (2 Gm.) [31 grs.]; tartaric acid, three grammes (3 Gm.) [46 grs.]; sodium bicarbonate, forty-five grammes (45 Gm.) [1 oz. av., 257 grs.]. Reduce the ingredients, separately, to a fine powder, and mix them thoroughly. *Note.*—This preparation is popularly prescribed in New Orleans, under the name of 'Kamna-Fuga,' as an antipyretic, and is claimed to have some advantages over acetanilid itself"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—Analgesic and antipyretic. Considerably employed in *headache* (*megrim*), in doses of 5 to 10 grains. Uses practically those enumerated respectively under acetanilid and caffeine.

PULVIS AMYGDALÆ COMPOSITUS (N. F.)—COMPOUND POWDER OF ALMOND.

Preparation.—"Sweet almond, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; sugar, in fine powder, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; acacia, in fine powder, ten grammes (10 Gm.) [154 grs.]. Blanch the sweet almond, then dry them thoroughly with a soft cloth, and rub them lightly in a mortar, until they form a mass of smooth consistence. Mix the acacia and sugar, add them to the mass previously prepared, and rub the whole to a coarse powder, which is to be preserved in a lightly-covered jar. *Note.*—If 820 grains of this preparation be thoroughly triturated with 17 fluid ounces of water, gradually added, and the mixture finally strained, the product will be about 16 fluid ounces of *Mistura Amygdalæ* (*U. S. P.*)"—(*Nat. Form.*).

Uses.—To prepare almond mixtures. For almond mixture use 2½ ounces (av.) to 1 pint of water.

PULVIS ANTICATARRHALIS (N. F.)—CATARRH POWDER.

Synonym: *Catarrh snuff.*

Preparation.—"Morphine hydrochlorate, forty-one centigrammes (0.41 Gm.) [6.8 grs.]; acacia, in fine powder, twenty-five grammes (25 Gm.) [386 grs.]; bismuth subnitrate, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]. Mix them intimately by trituration"—(*Nat. Form.*).

Action and Medical Uses.—As its name indicates, this powder is designed by the framers of the formula, as a soothing snuff for *nasal catarrh.*

PULVIS AROMATICUS (U. S. P.)—AROMATIC POWDER.

Synonyms: *Pulvis cinnamomi compositus, Compound powder of cinnamon.*

Preparation.—"Ceylon cinnamon, in No. 60 powder, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; ginger, in No. 60 powder, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; cardamom, deprived of the capsules and crushed, fifteen grammes (15 Gm.) [231 grs.]; nutmeg, in No. 20 powder, fifteen grammes (15 Gm.) [231 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Triturate the cardamom and nutmeg with a portion of the Ceylon cinnamon, until they are reduced to fine powder; then add the remainder of the cinnamon and the ginger, and rub them together until they are thoroughly mixed." (*U. S. P.*).

Confectio Aromatica, or Aromatic Confection (*Electuarium aromaticum*).—The *U. S. P.*, 1870, directed to rub with aromatic powder an equal quantity (or sufficient) of honey to obtain a uniform mass of proper consistence for confections. This is somewhat hygroscopic, and slowly becomes granular. It may be restored by the incorporation of additional honey.

Action, Medical Uses, and Dosage.—These preparations are employed for the relief of *flatulent colic*, *nausea*, and *diarrhœa*. Dose, 5 to 20 grains. The powder, enclosed in a bag and moistened with hot whiskey or other alcoholic liquids, may be employed as a fomentation in *painful affections of the bowels*. It indelibly stains the linen if allowed to come in contact with it.

PULVIS ASCLEPIADIS COMPOSITUS.—COMPOUND POWDER OF PLEURISY ROOT.

Preparation.—Take of pleurisy root, spearmint, and sumach berries, each, in powder, 2 ounces; bayberry bark, and skunk cabbage, each, in powder, 1 ounce; pulverized ginger, ½ ounce. Mix them.

Action, Medical Uses, and Dosage.—Very useful diaphoretic in *coughs*, *colds*, and as a drink in *febrile diseases*. Two drachms of the powder may be infused in ½ pint of boiling water, sweetened, and drank in wineglassful doses, every 1 or 2 hours. Or in *common colds*, the ½ pint of warm infusion may be taken at a draught, and repeated in an hour if necessary (Wm. S. Merrell).

PULVIS CAMPHORÆ COMPOSITUS.—COMPOUND POWDER OF CAMPHOR.

Preparation.—Take of tannic acid, kino, camphor, each, in powder, 20 grains; opium, in powder, 10 grains. Mix well together, and divide into 20 powders.

Action, Medical Uses, and Dosage.—These powders are stimulant, antispasmodic, anodyne, and astringent, and have proved highly successful in the treatment of *Asiatic cholera*, *cholerine*, and severe *cholera morbus*. They speedily check the discharges, and relieve the *pains* or *cramps*. The dose is 1 powder after each discharge from the bowels, or oftener, if the urgency of the case requires it. The powders may be given in molasses, quince syrup, or blackberry jelly. When more stimulus is required. 1 or 2 grains of capsicum may be added to each dose (J. King).

Related Powders.—Pulvis Catechu Compositus (N. F.), *Compound powder of catechu.* "Catechu, in fine powder, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; kino, in fine powder, twenty grammes (20 Gm.) [309 grs.]; krameria, in fine powder, twenty grammes (20 Gm. [309 grs.]; cinnamon, in fine powder, ten grammes (10 Gm.) [154 grs.]; nutmeg, in fine powder, ten grammes (10 Gm.) [154 grs.]. Mix them intimately, pass the powder through a fine sieve, and afterward rub it lightly in a mortar. Keep it in a stoppered bottle. *Note.*—This preparation is official in the *Br. Pharm.*"—(*Nat. Form.*). Dose, 10 to 60 grains.

Pulvis Kino Compositus (N. F.), *Compound powder of kino, Pulvis kino cum opio.*—"Kino, in fine powder, seventy-five grammes (75 Gm.) [2 ozs. av., 282 grs.]; powdered opium, five grammes (5 Gm.) [77 grs.]; cinnamon, in fine powder, twenty grammes (20 Gm. [309 grs.]. Mix them intimately, pass the mixed powder through a moderately fine sieve, and afterward rub it lightly in a mortar. Keep it in a stoppered bottle. Every 20 grains of this preparation contain 1 grain of powdered opium. *Note.*—This preparation is official in the *Br. Pharm.*"—(*Nat. Form.*). Dose, 5 to 20 grains.

PULVIS CARBONIS LIGNI COMPOSITUS.—COMPOUND POWDER OF CHARCOAL.

Preparation.—Take of charcoal, 2 ounces; rhubarb, in powder, 1 ounce; bicarbonate of sodium, ½ ounce. Mix together.

Action, Medical Uses, and Dosage.—This preparation is very beneficial in *dyspepsia*, attended with *acidity of the stomach*, loss of appetite, *constipation*, or *diarrhœa*, and distress of the stomach after eating. It will prove useful in all derangements of the digestive functions where acidity of the stomach is present. The dose is a teaspoonful in water or Indian-meal gruel, 3 or 4 times a day. If cream of tartar, 1 ounce, be substituted for the bicarbonate of sodium, it will form an excellent laxative powder for *piles* (J. King).

PULVIS CRETÆ AROMATICUS (N. F.)—AROMATIC POWDER OF CHALK.

SYNONYM: *Confectio aromatica* (*Lond.*).

Preparation.—"Cinnamon, eight grammes (8 Gm.) [123 grs.]; saffron, six grammes (6 Gm.) [93 grs.]; nutmeg, six grammes (6 Gm.) [93 grs.]; cloves, three grammes (3 Gm.) [46 grs.]; cardamom, two grammes (2 Gm.) [31 grs.]; prepared chalk, twenty-three grammes (23 Gm.) [355 grs.]; sugar, fifty-two grammes (52 Gm.) [1 oz. av., 365 grs]. Mix the ingredients and reduce them to a fine powder. Pass this through a fine sieve, and afterward rub it lightly in a mortar. Keep it in a stoppered bottle. *Note.*—This preparation is equivalent to the *Pulvis Cretæ Aromaticus* of the *Br. Pharm.* This authority adds the following note: "If a product of bright color be desired, the saffron may previously be moistened and triturated with a little water or alcohol, or the fresh and faintly damp mixture may be subjected to considerable pressure in the triturating process"—(*Nat. Form.*).

Action, Medical Uses, and Dosage.—This agent is employed in *diarrhœa* caused by offending material in the stomach, which should first be removed by gentle catharsis, after which the powder may be administered. It is also useful in diarrhœa produced by changes of temperature and water. Dose, 30 to 60 grains.

Related Powder.—PULVIS CRETÆ AROMATICUS CUM OPIO (N. F.), *Aromatic powder of chalk with opium.* "Aromatic powder of chalk (F. 317), ninety-seven and one-half grammes (97.5 Gm.) [3 ozs. av., 192 grs.]; powdered opium, two and one-half grammes (2.5 Gm.) [38.6 grs.]. Mix them intimately. Every 40 grains of this preparation contain 1 grain of powdered opium. *Note.*—This preparation is official in the *Br. Pharm.*"—(*Nat. Form.*). Used like the preceding. Dose, 10 to 20 grains.

PULVIS CRETÆ COMPOSITUS (U. S. P.)—COMPOUND CHALK POWDER.

Preparation.—"Prepared chalk, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; acacia, in fine powder, twenty grammes (20 Gm.) [309 grs.]; sugar, in fine powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix them intimately"—(*U. S. P.*).

Uses.—This powder is designed as a ready ingredient for the preparation of *chalk mixture.* Precipitated chalk should not be used. Dose, 10 to 40 grains.

PULVIS CYPRIPEDII COMPOSITUS.—COMPOUND POWDER OF YELLOW LADIES'-SLIPPER.

SYNONYM: *Nerve powder.*

Preparation.—Take of yellow ladies'-slipper root, pleurisy root, skunk cabbage root, and scullcap, each, in powder, 1 ounce. Mix them.

Action, Medical Uses, and Dosage.—This powder is useful to allay *irritability* or *excitability of the nervous system*, to relieve *spasms*, and to produce sleep in restless, wakeful, or excited conditions. When *acidity of the stomach* is present, it is common to add bicarbonate of sodium, 1 ounce. The dose is from ½ to 1 drachm, 3 times a day, or as required. It is usually administered in tea or water (J. King).

PULVIS EFFERVESCENS COMPOSITUS (U. S. P.)—COMPOUND EFFERVESCING POWDER.

SYNONYMS: *Seidlitz powder, Aperient effervescing powders, Pulveres effervescentes aperientes* (*U. S. P.*, 1870), *Effervescent tartrated soda powder, Pulvis sodæ tartaratæ effervescens, Pulvis aërophorus seydlitzensis.*

Preparation.—"Sodium bicarbonate, in fine powder, thirty-one grammes (31 Gm.) [1 oz. av., 41 grs.]; potassium and sodium tartrate, in fine powder, ninety-three grammes (93 Gm.) [3 ozs. av., 123 grs.]; tartaric acid, in fine powder, twenty-seven grammes (27 Gm.) [417 grs.]. Mix the sodium bicarbonate intimately with the potassium and sodium tartrate, divide the mixture into twelve (12) equal parts, and wrap each part in a separate paper of some pronounced color, as *blue*, Then divide the tartaric acid also into twelve (12) equal parts, and wrap each part in a separate paper of a color distinctly different from that used for wrapping the mixture, as *white*. Keep the powders in well-closed vessels"—(*U. S. P.*).

History.—This powder received its name from the Seidlitz Saline Springs of Bohemia, though the foregoing laxative constituents do not represent those of the springs named. As found upon the market, the Seidlitz powder is very variable in regard to proportion. To properly prepare them, each part should be weighed, strictly following the official directions, making the Seidlitz mixture of 3 parts of Rochelle salts and 1 part of sodium bicarbonate, and, as is directed, placing the alkaline powder in a blue paper. Then in a white paper place the tartaric acid. The *white paper* should contain, by weight, 35 grains of tartaric acid; the *blue paper*, 160 grains of Seidlitz mixture. When the powders are separately dissolved in water, and the solutions slowly mixed, the acid reacts with the sodium bicarbonate, liberating carbonic acid gas, and forming sodium tartrate, which adds somewhat to the laxative action of the Rochelle salt. The powders should be kept in a dry place, lest the acid should absorb sufficient moisture to dissolve it.

Action, Medical Uses, and Dosage.—The saline laxative, Seidlitz powder, is very popular as a laxative, especially where there is a slight rise of temperature, and particularly in warm weather. They should be used with care in very young children and the aged and debilitated. Preferably, the powders should be dissolved in separate glasses, using about 5 or 6 fluid ounces of water for the saline powder, and 1 or 2 fluid ounces for the acid powder. The two solutions should then be gradually mixed together and taken while effervescing. Under no circumstances should one solution be swallowed after the other, lest the liberation of carbon dioxide in the stomach should give rise to serious distension, if not rupture, of that organ. The usual dose for an adult is the contents of a white and blue paper (see also *Potassii et Sodii Tartras*).

Related Powder.—PULVERES EFFERVESCENTES (*U. S. P.*, 1870), *Effervescing powders, Soda powders.* "Take of bicarbonate of sodium, in fine powder, 360 grains; tartaric acid, in fine powder, 300 grains. Divide each of the powders into 12 equal parts, and keep the parts, severally, of the bicarbonate and of the acid in separate papers of different colors"—(*U. S. P.*, 1870). Each acid powder contains 25 grains; each alkaline powder 30 grains. They may be administered in water, both being dissolved at one time in one solution, or separate solutions may be prepared and mixed. The acid reacts upon the alkaline compound, producing sodium tartrate, while carbon dioxide escapes.

PULVIS GLYCYRRHIZÆ COMPOSITUS (U. S. P.)—COMPOUND POWDER OF GLYCYRRHIZA.

SYNONYM: *Compound liquorice powder.*

Preparation.—"Senna, in No. 80 powder, one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.]; glycyrrhiza, in No. 80 powder, two hundred and thirty-six grammes (236 Gm.) [8 ozs. av., 142 grs.]; washed sulphur, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; oil of fennel, four grammes (4 Gm.) [62 grs.]; sugar, in fine powder, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Mix the oil of fennel thoroughly with about one-half of the sugar, then add the remainder of the sugar and the other ingredients, and mix thoroughly. Finally pass the powder through a No. 60 sieve, and keep it in well-closed vessels"—(*U. S. P.*).

Formerly powdered fennel was employed in the preparation of this powder. It has now been replaced with oil of fennel, which renders the powder less liable to take on an unpleasant odor. Moreover, the proportion of liquorice is increased over that of the *U. S. P.* (1880) formula, giving a pleasanter and more easily prepared preparation.

Action, Medical Uses, and Dosage.—A very efficient laxative, operating kindly in doses of 30 to 60 grains, administered in plenty of cold water.

PULVIS HYDRASTIS COMPOSITUS.—COMPOUND POWDER OF GOLDEN SEAL.

Preparation.—Take of golden seal, blue cohosh, and helonias, each, in powder, ½ ounce. Mix together.

Action, Medical Uses, and Dosage.—This powder is tonic and antispasmodic. It is very efficient in *dyspepsia, chronic inflammation of the mucous membrane of the stomach*, and will afford much relief in cases of distress of the stomach after eating, and in *aphthous inflammations of the mouth*. It may also be administered, to prevent a relapse, in *bilious colic*. The dose is from ½ to 1 drachm, 3 or 4 times a day, in water, tea, or wine, as the case may require (J. King).

PULVIS IODOFORMI COMPOSITUS (N. F.)—COMPOUND POWDER OF IODOFORM.

SYNONYM: *Iodoform and naphthalin.*

Preparation.—"Iodoform, in fine powder, twenty grammes (20 Gm.) [309 grs.]; boric acid, in fine powder, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; naphthalin, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; oil of bergamot, two and one-half cubic centimeters (2.5 Cc.) [41 ♏]. Triturate the naphthalin with the oil of bergamot, then mix it with the iodoform and boric acid, and triturate until a homogeneous powder is produced. *Note.*—This powder is used in many cases where a *diluted* preparation of iodoform, for external purposes, is desired. The odor of the iodoform is masked both by the oil of bergamot and by the naphthalin"—(*Nat. Form.*).

Medical Uses.—The object of this powder is sufficiently set forth in the preceding note.

PULVIS IPECACUANHÆ COMPOSITUS.—COMPOUND POWDER OF IPECACUANHA.

Preparation.—Take of pleurisy root, bloodroot, ipecacuanha, nitrate of potassium, each, in powder, 1 drachm. Mix them.

Action, Medical Uses, and Dosage.—This powder has diuretic and diaphoretic effects upon the system. It is useful in *febrile* and *inflammatory diseases*, and especially in cases where, from idiosyncrasy or other causes, opium is inadmissible. The dose is 5 or 10 grains, every 1 or 2 hours.

PULVIS IPECACUANHÆ ET OPII (U. S. P.)—POWDER OF IPECAC AND OPIUM.

SYNONYMS: *Dover's powder, Compound powder of ipecacuanha, Pulvis ipecacuanhæ compositus.*

Preparation and History.—"Ipecac, in No. 60 powder, ten grammes (10 Gm.) [154 grs.]; powdered opium, ten grammes (10 Gm.) [154 grs.]; sugar of milk, in No. 30 powder, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub them together into a very fine powder"—(*U. S. P.*).

Each 10 grains of Dover's powder contain of opium and ipecacuanha, each, 1 grain, and sugar of milk, 8 grains. Formerly potassium sulphate was employed in the place of milk sugar. The potassium salt is still directed in the *British Pharmacopœia*, giving to the preparation of the latter a somewhat saline taste. The sugar of milk in this preparation is employed simply as a diluent. By triturating it in coarse powder, it serves to further divide the vegetable constituents. For its mechanical effects, however, the sulphate of potassium is preferable on account of the greater hardness of its particles. Dover's powder was named from its introducer, Dr. Dover. As originally proposed by him, and as now directed in the *French Codex*, with but little modification, potassium nitrate and sulphate (4 parts each) were mixed in a crucible, at red heat, and cooled; sliced opium (1 part) was added and thoroughly rubbed to a powder, after which ipecacuanha and liquorice, both powdered (1 part each), were incorporated with the other ingredients. Dover's powder is a light-brown powder, having the odors of both opium and ipecac, and a bitterish and nauseous taste.

Action, Medical Uses, and Dosage.—Dover's powder, according to the dose administered, is an excellent stimulant, sedative, anodyne, and narcotic. It has a better action than either of its chief ingredients administered separately. It is a very good agent to improve the quality of the skin, the necessary moisture being induced by the ipecac to ensure the favorable action of opium, for the specific indication for the latter is a moist skin and tongue, and soft, open pulse. As a pain-relieving agent and to promote sleep, it may be used where opium alone would not be tolerated. Though profuse perspiration may be produced by it, it is also capable of checking that secretion as shown by the favorable action of 5-grain doses of the powder given to control the *colliquative sweats of phthisis*. It should be given a half hour before the sweating begins. Dover's powder sometimes causes sickness at the stomach, and should never be followed immediately after its administration with warm drinks, but they may be used later, if desired. As a pain-reliever, or stimulant to the internal organs, or as a hypnotic, it is admissible when there is no nausea, inflammation of the brain, or high temperature. It is an efficient drug in *rheumatism*, *the incipient stage of inflammations*, and to control *cough*. Hot applications to the abdomen and 5-grain doses of Dover's powder with 1 grain of camphor, every ½ or 1 hour, give marked relief in *dysmenorrhœa*. Without the camphor, it is very efficient in *amenorrhœa* from cold, being used together with external heat. It allays nervous excitation in cases of *abortion*, and assists in controlling *uterine* and *pulmonary hemorrhages;* 2 or 3 grains of the powder, with a like quantity of quinine, forms an efficient treatment in *neuralgia*, with hot, dry skin. In *dysentery*, it assists the action of other remedies, as well as controlling peristaltic movements, while in *irritative diarrhœa*, after a mild laxative, it controls any *spasmodic bowel complications* that may supervene. It may be used in *enteritis*, both to control the inflammation and the movements of the bowels. It is useful in the early stage of *renal catarrhal inflammations* and in *granular degeneration of the kidneys*, chiefly for the purpose of maintaining a good circulation and a moist condition of the skin. Dose, 2 to 10 grains, preferably in capsules.

PULVIS IPECACUANHÆ ET OPII COMPOSITUS.—COMPOUND POWDER OF IPECACUANHA AND OPIUM.

SYNONYM: *Diaphoretic powder.*

Preparation.—Take of opium, in powder, 10 grains; camphor, in powder, 40 grains; ipecacuanha, in powder, 20 grains; bitartrate of potassium, 160 grains; Mix them (Beach's *Amer. Prac.*).

In preparing the powder, the camphor must first be reduced to powder by trituration with a few drops of alcohol, then add a small portion of the bitartrate of potassium, continue the trituration until the camphor has been still further divided, add the opium in powder, then the ipecacuanha, and, lastly, the remainder of the bitartrate, and triturate all together for 15 or 20 minutes.

Action, Medical Uses, and Dosage.—This powder is an excellent anodyne and diaphoretic, and is, perhaps, superior to any other preparation in its diaphoretic effects upon the system. It is of great efficiency in all *febrile* and *inflammatory diseases*, *diarrhœa*, *dysentery*, *cholera morbus*, *gout*, *rheumatism*, *after-pains*, all cases of *nervous irritability* or *excitement*, and whenever an anodyne conjoined with a diaphoretic is indicated. It favors perspiration without augmenting the heat of the body. The above is the original formula, but practitioners vary in preparing it according to their favorite views; thus some omit the cream of tartar and substitute nitrate of potassium or bicarbonate of sodium, while others omit the opium, substituting in its place lactucarium or twice the quantity of oleoresin of cypripedium, rendered dry by the addition of magnesia. Dose, 3 to 5 grains every

3 or 4 hours in febrile or inflammatory diseases, and, in some cases, 10 grains, 3 times a day. Its action may be materially promoted as a diaphoretic by warm drinks, such as catnip, balm, or sage tea, lemonade, etc., which, however, should not be given immediately after the administration of the powder, lest vomiting be provoked. In *rheumatism*, *pneumonia*, *cerebral affections*, *hepatic diseases*, etc., it is frequently combined with small doses of resin of podophyllum.

PULVIS JALAPÆ COMPOSITUS (ECLECTIC).—COMPOUND POWDER OF JALAP.

SYNONYM: *Antibilious physic.*

Preparation.—Take of Alexandria senna, in powder, 2 ounces; jalap, in powder, 1 ounce; cloves or ginger, in powder, 1 drachm. Mix them (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This forms an excellent purgative, useful in nearly all cases where such action is required. It acts with mildness and efficiency, influencing the whole alimentary tract, cleansing it of all abnormal accumulations, and stimulating the whole biliary apparatus to healthy action. It may be given to either sex, and at all ages, and is used in all *febrile*, *inflammatory*, or *chronic diseases*, being contraindicated in severe gastric or intestinal inflammation, and requires to be used cautiously and in moderate doses during pregnancy, menorrhagia, and certain other diseases. Dose, 1 drachm, put into a gill of boiling water, and allowed to stand till cold, then sweeten, if desired, stir, and drink the whole contents. Milk, wine, cider, lemonade, or coffee, etc., may be substituted, in proper cases, for the water. In febrile diseases, its utility will be much increased by adding about 10 grains of bitartrate of potassium to each dose.

Related Preparations.—PULVIS JALAPÆ COMPOSITUS (*U. S. P.*), *Compound powder of jalap*, *Pulvis purgans*, *Pulvis catharticus*, *Pulvis jalapæ tartaratus*. "Jalap, in No. 60 powder, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; potassium bitartrate, in fine powder, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub them together until they are thoroughly mixed"—(*U. S. P.*). This preparation is employed as a hydragogue cathartic in *ascites*, associated with portal and splenic obstructions. Dose, 10 to 30 grains.

PULVIS ALOES ET CANELLÆ (N. F.), *Powder of aloes and canella*, *Hiera picra.*—"Purified aloes (*U. S. P.*), in fine powder, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; canella, in fine powder, twenty grammes (20 Gm.) [309 grs.]. Mix them intimately"—(*Nat. Form.*). Dose, 3 to 12 grains.

PULVIS LEPTANDRÆ COMPOSITUS.—COMPOUND POWDER OF LEPTANDRA.

Preparation.—Take of dried alcoholic extract of leptandra, in powder, 1 drachm; resin of podophyllum, in powder, ½ drachm; sugar of milk, 5 drachms. Mix and triturate well together.

Action, Medical Uses, and Dosage.—This preparation is a cholagogue cathartic, and was formerly regarded of immense benefit in *epidemic dysentery*, in doses of 8 grains, repeated every 1 or 2 hours, until it operates freely, after which it may be given 2 or 3 times a day. It was also used with asserted advantage in *typhoid*, *remittent*, and *intermittent fevers*, with or without the addition of quinine sulphate; also in *biliary derangements*. The addition of 3 grains of santonin to each dose, and given twice a day, forms an admirable anthelmintic (J. King).

PULVIS LOBELIÆ COMPOSITUS.—COMPOUND POWDER OF LOBELIA.

SYNONYM: *Emetic powder.*

Preparation.—Take of lobelia, in powder, 6 drachms; bloodroot and skunk cabbage, in powder, each, 3 drachms; ipecacuanha, 4 drachms; capsicum, in powder, 1 drachm. Mix them.

Action, Medical Uses, and Dosage.—This is an excellent emetic, and may be employed in all cases where an emetic is indicated. It vomits easily and promptly, without causing cramps or excessive prostration. The dose is 2 drachms, $\frac{1}{4}$ of which ($\frac{1}{2}$ drachm) must be given every 15 minutes, in an infusion of boneset. Warm boneset, drank freely during the time of taking it, will very much facilitate its operation, and it will also be found that, in many cases, temperate water (at 60° F.) will be equally as effective in assisting the induction of emesis as an infusion, and much more agreeable (J. King). Compound powder of lobelia is an exceedingly efficient local application to the chest in *colds* and *broncho-pulmonic troubles* in general. For this purpose it should be sprinkled upon a larded or petrolated cloth and applied warm.

PULVIS MORPHINÆ COMPOSITUS (U. S. P.)—COMPOUND POWDER OF MORPHINE.

SYNONYMS: *Tully's powder, Pulvis camphoræ compositus Tully.*

Preparation and History.—"Morphine sulphate, one gramme (1 Gm.) [15.4 grs.]; camphor, nineteen grammes (19 Gm.) [293 grs.]; glycyrrhiza, in No. 60 powder, twenty grammes (20 Gm.) [309 grs.]; precipitated calcium carbonate, twenty grammes (20 Gm.) [309 grs.]; alcohol, a sufficient quantity to make sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]. Rub the camphor with a little alcohol, and afterward with the glycyrrhiza and precipitated calcium carbonate, until a uniform powder is produced. Then rub the morphine sulphate with this powder, gradually added, until the whole is thoroughly mixed. Finally, pass the powder through a No. 40 sieve, and transfer it to well-stoppered bottles"—(*U. S. P.*).

One grain of this powder contains $\frac{1}{60}$ grain of sulphate of morphine and about $\frac{1}{3}$ grain of camphor. It was introduced by Dr. William Tully, of New Haven, Conn., as a substitute for Dover's powder. The directions of the formula should be rigidly followed, as great care is necessary that the morphine salt may be uniformly distributed. It is best to prepare small amounts only, as by age the volatile camphor is likely to become dissipated, leaving the powder of uncertain strength. Keep in well-closed bottle, in a cool situation.

Action, Medical Uses, and Dosage.—This powder is used for the same purposes as Dover's powder and morphine sulphate. The dose is from 5 to 10 grains, representing respectively $\frac{1}{12}$ and $\frac{1}{6}$ grain of morphine sulphate.

PULVIS MYRICÆ COMPOSITUS (ECLECTIC).—COMPOUND POWDER OF BAYBERRY.

SYNONYM: *Cephalic powder.*

Preparation.—Take of bayberry bark and bloodroot, each, in powder, 1 drachm. Mix them (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This powder is used either alone or combined with an equal part of common snuff, as a snuff, in *catarrh, headache, polypus,* etc. In *obstinate affections of the nasal mucous membrane,* it is frequently combined with sesquicarbonate of potash, 1 or 2 drachms, and golden seal, $\frac{1}{2}$ ounce; or, with finely-powdered chloride of ammonium, 1 drachm. This powder should not be confused with the composition powder bearing the same name (see *Related Powder*).

Related Powder.—PULVIS MYRICÆ COMPOSITUS (N. F.), *Compound powder of bayberry, Composition powder.* "Bayberry, bark of the root, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; ginger, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; capsicum, five grammes (5 Gm.) [77 grs.]; cloves, five grammes (5 Gm.) [77 grs.]. Reduce the substances to a moderately fine powder. *Note.*—Bayberry root bark is derived from *Myrica cerifera,* Linné (Wax myrtle, Candleberry)" (*Nat. Form.*). This powder is practically the same as the *Thomson Composition Powder,* or *Number Six.* It is a valuable diaphoretic when given in teaspoonful doses, in warm infusion. Useful in breaking up *acute colds* and in the consequences arising therefrom.

PULVIS NIGRUM.—BLACK POWDER.

SYNONYM: *Emmenagogue powder.*

Preparation.—Take of flowers of sulphur, myrrh, steel filings, loaf sugar, each, in fine powder, 1 ounce; white wine, $\frac{1}{2}$ pint. Mix together, and, by means of a gentle heat, evaporate till nearly dry. Pulverize the mass when cold, and keep it in well-stoppered bottles (Beach's *Amer. Prac.*). Reduced iron may be substituted for the steel filings.

Action, Medical Uses, and Dosage.—This not very scientific compound has been used with much success in the treatment of primary or idiopathic *amenorrhœa, chlorosis*, etc. The dose is ½ drachm, to be repeated 3 times a day; it may be taken in syrup, or molasses, or in the form of pills. It will also be found an excellent remedy in several forms of *cutaneous disease.*

PULVIS OPII COMPOSITUS.—COMPOUND POWDER OF OPIUM.

Preparation.—"Take of opium, in powder, 1½ ounces (av.); black pepper, in powder, 2 ounces (av.); ginger, in powder, 5 ounces (av.); caraway fruit, in powder, 6 ounces (av.); tragacanth, in powder, ½ ounce. Mix them thoroughly, pass the powder through a fine sieve, and finally rub it lightly in a mortar. Keep it in a stoppered bottle"—(*Br. Pharm.*, 1885 and 1898). This contains the dry constituents of confection of opium, 10 per cent of the latter being present.

Action, Medical Uses, and Dosage.—Used like confection of opium. Dose, 2 to 5 grains.

PULVIS PODOPHYLLI COMPOSITUS.—COMPOUND POWDER OF MANDRAKE.

Preparation.—Take of blue flag, mandrake, bitter root, swamp milkweed, each, in powder, 1 ounce; bloodroot, ½ ounce. Mix together.

Action, Medical Uses, and Dosage.—This powder is cathartic and alterative, and is useful in cases of *obstinate constipation, hepatic derangements, dyspepsia, worms*, and in *scrofulous, rheumatic*, and *syphilitic affections.* The dose is ½ or 1 drachm, repeated 3 times a day. It may be administered in water or tea (J. King).

PULVIS QUININÆ COMPOSITUS.—COMPOUND POWDER OF QUININE.

Preparation.—Take of sulphate of quinine, ferrocyanide of iron, each, 1 drachm. Mix thoroughly together.

Action, Medical Uses, and Dosage.—This powder is tonic, febrifuge, and antiperiodic. It was formerly much employed by American practitioners in *febrile* and *inflammatory diseases*, and in all diseases in which there is a least tendency to periodicity. As a tonic, it is either used alone, or frequently in combination with other tonics, as hydrochlorate of berberine, etc. The dose is from 3 to 6 grains of the powder, repeated 2, 3, or 4 times a day, according to symptoms. It was introduced to the profession, as an agent in the above diseases, by the late Prof. I. G. Jones, M. D., of Columbus, Ohio.

PULVIS RESINÆ PODOPHYLLI COMPOSITUS.—COMPOUND POWDER OF RESIN OF PODOPHYLLUM.

SYNONYM: *Hydragogue powder.*

Preparation.—Take of resin of podophyllum, 4 grains; bitartrate of potassium, 3 drachms. Mix intimately together.

Action, Medical Uses, and Dosage.—This is an active hydragogue, and may be employed in *dropsy, obstructed menstruation*, etc. Dose, 20 grains, administered every 2 hours, until it operates sufficiently. The addition of about 1 or 2 grains of capsicum to each dose, will render it much more speedy in its operation.

Related Powder.—SWEET'S RED POWDER. A preparation termed *Sweet's red powder*, has been considerably employed by many practitioners. It causes emesis as well as catharsis, and, as an alterative, is reputed of considerable efficacy in many chronic diseases. It is prepared as follows: Take of mandrake root, in fine powder, 5 ounces; bloodroot, in fine powder, 1 ounce. Place the powders in a percolator and thoroughly exhaust with alcohol. Evaporate the tincture obtained to the consistence of molasses, and, while hot, add to it finely-powdered white sugar, 6 ounces; croton oil, to which a little salt of tartar has been added to neutralize the acrid principle, 1 drachm; and oil of cloves, ½ drachm. Mix thoroughly together, spread on glass or on a plate to dry, finely powder, and bottle. The dose is from 5 to 30 grains. Probably this powder might be prepared as follows: To 6 ounces of finely-powdered white sugar, add 1 drachm of croton oil, prepared as above, and ½ drachm of oil of cloves; mix, triturate thoroughly together, and, continuing the trituration, add, gradually, 160 grains of resin of podophyllum and 46 grains of sanguinarine.

PULVIS RHEI COMPOSITUS (ECLECTIC).—COMPOUND POWDER OF RHUBARB.

SYNONYM: *Neutralizing powder.*

Preparation.—Take of rhubarb, bicarbonate of potassium, and peppermint leaves, each, in powder, 1 ounce. Mix together (Beach's *Amer. Prac.*).

Action, Medical Uses, and Dosage.—This powder is an invaluable remedy in *diarrhœa, cholera morbus, dysentery, summer complaint of children, acidity of stomach, heartburn*, and as a mild cathartic during *pregnancy*. The dose is from ½ to 2 drachms, every 1, 2, or 3 hours, as may be required (see *Syrup of Rhubarb and Potassa*).

Related Preparations.—PULVIS RHEI COMPOSITUS (*U. S. P.*), *Compound powder of rhubarb, Gregory's powder, Magnesia and rhubarb, Pulvis antacidus, Pulvis infantum, Pulvis magnesiæ cum rhei.* "Rhubarb, in No. 60 powder, twenty-five grammes (25 Gm.) [386 grs.]; magnesia, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; ginger, in No. 60 powder, ten grammes (10 Gm.) [154 grs.]; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Rub them together until they are thoroughly mixed"—(*U. S. P.*). To properly prepare this powder, the rhubarb and ginger should first be rubbed together, and the magnesia, on account of its lightness, be gradually added and incorporated, after which the whole should be put through a bolting-cloth sieve. When fresh and dry the powder is of a yellowish color; upon absorbing moisture, or in aqueous or alcoholic suspension, a deep-red color ensues, owing to a reaction between the magnesia and rhubarb constituents. Dose, 5 to 60 grains.

PULVIS RHEI ET MAGNESIÆ ANISATUS (N. F.), *Anisated powder of rhubarb and magnesia, Compound anise powder.* "Rhubarb, in fine powder, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; heavy magnesia, calcined, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; oil of anise, eight cubic centimeters (8 Cc.) [130 ♏]; alcohol, ten cubic centimeters (10 Cc.) [162 ♏]. Mix the powders, add the oil of anise, previously dissolved in the alcohol, and triturate until a uniform mixture results"—(*Nat. Form.*).

PULVIS SPIGELIÆ COMPOSITUS.—COMPOUND POWDER OF SPIGELIA.

SYNONYM: *King's entozoic powder.*

Preparation.—Take of pink root, bitter root, swamp milkweed, mandrake, each, in very fine powder, 2 ounces; balmony, in very fine powder, 4 ounces. Mix intimately together.

Action, Medical Uses, and Dosage.—This is a very bitter, but certain remedy for any kind of *worms* that may exist in the human alimentary canal. It not only destroys the worms, but also removes the morbid mucous secretion in which they abound, and which is so favorable to their production. The dose for a child a year old is from 5 to 8 grains, in a teaspoonful of molasses or syrup; for an adult, from 10 to 20 grains, in ½ tablespoonful of molasses. The dose is to be repeated every 1 or 2 hours until it operates freely, after which repeat the dose only 3 times a day for several days in succession. When worms are present, the stools produced by this powder will be mucous or slimy, often whitish, containing particles resembling the external integuments of the entozoa, or the appearance of worms cut up. An infusion of this powder, to which a small portion of tincture of asafœtida has been added, forms an excellent injection for the removal of *ascarides* or *thread worms;* it may be repeated whenever desired (see *Compound Fluid Extract of Spigelia*).

PULVIS STYPTICUS.—STYPTIC POWDER.

Preparation.—Take of sulphate of iron, in powder, 2 ounces; alum, in powder, 1 ounce. Mix them, and calcine, by a red heat until a reddish substance is formed. It undoubtedly contains a portion of acid. When cold, pulverize the mass, and keep it in well-stopped bottles.

Action, Medical Uses, and Dosage.—This powder is styptic, and is frequently employed in the treatment of *external hemorrhages* and *bleeding piles*, either alone, or in combination with stramonium ointment, poke ointment, oil of fireweed, etc. Given internally, in doses of 3 grains, combined with capsicum, 1 grain, it has proved effectual in *passive hemorrhages from the lungs and uterus.*

PULVIS TALCI SALICYLICUS (N. F.)—SALICYLATED POWDER OF TALCUM.

Preparation.—"Salicylic acid, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; boric acid, in fine powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; talcum, in fine powder, eight hundred and seventy grammes (870 Gm.) [1 lb. av., 14 ozs., 301 grs.]. Mix them intimately. *Note.*—The corresponding preparation of the *German Pharmacopœia* has the title *Pulvis Salicylicus cum Talco*, and contains 10 parts of wheat starch in place of boric acid"—(*Nat. Form.*).

Medical Uses.—This agent is used as a dusting powder for *irritated surfaces, intertrigo, excoriations*, etc. (see *Talcum*, under *Liquor Sodii Silicatis*).

PULVIS TRAGACANTHÆ COMPOSITUS.—COMPOUND POWDER OF TRAGACANTH.

Preparation.—"Take of tragacanth, gum acacia, starch, each, in powder, 1 ounce (av.); refined sugar, in powder, 3 ounces. Rub them well together"—(*Br. Pharm.*, 1885 and 1898).

Uses.—This preparation forms a good pill excipient, especially for ferrous carbonate, and may be used to form a mucilage in which to suspend the heavier powders.

Related Preparation.—PULVIS ACACIÆ COMPOSITUS (N. F.), *Compound powder of acacia, Pulvis gummosus* (*Ger. Pharm.*). "Acacia, in fine powder, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; glycyrrhiza, in fine powder, thirty-four grammes (34 Gm.) [1 oz. av., 87 grs.]; sugar, in fine powder, sixteen grammes (16 Gm.) [247 grs.]. Mix them intimately"—(*Nat. Form.*).

PULVIS XANTHOXYLI COMPOSITUS.—COMPOUND POWDER OF XANTHOXYLUM.

Preparation.—Take of oleoresin of prickly ash bark, hydrochlorate of berberine, and sulphate of quinine, each, 1 drachm; sugar of milk, a sufficient quantity. Mix together, adding just enough sugar of milk to form the mass into a powder, and then divide into 60 powders.

Action, Medical Uses, and Dosage.—This is a valuable stimulating tonic and alterative, and may be employed in cases requiring such action, as in *debility of the digestive functions, dyspepsia, convalescence from fevers, diarrhœa*, and *dysentery, hepatic torpor, periodical headache, scrofula*, and other chronic diseases accompanied with excessive *debility*. The dose is 1 powder, to be repeated 3 or 4 times a day. It may be given in water, milk, molasses, syrup, or wine, as symptoms may indicate. One powder contains a grain, each, of the three medicinal agents entering into its composition (J. King).

PYCNANTHEMUM.—PYCNANTHEMUM.

The plant *Pycnanthemum pilosum*, Nuttall.

Nat. Ord.—Labiatæ.

COMMON NAMES: *Basil*, or *Wild basil.*

Botanical Source.—This is an indigenous perennial plant, with long and soft whitish hairs, and a subsimple stem, from 1 to 2 feet in height. The leaves are sessile, nearly entire, lanceolate, acute at both ends, pilose beneath; floral ones not whitened. The flowers are white, in large, terminal, sessile heads. Calyx teeth ovate-lanceolate, acute, and with the lanceolate bracts canescently villous and awnless. Corolla pubescent; stamens exserted (G.—W.).

History.—This plant is found in low grounds, dry hills, and plains, from Ohio and Illinois extending southward, and flowering in July and August. The whole plant is used, and yields its virtues to boiling water. It has the taste and odor peculiar to the mint family.

Action, Medical Uses, and Dosage.—Pycnanthemum is diaphoretic, stimulant, antispasmodic, carminative, and tonic. A warm infusion is very useful in *puerperal*, *remittent*, and other forms of *fever*, *coughs*, *colds*, *catarrhs*, etc., and is of much benefit in *spasmodic diseases*, especially *colic*, *cramp of the stomach*, and *spasms of infants*. The cold infusion is a good tonic and stimulant during convalescence from exhausting diseases. Dose of the infusion, either warm or cold, from 1 to 4 fluid ounces, 3 or more times a day.

Related Species.—There are several species of this genus, which possess similar medicinal properties, as the *Pycnanthemum clinopoiodes*, Torrey and Gray; *Narrow-leaf Virginian thyme*, or *Prairie hyssop*, a pubescent plant with white flowers, sessile, lance-linear, entire, and punctate leaves, terminal and corymbed heads, and acuminate bracts. Also the *P. aristatum*, Michaux, or *Wild basil*, with lance-ovate, subserrate, pubescent, acuminate, and short petiolate leaves; hirsute, terminal, capitate, and subterminal verticils; bracts lance subulate, the calyx terminated by awns (G.—W.). *P. incanum*, also called *Wild basil*, *Mountain mint*, and sometimes *Horsemint*, is used like *Monarda*. *P. linifolium*, Pursh, is a smooth plant, also called *Virginia thyme*. This, as well as the *P. lanceolatum*, Pursh, which resembles it in its bitter, resinous taste, has been employed in *dyspepsia* and *hydrophobia*. Dr. Charles Mohr found in *P. linifolium* volatile oil, a caoutchouc-like resin, a bitter, greenish-yellow resin, soluble in 65 per cent alcohol, gum, some sugar, and tannin closely related to *caffeotannic acid;* no alkaloid (*Proc. Amer. Pharm. Assoc.*, 1876, p. 515). Mr. Harold C. Barker, making a complete analysis of this species collected while in flower, confirmed the absence of alkaloids or glucosids (*Amer. Jour. Pharm.*, 1894, p. 169). The same author found *P. lanceolatum* to contain at least 1.5 per cent of volatile oil, the odor of which resembles that of pennyroyal. Alkaloids, glucosids, and starch were absent, while tannin and small amounts of inulin and sugar were present (*ibid.*, 1894, pp. 65 and 172).

PYRETHRUM (U. S. P.)—PYRETHRUM.

The root of *Anacyclus Pyrethrum* (Linné), De Candolle (*Anthemis Pyrethrum*, Willdenow; *Matricaria Pyrethrum*, Baillon).

Nat. Ord.—Compositæ.

COMMON NAMES: *Pellitory*, *Pellitory root*, *Pellitory of Spain*, *Spanish chamomile.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 151.

Botanical Source, History, and Description.—This is the *Anthemis Pyrethrum* of Willdenow, the name of which has been changed by De Candolle, and the plant placed in a new genus on account of a difference in the structure of its seeds. The stems are numerous, procumbent, somewhat branched, and pubescent. The radical leaves are spreading, petiolated, smoothish, and pinnately divided; the segments much-cleft into linear, subulate lobes; and the cauline leaves sessile. Branches 1-headed. Receptacle convex, with oblong-obovate, obtuse paleæ; ray sterile, ligulate, and white; of the disk, fertile, with 5 callous teeth, and yellow (L.). Pellitory of Spain, or Spanish chamomile, inhabits Barbary, Arabia, Syria, etc. The root is the official part, and is officially described as "from 5 to 10 Cm. (2 to 4 inches) long, and 1 to 2 Cm. ($\frac{1}{4}$ to $\frac{3}{4}$ inch) thick, somewhat fusiform, nearly simple, annulate above, wrinkled below; externally dark grayish-brown; internally brownish-white; fracture short; bark rather thick, containing 2 circles of resin cells, and surrounding the slender wood-bundles and medullary rays, the latter having about 4 circles of shining resin-cells; inodorous, pungent, and very acrid"—(*U. S. P.*). The root, when chewed, produces a peculiar sensation of pricking in the lips and tongue, and a glow of heat, with an increase of the salivary discharge. It may be readily distinguished from *False pellitory root*, identified by Mr. E. M. Holmes (*Amer. Jour. Pharm.*, 1892, p. 90), as derived from *Corrigiola telephiifolia*, a Morocco plant, chiefly by the appearance of its cross-section (see illustration, *loc. cit.*).

Chemical Composition.—In 1835, Koene found it to contain a brown acrid resin, insoluble in caustic potash; an acrid, brown fixed oil, soluble in caustic potash; a yellow, acrid oil, also soluble in this solvent; a trace of tannic acid; gum, inulin, various salts, and lignin. Alcohol or ether dissolves its active principle. This is claimed by Buchheim (1876) to be an alkaloid, *pyrethrine*, a body splitting into *piperidine* and an acid, resembling *piperic acid*, called *pyrethric acid*, when treated with alcoholic solution of caustic potash (see *Piperinum*). The *pyrethrin* of Thompson (*Pharm. Jour. Trans.*, Vol. XVII, 1887, p. 567) is an ether-extract, composed of acrid fat and resin. This author found the cortical portion of the root to contain 5 per cent of pyrethrin. Volatile oil is likewise present. Dunstan and Garnett (*Jahresb. der Pharm.*, 1895, p. 64) isolated from the resin crystallizable *pellitorin*, insoluble in water, diluted acids, and alkalies, soluble in alcohol. It resembles *piperovatin* ($C_{16}H_{21}NO_2$), the non-basic, active principle isolated by the same authors from the resin obtained from the leaves of *Piper ovatum*. Both are pyridine derivatives.

Action, Medical Uses, and Dosage.—It is an energetic local irritant and sialagogue, and acts as a rubefacient when applied externally. Its ethereal tincture relieves *toothache*. The root chewed has been found useful in some *rheumatic* and *neuralgic affections of the head and face*, and in *palsy of the tongue*. The decoction has been used as a gargle in *relaxation of the uvula*. Severe acronarcotic symptoms, with inflammation of the alimentary tract and bloody stools, were produced in a young child by less than a drachm of the tincture. The dose is from 30 to 60 grains as a masticatory. Oil of pellitory is made by evaporating the ethereal tincture; it is an excellent remedy for *toothache*.

Related Species and Drugs.—*Anacyclus officinarum*, Hayne, *German pellitory*. A cultivated plant of Germany. By some considered an annual form of *Anacyclus Pyrethrum*. Its action is the same as, but weaker than, the latter.

SWEET PELLITORY, ascertained by Dr. Dymock to be derived from *Tanacetum umbelliferum*, Boissier, is a Persian drug, imported into Bombay, of a sweetish taste and an odor resembling that of Chaulmoogra oil. It contains only a small amount of *pyrethrin* (see D. Hooper, *Amer. Jour. Pharm.*, 1890, p. 504).

INSECT POWDERS.—These are yellowish or drab-colored powders, obtained chiefly from the flowers of two plants—*Chrysanthemum* (*Pyrethrum*) *roseum*, with rosy flowers, a native of the Caucasus, and yielding the *Persian insect powder* (*Persian pellitory*, Guirila); and *Chrysanthemum cinerariæfolium*, Visiani, with white flowers, yielding *Dalmatian insect powder*.

The Persian insect powder is now almost entirely displaced in commerce by the superior Dalmatian powder, which is exported from Trieste. When well kept, free from moisture, the powder retains its activity for years. The mode of its cultivation and collection, in Dalmatia, is jealously guarded as a secret. The powder destroys aphides, house flies, mosquitoes, and, in the form of a dust spray, is applied to keep insects from hot-house plants. The powder, in order to be effectual, must come into actual contact with the insect. The class of hemiptera (true bugs) spiders, hairy caterpillars, and other insects, are proof against it (*Kew Bulletin*, through *Pharm. Jour. Trans.*, Vol. VII, 1898, p. 505). Insect powders are considerably subject to adulterations. A bright-yellow color indicates the presence of curcuma, fustic, chrome yellow, etc. (For detection, see W. L. Howie, *Amer. Jour. Pharm.*, 1883, p. 361.) The addition of 10 per cent of powdered quillaja bark in commercial powder, while it produces sneezing in man, merely dilutes the powder with inert matter as far as its action on insects is concerned (Cæsar and Loretz, 1898). Another adulteration consists in substitution by the Hungarian daisy. The latter yields 9.30 per cent of ash, while the flowers of *C. cinerariæfolium* yield only 6.5 per cent. (For botanical and chemical distinctions, see G. M. Beringer, *Amer. Jour. Pharm.*, 1889, p. 1; also J. Schrenk, *ibid.*, p. 295.) According to George R. Durrant (*ibid.*, 1897, pp. 359-366), the insect powders of commerce are grossly adulterated. The toxic properties are due partly to volatile oil (0.5 per cent in picked specimens of closed flowers, less in open flowers), but principally to a soft acid resin, 4.8 per cent of which is found in selected closed, less than 4 per cent in half open, and still less in fully open flowers. The whole plant contains but traces. Admixture with the inert stems is recognized by the presence of chlorophyll—0.5 per cent of the latter was found in a mixture of flowers, but commercial powders yielded from 50 to 80 per cent of chlorophyll, referred to total ether extract. Thus the powders may be assayed by determining the weight of ether-extract obtainable therefrom; good powders should yield not less than 3.75 per cent of a pure yellow color and the pleasant and characteristic odor of the flowers. The best powders examined yielded 5.5 per cent of pure extract. Prof. J. M. Francis (*Pharm. Jour. Trans.*, from *Bull. of Pharm.*, Vol. XII, 1898, p. 5) contends that this standard of purity, while correct, is too strict, and would have the effect of increasing the price of the powders. Samples, of which one-third consists of stems, are stated to yield practically the same effect. (For a résumé of the chemical history of the powders, which is contradictory, probably owing to the difficulty of obtaining pure specimens, see G. R. Durrant, *loc. cit.*) A tincture of the flowers is said, by Maisch, to cause vesication like Rhus Toxicodendron. Insect powder is not poisonous to man, but, as stated above, is destructive to certain insect pests. It may be used in powder, in aqueous solution, and in fumigations. (For a list of less active plants, see H. Kalbrunner, *Amer. Jour. Pharm.*, 1875, pp. 25 and 399.)

PYROGALLOL (U. S. P.)—PYROGALLOL.

FORMULA: $C_6H_3(OH)_3$. MOLECULAR WEIGHT: 125.7.

"A triatomic phenol obtained chiefly by the dry distillation of gallic acid. Pyrogallic acid should be kept in dark amber-colored bottles"—(*U. S. P.*).

SYNONYMS: *Pyrogallic acid, Acidum pyrogallicum.*

Preparation.—Pyrogallol was first obtained by Scheele, in 1786, by the dry distillation of gallic acid, hence the name pyrogallic acid. Upon heating well-dried gallic acid, in a retort, to a temperature of from 200° to 210° C. (392° to 410° F.), by means of an oil-bath, the yield will be only 30 per cent, while the theoretical yield should be 74 per cent, according to the equation: $C_6H_2(OH)_3.CO_2H + C_6H_3(OH)_3 + CO_2$. A quantitative yield is obtained on heating gallic acid with water, for half an hour, to the temperature of from 210° to 220° C. (410° to 428° F.), in a closed vessel, with provision for the carbon dioxide to escape. The resultant solution of pyrogallol is purified by boiling with animal charcoal; it is then filtered and evaporated to crystallization. An absolutely pure product is obtained by sublimation under reduced pressure. Prof. T. E. Thorp's process (*Amer. Jour. Pharm.*, 1881, p. 236) consists in heating 10 Gm. of gallic acid with 30 Cc. of pure glycerin, on a sand-bath, to a temperature of from 190° to 200° C. (374° to 392° F.). When carbonic acid gas is no longer given off, all the gallic acid will be quantitatively converted into pyrogallol. This method is especially adapted for photographic needs; the final product, when diluted with water, to make one liter, is ready for use. P. Cazeneuve (*ibid.*, 1892, p. 604) heats a mixture of gallic acid (1 part) and aniline (2 parts) to 120° C. (248° F.) until carbonic acid gas ceases to be given off; on cooling, aniline pyrogallate crystallizes. Benzol or toluol dissolves its aniline constituent, while pyrogallol remains.

Description and Tests.—Pyrogallol consists of "light white, shining laminæ, or fine needles, odorless, and having a bitter taste; acquiring a gray or darker tint on exposure to air and light. Soluble, at 15° C. (59° F.), in 1.7 parts of water, and in 1 part of alcohol; very soluble in boiling water, and in boiling alcohol; also soluble in 1.2 parts of ether. When heated to 131° C. (267.8° F.), pyrogallol melts, and may be sublimed unchanged. When ignited, it is consumed, leaving no residue. The aqueous solution, which is at first neutral and colorless, gradually acquires, by exposure to the air, a brown color and an acid reaction, due to absorption of oxygen. The same change of color takes place very rapidly if the solution contains a caustic alkali"—(*U. S. P.*). On account of this property, an alkaline solution of pyrogallol is made use of in gas analysis, for the purpose of absorbing oxygen. "The aqueous solution (1 in 10) of pyrogallol reduces solutions of the salts of silver, gold, and mercury, even in the cold. When freshly prepared, 1 Cc. of the aqueous solution (1 in 20) is colored brownish-red by a few drops of ferric chloride T.S., and this color is changed to deep bluish-black on the addition of 1 or 2 drops of ammonia water. A bluish-black color is also produced in the aqueous solution of pyrogallol by freshly prepared ferrous sulphate T.S."—(*U. S. P.*). By the latter reaction, pyrogallol is distinguished from gallic acid, which remains unaltered by ferrous sulphate, if the air be excluded. Agitated with lime-water, pyrogallol gives a purple coloration, changing to brown and, finally, to black, at the same time becoming turbid. Chemically, pyrogallol is a triatomic phenol, the three hydroxyl groups being in consecutive position, while in its isomer, *phloroglucin*, these groups are symmetrically arranged. As stated above, pyrogallol is distinguished by its affinity for oxygen, to which is due its reducing action upon salts of metals. It is much used in photography to develop the latent image upon the collodion film after it has been exposed to the action of light. It is also employed in dyeing hair black. Pyrogallol is intensely poisonous.

Action and Medical Uses.—That pyrogallol is an intense poison, has been demonstrated by experiments upon animals and accidental poisoning by its absorption when used locally upon man. Hepatic changes, similar to those produced by phosphorus, have been observed in lower animals. In man, Danilevsky states that doses of 5 to 10 grains, twice daily, appeared to produce no serious symptoms, but cases of death are on record from its absorption, when used topically in skin affections. The chief symptoms have been rigor, followed by headaches, general malaisé and fever, vomiting of mucus, diarrhœa, black or brown urine of an acid character and containing albumins, pallid, cyanotic lips, greenish skin, rapid action of heart and lungs, restlessness, sleeplessness, coma, and death from collapse. Disorganization of the red corpuscles also takes place. Pyrogallol stains clothing permanently and the skin transiently. It is not used as an internal medicine, but in ointments and solutions of from 5 to 20 per cent strength, it has been very successfully applied to *psoriasis*, *lupus*, *epithelioma*, and similar *disorders of the skin.* It should be applied only to the lesions and not to the sound skin, and but limited areas should be treated at a time, lest absorption of sufficient of the drug to produce poisoning takes place. In psoriasis, of course, only benefit is derived, for the disease is not wholly a local one. In lupus, it acts best in the diffuse superficial forms, causing the nodules to become destroyed and separate from the sound tissues. In epithelioma its action is slow. Warm poultices, repeatedly applied, hasten its action, and hydrochloric acid, internally, tends to prevent or lessen its liability to produce toxic effects. An ointment of it (20 per cent) is said to have served well in *syphilitic phagedena.*

Derivative of Pyrogallol.—GALLACETOPHENONE, *Trioxyacetophenone*, *Alizarin yellow* ($C_6H_2.[OH]_3C_2H_3O$). This substitution compound may be considered as pyrogallol, in which 1 atom of hydrogen of the benzene ring is replaced by the acetyl group (CH_3CO). It was prepared by Nencki and Sieber by heating together a mixture of glacial acetic acid, pyrogallol, and zinc chloride. The substance forms a yellow, crystalline powder, melting at 168° C. (334.4° F.), or 170° C. (338° F.). It dissolves easily in boiling water, ether, alcohol, and glycerin. Its reaction is neutral or but feebly acid. Cold water sparingly dissolves it (1 in 600). This substance is not so poisonous as pyrogallol, produces no stains, and has been used as a substitute for that body. A solution (10 per cent) has been employed with success in *psoriasis.*

PYROLA.—PYROLA.

The herb of *Pyrola rotundifolia*, Linné.

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Canker lettuce*, *Shin-leaf*, *False wintergreen*, *Pear-leaf wintergreen.*

Fig. 204.

Pyrola rotundifolia.

Botanical Source.—This is a perennial, low, scarcely suffruticose evergreen herb. The leaves are radical, or nearly so, orbicular-ovate, nearly 2 inches in diameter, smooth, shining, thick, entire, or crenulate, usually shorter than the petiole, with conspicuous, reticulate veins. The petioles are margined, and as long as, and usually much longer than the leaf. The scape is mostly racemose, 3-angled, 6 to 12 inches high, with scaly bracts at the base and in the middle. The flowers are many, large, fragrant, white, drooping, about ¾ inch broad, and borne in an oblong, terminal raceme. Calyx 5-parted, persistent; lobes lanceolate, acute, with somewhat spreading tips, ½ or ⅓ the length of the petals. Petals 5, roundish-obovate, nearly spreading, concave, deciduous. Stamens 10, ascending; filaments awl-shaped, naked; anthers large, pendulous; stigmas exserted beyond the ring; style declining and curved, and longer than the petals. The capsule is 5-celled, 5-valved, opening at the angles, and many-seeded (W.—G.).

History and Chemical Composition.—This plant is common in damp and shady woods throughout various parts of the United States, bearing numerous white flowers in June and July. The whole plant is used, and imparts its medicinal properties to water. *P. elliptica*, Nuttall; *P. secunda*, Linne; and *P. chlorantha*, Swartz, possess like properties. Mr. E. N. Smith (*Amer. Jour. Pharm.*, 1881, p. 549) found the leaves of *P. elliptica*, *P. chlorantha*, and *P. rotundifolia* var. *asarifolia*, Michaux, to contain *arbutin*, *ericolin*, *urson*, tannic, gallic, and malic acids, gum, sugar, albumen, little volatile oil, and some coloring matter.

Action, Medical Uses, and Dosage.—Round-leaved pyrola is tonic, astringent, diuretic, and antispasmodic. Used in decoction, both internally and externally, in various *cutaneous eruptions*, likewise in a *carcinomatous* or *scrofulous taint of the system*, and in *leucorrhœa*, and some *uterine diseases*. As a local application, it will be found of service in *sore throat*, and *ulcerations of the mouth*, *indolent ulcers*, *ophthalmia*, etc., and forms an excellent soothing poultice for *boils*, *carbuncles*, and all *painful tumors* or *swellings*. The decoction, taken internally, is valuable in many *urinary affections*, relieving irritation, and is reputed very useful in *gravel*, *hematuria*, and *ulceration of the bladder*, and in some *nervous diseases*. The decoction and extract have been used with success in *convulsions*, and once formed a large portion of a popular nostrum for *epilepsy*. Dose of the decoction, 1 or 2 fluid ounces, 3 or 4 times a day; of the extract, from 2 to 5 grains. A strong tincture of the fresh plant (℥viii to alcohol, 76 per cent, Oj) may be given in doses of from 1 to 30 drops.

Specific Indications and Uses.—To relieve irritation of the urinary tract.

PYROXYLINUM (U. S. P.)—PYROXYLIN.

SYNONYMS: *Soluble gun-cotton*, *Colloxylin*, *Collodion cotton*, *Lana collodii.*

Preparation.—"Purified cotton, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; nitric acid, fourteen hundred cubic centimeters (1400 Cc.) [47 fl℥, 163 ♏]; sulphuric acid, twenty-two hundred cubic centimeters (2200 Cc.) [74 fl℥, 187 ♏]; alcohol, ether, water, each, a sufficient quantity. Mix the acids gradually in a glass or porcelain vessel, and, when the temperature of the mixture has fallen to 32° C. (90° F.), add the purified cotton. By means of a glass rod imbue it thoroughly with the acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of water, and subsequently with alcohol, and pressed, is found to be soluble in a mixture of one (1) volume of alcohol and three (3) volumes of ether. Then remove the cotton from the acids, transfer it to a larger vessel, and wash it, first, with cold water, until the washings cease to have an acid taste, and then with boiling water, until they cease to redden blue litmus paper. Finally, drain the pyroxylin on filtering paper, and dry it in small, detached pellets, by means of a water-bath or steam-bath, at a temperature not exceeding 60° C. (140° F.). Keep the pyroxylin, loosely packed, in well-closed vessels containing not more than about 25 Gm., in a cool and dry place, remote from lights or fire"—(*U. S. P.*).

In this process, the cellulose of the cotton is converted into cellulose nitrates of variable composition. If nitric acid of the highest concentration (specific gravity 1.48 to 1.5) be used, a *cellulose hexa-nitrate* ($C_{12}H_{14}[NO_3]_6O_{10}$) is formed, which, together with the *penta-nitrate*, constitutes gun-cotton proper. These nitrates are insoluble in a mixture of alcohol and ether, also in methyl alcohol and acetic ether, hence can not be used in the preparation of *collodium* (which see). When the nitric acid is allowed to act upon the cotton for a shorter time, or if a weaker acid be used for a correspondingly longer time, as in the above *U. S. P.* process, the *di-*, *tri-*, and *tetra-nitrates of cellulose* are formed, which are soluble in the above alcohol-ether mixture, also in acetic ether and in methyl alcohol. It is important regarding the keeping qualities of both gun-cotton and pyroxylin, that the nitric acid or the potassium nitrate (which is sometimes employed in the place of the acid) be free from chlorides, and the cotton be absolutely deprived of its fatty and waxy matter previously, otherwise slow decomposition, with evolution of red, nitrous vapors, or even dangerous explosions will occur. For the same reason the finished product must be absolutely freed from its adhering acid by thorough washing.

Description and Uses.—Pyroxylin does not materially differ in appearance from ordinary cotton. It is, perhaps, somewhat rougher to the touch. Pyroxylin and gun-cotton were formerly termed *nitro-cellulose*, which name is inappropriate, because these products do not contain the nitro group (NO_2) as does, for example, nitrobenzol ($C_6H_5NO_2$). They are cellulose ethers of nitric acid 2, 3, or 4 atoms of hydrogen of the cellulose molecule ($C_{12}H_{20}O_{10}$) being replaced by the nitric radical; thus the tri-nitrate has the formula $C_{12}H_{17}(NO_3)_3O_{10}$. Cellulose hexa-nitrate differs from cellulose also by being insoluble in cupric ammonium sulphate (Schweitzer's reagent).

The various cellulose nitrates, when treated with warm alkalies, are gradually deprived of their nitric acid. Cold, concentrated sulphuric acid also expels nearly all nitric acid. Treatment of these nitrates with reducing agents, such as potassium sulphydrate (KSH) or ferrous acetate, etc., likewise denitrates these compounds with regeneration of cellulose (see Durand Woodman, *Amer. Jour. Pharm.*, 1892, p. 481). When the nitrate is boiled with ferrous sulphate and hydrochloric acid, all of the nitrogen is expelled in the form of nitric oxide (NO), the volume of which may be measured (Schloesing's method) by means of this reaction; the degree of nitration of pyroxylin or gun-cotton may, therefore, be determined.

Pyroxylin should be kept free from moisture, and should be put *loosely* into the container. Gun-cotton, when subjected to a sudden percussion, especially by the intervention of fulminating mercury, explodes violently. When ignited in small quantities, it quietly, although rapidly, burns off; when thoroughly saturated with water, it is perfectly harmless. The chief products of its combustion are nitrogen, nitric oxide, carbon monoxide, carbon dioxide, water vapor, methane, etc. As it leaves no residue upon burning, the combustion may be said to be practically smokeless; for this reason gun-cotton is used in the preparation of smokeless powder. Gun-cotton has also been recommended as a filtering medium for strong oxidizers, such as solution of potassium permanganate, nitric acid, chromic acid, etc. Pyroxylin is not used in medicine, but is chiefly employed in preparing collodion (which see).

PYRUS.—APPLE TREE.

The bark of *Pyrus malus*.

Nat. Ord.—Rosaceæ.

COMMON NAME: *Common apple tree.*

Botanical Source.—This is a well-known tree, growing from 20 to 40 feet high, with rigid, crooked, spreading branches, and a rough, blackish bark. The leaves are from 2 to 3 inches long, about $\frac{2}{3}$ as wide, ovate, or oblong-ovate, serrate, acute, or short-acuminate, pubescent above, tomentose beneath, and on petioles from $\frac{1}{2}$ to 1 inch in length. The flowers are large, fragrant, expanding with the leaves, of pale-rose color, and borne in subumbellate corymbs. The calyx-tube is urn-shaped, with limb 5-cleft; the pedicels and calyx villose-tomentose. Petals 5, roundish, or obovate, with short claws. Stamens numerous; styles 5, united, and villose at base. Fruit or pome globose (W.).

History and Chemical Composition.—The apple tree is a native of Europe, naturalized in this country, and flowers from April to June. There are, probably, nearly 1000 varieties cultivated in the United States, and all of which are said to be derived from the *Wild crab* (*Pyrus coronaria*, Linné). From the fruit cider is manufactured, and both the fruit and its cider are much used for domestic and medicinal purposes. The percentage composition of non-dried apples, according to the average of 36 analyses communicated by J. König (*Chemie der Menschl. Nahrungs und Genussmittel*, 3d ed., 1893) is as follows: Water (84.79), nitrogenous matter (0.36), free acid (chiefly in ripe fruits; *malic acid*, 0.82), sugar (invert sugar, with notable amounts of cane sugar, 7.22), nitrogen-free matter (starch, gum, pectin matter, 5.81), woody fiber and seeds (1.51), ash (0.49). Apples are used in the preparation of *Extractum Ferri Pomatum* and *Tinctura Ferri Pomata*, which are official in the *German Pharmacopœia*. The bark of the apple tree is bitter, and has also been employed in medicine. It contains a principle called *phloridzin*. The root bark is the most active, and yields its virtues to boiling water. Rochleder obtained a yellow coloring matter, which he named *quercetin*. The leaves, according to Rochleder, contain a well-crystallizable body, isomeric with phloridzin, called *isophloridzin*. The seeds contain *amygdalin* (about 0.6 per cent).

Phloridzin, *phlorizin*, or *phloridzite* ($C_{21}H_{24}O_{10}.2H_2O$), was discovered, in 1835, by De Koninck and Stas. It is a bitter glucosid which exists in the bark of the trunk and roots of the apple, pear, cherry, and plum trees. The fresh root-bark of the apple tree contains about 3 to 5 per cent, the leaves about 0.8 per cent of this principle, while the dry root-bark does not contain it. To prepare it, the fresh bark of the root of the apple tree is boiled for 2 hours in a quantity of water sufficient to cover it. This water is decanted off, and the boiling repeated with a second portion. This last decoction must be kept separate from the first. It commonly deposits in 24 hours a considerable quantity of granular crystals of phloridzin, which, when dissolved in distilled water and treated with animal charcoal, are rendered quite pure. Another process is to digest the fresh bark of the root in weak alcohol at about the temperature of 50° C. (122° F.), continuing the digestion for 8 or 10 hours. The greater part of the alcohol is then distilled off, and the residue set aside to crystallize. Purify as in the other process.

Phloridzin forms small, white, silky needles, has a bitter taste, followed by sweetishness, is soluble in 1000 parts of cold water, but at temperatures from 24.4° to 100° C. (76° to 212° F.), it dissolves in all proportions. It is very soluble in absolute alcohol, but little soluble in ether, has a neutral reaction, and a specific gravity of 1.4298. Its alcoholic solution is optically lævo-rotatory. At 100° C. (212° F.), it loses its water of crystallization, which is not absorbed again even in a moist atmosphere. It melts at about 107° C. (224.6° F.), solidifying upon further heating at 130° C. (266° F.), and melting again at 160° C. (320° F.). Its aqueous solution is precipitated by basic acetate of lead. Boiling with diluted mineral acids converts it into dextrose and crystallizable *phloretin* ($C_{15}H_{14}O_5$), hardly soluble in water and ether, easily soluble in alcohol and alkalies. Boiling with concentrated alkali converts it into *phloroglucin* ($C_6H_3[OH]_3$) and *phloretic acid* ($C_9H_{10}O_3$). (For further details, see Husemann and Hilger, in *Pflanzenstoffe*, 1884, p. 1001.)

Action, Medical Uses, and Dosage.—Apple tree bark is tonic and febrifuge, and a decoction of it has been used with advantage in *intermittent*, *remittent*, and *bilious fevers*, and in convalescence from exhausting diseases. It may be given in doses of 1 to 4 fluid ounces, 3 times a day. A strong decoction or syrup of the sweet apple tree bark has been employed with success in some cases of *gravel*. The fruit, or apple, contains both malic and acetic acids, has a pleasant and refreshing flavor, and is a useful and healthy article of diet. However, it should not generally be eaten by dyspeptics, or patients afflicted with *gout*, *rheumatism*, *renal*, and *cutaneous diseases*. If indications for an acid are present, however, it is not especially contraindicated by *rheumatism* and *dyspepsia*. When baked, stewed, or roasted, it becomes valuable as an agreeable and healthy diet in *febrile diseases*, *exanthemata*, etc., and is more easily digested than when raw; it is also slightly laxative, and is beneficial in cases of *habitual constipation*. Raw apples should always be well masticated before being swallowed, as otherwise, they may become a source of serious difficulties, especially with children. An apple tea may be made for fever patients, by boiling a tart apple in ½ pint of water, and sweetening with sugar.

Cider forms not only a refreshing and agreeable drink for patients with fever, but actually exerts a salutary medicinal influence, especially where the tongue is coated deep-red, brown, or black. I have used cider, in which horseradish has been steeped, as an efficient remedy in *dropsy*, for many years; and it is now used in the preparation of a valuable agent for this disease, the *Compound Infusion of Parsley*. Cooked apples form an excellent local application in *ophthalmic inflammation*, *erysipelatous inflammations*, *sore* and *swelled throat* in *scarlatina*, *ulcers*, etc. (J. King).

Phloridzin is tonic and antiperiodic, and has cured cases of *intermittent fever*, even where quinine has proved ineffectual; its dose is from 5 to 20 grains. Unlike quinine, it does not cause gastralgia.

Related Species.—*Cratægus oxyacantha*, Linné (*Nat. Ord.*—Rosaceæ), *Haw*, *Hawthorn*, *English hawthorn*. The fruit and bark of this shrub, or small tree, have been introduced into medicine as a heart remedy. The shrub grows abundantly in woods and thickets throughout Europe, central and northern Asia. In England it is cultivated for hedging purposes, and is familiarly known as Hawthorn. The fresh bark of the young branches contains a bitter crystallizable principle, soluble in water, insoluble in ether, little soluble in alcohol. Claims are made for this drug as a curative remedy for *organic and functional heart disorders*, including *cardiac hypertrophy*, with *mitral regurgitation* from valvular insufficiency, and *angina pectoris*. Sometimes *spinal hyperæmia* is associated with the latter, when both are said to be relieved by the drug. The drug should be studied with a view to its adaptability to cases "characterized by pain, præcordial oppression, dyspnœa, rapid and feeble heart-action, evidence of cardiac hypertrophy, valvular insufficiency, and marked anemia" (*Ec. Med. Jour.*, 1898, p. 176). Prof. J. A. Jeançon, M. D., employs it for *venous stasis*. The dose is from 1 to 20 drops, 3 or 4 times a day.

QUASSIA (U. S. P.)—QUASSIA.

"The wood of *Picræna excelsa* (Swartz), Lindley"—(*U. S. P.*) (*Picrasma excelsa*, Planchon).

Nat. Ord.—Simarubeæ.

COMMON NAMES: *Quassia wood*, *Bitter wood*, *Bitter ash*, etc.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 57.

Botanical Source.—This is the *Quassia excelsa* of Linnæus, and the *Simaruba excelsa* of De Candolle, and is known by the various names of *Lofty quassia*, *Bitter wood*, *Bitter ash*, etc. This is a tree, growing from 50 to 100 feet high, with an erect stem, 3 feet or more in diameter at the base, gradually becoming smaller as it ascends. The bark is grayish and smooth. Leaves alternate and unequally pinnate; leaflets opposite, short-petioled, oblong, acuminate, unequal at the base, blunt at the apex, and veiny-glabrous. Flowers small, pale or yellowish-green, polygamous; racemes toward the end of the branchlets, axillary, very compound, panicled, sub-corymbose, dichotomously branched, spreading, and many-flowered. Peduncles compressed, downy, and rufescent. Sepals 5, minute. Petals 5, longer than the sepals. Filaments of the male flowers much longer than the petals; in the fertile of the same length. In the male, merely the rudiments of the pistil; in the fertile, ovaries 3; style longer than the stamens, triquetrous, and trifid. Anthers roundish. Stigmas simple and spreading. Fruit, 3 drupes, one only being perfected, size of a pea, black, shining, fixed on a hemispherical receptacle; nut solitary and globose, with the shell fragile (L.).

Fig. 205.

Picræna excelsa.

History and Description.—Picræna excelsa is common on the plains and lower mountains of Jamaica and other neighboring islands. It flowers in October and November, and in the two succeeding months matures its fruit. The wood of this tree furnishes the quassia of commerce, being substituted for the true Surinam quassia (*Quassia amara*). Though the Pharmacopœia retains the genus name, *Picræna*, the latter has now been united to the genus *Simaruba* (Lloyd, *West. Drug.*, Jan., 1897, p. 7). It is imported in logs and sticks, varying from 2 inches to 1 foot in diameter, and from 1 to 6 or 8 feet in length, occasionally larger than a man's body, and split into quarters, and frequently retaining a friable and feebly attached cortex, which has similar medicinal powers with the wood. These are undoubtedly obtained from portions of the tree itself, instead of from its root. The wood is white, but changes to yellow under the action of the air. The bark is thin, dark-brown, or thick, grayish-brown, wrinkled, and traversed by reticulating lines. The wood is often turned into cups and sold as *quassia* or *bitter cups*, for when water is poured into them, it partakes of the bitterness of the wood. The *U. S. P.* describes it as occurring "in billets of various sizes, dense, tough, of medium hardness, porous, with a minute pith, and narrow, medullary rays; inodorous, and intensely bitter. In the shops it is usually met with in the form of chips or raspings of a yellowish-white color"—(*U. S. P.*). Quassia was introduced into medicine by Dr. John Lindsay, of Jamaica, in 1791. It was used on that island as a domestic remedy for fluxes and fevers, and yields its medicinal virtues to water and alcohol.

Chemical Composition.—The chief constituent of quassia is the bitter *quassiin* or *quassin*. It was first obtained by Winckler, in 1835, from the wood of *Quassia amara*. Subsequently, it was studied by Wiggers (1837) who gave a detailed method for its preparation (see this *Dispensatory*, preceding edition).

A. Christensen (*Archiv der Pharm.*, 1882, p. 481) obtained pure quassiin by precipitating an aqueous infusion, concentrated by evaporation, with tannic acid, decomposing the precipitate with lead carbonate, and extracting with alcohol. The yield from *Picræna excelsa*, in one instance, was 0.06 per cent. *Quassiin* thus obtained, crystallizes in thin, rectangular scales, of an intensely bitter taste, permanent in the air, and forming neutral solutions with water. It melts at 205° C. (401° F.), and is soluble in 735 parts of water, at 15° C. (59° F.), when saturated at a higher temperature. It is more soluble in boiling water, easily soluble in boiling alcohol, and in warm alkalies, also in chloroform, in 30 parts of 84 per cent alcohol at 15° C. (59° F.), soluble, with difficulty, in ether and petroleum ether. It is not a glucosid. Pure solutions of quassiin are not fluorescent. Fried. Massute (*Archiv der Pharm.*, 1890, pp. 147–171) pronounces the quassiins of different observers, including those obtained by himself, to constitute an homologous series, the bitter principles of *Quassia amara* (*quassiin*) and of *Picrasma excelsa* (*picrasmin*) probably belonging to different groups. Both are mixtures of several quassiins (see also formulæ in *Amer. Jour. Pharm.*, 1890, p. 338). The precipitates obtained in solutions of quassiin, with alkaloidal reagents, are due to the presence of a crystallizable base discovered in the wood of *Quassia amara*. This substance is insoluble in chloroform and ether, soluble, with difficulty, in water and cold alcohol, readily soluble in acidulated alcohol, with ultramarine-blue fluorescence. It seems to occur also in the bark of *Picræna excelsa* in comparatively large quantity. Oliveri and Denaro (1885) established *quassiin* ($C_{32}H_{44}O_{10}$) to be a derivative of the hydrocarbon *anthracene* ($C_{14}H_{10}$). Merck (*Jahresb. der Pharm.*, 1895, p. 457) obtained crystallizable, tasteless *quassol* in the manufacture of quassiin.

Action, Medical Uses, and Dosage.—Quassia is tonic, febrifuge, and anthelmintic. The stomach is deranged by its long-continued use. A strong infusion, by enema, produced serious narcotic symptoms and collapse in a child of 4 years. It is used sometimes in *remittent* and *intermittent fevers;* likewise in *dyspepsia*, *debility* during convalescence from exhausting diseases, and for *worms*. It preserves animal matters from decay, which is a property possessed more or less by all simple bitters. The decoction, administered by way of injection, will remove *ascarides*. An infusion may be made by macerating for 12 hours 3 drachms of the rasped or ground quassia in a pint of cold water; the cold water does not dissolve the extractive matter. Of this a wineglass half full may be taken 3 times a day, either alone, or with some ginger tea, and will be found useful for feeble, emaciated persons, with impaired digestive organs. Or an extract, made by evaporating the decoction to a pilular consistence, may be given in doses of 1 grain, 3 or 4 times a day, and which will be found less offensive to the stomach than the infusion or decoction. Quassia, in connection with sulphuric acid, enters largely into the composition of an anti-bacchanalian elixir, for the cure of *drunkenness*.

Dr. W. Ferguson gave to Dr. John King the following formula for the preparation of this elixir, which he has used with much advantage: Take of tincture of calumba, compound tincture of gentian, tincture of cascarilla, each, 1 fluid ounce; infusion of quassia, 1 pint; elixir of vitriol, 2 fluid drachms and 40 minims. Mix. The dose is a tablespoonful every 1 or 2 hours, or it may be taken every 4 or 6 hours, in doses of 2½ fluid ounces. Frequent bathing of the head in cold water is a valuable auxiliary. It acts as a tonic; in some cases its first action is that of emesis. Its use must be persisted in for some time, that the stomach may retain tone and vigor. It frequently destroys the appetite for alcoholic drinks.

On flies and other insects, quassia acts as a powerful narcotic poison, and the alcoholic extract when introduced into the cellular tissue kills small animals. Mr. Brande, in his work on chemistry, recommends a strong decoction of quassia, well sweetened with brown sugar or molasses, as an effectual poison for flies, and far preferable to the poisonous articles generally used to destroy them. It is certainly worth the trial. A very excellent injection for ascarides (thread-worms), is a strong infusion of 3 parts of quassia, and 1 of mandrake root, to every ounce of which a fluid drachm of tincture of asafœtida may be added. For a child 2 years old, 2 fluid ounces may be injected into the rectum twice a day. Diluted carbolic acid may be substituted for the asafœtida, if desired. Dose of the powder, 30 grains; of the infusion, from 1 to 3 fluid ounces; of the tincture, 1 or 2 fluid drachms; of the extract, from 2 to 10 grains; and of quassiin, ½ to 1 grain.

Related Species and Drugs.—*Quassia amara*, Linné, *Bitter quassia*, is a shrub, or moderately-sized branching tree, having a grayish bark. Leaves alternate, unequally pinnate; leaflets in 2 pairs, opposite, entire, smooth, elliptical, acute at each end; petiole winged, joined, with the joints obovate. Flowers large, scarlet, distant, hermaphrodite, in long, 1-sided, simple, terminal, rarely branched racemes. Pedicels bracteate at the base, jointed below the apex, and there having 2 little bracts. Calyx short, 5-parted. Corolla of 5 petals, longer than the sepals, arranged in a tubular manner. Stamens 10, longer than the petals. Ovaries 5, placed on a receptacle broader than themselves; styles 5, distinct at the base, there united into a very long one, terminating in a nearly equal, 5-furrowed stigma. Fruit drupaceous (L.). Quassia amara inhabits Surinam, Guiana, Colombia, Panama, and the West Indian Islands, flowering in November and December. A negro, residing in Surinam, named Quassi, had obtained a very great reputation in the cure of epidemic malignant fevers of that place. His remedy was kept secret, until 1756, when he was induced to make it known to Daniel Rolander and to C. G. Dahlberg (see account in *Western Druggist*, 1897, p. 7). The bark, wood, and root are intensely bitter, and have proved very efficient in *malignant fevers*. The medicinal parts of this tree seldom reach this country at present, and the wood of *Picræna excelsa* is now substituted for it. Its bitter principle is probably *quassiin*, though Massute (1890) states that there are four principles, all differing from those of *Picræna excelsa*, and varying in solubility and fusing points (see *Picræna excelsa* above for further details).

SURINAM QUASSIA BARK and JAMAICA QUASSIA BARK are both possessed of the bitterness of the woods.

Samadera indica, Gaertner, a tree belonging to the same order as the quassia tree; it is indigenous to Ceylon, and has a very bitter bark; also the wood and the seeds are bitter. The bark is used as a febrifuge on the Malabar coast; the leaves are externally applied in erysipelas (Dymock, Warden, and Hooper, *Pharmacographia Indica*, Vol. I, 1890, p. 294). De Vrij, in 1872, obtained from the seeds 33 per cent of a bitter, light-yellow, non-drying fixed oil, and a bitter principle, *samaderin*, which is amorphous, soluble in water and alcohol, and can be removed from its aqueous solution by animal charcoal. It turns violet-red with sulphuric acid. Tonningen (1858) had obtained a scaly, bitter substance, giving the same reaction. Flückiger believes it to be identical with *quassiin*.

Simaba cedron, Planchon.—CEDRON SEED is the fruit of *Simaba cedron*, a species of *Simarubeæ*, closely allied to the tree that produces quassia bark. This is a small tree, native of New Granada and neighboring parts of South America. It is characterized by having large pinnate leaves, consisting of numerous narrow leaflets and very large panicles of flowers. All parts of the tree are bitter. The fruit is about the size of a "swan's egg," and contains a single seed. The seeds are intensely bitter, and are esteemed by the natives as an antidote in the *bites of poisonous snakes, insects*, etc. The seeds appear to possess tonic and febrifuge properties, and are recommended for *malarial diseases*, and to improve the conditions of the digestive powers when enfeebled, and in *dyspepsia*. For these purposes, an infusion may be employed, or a fluid extract may be taken, in doses of from 1 to 10 minims, repeated 3 or 4 times a day. *Cedrin*, in bitter, silky, acicular crystals, was obtained by Lewy, in 1851, from the seeds, by removing the fat with ether and extracting the residue with alcohol. Tanret (1880) believes it identical with an emetic principle obtained by him from the seed of *Simaba Valdivia*, Planchon, which he named *valdivin* ($C_{36}H_{48}O_{20}+5H_2O$). It is crystalline, neutral, soluble in chloroform and alcohol, and sparingly soluble in cold water (1 in 600), insoluble in ether. The aqueous solution foams when shaken. The principle is decomposed by alkalies.

Simaba ferruginea, St. Hilaire, of Brazil and Central America, is similar to the preceding (see *Amer. Jour. Pharm.*, 1880, p. 326).

Simaruba officinalis, De Candolle.—*Simaruba*, called in Jamaica *Mountain damson*, is a tree with long, horizontal, creeping roots, and a trunk about 60 feet in height, alternately branched at the summit; the old bark is grooved and blackish; the young smooth, ash-colored, spotted yellow. Leaves alternate and abruptly pinnate, with a long, naked petiole, sometimes nearly 14 inches long; leaflets alternate, 2 to 9 on each side, about 2 inches long, oval, smooth, firm, mucronate, on short footstalks, and whitish underneath. Flowers yellowish-white, some male, others female, mixed upon branched, scattered panicles, very small (Dr. Wright states that the male and female flowers, in Jamaica, are on different trees, or diœcious). Calyx small, cup-shaped, 5-parted. Petals stiff, sharp-pointed, whitish, fixed between a membranous disk and the calyx. Stamens 10, nearly equal; filaments each arising out of a small, rounded, velvety scale; anthers oblong, incumbent. Capsules 5, ovate, blackish, disjointed, placed on a fleshy disk, with a rather fleshy pericarp (L.—Wi.). Simaruba grows in Jamaica, Guiana, and other parts of South America. It is found in sandy places, flowering from October to January. The root bark is the medicinal part. The bark is rough, scaly, tuberculated, light, tough, yellowish-brown in its substance, but tinged with gray externally, odorless, not easily powdered, and intensely bitter (C.—Ed.). Water or alcohol takes up its properties. Morin found it to contain bitter *quassiin*, gummy matter, resin, and traces of a volatile oil, having a benzoic odor. *Simaruba medicinalis*, Endlicher, has a similar root bark, and is similarly employed. Simaruba is apt to excite vomiting and purging when taken in large doses. In smaller doses it is tonic, and may be used in infusion in all cases where simple bitter tonics are indicated. It may be used in all cases as a substitute for quassia. It was at first introduced to the profession as a calmative astringent in *chronic dysentery* and *diarrhœa*. However, it merely acts as a tonic, proving very useful in weakened conditions of the digestive apparatus, but injurious in dysentery when improperly administered. The infusion is the best form for exhibition; a drachm or so may be added to ½ pint of boiling water, and given in doses of a tablespoonful every 2 hours. Foy recommends a compound infusion, made by placing in 1 pint of boiling water, 2 drachms, each, of coarsely-bruised simaruba and wormwood; digesting for 15 or 20 minutes, then straining, and adding 1 fluid ounce of syrup of gentian. The dose is a wineglassful, 2, 3, or 4 times a day, and may be used in *dyspepsia, anorexia*, and in convalescence from *intermittents*. Simaruba is seldom used at present.

Picrasma quassioides.—A Himalayan tree, resembling ailanthus, and possessing a very bitter wood and bark, in which Dymock and Warden (*Pharm. Jour. Trans.*, Vol. XX, 1889, p. 41) found a crystallizable principle, probably *quassiin*, a fluorescing, bitter, resin-like principle, and at least one other amorphous, bitter substance, probably the amorphous quassiin of Adrian and Moreaux (*Jahresb. der Pharm.*, 1883, p. 298). The wood yielded 1.7 per cent of ash. They also intimated the probable presence of an alkaloid. The bark has been suggested as a substitute for quassia.

Cascara Amarga.—This is the Honduras Bark, supposed to come from a species of *Picrasma*. Mr. F. A. Thompson (*Therapeutic Gazette*, 1884, p. 8; also see J. Moeller and A. Atkinson, in *Jahresb. der Pharm.*, 1883–84, p. 299) found it to contain 3 per cent of a brownish-yellow, amorphous alkaloid of a sweetish, afterward bitter, taste. He gave it the name *picramnine*. Honduras bark has been recommended for *syphilitic affections*.

Byttera febrifuga, or *Bitter ash*, of M. Bélanger, West Indies, is now thought to be the *Quassia excelsa* of Linné.

Chaparro amargoso (*Nat. Ord.*—Simarubaceæ).—This is a small, thorny bush growing on thin mesquite land in southwestern Texas. The flowers are pink and the fruit, when ripe, cherry-red. All parts of the shrub have a peculiar and intensely bitter taste, and possess medicinal properties, though the tendrils are selected for use, as they contain the most active constituents. It yields its virtues fully to water on prolonged boiling (2 hours). Chaparro was introduced into medicine by Sharp & Dohme, of Baltimore, Md., upon the statement of Dr. J. W. Nixon, of Wrightsboro, Texas, and indorsed by numerous other physicians who have used it in private as well as hospital practice, that it was an efficient antidysenteric remedy, especially applicable to those intractable forms of *Mexican dysentery* or "*camp flux*." It is applicable to both acute and chronic conditions. Under the names of *Bisbi* and *Amargosa*, it has long been used by the natives in *bowel disorders*. A plain and aromatic fluid extract have been put upon the market by Sharpe & Dohme, the dose of which is 15 drops to 2 fluid drachms.

QUERCUS ALBA (U. S. P.)—WHITE OAK.

The bark of *Quercus alba*, Linné.

Nat. Ord.—Cupuliferæ.

Common Name: *Oak bark*.

Illustrations: White oak and others in Bentley and Trimen's *Medical Plants*, 248, 250, 251.

Botanical Source.—*Quercus alba* is a forest tree, varying in size according to the climate and the soil, attaining the height of from 60 to 90 feet, with a diameter of 3 to 6 feet. It is covered with a whitish bark, often interspersed with dark spots. The leaves are oblong, pinnatifid, sinuate, smooth, bright-green above, pale or glaucous beneath, dilated above, and obliquely divided into from 3 to 5 lobes, which are oblong, or linear, obtuse, mostly entire, and sometimes tapering at their base. The flowers are monœcious and amentaceous. Cup hemispherical, naked, much shorter than the acorn, deep, and tuberculate. Acorns are large, ovate, coriaceous, 1-celled, 1-seeded, surrounded at base by the cup, and are solitary, or borne in pairs upon long peduncles (W.—G.).

History and Description.—Quercus is a very extensive and valuable genus, consisting of many species, a large proportion of which grow in the United States. Their usual character is that of astringents, and the one above described, also *Quercus rubra* and *Quercus tinctoria*, are those which have been more particularly employed in medicine. The bark of the tree is the official portion. White oak grows throughout the Union, but is more abundant in the middle states. Its wood is strong and durable, and is extensively employed in ship-building, cooperage, carriage-making, etc. (W.). Tanners occasionally make use of its bark, but that of the *Q. rubra*, Linné (*Red oak*), *Q. tinctoria*, Bartram (*Black oak*), *Q. coccinea*, Wangenheim (*Scarlet oak*), and *Q. elongata*, Willdenow, are commonly used. White-oak bark is the one chiefly used in medicine. Its epidermis contains no astringency, and should, therefore, be removed. The bark thus prepared is of a pale-brownish color, faintly odorous, very astringent, with a slight bitterness, tough, breaking with a stringy or fibrous fracture, and not readily powdered. Its astringency is imparted to water or alcohol. The best time for gathering the bark is in the spring, when it contains the most tannic acid.

The bark of *Quercus alba* is described by the *U. S. P.* as "in nearly flat pieces, deprived of the corky layer, about 5 Mm. ($\frac{1}{5}$ inch) thick; pale-brown; inner surface with short, sharp, longitudinal ridges; tough; of a coarse, fibrous fracture, a faint, tan-like odor, and a strongly astringent taste. As met with in the shops, it is usually an irregularly coarse, fibrous powder, which does not tinge the saliva yellow"—(*U. S. P.*). The latter provision aims to exclude black oak (*Quercus tinctoria*). The bark of *Quercus Robur*, Linné, is official in the *German Pharmacopœia*, and was official in the *British Pharmacopœia*, 1885, but is excluded in the present edition (1898).

Chemical Composition.—In addition to the chief constituent, *quercitannic acid*, and its decomposition product, *oak-red*, oak bark contains terpene-resin, fat, wax, chlorophyll, bitter matter, ellagic and gallic acids; all of the latter substances are soluble in ether. *Pectin*, the carbohydrate *lævulin* ($C_6H_{10}O_5$), and the sugar, *quercit* ($C_6H_{12}O_5$), are also present. *Quercitannic acid* ($C_{17}H_{16}O_9$, Etti, *Amer. Jour. Pharm.*, 1884, p. 135; $C_{28}H_{28}O_{14}$, water-soluble; and $C_{28}H_{26}O_{11}$, much less soluble, Löwe, 1881) is not identical with gallotannic acid, and is an unstable substance, having a tendency to give off water, forming anhydrides, which are coloring matters (*phlobaphenes*), one of which is *oak-red* ($C_{28}H_{22}O_{11}$). According to Prof. Trimble (*The Tannins*, Vol. II, p. 49), each species of oak has its characteristic phlobaphene, *e. g.*, *quercitrin* is that which characterizes *Quercus tinctoria*. Prof. Trimble (*loc. cit.*) found the dried inner bark of white oak, collected in March, to contain 6.96 per cent of tannin, while a specimen of galls from leaves of the same species yielded 17.89 per cent. The highest percentage of oak-bark tannin recorded is 14.21, found in the bark of *Quercus bicolor*. (Also see investigation on the tannin of *Quercus alba*, by Prof. Henry Kraemer, *Amer. Jour. Pharm.*, 1890, p. 236.)

Action, Medical Uses, and Dosage.—Oak bark is slightly tonic, powerfully astringent, and antiseptic. It is useful internally in *chronic diarrhœa*, *chronic mucous discharges*, *passive hemorrhages*, and wherever an internal astringent is required. In *colliquative sweats*, the decoction is usually combined with lime-water. It is, however, more generally used in decoction, as an external agent, which forms an excellent gargle for *relaxed uvula* and *sore throat*, a good stimulating astringent lotion for *ulcers* with spongy granulations, and an astringent injection for *leucorrhœa*, *prolapsus ani*, *hemorrhoids*, etc. The ground bark, made into a poultice, has proved useful in *gangrenous* or *mortified conditions*. In sickly, debilitated children, and in severe *diarrhœas*, especially when the result of *fevers*, the decoction, given internally, and used as a bath to the body and limbs, 2 or 3 times a day, will be found very efficient. When given for *diarrhœa* or *dysentery*, it should be combined with aromatics, and sometimes with castor oil. A bath is often advantageous in some *cutaneous diseases*. The green bark of elder and white oak bruised together, or in strong decoction, forms a very useful and valuable application to *abrasions*. Dose of the decoction, 1 to 2 fluid ounces; of the extract, from 5 to 20 grains. A coffee made from roasted acorns, has been highly recommended in the treatment of *scrofula*.

Specific Indications and Uses.—Relaxation of mucous membranes, with unhealthy discharge; ulcerations, with spongy granulations.

Related Species.—*Quercus rubra*, Linné, or *Red oak*, is a lofty, wide-spreading tree, attaining the height of about 70 feet, with a diameter of 3 or 4 feet. Leaves 6 to 10 inches in length, on long petioles, oblong, smooth on both sides, pale beneath, obtusely sinuate, with short and entire, or sparingly dentate, mucronate lobes, 4 to 6 on each side. Fructification biennial. Acorns oblong-ovoid, about an inch long, surrounded at base by a saucer-shaped, shallow, even cup, very much shorter than the acorn, of very small and close scales, and subsessile (G.—W.). *Red oak* is more common in the northern states and Canada; its wood is reddish and coarse-grained, and used principally for fuel. Its bark is extensively used in tanning. It contains considerable tannin, and is generally employed as an external agent. An extract of the bark, as well as the potash obtained from its ashes, were both formerly much employed as local applications in the treatment of *cancer*, *indolent ulcers*, etc. Prof. Scudder valued a combination of rumex, red-oak bark, and alnus, both locally and internally, in *eczema*, and obstinate *scrofula*, with "*old ulcers*, feeble tissues, and cicatrices."

Quercus tinctoria, Bartram (*Q. velutina*, Lamarck), *Quercitron*, or *Black oak*, is one of the loftiest trees in the forest, frequently attaining the height of 80 to 100 feet, with a diameter of 4 or 5 feet. Bark deeply furrowed, black or deep-brown. Leaves 6 to 8 inches long, obovate, oblong, more or less rusty-pubescent beneath, finally glabrous, slightly or sometimes deeply sinuate-lobed, with oblong, obtuse, mucronate, somewhat toothed lobes. Acorns brown, nearly spherical or depressed-globose, about one-half immersed in a deep, thick, flat, conspicuously scaly cup, which is subsessile. The leaves turn dark-red after frost (G.—W.). This species was regarded by Prof. Asa Gray as a variety of the *Scarlet oak* (*Q. coccinea*, Wangenheim).

Black oak is common to the United States; the bark of this forest tree is much used in tanning and for dyeing. It has a strong odor, a very bitter, styptic taste, and when masticated imparts a yellow tinge to the saliva (compare *Quercus alba*). It is seldom employed internally on account of its disposition to derange the bowels, but is valuable as an external astringent. It contains tannin, *quercitrin*, and *quercetin*. The dye-stuff, called *quercitron*, is the inner bark of this tree, and is much used in Europe as a yellow dye-stuff. Chevreul obtained therefrom the coloring principle, which he named *quercitron;* it has since been named *quercitric acid* (*quercitrin*), on account of its forming salts with bases. It is obtained by allowing a concentrated aqueous infusion or decoction to crystallize; the substance is purified by recrystallization from diluted alcohol. By another, method, the bark is exhausted with alcohol, and the tannin removed by means of a moistened animal membrane; after filtering, the alcohol is distilled, and the residue recrystallized. *Quercitrin* $C_{36}H_{38}O_{20}$, Liebermann and Hamburger, 1879; $C_{21}H_{22}O_{12}$, J. Herzig, 1893) forms sulphur-yellow, microscopic plates, in aqueous or alcoholic solution of neutral reaction and faintly bitter taste. It is little soluble in ether and cold water (2485 parts), more soluble in hot water (143 parts; 425 parts by another statement). Soluble in 23 parts of cold, 3.9 parts of boiling alcohol, readily soluble in alkalies and aqua ammoniæ. Neutral lead acetate precipitates it from solution. Its solution is colored dark-green by ferric chloride. It is a glucosid, being hydrolyzed, by boiling with diluted acids, into crystallizable *quercetin* ($C_{24}H_{16}O_{11}$, Liebermann and Hamburger; $C_{15}H_{10}O_7$, J. Herzig, 1891) and *isodulcite* ($C_6H_{14}O_6$), *Quercitrin*, or similar principles, occurs also in the leaves and cotyledons of the horse-chestnut, in the leaves of the ash tree, in *Rhus Coriaria*, or sumach, in *Sophora japonica* (*sophorin*), *Viola tricolor*, *Thuja occidentalis* (*thujin*), etc. These all stand in close chemical relationship to one another (see Rud. Wachs, *Amer. Jour. Pharm.*, 1894, p. 35; also see graphic formula of quercitrin given by J. Herzig, in *Chem. Centralblatt*, 1893, p 433). *Quercetin* is likewise frequently found in nature, *e.g.*, in the horse-chestnut, in *Podophyllum*•(which see), in the outer skin of the onion (Perkin and Hummel, 1893), in fustic wood (from *Rhus cotinus*), in the bark of the apple tree, in Gambier catechu (A. G. Perkin, *Chem. Centralblatt*, Vol. II, 1897, p. 1047), etc.

Quercus Robur, Linné, is the species official in the *British Pharmacopœia*, 1885, the bark being collected in the spring time. *Quercin*, a neutral bitter principle, obtained from the European oak bark (*Quercus Robur*), by Gerber (1831), was probably impure *quercite* (see (*Quercus alba*).

Quercus suber, Linné.—The *Live oak*, growing in the Mediterranean region, especially Algeria and Spain. Its suberous layer furnishes commercial *cork*. According to K. Kügler (*Dissert.*; see *Amer. Jour. Pharm.*, 1884, p. 240; also *Archiv der Pharm.*, 1884, pp. 217–230), air-dry cork leaves about 0.58 per cent of ash, one-fourth of which is manganese, and another fourth is lime. Chloroform extracts about 12.5 per cent of soluble matter, of which one-third consists of *cerin* ($C_{20}H_{32}O$) (not the cerotic acid or cerin of beeswax). It is imbedded in the cork-cells in the form of small prisms (Höhnel, 1877). Boiling alcohol now takes up from 5 to 6 per cent of *tannin* and *phlobaphene* (coloring matters due to altered tannin). Alcoholic caustic potash now dissolves the peculiar fat, *suberin*, which is saponifiable, upon heating the solvent, into glycerin (2.65 per cent) and fatty acids (30 per cent), the latter consisting of stearic and *phellonic acids* ($C_{22}H_{42}O_3$); a little *coniferin* was also extracted and converted into vanillin. Water now extracted from the cork 8 per cent of *humin compounds* and left 22 per cent of cellulose. Gilson 1890; see Flückiger, *Amer. Jour. Pharm.*, 1890, p. 367) finds that solution of sodium carbonate abstracts the coloring matter of cork, while it leaves *suberin* unaffected. The latter may then be extracted by a hot, 3 per cent alcoholic potash solution. By oxidation of cork with nitric acid, a mixture of acids, possessing a waxy appearance, is obtained (*cerinic acid*), from which *suberic acid* ($C_6H_{12}[COOH]_2$) was isolated by Brugnatelli. The fat, *suberin*, should not be confounded with the cork, reduced to a fine powder, sold under the name *suberin*. This tree has been introduced into our southern states. Suberin has been used as a dusting powder for *intertrigo*, *chapped surfaces*, etc.

Quercus virens, Aiton, *Live oak*, and *Quercus falcata*, Michaux, *Spanish oak*, yield bark very rich in tannin.

Quercus agrifolia, Née; *Quercus chrysolepsis*, Liebman; and *Quercus oblongifolius*, Torrey, all of the Pacific slope, are known as *Live oaks*.

SEMEN QUERCUS, *Acorns.*—Contain fixed oil, volatile oil, bitter substance, starch (about 38 per cent ,citric acid, uncrystallizable sugar, and a crystallizable sugar, called by Dessaignes (1851) *quercit* $C_6H_7[OH]_5$). Roasted acorns (*Semen Quercus Tostum*) were formerly used to check *hemorrhage*, and to cure *scrofula* and *indigestion*.

QUILLAJA (U. S. P.)—QUILLAJA.

"The inner bark of *Quillaja Saponaria*, Molina"—(*U. S. P.*).

Nat. Ord.—Rosaceæ.

COMMON NAMES AND SYNONYM: *Soap-tree bark*, *Soap bark; Quillaia* (*Pharm.*, 1880).

Botanical Source.—The soap-bark tree is a medium-sized tree, bearing alternate, entire, or subdenticulate, oval, or oblong leaves. The flowers are pedunculate and axillary, have no corolla, the same branch bearing both male and female flowers. Thick bark and a very hard wood are furnished by it.

History and Description.—This tree is a native of Chili, and is known as Cullay, Quillilia, Quillaja, and Soap tree. The bark is the part employed; it is rough, dark-colored externally, and very tough. It has no odor, but workmen dislike to powder it, in consequence of the irritating properties of the dust. The taste is acrid and disagreeable. Quillaja bark is said to be used in its native country for washing clothes, and removing grease spots, and in this country it is employed for cleaning delicate ribbons, garments, and wool. It depends upon *saponin* for its value in this respect, foaming when rubbed with water. It is also used by the natives of Chili and Peru for washing the hair, thus: Soap-tree bark, in powder, 100 parts; alcohol, 400 parts; essence of bergamot, 20 drops. Mix. Saponin is a very energetic sternutatory, and acts as an emeto-cathartic and diuretic. This tree has been introduced in Hindustan. The *U. S. P.* describes the bark as in "flat, large pieces, about 5 Mm. (⅕ inch) thick; outer surface brownish-white, often with small patches of brown cork attached, otherwise smooth; inner surface whitish, smooth; fracture splintery, checkered with pale-brownish bast fibers imbedded in white tissue; inodorous; taste persistently acrid; the dust very sternutatory. The infusion of quillaja foams like soap-water"—(*U. S. P.*). (On the microscopical appearance of powdered quillaja, see L. E. Sayre, *Amer. Jour. Pharm.*, 1897, p. 438.)

Chemical Composition.—The foaming properties of an aqueous infusion of quillaja bark are partly due to *saponin* ($C_{19}H_{30}O_{10}$, E. Stütz, 1884). It is a non-poisonous, tasteless, amorphous, white powder, and does not cause sneezing. It is readily soluble in water, insoluble in pure ether and alcohol. It is a glucosid, and is decomposed into sugar and crystallizable *sapogenin*, upon boiling with diluted acids. Stütz found 2 per cent of saponin in the bark. The poisonous irritant and sternutatory properties of the latter are due to amorphous *quillajic acid* (also $C_{19}H_{30}O_{10}$, R. Kobert, *Amer. Jour. Pharm.*, 1889, p. 142) and *sapotoxin* (Kobert and Pachorukow, 1888). *Quillajic acid* is insoluble in ether, quite soluble in cold alcohol and in chloroform, soluble in water. It is precipitated from solution both by neutral and basic lead acetate, while *sapotoxin* is precipitated only by basic lead acetate. The latter constituent is soluble in water, insoluble in ether, and soluble only in boiling alcohol. Its aqueous solution foams upon shaking. The total quantity of saponin-like bodies is about 8.8 per cent. The bark also contains small quantities of *tannic acid* and a bitter principle. Upon incineration, the bark yields not less than 13 per cent of ash, the wood only 1.48 per cent; the bark contains 11.5 per cent of calcium oxalate with some tartrate (Flückiger, *Pharmacognosie des Pflanzenreichs*, 3d ed., 1891, p. 616).

Action, Medical Uses, and Dosage.—Powdered soap bark, when inhaled, provokes violent sneezing. Internally, it acts somewhat like senega, rendering expectoration easy, while upon the gastro-intestinal tract, it does not produce irritating effects. Being less acrid than senega, it is more agreeable to administer, and may be used in infusion or syrup (fluid extract, 2 parts; syrup, 10 parts). It has been employed to quiet *cough*, with tenacious secretions; in *chronic bronchitis*, with bronchial dilatation; *emphysema*, etc. *Dropsy* is also reputed to have been cured with it. Locally, a saponaceous aqueous solution is valued for use upon the skin where soap is objectionable, to correct fetid exhalations of the axilla, feet, etc., and to remove the greasiness of the skin in treating *cutaneous ulcers* and *eruptions*. The scalp may be cleaned with it, and a tincture of it is reputed useful in *alopecia*. A snuff of powdered quillaja is said to be useful in *coryza*, and to have effected a permanent cure in *chronic rhinitis*. A watery solution of the dried aqueous extract is considerably used in pharmacy as an emulsifying agent for oils—castor oil, cod-liver oil, etc.—and as a froth-producer for soda-water syrups. Dose of infusion (bark ℥ss to water Oj), ½ to 1 ounce, several times a day; of the syrup, fl℥i to fl℥ij.

QUINIDINÆ SULPHAS (U. S. P.)—QUINIDINE SULPHATE.

FORMULA: $(C_{20}H_{24}N_2O_2)_2H_2SO_4+2H_2O$. MOLECULAR WEIGHT: 780.42.

"The neutral sulphate of an alkaloid obtained from the bark of several species of Cinchona (*Nat. Ord.*—Rubiaceæ). Quinidine sulphate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

SYNONYMS: *Chinidinum sulfuricum*, *Sulphate of conquinine*, *Conchininum sulphuricum*.

Source and History.—The base, *quinidine*, occurs in the bark of *Cinchona Calisaya*, in *Pitaya barks* (as much as 1.6 per cent, Hesse), and in other species of

Cinchona. The alkaloid was discovered by Henry and Delondre, in 1833, but was subsequently regarded by them as a hydrate of quinine. Later (1847), Winckler applied the name quinidine to a base which, through the researches of Pasteur (1853), is now known as *cinchonidine*. Pasteur also established the physical and chemical characteristics of *quinidine*, pronouncing it isomeric with quinine. It was previously (1849) called *beta-chinin* by van Heijningen, and subsequently received the names *cinchotine* (Hlasiwetz), *beta-chinidine* (G. Kerner), and the much contested name *conchinine* (Hesse, 1865). (For interesting historical details, see G. Kerner, *Archiv der Pharm.*, 1880, p. 259.) The sulphate of this base is the official salt. The older *Chinidinum sulphuricum* of commerce was a variable mixture, mostly containing cinchonidine sulphate.

Preparation.—Quinidine is prepared from the mother liquors resulting from the preparation of quinine sulphate, especially from the mixture of alkaloids known as *chinoidine* (see *Chinoidinum*). De Vrij (1857) isolated it by means of the characteristic hydriodate, which is little soluble in alcohol, and very little in water (1 in 1200 at ordinary temperature). O. Hesse (1865) removed quinine and cinchonidine by means of the insoluble tartrate, and precipitated quinidine from the filtrate in the form of the hydriodate. (For details, see Husemann and Hilger, *Pflanzenstoffe*, 1884, p. 1467.)

Description and Tests.—Quinidine ($C_{20}H_{24}N_2O_2$) crystallizes from alcohol with 2½ molecules of water, in the form of monoclinic prisms, which effloresce upon exposure to the air, losing ½ molecule of water. From ether, quinidine crystallizes with 2 molecules of water, in the form of rhombohedra, which are permanent in the air. From a hot, aqueous solution, it also falls out in the form of efflorescent crystals (De Vrij, 1856). The water of crystallization is expelled at a temperature of 120° C. (248° F.). Quinidine is bitter to the taste, and has an alkaline reaction. It has the same formula as quinine, and, like the latter, forms a fluorescent solution with diluted sulphuric acid; but is optically dextrorotatory, while quinine is lævo-rotatory. It is soluble in 2000 parts of water at 15° C. (59° F.), and in 750 parts at 100° C. (212° F.); it is likewise dissolved by 26 parts of 80 per cent alcohol, by 22 parts of ether at 20° C. (68° F.), and by 3.7 parts of boiling absolute alcohol. It is hardly soluble in chloroform. With acids it forms two series of crystallizable salts, viz.: neutral and acid salts. They are, as a rule, more soluble than the quinine salts. With chlorine water, followed by ammonia, it gives the green *thalleioquin* reaction like quinine (see *Tests* below), but it differs from the latter by forming a rather soluble mono-tartrate, and a characteristic, nearly insoluble hydriodate (see *Preparation* above).

Quinidine Sulphate (the neutral salt) is officially described as follows: "White, silky needles, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 8 parts of alcohol; in 7 parts of boiling water, and very soluble in boiling alcohol; also in 14 parts of chloroform, and in acidulated water; almost insoluble in ether. When heated to 120° C. (248° F.), the salt loses its water of crystallization (4.6 per cent). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution of the salt, when acidulated with sulphuric acid, has a decided blue fluorescence. On treating 10 Cc. of an aqueous solution (about 1 in 1600) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate. A cold, saturated, aqueous solution of the salt yields a white precipitate with potassium iodide T.S. (difference from quinine sulphate). An aqueous solution of the salt yields, with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid. Quinidine sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities), nor produce a red color with nitric acid (difference from morphine). If a small quantity of ammonia water be added to 3 Cc. of an aqueous solution of the salt saturated at 15° C. (59° F.), a white precipitate (quinidine) will be produced, which requires more than 30 Cc. of ammonia or more than 30 times its weight of ether to dissolve it (absence of more than small proportions of other cinchona alkaloids)" (*U. S. P.*). (Compare *Quinina.*)

Action, Medical Uses, and Dosage.—Quinidine appears to possess similar medicinal properties to quinine, in similar doses, being regarded, however, a little less powerful. Its salts (as the sulphate) appear to be best adapted for medicinal use, principally on account of their ready solubility. Dose, from 1 to 5 grains, 3 times a day, or oftener, if required. In severe *intermittents*, as high as 10 grains may be administered for a dose. In malignant cases, 40 grains may be given in divided amounts.

Related Salts.—Quinidinæ Bisulphas ($C_{20}H_{24}N_2O_2.H_2SO_4.4H_2O$), *Acid quinidine sulphate*. This salt is produced by dissolving neutral quinidine sulphate in the equivalent quantity of diluted sulphuric acid, and slowly evaporating the solution. It forms long, asbestos-like, colorless crystals, readily soluble in water, and losing their water of crystallization (14.5 per cent) at a temperature near 120° C. (248° F.).

Quinidinæ Hydriodas ($C_{20}H_{24}N_2O_2.HI$), *Quinidine hydriodate*.—Neutral solutions of potassium iodide and quinidine sulphate react upon each other, producing a crystalline, white precipitate; or, if the solutions be dilute and warm, scale-like, colorless prisms. Cold water sparingly dissolves it (1 in 1270, at 10° C. [50° F.]), hot water and alcohol but little more freely. It does not crystallize with water, and the proportion of iodine is a little over 28 per cent.

Quinidinæ Bihydriodas ($C_{20}H_{24}N_2O_2.[HI]_2.3H_2O$), *Quinidine bihydriodate*.—A salt containing nearly 44 per cent of iodine and 8.5 per cent of water, produced like the preceding, excepting that the quinidine sulphate is employed warm and acidulated with diluted sulphuric acid. It forms an orange-colored, crystalline powder, or shining, crystalline prisms of a golden-yellow color. It is quite freely soluble in hot water and alcohol, and in cold water (90 parts). When heated to 120° C. (248° F.), the water of crystallization is expelled, and the color changes to brownish-yellow. If the salt be exposed to moist air, part of the water will be reabsorbed.

QUININA (U. S. P.)—QUININE.

Formula: $C_{20}H_{24}N_2O_2+3H_2O$. Molecular Weight: 377.22.

"An alkaloid obtained from the bark of various species of Cinchona (*Nat. Ord.*—Rubiaceæ). Quinine should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Source, History, and Preparation.—Quinine was first identified and differentiated from cinchonine by Pelletier and Caventou, in 1820. It always occurs together with cinchonine, and frequently also with quinidine and cinchonidine, in the barks of all species of *Cinchona*, especially *C. Calisaya*, *C. officinalis*, and *C. Ledgeriana*. A hybrid of the latter species, and *C. succirubra*, grown in Java, are remarkably rich in quinine (see J. B. Nagelvoort, *Amer. Jour. Pharm.*, 1898, pp. 345 and 424; also see table, p. 549). The alkaloids are combined in the bark with kinotannic acid, and can not be extracted by means of a cold, aqueous infusion (see *Quininæ Sulphas* for the isolation of quinine from Cinchona barks). From aqueous solutions of quinine salts, the anhydrous base may be precipitated in the form of a curdy, amorphous mass, by the careful addition of aqua ammoniæ; when allowed to remain in contact with the precipitant fluid, the amorphous precipitate absorbs 3 molecules of water, and becomes crystalline. From solution in diluted alcohol, quinine likewise crystallizes with combination of water in the form of fine needles.

Description.—Quinine, as demanded by the *U. S. P.*, is "a white, flaky, amorphous, or crystalline powder, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 1670 parts of water, and in 6 parts of alcohol; in 760 parts of boiling water, and in 2 parts of boiling alcohol; in 23 parts of ether, 5 parts of chloroform, and 200 parts of glycerin; also soluble in carbon disulphide, benzin, benzol, ammonia water and diluted acids"—(*U. S. P.*). Quinine is less soluble in diluted fixed alkalies than in water, which is shown by the turbidity produced when a solution of sodium hydroxide is added to a saturated solution of quinine in water. It dissolves in about 2150 parts of lime-water, and crystallizes from benzol solution with benzol chemically combined. The *U. S. P.* makes for quinine the further requirements: "When heated to about 57° C. (134.6° F.), it melts; at 100° C. (212° F.), it loses about 9 per cent (or about 2 molecules) of its water of crystallization, the remainder being expelled at 125° C. (257° F.). The anhydrous alkaloid, when pure, melts at 173° C. (343.4° F.). Upon ignition, it is consumed, leaving no residue"—(*U. S. P.*). When heated in a dry glass tube, either by itself, or together with sugar, starch, etc., quinine salts yield a tar of carmine-red color (compare Grahe's test, p. 550; also see Flückiger, *Pharm. Chemie*, Vol. II, 1888, p. 558). "Quinine has an alkaline reaction upon litmus paper. A solution of quinine in diluted sulphuric acid has a vivid, blue fluorescence"—(*U. S. P.*).

The fluorescence is probably the most delicate test for quinine, and may still be observed in a solution of 1 in 50,000 (T. G. Wormley, *Amer. Jour. Pharm.*, 1894, p. 570); but its sensitiveness is impaired by the presence of small quantities of sodium chloride or hydrochloric acid, also by potassium ferrocyanide, potassium thiocyanate, sodium hyposulphite, and by phenacetine (Sestini and Campani 1892). Solutions of quinine are optically lævo-rotatory, the rotation being increased by acids.

Chemically, quinine ($C_9H_6[OCH_3]N.C_9H_{11}[OH]N.CH_3$) is a derivative of the base *quinoline* (*chinoline*, C_9H_7N), comprising 2 molecules of the latter, both of unequal basicity. As a strongly diacid base, quinine forms, with acids, two series of salts—*neutral* (in reaction) and *acid* salts—or, according to the French nomenclature, which assumes two equally basic nitrogen atoms in the quinine molecule—*basic* and *neutral* (the really acid) salts. Thus the normal quinine sulphate of the *U. S. P.* (which see) is called basic quinine sulphate, or quinine sub-sulphate in the *French Codex*. At water-bath heat, quinine expels ammonia from ammonium sulphate with formation of quinine sulphate. Some of the quinine salts, *e. g.*, the neutral tartrate, are characterized by being sparingly soluble in water. The neutral quinine sulphate is less soluble in water than the sulphates of the related alkaloids (see *table*, p. 1625). Quinine solutions exposed to direct sunlight, quickly turn yellow, and gradually deposit a brown flocculent body, which is devoid of alkaloidal characteristics. Flückiger, who first observed it, named this precipitate *quiniretin*. Heated with glycerin to 190° C. (374° F.), quinine is converted into an isomeric, amorphous body, *quinicine*. Its solutions are dextrorotatory. By distilling quinine or cinchonine with caustic potash, quinoline, pyridine, its homologues are formed. By oxidation of quinine with chromic acid or potassium permanganate, a series of compounds is formed, viz.: the weak base *quitenine* ($C_{19}H_{22}N_2O_4$), *quininic acid* ($C_{11}H_9NO_3$), and, ultimately, *cinchomeronic acid* ($C_7H\ NO_4$), which is a dibasic pyridine acid ($C_5H_3N[COOH]_2$).

Tests.—Quinine and quinine salts, in aqueous solution, form amorphous precipitates with alkaloidal reagents, *e. g.*, tannin, iodine in solution of potassium iodide, Mayer's solution, picric acid, phosphomolybdic acid, etc. A characteristic test for quinine, which, however, is also given by quinidine, consists in the formation of *herapathite*, or *iodo-sulphate of quinine*, discovered by Bouchardat (1845), and further studied by Dr. W. B. Herapath, in England (1852). It is obtained by adding an alcoholic solution of iodine, drop by drop, to a warm solution of quinine sulphate in glacial acetic acid. A black precipitate is formed, which, when washed with cold alcohol and recrystallized from warm alcohol, is deposited in large, rectangular plates, which are brilliant green and of a metallic lustre by reflected light, and olive-green by transmitted light. They have the property possessed by tourmaline, of polarizing the light passing through it. Its composition, according to Jörgensen, is $(C_{20}H_{22}N_2O_2)_2.3H_2SO_4.2IH.4I$. It is soluble in acetic acid, and in 650 parts of cold, and 50 parts of hot alcohol. A. Christensen finds that quinine may be determined quantitatively by converting it into this compound, as suggested by De Vrij (*Amer. Jour. Pharm.*, 1882, p. 58).

Another characteristic test for quinine, which, however, is also obtained with quinidine, consists in the formation of the emerald-green compound, *thalleioquin*, by the action of chlorine, followed by ammonia, upon quinine. The reaction was first observed by Alexander Roper, in London (1832), and rediscovered by J. J. Andre, in Metz (1835), and by H. A. Meeson, in London (1835). Brandes and Leber (1838) gave it the above name (Flückiger, *Pharm. Chemie*, Vol. II, 1888, p. 564). The test was modified by Flückiger (bromine being used instead of chlorine), and is given by the *U. S. P.* as follows: "On treating 10 Cc. of an aqueous, acidulated solution (about 1 in 1500) of quinine with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate"—(*U. S. P.*). Prof. Flückiger (*loc. cit.*) places the sensitiveness of this test at more than 1 in 20,000. This test is interfered with by phenacetine (Sestini and Campani, 1892). Vogel's test consists in the formation of a rich-red color, which is obtained when chlorine water is added to the quinine solution, followed by potassium ferrocyanide, and, lastly, aqua ammoniæ. (For further details regarding these tests, see T. G. Wormley, *loc. cit.*) The *U. S. P.* further directs: "Quinine should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities), nor produce a red color with nitric acid (difference from morphine)"—(*U. S. P.*). The absence of morphine may also be established by allowing the substance to act upon a mixture of potassium ferricyanide and ferric chloride; if no blue precipitate (Prussian blue) is formed, morphine can not be present. However, the formation of a blue precipitate may be due to the presence of some reducing substances other than morphine; therefore, additional tests for morphine must be applied (*Amer. Jour. Pharm.*, 1872, p. 540). To test quinine for the presence of other Cinchona alkaloids, the *U. S. P.* gives the following directions, which are based on *Kerner's test* for Cinchona alkaloids: "If 2 Gm. of quinine be mixed, in a small mortar, with 1 Gm. of ammonium sulphate and 10 Cc. of distilled water, the mixture thoroughly dried on a water-bath, the residue (which should be strictly neutral to test-paper) agitated with 20 Cc. of water, then allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, and filtered through a pellet of glass-wool, 5 Cc. of the filtrate, transferred to a test-tube, and gently mixed, without shaking, with 7 Cc. of ammonia water (specific gravity 0.960), should produce a clear liquid. If the temperature during the maceration has been 16° C. (60.8° F.), 7.5 Cc. of ammonia water may be added; if 17° C. (62.8° F.), 8 Cc. In each case, a clear liquid indicates the absence of more than small proportions of other Cinchona alkaloids"—(*U. S. P.*). This test depends on the fact that those Cinchona alkaloids whose sulphates are soluble in water, are themselves insoluble, or nearly so, in ammonia water; quinine, which forms a very little soluble, neutral sulphate, is quite soluble in ammonia water. The above directions, especially with regard to the temperatures and the strength of ammonia, must be strictly observed, in order to arrive at trustworthy results (see comment on Kerner's as well as other tests, by E. Jungfleisch, *Amer. Jour. Pharm.*, 1887, pp. 136–146; and O. Hesse, *ibid.*, pp. 404–414). Hesse's test differs from Kerner's in the employment of ether, instead of ammonia, as a precipitant of the Cinchona alkaloids other than quinine. Shimoyama (*Amer. Jour. Pharm.*, 1885, p. 630) and L. Schaefer (*ibid.*, 1887, p. 153) make use of the comparative insolubility of quinine oxalate in water, in order to determine the quantity of the latter alkaloid. (See review of this and other processes, by W. Lenz, *ibid.*, 1889, p. 146.) The following table (page 1625) gives the principal distinctive characteristics of the alkaloids quinine, quinidine, cinchonine, and cinchonidine.

Uses.—(See *Quininæ Sulphas.*) The alkaloid quinine is used in practical medicine in the form of its salts, the sulphate and hydrochlorate being mostly employed.

Quinine Salts.—QUININÆ ACETAS, *Quinine acetate* ($C_{20}H_{24}N_2O_2.C_2H_4O_2$). Mix a hot solution of 17 parts of quinine sulphate (dried by spontaneous efflorescence) with a hot solution of 6 parts of sodium acetate, and allow to cool. Long, white needles of the salt will form, containing 84 per cent of quinine. They are freely soluble in hot water and diluted acids, but not readily soluble in cold water. The salt loses acetic acid when warmed on the water-bath. (See also remarks on quinine acetate, by Prof. Maisch, *Amer. Jour. Pharm.*, 1858, p. 385.)

QUININÆ BENZOAS, *Quinine benzoate* ($C_{20}H_{24}N_2O_2.C_7H_6O_2$).—Obtained by allowing a hot alcoholic solution of quinine (8 parts) and benzoic acid (3 parts) to crystallize. Small prismatic crystals, containing about 72.5 per cent of base, and sparingly soluble in water (1 in 373 parts, at 10° C. [50° F.]).

QUININÆ ARSENAS, *Quinine arsenate, Quiniæ arsenias, Arseniate of quinia* ($[C_{20}H_{24}N_2O_2]_2H_3AsO_4.8H_2O$).—In a glass vessel place arsenic acid, $1\frac{1}{2}$ drachms; quinine, 5 drachms; distilled water, 6 fluid ounces. Boil till all is dissolved, filter, and allow to crystallize spontaneously. To purify, redissolve, and again crystallize. This salt was introduced, in 1845, by Bourieres, and recommended in *fever and ague*, and other *periodical diseases;* also used in *obstinate cutaneous affections.* Its dose is $\frac{1}{5}$ grain, 2, 3, or 4 times a day. The above formula is that of O. Hesse, who obtains the salt in the form of long, white prisms, sparingly dissolved by cold water, but readily soluble in hot water. It contains 12.3 per cent of arsenicum (counted as arsenic pentoxide, As_2O_5) and 69.4 per cent of quinine.

QUININÆ ARSENIS, *Quinine arsenite* ($[C_{20}H_{24}N_2O_2]_3H_3AsO_3.4H_2O$).—For Dr. Ringdon's old process (1847), see this *Dispensatory*, preceding edition. O. Adler (1879) obtains this salt in the form of white needles by digesting, for 24 hours, a mixture of quinine hydrochloride (3 parts

ALKALOIDS	SOLUBILITY IN				SOLUBILITY IN WATER OF				Thalleioquin Test
	Water	Alcohol	Ether	Aqua Ammoniæ	Neutral Sulphate	Hydriodate	Neutral Tartrate	Oxalate	
QUININE, $C_{20}H_{24}N_2O_2$ Lævo-rotatory Sulphate fluorescent	1670 parts 1960 parts (Merck's *Index*)	6 parts	23 parts	Soluble	$B_2.SO_4H_2.7H_2O$ Water, 740 parts Alcohol, 65 parts Chloroform, 680 parts Chloroform, 1000 parts, if alcohol-free (Rice) (Insoluble)	Quite soluble	Insoluble	Insoluble (1446 parts)	Gives Thalleioquin and Herapathite tests.
QUINIDINE, $C_{20}H_{24}N_2O_2$ Dextro-rotatory Sulphate fluorescent	2000 parts	26 parts of 80 per cent	35 parts	Little soluble	$B_2.SO_4H_2.2H_2O$ Water, 100 parts Alcohol, 8 parts Chloroform, 14 parts	Insoluble in water (1270 parts) and diluted alcohol Characteristic	Soluble in 30 to 40 parts	Soluble in 151 parts, at 15° C.	Analogous to quinine.
CINCHONINE, $C_{19}H_{22}N_2O$ Dextro-rotatory Sulphate non-fluorescent	3760 parts	116 parts	526 parts	Insoluble	$B_2.SO_4H_2.2H_2O$ Water, 66 parts Alcohol of 80 per cent, 6 parts Chloroform, 78 parts Ether, insoluble	Quite soluble	Soluble in 30 to 40 parts	Soluble in 104 parts, at 10° C.	White precipitate.
CINCHONIDINE, $C_{19}H_{22}N_2O$ Lævo-rotatory Sulphate non-fluorescent	1680 parts	20 parts	76 parts	Insoluble on standing	$B_2.SO_4H_2.3H_2O$ Water, 70 parts Alcohol, 66 parts Chloroform, 1316 parts (Insoluble)	Soluble	Insoluble (1200 parts)	Soluble in 228 parts, at 15° C.	

and silver arsenite (1 part), in the presence of diluted alcohol (of 70 per cent). This compound is soluble in alcohol (cold, 15; hot, 6), chloroform (8), benzene (20), ether (25), and boiling water (150 parts).

Quininæ Citras, *Quinine citrate* ($[C_{20}H_{24}N_2O_2]_2.C_6H_8O_7.7H_2O$, O. Hesse).—This salt may be obtained either by double decomposition of solution of quinine hydrochlorate and an acidulated solution of sodium citrate, or by simply saturating a heated, aqueous solution of citric acid with the theoretical quantity of quinine. Upon cooling, white, prismatic crystals are obtained, which are very sparingly soluble in cold water (see K. F. Mandelin, on the citrates of quinine, *Archiv der Pharm.*, 1879, pp. 129–144).

Quininæ Lactas, *Quinine lactate.*—Obtained by dissolving quinine in lactic acid to saturation, and evaporating the solution. Silky, acicular crystals are produced, soluble in water and alcohol (see Vigier, *Pharm. Jour. Trans.*, Vol. XIX, 1889, p. 862). This salt is adapted for hypodermatic uses, and has been used locally in *gonorrhœa*.

Quininæ Phosphas, *Quinine phosphate* ($[C_{20}H_{24}N_2O_2]_2H_3PO_4.8H_2O$, O. Hesse).—Prepared by saturating warm, diluted phosphoric acid with quinine, or by double decomposition between sodium phosphate and quinine hydrochlorate. From hot, aqueous solution, it forms long, silky, acicular crystals, containing 72.7 per cent of base, and is very sparingly soluble in water.

Quininæ Phenyl-Sulphas, *Phenylated* or *Carbolated quinine sulphate* ($[C_{20}H_{24}N_2O_2]_2.SO_3.C_6H_6O.2H_2O$, O. Hesse, 1889).—Dissolve crystallized quinine sulphate (10 parts) in alcohol, and add to the solution carbolic acid (nearly 1 part), also dissolved in alcohol. Colorless needles are precipitated which contain over 75 per cent of base. By washing with alcohol and ether, the taste and odor of phenol may be entirely removed. The salt is somewhat soluble in cold water, but insoluble in alcohol. An acid phenol-sulphate ($C_{20}H_{24}N_2O_2.SO_3.C_6H_6O.3H_2O$) was similarly obtained by O. Hesse, by adding to a hot, aqueous solution of quinine bisulphate ($C_{20}H_{24}N_2O_2.H_2SO_4+7H_2O$) an equivalent quantity of carbolic acid.

Quininæ Carbolas, *Carbolate of quinine* ($C_{20}H_{24}N_2O_2.C_6H_6O$), was prepared by J. Jobst (1875), by bringing together molecular quantities of quinine and carbolic acid in aqueous or alcoholic solution. Crystals are obtained, which, when dried at 130° C. (266° F.), have the above composition. It dissolves in 400 parts of water at 16° C. (60.8° F.), in 80 parts of 90 per cent alcohol at 13° C. (55.4° F.), and slightly in ether. By an earlier formula, a carbolate in pills was made as follows: Twelve parts of carbolic acid and 20 parts of quinine are dissolved in 60 parts of stronger alcohol. The solution is then filtered, distilled, and evaporated to the consistence of turpentine, when some extract of acorus, or gentian, and some pulverized cinnamon may be added to it, to form it into a pill mass. This may be made into pills containing, each, 1 grain of carbolic acid and $\frac{6}{10}$ of a grain of quinine, of which from 3 to 6 pills may be given daily in *puerperal diseases*, *furunculi*, *carbuncles*, *typhous conditions*, and *pyæmia* (Braun). It is found that the irritating properties of carbolic acid are much diminished when in combination with bases, and even when combined with a base as weak as quinine, it can be given in much larger relative doses than when administered in its isolated form (*Jahrbücher der Gesammten Medizin*, Aug., 1867).

Iodide of Quinine.—The iodide of quinine is obtained by adding a solution of 24 parts of iodide of potassium (4 molecules) in 8 parts of water, by drops, to a strong solution of 20 parts (1 molecule) of bisulphate of quinine ($C_{20}H_{24}N_2O_2.H_2SO_4+7H_2O$). Wash the precipitate quickly, and dry it, avoiding operation in the light. It is tonic, alterative, and resolvent, and has been found efficient, in doses of from $\frac{1}{2}$ to 2 grains, in *scrofulous enlargements of the glands;* or it may be made by decomposing a solution of 1 molecule of hydrochlorate of quinine with a solution of 4 molecules of iodide of potassium. When dry, iodide of quinine, thus prepared, has the properties of a resin, is easily reduced to a white, inodorous powder, extremely bitter, and permanent in the air. It is soluble in warm water, alcohol, or ether, forming clear and colorless solutions, which deposit the iodide of quinine on evaporation. Concentrated sulphuric and nitric acids, and chlorine, decompose it instantly, with elimination of iodine (compare *Amer. Jour. Pharm.*, Vol. IX, 1837–38, p. 353). The composition of these iodides is variable. The substance known as Herapathite (see *Quinina*), is related to this class.

Quininæ Iodas, *Quinine iodate* ($C_{20}H_{24}N_2O_2.HIO_3$).—To a warm, aqueous solution (1 in 10) of iodic acid, add the molecular proportion of freshly precipitated, moist quinine, with continued agitation. Evaporate the mass at a temperature not exceeding 15.5° C. (60° F.), and place it in a vacuum over sulphuric acid to dry. White, pearly needles, soluble in boiling water without decomposition, sparingly soluble in cold water (1 in 700), in ether and chloroform, readily dissolved by alcohol (C. A. Cameron, *Amer. Jour. Pharm.*, 1882, p. 417). A *bijodate* ($C_{20}H_{24}N_2O_2.[HIO_3]_2$), prepared by E. Merck, is easily soluble in water (*Jahresb. der Pharm.*, 1897).

Quininæ Hydriodas Acidus, *Acid quinine hydriodate* ($C_{20}H_{24}N_2O.[HI]_2.5H_2O$).—Transparent, glossy, prismatic, or scale-like crystals are formed when potassium iodide is added to an acidulated, warm solution of quinine in molecular proportion. At 120° C. (248° F.) the salt becomes anhydrous, but when exposed to a moist atmosphere, $2H_2O$ are again taken up. The salt may also be obtained by dissolving quinine in excess of aqueous hydriodic acid.

Quininæ Hydriodas, *Quinine hydriodate* ($C_{20}H_{24}N_2O_2.HI$).—This salt may be obtained by dissolving quinine in the molecular quantity of aqueous hydriodic acid, and allowing the solution to evaporate spontaneously. These hydriodides (hydriodates) must not be confused with the *iodides of quinine*, which are addition products of iodine and quinine (see above).

Quininæ Salicylas, *Quinine salicylate* ($C_{20}H_{24}N_2O_2.C_7H_6O_3$).—This salt may be obtained by double decomposition of ammonium salicylate with quinine hydrochloride; a curdy precipitate of this salt is formed, while from alcoholic solution it forms prismatic anhydrous crystals. Soluble in alcohol of 90 per cent (20 parts), ether (120), and water (225 parts). M. Yvon prepares the salt by dissolving 1.6 Gm. of sodium salicylate in 50 Cc. of water, heating to boiling, and adding 4.36 Gm. of quinine sulphate. After boiling a few minutes, decomposition is complete. Cool to 35° C. (95° F.), and filter rapidly, wash with luke-warm, then with cold water, until all sodium sulphate is washed out (*Jahresh. der Pharm.*, 1879, p. 174).

Quininæ Quinas, *Quinine quinate (kinate)*.—Obtained by double decomposition of barium kinate and quinine sulphate, and evaporating to dryness. It is neutral, non-crystalline, and readily soluble in water. A solution in water (1 in 4) has been recommended by Collier for hypodermatic use (*Amer. Jour. Pharm.*, 1878, p. 487).

Quininæ Sulphovinas, *Quinine sulphovinate.* Prepared by mixing a solution of sodium sulphovinate (16.6 parts) in 90 per cent alcohol (200 parts), and a solution of quinine sulphate (42.8 parts) in alcohol of the same strength (600 parts). Filter from the precipitated sodium sulphate, and evaporate. It forms, with difficulty, prismatic crystals, very bitter, readily soluble in alcohol and water (1 in 3), as well as in glycerin and acetic ether, insoluble in ether, benzol, and fixed oils, and perfectly neutral (P. Carles, *Amer. Jour. Pharm.*, 1878, p. 343). The sulphovinate of sodium employed herein, is prepared by carefully adding to 1000 Gm. of strong alcohol 1000 Gm. of sulphuric acid, with continuous agitation, setting aside for several hours, diluting with 4 liters of distilled water, neutralizing with barium carbonate, and decomposing the filtrate with sodium carbonate, evaporating on a water-bath, and allowing to crystallize (*ibid.*, 1877, p. 443).

Quininæ Tannas, *Quinine tannate* (*Chininum tannicum*).—The *Ger. Pharm.* (1870) directed: Take of quinine sulphate, 1 part; dissolve it with a few drops of diluted sulphuric acid in distilled water, 30 parts; and add gradually a solution, previously made, of tannic acid, 3 parts; cold water, 30 parts. Let the precipitate subside in a cool place, collect it on a filter, wash with a small quantity of water, and dry it at a very gentle heat. The product is a yellowish, amorphous powder, of a peculiar odor, and bitter, astringent taste. It is sparingly soluble in alcohol, and very sparingly in water. In hot water it melts into a mass. The product, by analysis of J. Jobst (*Archiv der Pharm.*, 1878, p. 334), corresponds to the formula $C_{20}H_{24}N_2O_2.3C_{14}H_{10}O_9+8H_2O$, and contains about 22.5 per cent of quinine, while a neutral tannate, prepared by the author, had 31 per cent of quinine, corresponding to the formula $C_{20}H_{24}N_2O_2.2C_{14}H_{10}O_9+4H_2O$. A tasteless quinine tannate was introduced by M. Rozsnyay (1875). It is prepared by dissolving the quinine sulphate in boiling water, and adding to the solution the tannin, neutralized with diluted ammonia. The product is entirely tasteless. (For the process of the *Hungarian Pharmacopœia*, see *Amer. Jour. Pharm.*, 1888, p. 515.) J. Jobst (*loc. cit.*) found some tasteless quinine tannates deficient in quinine, probably owing to the employment of boiling water in preparing them. De Vrij (*Amer. Jour. Pharm.*, 1892, p. 142) obtains quinine tannate, containing 20 per cent of quinine, by triturating pure quinine (1 part) with tannic acid (4 parts), and water (10 parts), and evaporating to dryness at a temperature not exceeding 60° C. (140° F.) (also see R. Rother, *Amer. Jour. Pharm.*, 1883, p. 173). Quinine tannate is much less bitter than the other quinine salts. Its administration should be at once followed by some acidulous draught, as lemonade, etc., in order to insure its solution in the stomach. It is subastringent.

Quininæ Ferrocyanas, *Quinine ferrocyanate.*—Four parts of quinine sulphate and enough distilled water to form not too thick a mixture, are mixed with a concentrated solution of one part of potassium ferrocyanide; the whole is heated to boiling for a few seconds, then allowed to cool. The mother liquor, which yields more of the salt upon concentration, is poured off from the resin-like mass, the latter washed with hot water and crystallized from boiling alcohol. Small, yellowish needles, bitter, slightly soluble in water, freely in alcohol, efflorescent in the air (J. M. Maisch, *Amer. Jour. Pharm.*, 1877, p. 442).

Allied Principles.—Lantanine, an alkaloid from *Lantana brasiliensis*, *Brazilian verbena*, *Yerba sagrada*, said to resemble quinine in action, has been isolated from this plant by Negrete (1885). From 15 to 30 grains are administered in a day as an antiperiodic, preferably immediately after a paroxysm.

Vieirin.—A body obtained from the bark of a Brazilian tree, *Remijia vellozii*. Substituted, in doses of 1 to 4 grains, in Brazil, for quinine as an antiperiodic and tonic.

Bergenin, a crystallizable, bitter principle, has been isolated from *Saxifraga cordifolia*, *S. sibirica*, and *S. crassifolia*, by Garreau and Machelart (1881). It is sparingly soluble in alcohol (165 parts) and water (830 parts, at 15° C. [59° F.]). Said to be a valued nerve tonic, its action being intermediate between quinine and salicin. It occurs together with tannin and starch. *Saxifraga ligulata* contains an abundance of tannic and gallic acids (Hooper). In India, it is used as a remedy for *dysentery*.

QUININÆ BISULPHAS (U. S. P.)—QUININE BISULPHATE.

Formula: $C_{20}H_{24}N_2O_2H_2SO_4+7H_2O$. Molecular Weight: 546.88.

Synonyms: *Acid quinine sulphate*, *Quininæ sulphas acidus*, *Chininum bisulfuricum*, *Sulfate de Quinine neutre* (*French Codex*).

"Quinine bisulphate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Preparation.—In warm distilled water (1000 grains), suspend quinine sulphate (200 grains). Then to the mixture add of diluted sulphuric acid (official) 230 grains. Filter and set aside in a warm place. The crystals which form should then be dried over sulphuric acid, at a temperature of from 10° to 15° C. (50° to 59° F.). The yield is 250 grains. This corresponds about to the theoretical yield according to the equation: $(C_{20}H_{24}N_2O_2)_2.H_2SO_4+7H_2O+H_2SO_4=2C_{20}H_{24}N_2O_2.H_2SO_4+7H_2O$. Keep the product in a dark, cool, place, in a well-stoppered vial (see *Quininæ Bisulphas*, under *Related Compounds*).

Description and Tests.—"Colorless, transparent or whitish, orthorhombic crystals, or small needles, odorless, and having a very bitter taste. Efflorescing on exposure to the air. Soluble at 15° C. (59° F.), in 10 parts of water, and in 32 parts of alcohol; very soluble in boiling water and in boiling alcohol. When heated at 100° C. (212° F.), the salt loses all its water of crystallization (nearly 23 per cent); at 135° C. (275° F.), it is converted into quinicine sulphate, which dissolves in diluted sulphuric acid with a yellow color without any blue fluorescence. On ignition, the salt is slowly consumed, leaving no residue. The aqueous solution of the salt has a strongly acid reaction, and a blue fluorescence"—(*U. S. P.*).

"On treating 10 Cc. of an aqueous solution (about 1 in 1000) of the salt with 2 drops of bromine T.S., and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more diluted solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate"—(*U. S. P.*). (See *Thalleioquin reaction*, under *Quinine.*) "Ammonia water added to the aqueous solution of the salt throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid. Quinine bisulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*). If 1 Gm. of the salt be dried at a temperature of 100° C. (212° F.), until it ceases to lose weight, the remainder, cooled in a desiccator, should weigh not less than 0.77 Gm. (corresponding to 7 molecules, or 23 [22.98] per cent of water of crystallization). If 2 Gm. of the salt, dried at 100° C. (212° F.), be agitated with 16 Cc. of water, the mixture made exactly neutral with ammonia water, then brought to the volume of 20 Cc. by the addition of water, and macerated for half an hour at 15° C. (59° F.), upon proceeding further as directed for the corresponding test under Quinine (see *Quinina*), the results there given should be obtained"—(*U.S.P.*).

Action, Medical Uses, and Dosage.—Same as *Quinine Sulphate*. When the latter is made into solution by means of diluted sulphuric acid or aromatic sulphuric acid and water a solution of quinine bisulphate is formed.

Related Compound.—*Quininæ tetrasulphas, Quinine tetrasulphate, Quininæ bisulphas, Quinine bisulphate*, according to the French nomenclature (see *Quinina*). Quinine tetrasulphate obtained by Hesse (*Lieb. Ann.*, 1875), has the composition $C_{20}H_{24}N_2O_2(H_2SO_4)_2.7H_2O$. When exposed to light the crystals assume a brownish-red color. Water readily dissolves them with marked blue fluorescence. When boiled in alcohol and the solution cooled a gelatinous magma is formed, which, when dried, produces very small prismatic crystals containing 5 molecules of water.

QUININÆ HYDROBROMAS (U. S. P.)—QUININE HYDROBROMATE.

FORMULA: $C_{20}H_{24}N_2O_2HBr+H_2O$. MOLECULAR WEIGHT: 422.06.

SYNONYMS: *Chininum hydrobromicum, Chininum hydrobromatum.*

"Quinine hydrobromate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Preparation.—This salt, the neutral hydrobromate of quinine, may be prepared by adding ten grammes (10 Gm.) [154 grs.] of quinine sulphate to eighty cubic centimeters (80 Cc.) [2 fl℥, 339 ♏] of water, boiling, and slowly adding a solution of three and four-tenths grammes (3.4 Gm.) [54 grs.] of barium bromide in twenty cubic centimeters (20 Cc.) [325 ♏] of water. A precipitate of barium sulphate is formed, according to the equation: $(C_{20}H_{24}N_2O_2)_2.H_2SO_4+7H_2O+BaBr_2=2C_{20}H_{24}N_2O_2.HBr+H_2O+BaSO_4+6H_2O$. The supernatant solution which should rather contain a very slight excess of quinine sulphate than barium bromide (tested by quinine sulphate solution), is then evaporated to crystallization. M. Boille (*Amer. Jour. Pharm.*, 1874, p. 563) obtains the salt in the same manner, except by operating with alcoholic instead of aqueous solutions; barium bromide is soluble in alcohol while any admixed chloride would remain undissolved.

Description and Tests.—This salt is officially described as occuring in "white, light, silky needles, odorless, and having a very bitter taste. The salt is liable to lose water on exposure to warm or dry air. Soluble at 15° C. (59° F.), in 54 parts of water, and in 0.6 part of alcohol; very soluble in boiling water and in boiling alcohol; also soluble in 6 parts of ether, and in 12 parts of chloroform. When heated at 100° C. (212° F.), the salt loses its water of crystallization (4.25 per cent). At 152° C. (305.6° F.), it begins to fuse, and becomes a syrupy liquid at 200° C. (392 F.). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution. when acidulated with sulphuric acid, has a vivid, blue fluorescence"—(*U. S. P.*). "On treating 10 Cc. of an aqueous solution (about 1 in 1300) with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more diluted solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate"—(*U. S. P.*). (See *Thalleioquin reaction*, under *Quinine*.) "Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. On precipitating a saturated aqueous solution of the salt with sodium hydrate T.S., filtering, supersaturating the filtrate with acetic acid, adding chloroform and a little chlorine water, and shaking, the chloroform will separate with a yellow color. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should not weigh less than 0.957 Gm. (corresponding to 1 molecule, or 4.24 per cent of water of crystallization). Quinine hydrobromate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities), nor produce a red color with nitric acid (difference from morphine). If 3 Gm. of the salt (which must have been previously ascertained to be strictly neutral, or have been rendered so) be mixed, in a small capsule, with 1.2 Gm. of crystallized sodium sulphate and 30 Cc. of water, the mixture thoroughly dried on a water-bath, the residue agitated with 30 Cc. of water, and allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*) the results there given should be obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt may be administered in *neuralgia* of congestive form, with tendency to congestion of the brain, and especially to females during the menstrual period. The dose is from 4 to 6 grains, in pill form, given 6 hours before the expected paroxysm; or 1 grain every hour. The dose of this salt is the same as that of the sulphate.

Related Salts.—QUININÆ HYDROBROMAS ACIDUS, *Acid quinine hydrobromate* ($C_{20}H_{24}N_2O_2[HBr]_2.3H_2O$). Dissolve quinine sulphate (10 Gm.) in water (80 Cc.), add of a 10 per cent sulphuric acid a sufficient quantity (about 11.8 Gm.) to convert the neutral into the acid sulphate; then precipitate with solution of 6.80 Gm. of barium bromide in 25 Cc. of water. Care must be taken that barium bromide be not in excess (see *Quininæ hydrobromas*). Filter out the barium sulphate formed and evaporate the solution to crystallization. The crystals are freely soluble in alcohol and in water (1 in 6). This salt was introduced as a preferable form for hypodermatic use. It may also be prepared by dissolving quinine in an excess of hydrobromic acid.

QUININÆ BROMAS, *Quinine bromate* ($C_{20}H_{24}N_2O_2.HBrO_3$).—Prepared either by neutralization of quinine with bromic acid, or by double decomposition of barium bromate and quinine sulphate (C. A. Cameron, *Amer. Jour. Pharm.*, 1882, p. 418; also see C. G. Johnson, *ibid.*, 1889, p. 119). It forms long needles aggregated into asbestos-like masses. Freely soluble in warm water, alcohol and diluted acids; sparingly soluble in cold water (1 in 250). In contact with concentrated sulphuric acid it detonates.

QUININÆ HYDROCHLORAS (U. S. P.)—QUININE HYDROCHLORATE.

FORMULA: $C_{20}H_{24}N_2O_2HCl+2H_2O$. MOLECULAR WEIGHT: 395.63.
SYNONYM: *Muriate of quinine.*

"Quinine hydrochlorate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Preparation.—This salt (the normal hydrochlorate) may be prepared by dissolving quinine in warm hydrochloric acid and allowing to crystallize. It has also been prepared by the double decomposition of quinine sulphate with barium- or calcium chloride. In order to avoid contamination with barium salt, quinine sulphate in alcoholic solution and sodium chloride are allowed to react with each other (R. Rother, *Amer. Jour. Pharm.*, 1883, p. 173). D. Vitali (*ibid.*, 1899, p. 231) prepares the normal hydrochlorate by warming 17 parts of potassium chloride with an aqueous solution of 100 parts of normal quinine sulphate, and evaporating to dryness on a water-bath; the residue is then extracted with 95 per cent alcohol which dissolves the quinine salt while potassium sulphate remains undissolved. The yellow solution is decolorized by animal charcoal and evaporated to crystallization. Similarly, the acid salt is obtained (see *Related Salts*).

Description and Tests.—"White, silky, light and fine, needle-shaped crystals, odorless, and having a very bitter taste. The salt is liable to lose water when exposed to warm air. Soluble, at 15° C. (59° F.), in 34 parts of water, and in 3 parts of alcohol; in 1 part of boiling water, and very soluble in boiling alcohol; also soluble in 9 parts of chloroform. When heated to 120° C. (248° F.), the salt loses its water of crystallization. At about 156° C. (312.8° F.), it begins to melt, but it is not fully melted until the temperature reaches 190° C. (374° F.). On ignition, it is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral or faintly alkaline to litmus paper. The saturated aqueous solution of the salt does not give any blue fluorescence, which, however, appears to some extent upon diluting the solution with water, and markedly so upon addition of diluted sulphuric acid"—(*U. S. P.*). "On treating 10 Cc. of an aqueous solution (about 1 in 1400) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with silver nitrate T.S., a white precipitate insoluble in nitric acid"—(*U. S. P.*). Dr. Vulpius (*Amer. Jour. Pharm.*, 1882, p. 409) reports that 10 Gm. of a 1 per cent silver nitrate solution, added drop by drop to 50 Gm. of a 1 per cent quinine hydrochloride solution, did not produce a silver chloride precipitate when the quinine solution was kept in a rotating motion; but the first drop precipitated immediately when the solution was at rest. The possible formation of a soluble double salt is suggested. The *U. S. P.* further directs: "If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should not weigh less than 0.9 Gm. (corresponding to 2 molecules, or 9 per cent of water of crystallization). Quinine hydrochlorate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities), nor produce a red color with nitric acid (difference from morphine). The aqueous solution of the salt should not be rendered turbid by diluted sulphuric acid (absence of barium), and should not be rendered more than slightly turbid by barium chloride T.S. (limit of sulphate). If 3 Gm. of the salt (which must have been previously ascertained to be strictly neutral, or have been rendered so) be mixed, in a small capsule, with 1.5 Gm. of crystallized sodium sulphate and 30 Cc. of water, the mixture thoroughly dried on a water-bath, the residue agitated with 30 Cc. of water, and allowed to macerate for half an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*), the results there given should be obtained"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—On account of its ready solubility this agent is eligible for hypodermatic employment, the dose so administered being from 1 to 4 grains. For general use by mouth it is not inferior to quinine sulphate and may be given in about $\frac{1}{6}$ less dose than that salt.

Related Salts.—QUININÆ HYDROCHLORAS ACIDUS, *Acid quinine hydrochlorate*, *Bimuriate of quinine* ($C_{20}H_{24}N_2O_2.[HCl]_2$). This salt may be obtained by Vitali's process for *quinine hydrochlorate* (which see); only instead of 17 parts take 25 parts of potassium chloride. Mr. G. M. Beringer (*Amer. Jour. Pharm.*, 1891, p. 117) advises: Take of quinine, precipitated, washed and dried at a temperature not exceeding 50° to 52° C. (120° to 125° F.), 37.8 Gm., hydrochloric acid (specific gravity 1.16) 22.82 Gm.; water, 60 Cc. Mix the acid and water, add the quinine, filter if necessary, and carefully evaporate to dryness. The salt is very readily soluble in water.

CHLORHYDRO-SULPHATE OF QUININE.—This represents a line of double salts containing quinine chemically combined with hydrochloric and sulphuric acids, *e. g.*, $(C_{20}H_{24}N_2O_2)_2 2HCl.H_2SO_4+3H_2O$. They are very easily soluble in water (see *Amer. Jour. Pharm.*, 1883, pp. 174 and 492).

QUININÆ SULPHAS (U. S. P.)—QUININE SULPHATE.

FORMULA: $(C_{20}H_{24}N_2O_2)_2H_2SO_4+7H_2O$. MOLECULAR WEIGHT: 870.22.

SYNONYMS: *Sulphate of quinia, Sulfas quinicus, Quiniæ sulphas* (formerly called *Disulphate of quinine*), *Basic sulphate of quinine of the French Codex, Diquinine sulphate.*

"Quinine sulphate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Preparation.—From barks containing relatively small amounts of cinchonine, quinine sulphate is obtained by boiling the powdered barks with water acidulated with sulphuric or hydrochloric acid, precipitating the bases with caustic soda, whereby kino-tannic acid, kino-red, etc., remain in solution, boiling out the quinine and small amounts of cinchonine, with 75 to 80 per cent alcohol, and adding to the solution dilute sulphuric acid to a very slight excess. After the alcohol is distilled off, the residue consists of a crystalline mass of crude quinine sulphate, which is pressed off and purified by washing with a little water, and treated with animal charcoal, then recrystallized from hot water. Drying the salt must be effected in the shade to prevent coloration. When barks are employed containing relatively large amounts of cinchonine, most of this base will be precipitated in the above process upon cooling the solution of the crude bases in 85 to 90 per cent alcohol. The mother liquor, upon distilling off part of the alcohol, yields an additional quantity of cinchonine; the mother liquor now resulting, is treated as above. In order to obtain quinine as much as possible free from quinidine, the latter is precipitated from alcoholic solution by means of hydriodic acid (see table under *Quinina*). Other methods of obtaining quinine sulphate are detailed in Husemann and Hilger, *Pflanzenstoffe*, Vol. II, 1884, p. 1421, and the preceding edition of this *Dispensatory*. In more recent years, preference is given to the following process: The powdered bark is intimately mixed with caustic lime, the mixture moistened with water, and the liberated bases extracted with such solvents as amyl alcohol, petroleum hydrocarbons and paraffin oils. These solvents do not take up the coloring and tannin substances of the barks. From the solution thus obtained, diluted acid abstracts the cinchona bases which are then precipitated by sodium carbonate, and subjected to further purification (see B. Hirsch and A. Schneider, *Commentar f. d. Arzneibuch*, Göttingen, 1895; also Flückiger and Power, *Cinchona Barks*, 1884, p. 79).

Description.—Two sulphates of quinine are official, that under present consideration being the neutral salt, or *diquinine sulphate* (compare *Quinina*). Pure quinine sulphate forms hard, heavy crystals, while the commercially preferred quinine sulphate occurs in feathery, light crystals, a quality which was long believed to be due to the presence of a small quantity of cinchonidine sulphate. P. Carles (*Amer. Jour. Pharm.*, 1892, p. 314) finds, however, that the salt may also be obtained in the feathery form by allowing it to crystallize in the presence of ammonium sulphate. The official salt is described as occuring in "white, silky, light and fine, needle-shaped crystals, fragile and somewhat flexible, making a very light and easily compressible mass, lustreless from superficial efflorescence after being for some time exposed to the air, odorless, and having a persistent, very bitter taste. The salt is liable to lose water on exposure to warm air, to absorb moisture in damp air, and to become colored by exposure to light. Soluble, at 15° C. (59° F.), in 740 parts of water, and in 65 parts of alcohol; in 30 parts of boiling water, and in 3 parts of boiling alcohol; also in 40 parts of glycerin, in about 680 parts of chloroform, and freely in dilute acids. When long exposed to the air, or when kept at 50° to 60° C. (122° to 140° F.) for some hours, it loses most of its water of crystallization (all except 2 to 3 molecules, or about 4.1 to 6.2 per cent), the last portion being slowly expelled at 100° C. (212° F.), more rapidly at 115° C. (239° F.). Upon ignition, the salt is slowly consumed, leaving no residue"—(*U. S. P.*). Mr. A. J. Cownley (*Pharm. Jour. Trans.*, Vol. III, 1896, p. 525) recommends that the air-dry (effloresced) salt $(C_{20}H_{24}N_2O_2)_2H_2SO_4.2H_2O$, containing 4.6 per cent of water, be recognized as the official salt; a definite standard would thus be established. "The aqueous solution of the salt is neutral to litmus paper, and has, especially when acidulated with sulphuric acid, a vivid, blue fluorescence"—(*U. S. P.*). (See also *Quinina.*)

Quinine sulphate is incompatible with alkalies and alkaline earths, such as caustic potash and soda, aqua ammoniæ, lime-water, magnesia, etc., on account of the precipitation of quinine produced by these agencies. It is also precipitated by the carbonates of alkalies and alkaline earths; by soluble barium and lead salts (insoluble sulphates being formed); it is likewise incompatible with potassium iodide, potassium chromate, oxalate, and all soluble tartrates, mercuric chloride (*Amer. Jour. Pharm.*, 1887, p. 403), tannic and gallic acids and a number of other compounds. (See enumeration in E. A. Ruddiman, *Incompatibilities in Prescriptions*, New York, 1897.)

Adulterations and Tests.—The former high price of quinine sulphate (see interesting list of prices since 1823 in *Druggists' Circular*, 1896, p. 32) has occasionally led to adulterations or substitutions, such as the addition of sugar, starch, salicin, or inorganic material such as calcium phosphate, gypsum ("tasteless quinine," *Druggists' Circular*, 1896, p. 297), magnesia, potassium nitrate (*Amer. Jour. Pharm.*, 1876, p. 571), sodium sulphate (J. Biel, *ibid.*, 1872, p. 540), etc. Substitution by cinchonine hydrochlorate has been repeatedly noted (*ibid.*, 1871, p. 92; 1880, p. 473). The presence of inorganic impurities is readily recognized by the residue left upon incineration. Treatment with boiling alcohol likewise leaves them undissolved, as well as sugar and starch. The latter is recognized by the iodine test, the former by precipitating the quinine with ammonia; the filtrate upon concentration should not possess a sweet taste. Starch and sugar also would carbonize with concentrated sulphuric acid. Salicin if present, would form a blood-red solution with the latter reagent (see *U. S. P. Tests* below). The presence of other cinchona bases (cinchonine and quinidine) may be ascertained by the tests of the *U. S. P.* subsequently given, in conjunction with those under *Quinina.* "On treating 10 Cc. of an aqueous solution (about 1 in 1300) of the salt with 2 drops of bromine water, then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate"—(*U. S. P.*). This is the *thalleioquin* test already recorded under *Quinina.* According to Hyde, this reaction succeeds best when calcium hypochlorite is used instead of bromine or chlorine. Acidulate the quinine solution with 1 drop of dilute sulphuric acid (1:4), filter the hypochlorite solution into the quinine solution until the blue fluorescence is just discharged. Now add to the faintly golden-yellow liquid a few drops of dilute ammonia (1:3); a brilliant emerald color will then appear (*Digest of Criticisms on the U. S. P.*, Part II, 1898). The *U. S. P.* further directs for quinine sulphate: "A cold, saturated aqueous solution of the salt remains unaffected by potassium iodide T.S. (difference from *quinidine sulphate*)"—(*U. S. P.*). (Compare table under *Quinina.*) "Ammonia water added to the aqueous solution of the salt throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid. Quinine sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities), nor produce a red color with nitric acid (difference from morphine)"—(*U. S. P.*). (Also see *Quinina.*) "If 1 Gm. of the salt be dried at a temperature of 115° C. (239° F.), until it ceases to lose weight, the residue should not weigh less than 0.838 Gm. (absence of more than 8 molecules, or 16.18 per cent of water)"—(*U. S. P.*). This test for the presence of water is quite necessary, because the light powder, even when effloresced and seemingly dry, is capable of mechanically holding quite large quantities of water; thus Dr. Kerner records 18 per cent in an apparently dry sample (see *Amer. Jour. Pharm.*, 1880, p. 425). "If 2 Gm. of the salt (which must have been previously ascertained to be strictly neutral to litmus paper, or have been rendered so) be dried, as far as possible, at 100° C. (212° F.), the residue then agitated with 20 Cc. of water, and the mixture macerated for ½ an hour at 15° C. (59° F.), with occasional agitation, upon proceeding further as directed under Quinine (see *Quinina*) the results there given should be obtained"—(*U. S. P.*). B. Hirsch (*Pharm. Rundschau*, 1893, p. 240) points out that the employment of 7 Cc. of ammonia in this test indicates an allowance of about 4 per cent of alkaloids other than quinine (*Digest. loc. cit.*). The *British Phar-*

copœia (1898) demands the absence of more than traces of cinchonine, quinidine, cupreine, and amorphous alkaloid, and makes an allowance of 3 per cent of total bases, chiefly cinchonidine, as obtained by Liebig's test (precipitation with ether and ammonia) for which detailed directions are given, as well as for the determination of quinidine, cinchonine, amorphous alkaloid, and cupreine (see *Cinchona*). In this connection, see scheme of analysis of quinine sulphate and hydrochlorate, by C. Hielbig, in *Amer. Jour. Pharm.*, 1888, p. 411.

Action, Medical Uses, and Dosage.—(Compare *Cinchona*.) To the taste, quinine sulphate is extremely bitter. It does not fully represent Cinchona, whose associated principles possess properties not present in quinine alone. In small doses, quinine is a nervous and vascular stimulant. In large doses, it is a sedative and muscular and cardiac depressant, and, if given in suficient amounts, which, however, must be very large, it is capable of producing death. Upon denuded surfaces, quinine acts as an irritant. It is antiseptic and antiputrefactive, and for these purposes Cinchona bark was applied to ulcers by Sir John Pringle as early as 1765. In various strengths, quinine checks fermentation in milk, urine, alcoholic fluids, etc., and prevents decomposition of the same. Upon entering the stomach, quinine is dissolved by the gastric fluid, such portions as are not dissolved passing into the intestines, where the alkaline juices also precipitate such portions of the dissolved salt as may come into contact with them. In small doses, the movements of the stomach are increased, and the flow of gastric juice augmented. Large doses check the flow of the latter and cause irritation of the stomach. If the stomach be already irritable, even small doses of quinine or cinchona increase the difficulty. In immoderate quantities, it first constipates and then causes diarrhœa. Upon the blood, quinine appears to impress the hæmoglobin, impairing its function, with the result of lessening the oxidizing (ozonizing) powers of the blood. The activity of the white blood-corpuscles are also said to be inhibited or lessened, and the discs even destroyed by this salt. It has also been shown that the amœboid movements of these bodies are inhibited. Small doses increase the action of the heart, while large doses depress it. The feeble cardiac movements, from large doses, are due to its action upon the cardiac motor ganglia; the vaso-motor system is also depressed by it. In health, very little effect is produced upon the body-heat by quinine, though, in febrile conditions, it tends to bring down the temperature. It has a tendency to restrain the cutaneous secretions. The cerebrum is stimulated by small doses, and a hyperemic state of the brain induced. Large doses, however, produce a partial anemia of the organ, due to contraction of the arteries and feeble heart-action. After death, however, the brain is found to be engorged with blood. Deafness is a common result after the injudicious use of quinine, but it is seldom permanent. The optic nerve and retina, through ischæmia, become perfectly white, resembling white atrophy, and temporary blindness results. Occasionally, permanent atrophy of the nerve, with blindness, remains. Upon the spinal cord, the chief effects are a lessening or abolishment of reflex excitability. This is attributed, not to a primary action upon the cord, but to stimulation of Setschenow's center of inhibition, situated at the base of the brain. Quinine first stimulates the lungs, increasing the respiratory functions. Toxic doses, however, produce dyspnœa and a variety of abnormal respiratory movements, finally ending in death, with symptoms of asphyxiation. The spleen is contracted by quinine, and, upon the uterus, it probably has no power to originate contractions, though it appears to assist normal uterine contractions when they have once begun. For this purpose it is valued in feeble and intermittent uterine action during labor. Notwithstanding this, it is the general opinion that it is a perfectly safe agent to administer in *threatened abortion*, due to miasmatic influence, or occurring in malarial districts.

Quinine rapidly diffuses itself into the blood in proportion to the quantity taken. It is found in all the secretions, the tears, the saliva, milk, sweat, and urine. Though some of it is probably eliminated by the bowels, the chief amount—at least one-half—passes out by way of the kidneys, hence the irritant effects sometimes produced upon the urinary tract. In acute inflammation of the renal organs, it increases the difficulty and may give rise to complete suppression, or to retention of urine. Small doses increase the elimination of urea, uric acid, and creatinin, while the excretion of these products is diminished by larger doses. Quinine occasionally produces skin eruptions, among which may be mentioned erythema, urticaria, herpes, roseola, and rarely purpura. The physiological action of quinine throws but little light upon the practical applications of the drug. No absolute explanation can be given of its mode of action in malarial and other periodical fevers. That it antagonizes the miasmatic poison is accepted, this poison probably consisting of low forms of organic life—micro-organisms (*Plasmodium malariæ*)—the multiplication of which it prevents, and the destruction of which it accomplishes. Quite recent investigations give weight to the opinion that it destroys the plasmodium in the system, for, when isolated, these micro-organisms have been destroyed by so dilute a solution as 1 part of quinine in 20,000 parts of water.

Sulphate of quinine is febrifuge, tonic, and antiperiodic. Small doses, frequently repeated, act as a stimulant tonic, strengthening the pulse, increasing muscular force, and invigorating the tone of the nervous system. In some persons it induces headache, sickness, or irregular action of the bowels, which effects are generally obviated by combining it with morphine, extract of stramonium, or both, and these effects will be almost certain to follow if gastro-enteritic irritation preexists. Large doses, as 20 grains, or ½ drachm, produce many unpleasant symptoms, and ought never to be used, except in the malignant conditions hereafter mentioned. Among these may be named sickness and pain at the stomach, mental confusion, giddiness, flushed countenance, palpitation, a sense of fullness, throbbing, and distension in the head, intense weighty headache, ringing in the ears, vomiting, numbness in the feet, twitchings of the limbs, deafness, blindness, delirium, and nervous excitation and restlessness. If this amount be administered for several days, muscular debility, with tremulousness, unsteady gait, somnolence or apathy, obtuse sensibility, and dilated pupils, may also be present. In toxic doses, deafness and blindness may be complete, the limbs become powerless, and unconsciousness supervenes. Upon discontinuing the use of the salt, the effects gradually pass off, occasionally, however, the aural and ocular disturbances persist for some time if the drug has been long administered. It is seldom that the severer symptoms, above mentioned, are observed, for, as soon as slight cinchonism has been produced, known by giddiness, a buzzing or ringing in the ears, slight headache, etc., the drug is usually discontinued.

"The evil results following large doses, or the injudicious administration of quinine, has caused many physicians to reject it altogether in their practice. This is wrong. Quinine is a safe and very superior remedy, in proper hands, and when the specific indications are observed. As well might we reject all active and useful agents, because, when improperly used, they produce deleterious consequences. It must also be remembered, that many of the symptoms following the use of quinine, are the legitimate results of disease itself, as an enlarged spleen, a deranged condition of the nervous system, etc., or were formerly the deplorable consequences of a combined mercurial treatment, which has been and still continues to be a fashionable practice in many portions of this section of the country. No sensible or well educated physician will ever object to the proper employment of the pure sulphate of quinine" (J. King).

Since the development of specific medication, a better understanding of the uses of quinine has been established. While the earlier Eclectic physicians recognized *periodicity* as its unquestionable indication, and, while they recognized the fact that "symptoms of irritability, wakefulness, or restlessness, must be first subdued," they carried the effect of the drug to such an extent as to "affect the head" daily. This would indicate that they did not always employ it in the same conditions in which it is now recognized with us as a specific agent. When quinine is specifically indicated, it will act kindly, and the head need not necessarily be impressed. The indications for the agent, and which they closely approached, as now understood by us, and followed with prompt results, are: *Periodicity*, the fever taking the form of *remittent* or *intermittent;* the *pulse is open and soft, the skin soft and moist, the tongue moist and cleaning, and the nervous system free from marked irritation*. To act kindly, the stomach must not be irritable, and must be in a condition to receive and absorb the drug. If the general condition of the system be such that there is marked nervous excitation, as dry tongue and skin, and a frequent, hard pulse, an aggravation of the existing condition is likely to take place under the use of quinine and its salts. When, however, these unfavorable conditions can be rectified by other agents, then the quinine salt will be kindly received, and will do good work. Generally, when such untoward conditions are present, there is some unrecognized complication of the liver, spleen, or stomach. The following excerpt from the last edition of this work, will serve to illustrate the manner in which the drug was used by the earlier Eclectics:

"Sulphate of quinine, in American practice, is used in all febrile diseases, without regard to the violence of the fever, or the degree of congestive enlargement of the liver or spleen; it is usually given during the intermissions or remissions, in doses sufficient to affect the head, each day; when, for that day, its administration is omitted; but should there be no apparent remissions, it is then given daily to produce the same influence upon the head, without, as before said, regard to the violence of the fever, etc. Previous to its administration, however, any symptoms of irritability, wakefulness, or restlessness, must be first subdued. It is frequently given in these cases, as well as in many other forms of disease, in combination with ferrocyanide of iron; which was first introduced to the profession, as a safe and efficient remedy in this class of maladies, by Prof. I. G. Jones. In typhus and typhoid fevers, it will be found of much service, in conjunction with small doses of extract of leptandra, or resin of podophyllum, sufficient to produce a daily alvine evacuation. In febrile relapses, acute rheumatism, neuralgia, dyspepsia, debility, convalescence from most acute and chronic diseases, dysentery, and in all epidemic diseases, and every disease characterized by periodicity, it may be given with every expectation of success. Combined with morphine, I have used it successfully in epilepsy, delirium tremens, and the convulsive diseases of intemperate persons. In dysmenorrhœa, in conjunction with extract of stramonium or belladonna, and resin of black cohosh, it proves almost a specific. It is generally contraindicated during the presence of gastric inflammation, or unusual irritation of the stomach, though the addition of morphine, in such cases, will sometimes prevent any hurtful consequences" (J. King).

Quinine is the great remedy for *malarial fevers.* It is seldom now employed in other fevers without periodicity, except as a tonic to prevent prostration. The rule for the administration of quinine, as an antiperiodic, is as follows: "Whenever an acute disease exhibits periodicity, we administer the agent during the intermission, or when there is the least excitement of the circulation; but if this can not be done, owing to the shortness of the intermission, we give it during the reaction" (Scudder, *Materia Medica*, p. 436). In all cases the specific indications, as given above, are to be observed. If given when a chill is on, it is likely to aggravate it, while, during the sweating stage, it is neither necessary nor productive of much good. As to the manner of administration, there is some difference of opinion—some preferring broken doses, others the single dose. Probably, if the indications are correct, the manner of administering it does not make any material difference, as the effect of the drug seems to have been as certain when given in either manner. Prof. Scudder, after getting the patient in the proper condition, preferred to give a single dose of 10 grains in 1 or 2 ounces of water, using sufficient sulphuric acid to effect a solution. This he believed to be the most certain and pleasantest mode of administration. Prof. Locke advises from 15 to 30 grains, depending upon the condition of the patient, 5-grain doses being administered during the intermission, every 3 hours, so that the last dose may be taken an hour before the expected chill. The following solution is recommended by Prof. Locke: ℞ Quinine sulphate, ʒi; diluted hydrochloric acid, gtt. xxx; water, fl℥ii. Mix. Dose, a teaspoonful or more, every 3 hours; each teaspoonful contains about 4 grains of quinine. Fluid extract of liquorice may be added, if desired. It must be remembered that all cases of *ague* are not cured by quinine; but, as a rule, uncomplicated ague yields to it, and for *congestive chill* it is the best remedy in use. In *malignant intermittent*, it is the remedy which gives the best results. But in some of these cases the stomach is not in a condition to receive the medicine. When such is the case a sinapism may be applied to the epigastrium, and capsicum or black pepper may be freely given with the quinine. The latter must be used in large quantities, and without regard to time. From 10 to 20-grain doses may be given until 40 to 60 grains are taken (Locke). In *remittent fever*, give it in the larger or smaller doses during the remission, accordingly, as the disease is of a malignant or non-malignant type. In *typhoid fever*, quinine is not, as a rule, indicated. In fact, as ordinarily prescribed in this affection, it does much harm to the vascular and nervous systems, as well as to the stomach. When, however, the specific indications for it are present, and prostration is imminent, it may be given in 1 or 2-grain doses, about 4 times a day, and usually with the mineral acids, unless the latter are otherwise contraindicated. The mixed type of fever, known as *typho-malarial fever*, is benefited by quinine, in proportion to the predominance of the malarial infection, provided the indications for the drug are present. It is less effective as the typhoid element predominates.

Quinine and its salts are not always curative in the so-called *malarial cachexia;* it often fails here, when arsenic, ceanothus, boletus, eupatorium, etc., succeed. Generally, however, it proves useful in many troubles depending upon a malarial origin. It is useful in *ague-cake.* It is frequently of value in children's diseases occurring in malarial districts, particularly when periodic in type. Other diseases supervening in one subject to ague, are often benefited by the judicious use of quinine. Thus it forms the whole or a part of the treatment in *muscular pain, rheumatism*, etc. We have had excellent results in severe rheumatic conditions of the shoulders, wrist, and fingers in several instances, from the use of a weak, hydrochloric acid solution of quinine sulphate, to which is added specific capsicum. Here it will aid macrotys and other antirheumatics. It is a remedy for *periodical neuralgiæ* and *periodical headaches.* There is no doubt that quinine possesses prophylactic powers in preventing malarial manifestations.

In *obstetrical practice*, quinine is frequently serviceable. Here it may be employed to remedy irregular and ineffective pains, and in cases where complications of a periodical nature arise. As with its antiperiodic virtues, small doses of opium associated with it, increase its oxytocic power. By its tonic and contractile action, it minimizes the danger of *post-partum hemorrhage.* In ocular therapeutics, it meets *periodical neuralgic pain*, and, locally applied, occasionally relieves *follicular conjunctivitis* and *trachoma.* Quinine is, with some physicians, the remedy most relied upon in *sunstroke.*

That the nervous system is pronouncedly affected by quinine, is evident from the great damage done by the improper and untimely administration of the drug. When indicated, however, it is one of the most important of stimulants of the cerebro-spinal centers. Thus, in many chronic forms of disease, with impaired nutrition and functional torpor, we find that quinine, administered according to its indications, will, in small doses (½ to 2 grains), restore the proper innervation and aid in a cure. In fact, in chronic affections there are two main conditions in which it always does good, and those are cases with enfeebled innervation, as mentioned, and those of malarial infection, with "obscure periodicity" (Scudder). Not only does it stimulate the cerebro-spinal centers, but so impresses the sympathetic ganglia, that waste and excretion are better performed and digestion, nutrition, and blood-making are improved. Thus it is frequently combined with iron and strychnine in cases of *general debility.* An exceedingly useful preparation for this purpose is the "compound tonic mixture." Quinine, in small doses, is effectual in *dyspepsia*, depending upon a nervous derangement of the stomach. It counteracts the poison of *erysipelas.* In *intermittent neuralgia*, with severe pain, and particularly when affecting the fifth nerve, quinine, combined with small doses of morphine, is one of the most certain of drugs. The *colliquative sweating* of pulmonary affections is checked by the following: ℞ Quinine sulphate, grs. xxx; aromatic sulphuric acid, flʒss; water, fl℥iv. Mix. Dose, a teaspoonful 3 times a day, the last dose being taken at bedtime (Locke). Quinine is occasionally of value in *puerperal fever*, *septicæmia*, and *diphtheria.* It is particularly useful for the debility following *surgical diseases*, where the discharges are copious and exhausting. It also tends to check the formation of pus. Sometimes it is indicated in *pneumonia*, but not for antipyretic effects. As a tonic, sulphate of quinine will be found useful in all diseases connected with an enfeebled state of the system, and especially in the debility resulting from exhausting diseases; in *chlorosis*, and in *anemic conditions* it should be given in union with chalybeates. Externally, sulphate of quinine, in solution, has formed a valuable application to *indolent ulcers*, *buboes*, *chancres*, and *chronic mucous inflammations.*

We have received good results in the treatment of *hay fever*, by the internal administration of a solution of quinine in water and hydrochloric acid, each dose containing 2 grains of the salt, and being administered 4 times a day. A solution of ½ grain of quinine sulphate in an ounce of water, is recommended by some as a douche in this affection. Quinine solution is often of service in *diphtheria*, being applied locally to the membrane, and in *gonorrhœa*, it has done good service by injecting it into the urethra.

Many times quinine, even when indicated, is not well borne by the stomach. In such cases, and particularly in children's diseases, most excellent results are obtainable from an inunction of quinine and lard or petrolatum, applied to the abdomen, groin, and arm-pits. Some physicians never employ it in any other manner in the disorders of childhood.

The dose of quinine sulphate, internally, is from ½ to 3 grains, repeated every 1, 2, 3, or 4 hours, as the urgency of the case may require. Large doses are improper, except in remittent and intermittent fevers, when the dose may range from 5 to 20 grains. A popular mode of administering quinine is in capsules. This, while pleasanter, is less effectual than the acidulated solutions. A solution of quinine sulphate may be made by adding 20 grains of the salt to 1 fluid drachm of elixir of vitriol, and, when dissolved, add 2 fluid ounces of water. The dose of this solution is 20 drops every hour, in about ½ ounce of water, or syrup of ginger. Another solution may be made by dissolving sulphate of quinine, tartaric acid, of each, 20 grains, in 2 fluid ounces of water. The dose is as above. A number of agents have been employed to mask the taste of quinine. Among these are liquorice, yerba santa, and yerbazin. The practice of using tannic acid is to be condemned, as it converts the most of the quinine into an insoluble and practically inert quinine tannate. The acetate, nitrate, phosphate, ferrocyanide, citrate, and hydrochlorate of quinine, possess similar properties, but are not usually preferred in practice.

Specific Indications and Uses.—Periodicity, pulse soft and open, tongue moist and cleaning; skin soft and moist, and nervous system free from irritation; intermittent and remittent fevers; periodical neuralgia; enfeebled innervation.

YERBAZIN, a preparation prepared by Eli Lilly & Co., is said to be free from many of the objections of other quinine maskers. It is a syrupy preparation, containing the quinine masking principle of yerba santa. It perfectly disguises the bitter taste of quinine without decomposing that salt, or converting it into a tannate. Twenty or more grains of quinine are rendered palatable by a fluid ounce of yerbazin, the salt being suspended in the latter by rubbing in a mortar, or violently shaking in a partially filled vial. Yerbazin is a specialty of the above-named firm.

QUININÆ VALERIANAS (U. S. P.)—QUININE VALERIANATE.

FORMULA: $C_{20}H_{24}N_2O_2C_5H_{10}O_2+H_2O$. MOLECULAR WEIGHT: 443.07.

SYNONYMS: *Chininum valerianicum, Quiniæ valerianas, Valerianate of quinia.*

"Quinine valerianate should be kept in well-stoppered bottles, in a dark place"—(*U. S. P.*).

Preparation.—Quinine valerianate may be prepared by warming moist quinine with a solution of valerianic acid in water (for Wittstein's directions, see this *Dispensatory*, preceding edition). Another process consists in the double decomposition between quinine hydrochlorate and sodium valerianate in aqueous solution (process of the old *Dublin Pharmacopœia*). R. Rother recommends as the most advantageous process the double decomposition of quinine sulphate and calcium valerianate in the presence of weak alcohol (see formula and details in *Amer. Jour. Pharm.*, 1883, p. 177).

Description and Tests.—Valerianate of quinine is described by the *U. S. P.* as occurring in "white, or nearly white, pearly, lustrous, triclinic crystals, having a slight odor of valerianic acid, and a bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 5 parts of alcohol; in 40 parts of boiling water, and in 1 part of boiling alcohol"—(*U. S. P.*). The salt is readily soluble in ether. According to Dr. Landerer (1875) the dry salt when triturated in a mortar, exhibits in the dark a beautiful phosphorescence. "When heated to about 90° C. (194° F.), the salt melts, forming a colorless liquid. At 100° C.

(212° F.), it loses its water of crystallization, and also begins to lose valerianic acid. On ignition, it is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral or slightly alkaline to litmus paper. The aqueous solution, when acidulated with sulphuric acid, exhibits a blue fluorescence, and emits the odor of valerianic acid"—(*U. S. P.*). A spurious valerianate has been met with, made by adding a few drops of oil of valerian to sulphate of quinine. This dissolves in about 30 parts of boiling water, depositing crystals of the sulphate on cooling. A thin film of oil will be seen on the surface of the water. "On treating 10 Cc. of an aqueous solution (about 1 in 1300) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more diluted solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. Quinine valerianate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities). The aqueous solution of the salt should not be rendered more than slightly turbid by barium chloride T.S. (limit of sulphate)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Valerianate of quinine is tonic, febrifuge, and sedative, and may be employed similarly to the tartrate of quinine and morphine. It was highly recommended by the late Prof. I. G. Jones in *hemicrania*, and in *febrile* or *other diseases*, to relieve restlessness, wakefulness, and nervous irritability. It is, however, an unstable and disagreeable salt and is but little employed. The dose is from ½ grain to 2 grains, every 1, 2, 3, or 4 hours, according to the nature of the case.

RANUNCULUS.—CROWFOOT.

The fresh bulbous base and flowering tops of *Ranunculus bulbosus*. Linné.

Nat. Ord.—Ranunculaceæ.

Common Names: *Crowfoot*, *Bulbous crowfoot*, *Buttercup*.

Illustration: Lloyd's *Drugs and Medicines of North America*, Vol. I, Plate VII.

Botanical Source.—Ranunculus bulbosus has a perennial, solid, fleshy, roundish, depressed bulbous base, resembling a cormus, sending out radicles from its under side; in autumn it gives off lateral bulbs near its top, which afford plants for the following year, while the old bulb decays. The root sends up annually, several erect, round, hairy, and branching stems, from 6 to 18 inches in height, which are furrowed, hollow, and bulbous at the base. Radical leaves on long petioles, ternate, sometimes quinate; segments variously cut, lobed and toothed and hairy. Cauline leaves sessile and ternate; upper ones more simple. Each stem supports several solitary, golden-yellow flowers, upon furrowed, angular, and hairy peduncles. Sepals oblong, hairy, reflexed against the peduncle. Petals 5, inversely cordate, longer than the sepals, and arranged so as to represent the shape of a small cup. At the inside of the claw of each petal is a small cavity, which is covered with a minute wedge-shaped emarginate scale. The stamens are numerous, and yellow, with oblong, erect anthers. Ovaries numerous, with reflexed stigmas. Receptacles spherical. Carpels acute, naked, diverging, tipped with very short recurved beaks (L.—G.—W.).

History.—This plant is common to Europe and the United States, growing in fields and pastures, and flowering in May, June and July. There are several species, possessing similar properties, and designated by the general name of *Buttercup;* among these the *R. acris*, Linné, *R. repens*, Linné, *R. sceleratus*, Linné, and *R. Flammula*, Linné, may be indifferently substituted, the one for the other. The leaves and unripe germens of these species are acrid, occasioning, when chewed, a singular, intense cutting sensation in the point of the tongue, which quickly ceases when the plant is removed. This acrid principle is entirely lost by drying, however carefully this process be managed; and it also disappears in the germens as the seeds, which are themselves bland, ripen. It passes over in the distillation of the fresh plants with water. When any part of these plants is chewed, it occasions much pain, inflammation, and sometimes excoriation of the several parts of the mouth, and much heat and pain in the stomach, if it be taken internally. The distilled water of *R. Flammula*, Linné, is said to act as an instantaneous emetic.

Chemical Composition.—The acrid principle of these plants resides in a yellow volatile oil having the pungency of oil of mustard or horseradish. Ether and chloroform extract its active principle, crystallizable *anemonol* or *anemone camphor*, an unstable body, decomposing spontaneously into inert *anemonin* and *anemonic* (*isoanemonic*) *acid* (see *Pulsatilla* and *Anemone;* also *Drugs and Medicines of North America*, Vol. I, p. 59).

Action, Medical Uses, and Dosage.—The above-named plants are too acrid to use internally, especially when fresh; but when applied externally, are powerfully rubefacient and epispastic. *Ranunculus bulbosus* is employed, in its recent state, in *rheumatic*, *neuralgic*, and *other diseases* where vesication and counter-irritation are indicated. Its action, however, is so uncertain, and sometimes so violent, causing very obstinate ulcers, that it is seldom used. It is sometimes used by the beggars of Europe to produce and keep open sores, for the purpose of exciting sympathy. "I have cured two obstinate cases of *nursing sore-mouth*, with an infusion made by adding 2 drachms of the recent root, cut into small pieces, to 1 pint of hot water; when cold, a tablespoonful was given 3 or 4 times a day, and the mouth frequently washed with a much stronger infusion" (J. King). Prof. Scudder suggested a fraction of a drop largely diluted of a tincture of the fresh root (℥viii to alcohol, 76 per cent, Oj) as a stimulant to the vegetative process. Acting upon homœopathic principles it has been employed with asserted benefit in *herpes* and *eczema*. The dose is a fraction of a drop, well diluted, every 2 to 4 hours.

RESINA (U. S. P.)—RESIN.

Synonyms: *Colophony, Rosin.*

Source.—The term *Resin* (see *Resinæ*) here has a special meaning, being applied to "the residue left after distilling off the volatile oil from turpentine"—(*U. S. P.*). It is better known by the names of *Rosin* or *Colophony*. The manufacture of this article is one of the leading industries of the southern states (see *Terebinthina* and *Oleum Terebinthinæ*). *Resina flava*, or *Yellow rosin*, contains some moisture, in consequence of the distillation not being carried to dryness; if this, while in a melted state, be shaken with water, it forms a lighter colored resin, termed *Resina alba*, or *White resin*. *Fiddlers' rosin*, or *Colophony*, is a translucent, brownish-yellow substance, the result of the distillation being continued until all water is expelled, or without the use of water.

Description and Chemical Composition.—As officially required, resin is "a transparent, amber-colored substance, hard, brittle, pulverizable; fracture glossy and shallow-conchoidal; odor and taste faintly terebinthinate. Specific gravity 1.070 to 1.080. Soluble in alcohol, ether, and fixed or volatile oils; also in solution of potassium or sodium hydrate"—(*U. S. P.*). It is heavier than water and melts at a moderate heat. When kept in powdered condition, it is liable to undergo spontaneous combustion (H. Hager, *Amer. Jour. Pharm.*, 1888, p. 455). When melted, it can be united with wax, fats, spermaceti, etc. Prof. Olmstead (*Amer. Jour. Pharm.*, 1850, p. 325) states that rosin added to lard gives it a degree of fluidity not before possessed by the lard, and also prevents the latter from forming those acids which corrode metals. A compound of 1 part of rosin to 4 of lard, may be used for various purposes; by incorporating a certain amount of black-lead, and applying a thin coating to iron stoves and grates it prevents them from rusting, forming a complete protection. The principal constituent of rosin is *abietic anhydride* ($C_{44}H_{62}O_4$, Maly, 1861-64) which dissolves in warm 70 per alcohol with absorption of water and formation of *abietic acid* ($C_{44}H_{62}O_5$), which falls out upon cooling. This acid forms colorless small crystals soluble in alcohol, wood alcohol, chloroform, ether, benzene, carbon disulphide and glacial acetic acid. It also dissolves readily in caustic alkali with formation of a resin soap (*e. g.*, sodium abietate). The acid absorbs oxygen upon exposure to the air. A series of esters (ethyl, methyl and glyceryl esters) of abietic acid has been prepared which have been used in the preparation of varnishes. By destructive distillation of the acid with reducing agents (zinc dust), homologues of benzene, naphtalene, and anthracene are formed.

Action, Medical Uses, and Dosage.—Rosin is seldom given internally. Its principal use is to form plasters and ointments, to which it is an excitant ingredient, and renders them more adhesive. Internally, pulverized rosin will be found very useful in doses of 30 to 60 grains in molasses, or linseed oil, 3 or 4 times a day, in *bleeding piles*. Applied locally, on lint or cotton, it will be found a very valuable styptic. The vapor from rosin has been inhaled in *chronic bronchitis*, and certain atonic *affections of the lungs* with benefit; and the fumes of burning rosin, if received upon the parts, will, it is said, remove the irritation attending *piles* and *prolapsus ani*. Half a drachm of powdered rosin, dissolved in a sufficient quantity of chloroform, so as to make a thick solution, will relieve *neuralgia of the teeth*, or *toothache*, by introducing a piece of cotton, which has been impregnated with the solution, into the hollow teeth.

RESINÆ.—RESINS.

Medicinal resins, sometimes termed *resinoids* or *concentrations*, are a class of agents obtained from medicinal plants or roots, etc., by precipitation from their alcoholic tinctures, either by means of water alone, or aided by distillation. Those at present in use are generally impure, and contain one or more, but not all, of the therapeutic virtues of the plants from which they are made. *Note.*—The "Strong Tincture" of the different resins, referred to in their *preparation*, is usually made by exhausting any quantity of the root, or bark, etc., of the crude agent, by percolation with official alcohol. The subsequent evaporation is to be carried on by distillation until the residue is of a syrupy consistence. Most of the Eclectic resinoids are now discarded in favor of liquid preparations of the drugs yielding them, but, for obvious reasons, it is best to record again the processes to be found in former editions of this work. Resinoids, as a rule, are no longer of importance to Eclectic physicians. The exceptions to the above remarks are resins of cimicifuga and podophyllum, and the alkaloids found in hydrastis and sanguinaria, which were introduced originally as Eclectic resinoids.

RESINA CAULOPHYLLI.—RESIN OF CAULOPHYLLUM.

SYNONYM: *Caulophyllin.*

Preparation.—Take of strong tincture of blue cohosh root, 1 pint; water, 1 gallon. Distill off the alcohol, and pour the syrupy residue into the water, allow the mixture to stand for 24 hours, or until there is no further precipitate, collect the precipitate on a filter, and then allow it to dry in a moderately warm place.

History, Description, and Chemical Composition.—As blue cohosh root contains but very little resin, this preparation is not deserving the name of resin, but as it has been heretofore considered the resinous principle of the root, I give it a place, for the present, among the resins. Mr. W. S. Merrell first manufactured this article. Mr. A. E. Ebert found it to consist of two resins, both soluble in alcohol, but one only of them soluble in ether, and an extractive body analogous to saponin, which, when shaken with water, produced a very thick and persistent froth, was freely soluble in alcohol and in alkaline solutions, and the aqueous solution of which reddened litmus (*Amer. Jour. Pharm.*, 1864, p. 206).

Dr. T. L. A. Greve states in relation to this agent: "Caulophyllin is the name given by our pharmaceutists to the dried and powdered alcoholic extract of blue cohosh root. It can hardly be termed a resinoid, as the root contains but little, if any, resin, nor would it be proper to name it the active principle in the sense that this term is applied to strychnine, santonin, and other proximate principles of a definite chemical constitution. It is simply a *concentrated medicine*, representing the medicinal activity of the crude drug in a condensed and convenient form." It will be seen from these remarks, coming from a reliable source, that the article now prepared for the profession as "*Caulophyllin*," is simply the dry alcoholic extract of the root (J. King).

Action, Medical Uses, and Dosage.—Resin of caulophyllum appears to exert a direct influence upon the uterus, acting as an alterative, uterine tonic, and parturient, according to the periods in which it is employed. In the more common unhealthy conditions of this organ and its appendages, known as *amenorrhœa*, *dysmenorrhœa*, *passive menorrhagia*, *leucorrhœa*, *congested cervix*, etc., it is equal to, if not surpassing, the resin of black cohosh. A combination of equal parts of resins of blue and black cohosh, and carbonate of ammonium, will be found especially valuable, not only in the above-named affections, but likewise in *epilepsy*, *hysteria*, in which diseases it is recommended as an antispasmodic, and in *rheumatism* and *dropsy*. This resin may also be advantageously combined with alcoholic extract of aletris, oleoresins of asclepias, senecio, etc., in many forms of disease of the female generative organs. It has been spoken of as a parturient, but we have no personal knowledge of its influence as such, though we are aware that the root from which it is prepared does exert a parturient effect. Added to resin of podophyllum, or other active purgatives, it prevents tormina, and is, probably, the best agent that can be employed for this purpose. I have found it of decided benefit in severe *after-pains*, *neuralgic dysmenorrhœa*, and in several *derangements of the menstrual function*. The ordinary dose is from ¼ to 1 grain, 2, 3, or 4 times a day. As a parturient, it should be given in doses of from 2 to 4 grains, and repeated at intervals of 15 to 30 or 60 minutes, after actual labor has commenced. Resin of caulophyllum may be advantageously combined with extract of dioscorea in *bilious colic* and *flatulence*. With resin of podophyllum and chloride of ammonium, it forms an excellent combination for some *nephritic diseases*, accompanied with pains of a spasmodic character (J. King). It is but little used at the present time.

RESINA CIMICIFUGÆ.—RESIN OF CIMICIFUGA.

SYNONYMS: *Resin of black cohosh*, *Cimicifugin*, *Macrotin*.

Preparation.—Take of strong tincture of black cohosh root, 1 pint; water, 1 gallon. Distill the alcohol from the tincture, and pour the syrupy residue into the water, allow the mixture to stand 24 hours, or until there is no further precipitate, collect the precipitate on a filter, wash it with water, and then allow it to dry in a cool place.

History and Description.—This valuable and useful remedy I have used with much success in my practice since 1835, and had the honor of calling the attention of practitioners to it in 1844, and again in the *Western Medical Reformer*, of 1846, but it was not received into general use among practitioners until its preparation on a large scale by Mr. W. S. Merrell. Resin of cimicifuga is a dark-brown or yellow substance, lighter colored after pulverization, of a faint, narcotic odor, a slightly bitter, feebly nauseous taste, and soluble in alcohol (J. King).

Action, Medical Uses, and Dosage.—The resin of black cohosh possesses alterative, nervine, and antiperiodic properties, without having the narcotic virtues of the root, which are to be had in the alcoholic or the ethereal extract. It also appears to exert a peculiar influence upon the uterus, on which account it has been termed a "uterine tonic." Prof. T. V. Morrow, M. D., during his life, expressed himself as having made an extensive use of this preparation in various affections peculiar to the female sex, and with success. Prof. Morrow writes: "My experience in the use of the resin of black cohosh, has demonstrated to my mind that there is a slight difference in the *modus operandi* of this form of the medicine, when compared with the usual forms in which the Cimicifuga racemosa has been used. That difference principally consists in the increased liability of the latter to produce a heavy, dull, and aching sensation in the forehead, in connection with a feeling of dizziness, while the former appears to manifest a greater tendency to produce aching, and somewhat painful sensations in the joints and limbs generally." Resin of cimicifuga has been employed advantageously in *intermittent fever*, *periodic diseases*, *leucorrhœa*, *amenorrhœa*, *dysmenorrhœa*, *menorrhagia*, *threatened abortion*, *sterility*, *rheumatism*, *scrofulous affections*, and in *prolapsus uteri*, not accompanied with an inflammatory condition of that organ or of its ligaments. It has also been successfully used in *dyspepsia*, *chronic gonorrhœa*, *gleet*, *smallpox*, etc., and its tincture has been found an excellent local application in *chronic conjunctivitis.* It may be advantageously combined with other uterine tonics and alteratives—as, extract of aletris, resin of caulophyllum, oleoresins of senecio, or asclepias, etc.; with extract of dioscorea it often improves the action of this agent in *flatulency*, and in *bilious colic*, rendering its influence more prompt and certain in certain obstinate cases. Made into a pill, with equal parts of extracts of dioscorea and cramp bark, it will be found highly beneficial in *flatulency*, *bilious colic*, *cramps of pregnant women*, *painful dysmenorrhœa*, *spasmodic affections*, *borborygmi*, and in *cholera morbus*, to remove the cramps. As a parturient, it is inferior to the powdered root, or to the resin of caulophyllum. In *pulmonary*, *rheumatic*, and *dyspeptic affections*, where there is a want of tone in the nervous system, it will prove a most valuable medicine, especially as an adjunct of other remedies. Its usual dose is from ½ to 3 grains, and, in some cases, even to 6 grains, repeated 3 times a day (J. King). It is but little used at the present day, but when employed, the specific indications for its use, practically those given under *Cimicifuga* (which see), should be regarded.

The preparation obtained by Prof. Wayne's process (see previous editions of this *Dispensatory*) appears to possess more of the active properties of the root than the ordinary resin, and may be used in all cases where the root or its tincture is indicated, in doses varying from ¼ to 1 grain (J. King).

RESINA COPAIBÆ (U. S. P.)—RESIN OF COPAIBA.

"The residue left after distilling off the volatile oil from copaiba"—(*U. S. P.*).

Synonyms: *Copaivic acid, Acidum copaibicum.*

Description.—"A yellowish or brownish-yellow, brittle resin, having a slight odor and taste of copaiba. Soluble in alcohol, ether, chloroform, carbon disulphide, benzol, or amyl alcohol"—(*U. S. P.*). This is a mixture of copaivic acid and neutral resinous matter. Its solution in alcohol reddens litmus, and has an acrid, bitterish taste. (For further details, see *Copaiba.*)

Action, Medical Uses, and Dosage.—(See *Copaiba.*) Dose, 1 to 15 grains, preferably in emulsion.

RESINA DRACONIS.—DRAGON'S BLOOD.

A resin derived from the fruit of *Calamus Draco*, Willdenow (*Dæmonorops Draco*, Blume).

Nat. Ord.—Palmæ.

Botanical Source.—*Calamus Draco* is a small palm growing in the islands of the Indian archipelago. While the plants are young the trunk is erect, and resembles an elegant, slender palm tree, armed with innumerable dark-colored, flattened elastic spines, often disposed in oblique rows, with their bases united. By age they become scandent, and overrun trees to a great extent. The leaves are pinnate, their sheaths in petioles armed as above described; leaflets single, alternate, ensiform, margins remotely armed with stiff, slender bristles, as are also the ribs; 12 to 18 inches long and about ¾ inch broad. The spadix of the female is hermaphrodite and inserted by means of a short, armed petiole on the mouth of the sheath opposite to the leaf, and is oblong and decompound, resembling a common oblong panicle. Spathes several, one to each of the 4 or 5 primary ramifications of the spadix, lanceolate and leathery; all smooth except the exterior or lower one, which is armed on the outside. Calyx turbinate, ribbed, mouth 3-toothed, by the swelling of the ovary split into 3 portions, and in this manner adhering, together with the corolla, to the ripe berries. Corolla 3-cleft; divisions ovate-lanceolate, twice as long as the calyx, and permanent. Filaments 6, very broad, and inserted into the base of the corolla. Anthers filiform, and seemingly abortive. Ovary oval; style short; stigmas 3-cleft; divisions revolute and glandular on the inside. The berry is round, pointed, and of the size of a cherry (L.—Roxb.).

History and Description.—Dragon's blood is a dark-red substance, which is imported from the East Indies, and which is procured from the berries of the *Calamus Draco*, by rubbing or agitating them in a bag, softening by heat the resinous exudation obtained, and making this up into masses. An inferior grade is obtained by boiling the crushed fruits in water (*Pharmacographia*). There are several sorts of it, one (*Red dragon's blood*), occuring in dark reddish-brown sticks, a foot or more in length, and from 3 to 6 lines in diameter, enveloped with palm leaves, and bound with narrow slips of cane; another occurs in reddish-brown lumps of the size and shape of an olive, also covered with leaves in a moniliform row; another, of very fine quality, is a reddish powder; a fourth occurs in large, irregular pieces or tears, while an inferior kind is in very large masses or lumps, *Lump dragon's blood*, presenting a heterogeneous fracture (P.). Dragon's blood is brittle, feebly sweetish, or almost tasteless, and odorless. It is not acted upon by water, but is almost all dissolved by alcohol, wood alcohol and ether, only impurities being left undissolved; partly soluble in chloroform and benzene. It fuses by heat, and emits a benzoic-acid-like fume on burning. Its solution stains marble a fine deep-red color.

Chemical Composition.—Herberger found dragon's blood to consist chiefly of a red resin (90.7 per cent) which he called *draconin*. He also established the presence of benzoic acid. Hlasiwetz and Barth by fusing dragon's blood with caustic potash obtained *benzoic*, *para-oxy-benzoic*, *oxalic* and probably *protocatechuic acids* E. Hirschsohn (*Jahresb. der Pharm.*, 1877, pp. 54 and 404) established the behavior of genuine dragon's blood toward solvents and reagents. It is soluble in alcohol and ether with red color, less so in chloroform; if the article is derived from *Pterocarpus Draco* of the West Indies, it will be but little soluble in chloroform. Petroleum ether abstracted only from 1 to 7 per cent of soluble matter. Dragon's blood, in connection with other resins, was investigated in recent years by Prof. Tschirch and his pupils. K. Dieterich (*Jahresb. der Pharm.*, 1896, p. 159) examined a specimen derived from *Dæmonorops Draco* (Java and Sumatra) and found it to contain: (1) *Dracoalban* (2.5 per cent) an amorphous indifferent, not fusible body, abstracted by ether and precipitated by alcohol; it has the formula, $C_{20}H_{40}O_4$; (2) *dracoresin* (13.58 per cent) soluble in petroleum ether, alcohol, and ether, of the formula, $C_{20}H_{44}O_2$, fusing at 74° C. (165.2° F.); (3) *red resin* (56.8 per cent), a mixture of two esters, namely, compounds of the alcohol, $C_8H_{10}O_2$ (*draco-resino-tannol*) with *benzoic acid* ($C_6H_5.COOH$) and with *benzoyl acetic acid* ($C_6H_5.CO.CH_2.COOH$); (4) a *resin* soluble in alcohol, insoluble in ether (0.33 per cent); (5) *phlobaphenes* (0.03 per cent); (6) woody fragments, etc. (18.40 per cent); (7) ash (8.30 per cent). *Draco-resino-tannol* yields, upon dry distillation, benzene (benzol), toluene, styrol, phenyl acetylene, phenol, resorcin, pyrogallol, phloroglucin, acetic acid and creosote.

Action, Medical Uses, and Dosage.—Dragon's blood was formerly considered an astringent, and used in doses of from 10 to 30 grains in *passive hemorrhages*, *diarrhœa*, etc. Its principal use is to color tooth powders, plasters, tinctures and varnishes, and to produce a mahogany wood-stain (aloes 1 part, dragon's blood 1 part, alcohol 15 parts).

Related Drugs.—SOCOTRA DRAGON'S BLOOD, or *Katir*, is the product of *Dracæna Schizantha*, Baker, or, according to Hunter, the *Dracæna Ombet* of Kotschy. It is produced in Socotra. It differs from the Sumatra drug in the absence of scales, and in not evolving benzoic acid vapors when heated (*Pharmacographia*).

CANARY ISLAND DRAGON'S BLOOD is the product obtained by incising the stem of *Dracæna Draco*, Linné, of the Canary Isles. *Pterocarpus Draco*, Linné, of West Indies and South America, yields a resin known also as dragon's blood, as does *Croton Draco*, Schlechtendal, the product of the latter, however, being more of the nature of kino (*Pharmacographia*). According to Prof. H. Trimble (*Amer. Jour. Pharm.*, 1895, p. 516), a specimen received from Jamaica was for the most part soluble in warm water and contained 46.7 per cent of tannin, referred to dry substance, hence it closely resembled kino. The foregoing are not in general commerce. For an analytical study of the various red resins known as dragon's blood, see J. J. Dobbie and G. G. Henderson, *Amer. Jour. Pharm.*, 1884, p. 327).

RESINA JALAPÆ (U. S. P.)—RESIN OF JALAP.

Preparation.—"Jalap, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Moisten the powder with three hundred (300) cubic centimeters [10 fl℥, 69 ♏] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed. gradually adding alcohol, until twenty-five hundred (2500) cubic centimeters [84 fl℥, 257 ♏] of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distill off the alcohol, by means of a water-bath, until the tincture is reduced to four hundred (400) grammes [14 ozs. av., 48 grs.], and add the latter, with constant stirring, to nine thousand (9000) cubic centimeters [304 fl℥, 155 ♏] of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice. by decantation, with fresh portions of water. Place it upon a strainer, and, having pressed out the liquid, dry the resin with a gentle heat, stirring occasionally until the moisture has evaporated"—(*U. S. P.*). The yield by this process is officially required to be not less than 12 per cent (see *Jalapa*), but this figure is now seldom attained with jalap imported from Mexico, about 7 to 8 per cent being the average yield. Prof. Flückiger ascribes the decrease in yield to fraudulent abstraction of resin by means of alcohol, probably practiced by some Mexican dealers. He advocates the cultivation of jalap in Europe, pointing out that the tubers in one instance where jalap was cultivated, yielded 22.7 per cent of resin, referred to dry material (*Amer. Jour. Pharm.*, 1890, p. 141; also see E. R. Squibb, *Ephemeris*, Vol. III, pp. 1095 and 1248). Mr. F. H. Alcock proposes an assay of jalap for resin by means of amyl alcohol (*Amer. Jour. Pharm.*, 1892, p. 534).

Description and Tests.—As officially demanded resin of jalap should be in "yellowish-brown, or brown masses or fragments, breaking with a resinous, glossy fracture, translucent at the edges, or a yellowish-gray or yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. Permanent in the air. Its alcoholic solution has a faintly acid reaction. Soluble in alcohol in all proportions; insoluble in carbon disulphide, benzol, and fixed or volatile oils. Not more than about 10 per cent of it is soluble in ether. On evaporating the ethereal solution, and dissolving the residue in potassium hydrate T.S., a reddish-brown liquid is formed, from which the resin is reprecipitated by acids. If that portion of resin of jalap which remained undissolved by ether be dissolved in potassium hydrate T.S., the addition of an acid does not precipitate it"—(*U. S. P.*). The resinous portion, not soluble in ether, is usually called *convolvulin* (W. Mayer). (For details regarding the chemistry of the resin, see *Jalapa*.) "Resin of jalap should not suffer any material loss of weight when heated at 100° C. (212° F.) (absence of water). Water triturated with it should neither become colored, nor take up anything soluble from it (absence of soluble impurities). On digesting 1 Gm. of resin of jalap for about an hour, with frequent agitation, in a glass-stoppered vial, with 10 Cc. of ammonia water, at a temperature of about 80° C. (176° F.), it should yield a solution which does not gelatinize on cooling (absence of common resin)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Jalap owes its cathartic powers to its resin; while its mucilage or gum has been reputed diuretic. The dose of the resin prepared, as stated above, is from 1 to 6 or 8 grains; it is apt to occasion much pain and griping, which may be frequently obviated by trituration with castile soap, resin of caulophyllum, or loaf-sugar.

RESINA PODOPHYLLI (U. S. P.)—RESIN OF PODOPHYLLUM.

SYNONYMS: *Podophyllin, Resin of mandrake, Resin of May-apple.*

Preparation.—The *U. S. P.* process for preparing podophyllin is as follows: "Podophyllum, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; hydrochloric acid, ten cubic centimeters (10 Cc.) [162 ♏]; alcohol, water, each, a sufficient quantity. Moisten the powder with four hundred and eighty cubic centimeters (480 Cc.) [16 fl℥, 111 ♏] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until sixteen hundred cubic centimeters (1600 Cc.) [54 fl℥, 49 ♏] of tincture are obtained, or until the tincture ceases to produce more than a slight turbidity when dropped into water. Distill off the alcohol, by means of a water-bath, until the tincture is reduced to a syrupy consistence, and pour it slowly, with constant stirring, into one thousand cubic centimeters (1000 Cc.) [33 fl℥, 391 ♏] of water, previously cooled to a temperature below 10° C. (50° F.), and mixed with the hydrochloric acid. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of cold water. Spread it, in a thin layer, upon a strainer, and dry the resin by exposure to the air in a cool place. Should it coalesce during the drying, or aggregate into lumps having a varnish-like surface, it should be removed, broken in pieces, and rubbed in a mortar. As this is liable to happen during warm weather, resin of podophyllum is preferably made during the cold season"—(*U. S. P.*).

The original process of this *Dispensatory* directs us to take of strong tincture of mandrake root (see *Resinæ*), 1 pint; water, acidulated with 18 fluid drachms of hydrochloric acid, 1 gallon. Mix the tincture and the acidulated water together, allow the mixture to stand for 24 hours, or until there is no further precipitate, collect the precipitate on a filter, wash it with water, and then allow it to dry in a warm place not exceeding 26.6° or 29.4° C. (80° or 85° F.). Or, the alcohol may first be removed by evaporation in a warm bath; and the resin then be allowed to precipitate. The resin has also been obtained by precipitation without heat, by adding a solution of alum to a saturated tincture of the root. This makes a yellow alum lake. Podophyllin prepared by means of alum has never been popular with Eclectic physicians.

History.—The resin of podophyllum has enjoyed a far more extensive use in medicine than the crude drug from which it is prepared. Though official in the *U. S. P.*, and, strange to say, now more extensively used by members of the regular school of medicine than by our own practitioners, *podophyllin* is an Eclectic drug, having been first discovered and introduced to the profession by Prof. John King.* The practitioners of the old school employ this resin in nearly all of their vegetable cathartic pills. Of its introduction, Prof. John King says: "This valuable agent I had the honor of introducing to the profession 26 years since. In 1835, I was first led to an examination of the resinous principle of this plant, as well as of the iris, cimicifuga, aletris, and several other plants, in consequence of some information given me by Prof. Tully, of Yale College, New Haven, Conn., relative to the resinous constituent of the Cimicifuga racemosa. And since August, 1835, I have prepared and used, more or less in my practice, in the treatment of various forms of disease, the resins of podophyllum, iris, cimicifuga, alcoholic extract of aletris, and several other medicinal plants. In July, 1844, I first called public attention to the resins of podophyllum and iris, in the *New York Philosophical Medical Journal*, Vol. I, No. 7, pp. 157-161, in which I recommended the mandrake resin in combination with an alkali, for hepatic diseases, scrofula, dropsy, leucorrhœa, syphilis, gonorrhœa, gleet, obstructed menstruation, etc., but of which it appears but little notice was taken by the profession. In April, 1846, I again called the attention of the profession to this, as well as many other concentrated preparations, in the *Western Medical Reformer*, Vol. V, No. 12, pp. 175-178. Now, as dates are the only reliable source of correct information in such matters, unless some one can show an earlier notice of these articles, and of their practical utility, than the above, their claims will naturally be considered doubtful. The credit of first preparing resin of podophyllum, and other concentrated preparations, for the use of the profession generally, it being part of his avocation, belongs to Mr. W. S. Merrell, druggist and chemist, of Cincinnati, who first manufactured it in June, 1847, since which time it has become an indispensable and highly important American remedy, and is used by all classes of physicians, being generally preferred to mercurials by those who have fairly tested it" (J. King, in *College Journal*, 1857, p. 557).

---

* Podophyllin was the first of the "Eclectic" resinoids, being discovered by Prof. John King, in 1835, and quickly followed by him with cimicifugin and the oleoresins of iris and aletris. These substances were introduced to commerce by the late W. S. Merrell, who took pains to at once bring them before the commercial world. The firm of B. Keith & Co., of New York, followed, and made a specialty of "resinoids." Grover Coe contributed to the movement by his widely-distributed book—*Concentrated Organic Medicines*. But the history of "American resinoids" would make a volume, and can not be undertaken herein. We have therefore, carried from former editions of this work, Prof. King's remarks verbatim, and append this note only.

Prof. King further adds: "I am indebted to the late F. D. Hill & Co., of Cincinnati (A. D., 1852), for the following process of manufacturing resin of podophyllum. Exhaust coarsely powdered mandrake root with alcohol, by percolation. Place the saturated tincture in a still, and distill off the alcohol; the residue will be a dark fluid of the consistence of molasses; sometimes it is thicker, and when this is the case add a small portion of it to some water, and if it does not form a yellow-whitish precipitate, a small quantity of alcohol must be added to it, or enough to cause the light precipitate. Then warm the thick residual fluid, and slowly pour it into three times its volume of cold water, which must be constantly agitated during the process. If poured in too fast, or without agitation, the fluid will fall to the bottom unchanged. Allow it to stand for 24 hours, at which time nearly all the resin of podophyllum will be precipitated, the addition of a sufficient quantity of muriatic acid will precipitate the remainder. The precipitated resin of podophyllum, of a whitish-yellow color, is now to be removed and placed on a linen filter, and washed several times with water, to remove any remaining acid, gum, etc., after which it is to be placed in thin layers on paper, and dried in a room of a temperature between 65° aud 90° F., or, if in summer, at the natural atmospheric temperature. It becomes a shade or two darker by drying in this manner, but if artificial heat be employed to hasten the process, or a higher temperature, the resin becomes quite dark."

Description.—Resin of podophyllin varies in color according to its mode of precipitation, being, when precipitated by heat, dark-brown; and when by acid, a light brownish-yellow; or greenish-olive if by alum. It is insoluble in water, oil of turpentine, and diluted nitric acid; soluble in alcohol. By partial oxidation of the resin, soon after its preparation, a portion of podophyllum resin ceases to be dissolved by alcohol. From 3 to 6 per cent of resin is obtained from the mandrake root.

J. U. Lloyd has previously printed the following description of podophyllin: "As made by precipitation of the residue of a pure alcoholic tincture in cold distilled water it presents the following characteristics: If alcohol is present, the resin separates as a light-colored, porous powder. If it be not present, the resin precipitates in a dark, nearly black, resinous cake. This, when powdered, is of a dark-gray, or often nearly brown color, and is the description preferred by Prof. King. If the alcoholic percolate be poured into alum water instead of pure water, the resin precipitates of a bright-yellow color, and dries easily. This yellow podophyllin is in reality an alum lake, and, while it is easier to make it (for it dries like chalk) than to make the pure resin, it has been strongly opposed by Prof. King, and has never been recognized by the *Pharmacopœia of the United States*. Podophyllin has a strong odor of May-apple, and is intensely active when made without alum."

As described by the *U. S. P.*, resin of podophyllin occurs as "an amorphous powder, varying in color from grayish-white to pale-greenish-yellow or yellowish-green, turning darker when exposed to a heat over 35° C. (95° F.); having a slight, peculiar odor, and a peculiar, faintly bitter taste. Permanent in the air. Its alcoholic solution has a faintly acid reaction. Soluble in alcohol in all proportions; ether dissolves 15 to 20 per cent of it; boiling water dissolves about 80 per cent, and deposits most of it again on cooling, the remaining, clear, aqueous solution having a bitter taste, and turning brown on the addition of ferric chloride T.S. Resin of podophyllum is also soluble in potassium or sodium hydrate T.S., forming a deep-yellow liquid, which gradually becomes darker, and from which the resin is reprecipitated by acids"—(*U. S. P.*). Mr. G. M. Beringer (*Amer. Jour. Pharm.*, 1894, p. 9) points out that the pharmacopœial statement regarding the solubility of the resin in ether is erroneous, and the statement of its solubility in boiling water (adopted from experiments by Prof. F. B. Power, 1877), due to abnormal experimentation. The solubility of the resin in ether is about 80 per cent, and in boiling water about 23 per cent. These conclusions are confirmed by Nagelvoort (*ibid.*, 1894, p. 279). According to Beringer, chloroform dissolves about 80 per cent of the resin.

Chemical Composition.—For details regarding the chemistry of resin of podophyllum (*podophyllin*), we refer the reader to the article *Podophyllum*. The name *podophyllin* was not coined by Eclectics, but was suggested by Mr. J. P.

Hodgson. Podophyllin may be assayed for *podophyllotoxin* by extracting 1 Gm. with cold chloroform, evaporating the greater portion of the solvent, and pouring the solution into 20 volumes of petroleum ether. The podophyllotoxin is collected on a tared filter, dried, and weighed. A. Kremel found commercial samples of resin of podophyllum to yield from 20 to 30 per cent of podophyllotoxin (*Amer. Jour. Pharm.*, 1889, p. 177).

Action, Medical Uses, and Dosage.—Podophyllin possesses the cathartic properties of the crude drug in an exalted degree. While it is slow in action, it is certain in its results. Some persons are so susceptible to the action of the drug, that a dose of $\frac{1}{2}$ grain will actively purge them. The ordinary cathartic dose of this resin generally requires from 4 to 8 hours to act, but this action is quite persistent, often producing copious alvine discharges for 1 or 2 days, and when over leaves the intestines in a normal condition, seldom being followed by the after-constipation so common from the use of ordinary purgatives. As with the crude drug the cathartic action of podophyllin is increased by common salt. From 4 to 8 grains operate as an active emeto-cathartic, with griping, nausea, prostration, and watery stools; from 2 to 4 grains, as a drastic cathartic, with nausea and griping; from $\frac{1}{2}$ to 2 grains generally operates as an active cathartic, leaving the bowels in a soluble condition; in very small doses, it is gently aperient and alterative. In doses of $\frac{1}{2}$ or 1 grain, it is one of our most valuable cholagogue cathartics, operating mildly, yet effectually, arousing the whole biliary and digestive apparatus to a normal action, and which is very persistent in its character. "The action of this resin in affections of the liver has been doubted or denied by some practitioners, but, as we think, on erroneous grounds, judging from the beneficial results following its use in these affections, whether those results be due to direct influence upon the liver, or to an indirect one. Certainly, its effects in this class of diseases, are superior to those of the so-termed cholagogue mercurials" (J. King). It likewise exerts a favorable influence on the cutaneous functions, producing and maintaining a constant moisture on the skin. In doses of from $\frac{1}{8}$ to $\frac{1}{2}$ grain, or rather in sufficient doses not to purge, it acts as a powerful alterative, and will induce ptyalism in some persons. This drug should not be given in bulk, but should be combined with ginger, hyoscyamus, leptandra, or resin of caulophyllum, or some form of alkali, which renders it less liable to nauseate or gripe. Should catharsis be too severe, an alkaline solution, with aromatics, by mouth or enema, will check it. A popular and good method of preparation is that of triturating it with milk sugar (*lactin*). This not only obviates, to a certain extent, its irritant action, but singularly increases its purgative qualities. During its administration, all articles of food difficult of digestion should be avoided. According to Prof. Locke, podophyllin prepared by alum water is apt to gripe. Eclectics long made use of this agent in those cases where mercurials were used by other practitioners, and found the result vastly in favor of resin of podophyllum. It appeared to fulfil all the indications for which mercurials were recommended and used.

It is not, however, for its cathartic use that podophyllin is most valued by the Eclectic profession, but rather for its specific effect when given in small doses. Properly administered it is a stimulant to the sympathetic nervous system, acting principally upon the parts supplied by the solar plexus. It improves digestion and blood-making and stimulates normal excretion. For its action upon the liver, repeated small doses of the trituration (1 to 100), or a daily pill of podophyllin ($\frac{1}{20}$ grain) and hydrastin ($\frac{1}{4}$ grain) is much to be preferred to its cathartic dose. It should be given in the same manner when its action on the pancreas and spleen is desired.

Few physicians appreciate the action of this drug, in small doses, in *gastric* and *intestinal disorders*. It exerts a peculiarly specific action on all forms of stomach and bowel trouble with atony, characterized by full and relaxed tissues, with mucous discharge. The case is never one of loss of function from irritability, but from atony. In the *summer disorders of children*, especially *cholera infantum*, it will be often indicated, and is quick to restore normal action when the bowels are loose, with passages of mucoid, slimy material. The movements of the child are sluggish, the tongue is coated a dirty yellowish-white, the superficial veins are full, and the countenance is dull and expressionless. In many cases of chronic disease, associated with feeble digestive power, which is but little improved by the ordinary stomach tonic, this remedy will render excellent service. The trouble is usually atony of the upper part of the small intestines, and the stimulant dose of triturated podophyllin overcomes the difficulty. Podophyllin is a favorite anti-constipation remedy. It is equally valuable in *costiveness* of the young child and in the aged. In very young babies this trouble will yield to: R Podophyllin, 2d dec. trit., grs. xxx; brown sugar, ʒii; aqua, ℥iv. Mix. Sig. Teaspoonful, 4 times a day. For adults the daily use of from 1 to 2 of the podophyllin and hydrastin pills ($\frac{1}{20}$ and $\frac{1}{4}$ grain) will generally be sufficient to overcome the trouble. The cathartic dose should never be employed for the relief of costiveness, or when a cholagogue action is required. When the stools are hard and grayish-white or clay-colored, and float upon water, the remedy is peculiarly effective, as it is also in dry stools, with tympanitic abdomen and wandering, colicky pains. *Flatulent colic* of children, when associated with constipation, will readily yield to small doses of this drug, while, as a remedy for *dysentery* and both *acute* and *chronic diarrhœa*, accompanied by portal sluggishness and hepatic torpor, few remedies will excel it. *Dyspepsia*, with atony and thickened mucous membranes secreting abundantly, calls for stimulant doses of podophyllin. The head feels full, the tissues and veins appear full and doughy, the skin is sodden, and a dirty coating covers the tongue from tip to base. R Podophyllin, $\frac{1}{20}$ grain, 3 times a day. *Cardialgia*, accompanied with constipation, yields to the trituration (1 to 100). This drug has been justly valued in *hepatic disorders.* In that state ordinarily known as "*biliousness*," this drug or specific iris can usually be depended upon. Indeed, they act very nicely in combination. There is dizziness, a bitter taste, the stools show an absence of bile, and greenish, bitter material is vomited. The remedy is often indicated in both *acute* and *chronic hepatitis*, though usually contraindicated in inflammations of the gastro-intestinal tract. Fullness in the region of the liver, with aching under the scapulæ and in the back of the neck, with dizziness, usually calls for this drug. In *icteric states*, with clay-colored stools, it may be alternated with chionanthus. The unpleasantness attendant upon the retention or passage of *biliary calculi*, is frequently relieved by this agent. There is great pain in the region of the gall bladder coursing to the left and downward. Sometimes there is constipation, as often diarrhœa. There is a bad taste, and the patient is often jaundiced. R Podophyllin, gr. ij, at night, followed in the morning with a large quantity of olive oil. In *hemorrhoids*, dependent on biliary insufficiency with portal inactivity, it may be given in alternation with sulphur, the podophyllin being particularly desired when there is constipation with tenesmus. The small dose alone is required, from $\frac{1}{20}$ to $\frac{1}{10}$ grain, 3 or 4 times a day.

Podophyllin may do good service in those forms of *cough* characterized by *bronchorrhœa*, especially if it be associated with *gastric catarrh.* Here minute doses of sulphur are also valuable. In *heart disease*, when aggravated by hepatic inactivity and portal torpor, the cardiac remedy will be rendered more efficient if associated with minute doses of this drug. It has long been recognized as a remedy for *rheumatism*, when the patient is sallow and inactive, presents fullness of tissue, and complains of dull pain and heaviness in the right hypochondrium. In *renal disorders*, when the general specific indications for its use are present, it will restore the secretory power of the kidneys. Podophyllin has long enjoyed the reputation of exerting a powerful action upon the whole glandular system. For a long time it was, and is still with many, a favorite remedy in *syphilitic manifestations.* For persistent *pustular conditions*, *eczema*, and *cracked* or *fissured skin*, Ellingwood declares it a good remedy. It acts powerfully as an alterative, one of the best in the whole domain of medicine, at the same time aiding and improving the digestive process.

Podophyllin is a remedy for *pain*, according to Prof. Scudder—that deep-seated pain in the ischiatic notches. It has served a good purpose in *inflammations* (when not of the digestive tract), accompanied with great constipation. Here the cathartic action is required, as it is also in the forming stage of *febrile diseases*, with the exception of typhoid fever. Still, if indicative fullness be present, the small dose will assist very materially in overcoming these disorders. For its derivative action in *brain disorders*, large doses will be necessary, as is also the case in *dropsy*. In *malarial troubles*, small doses of podophyllin should be alternated, or given with cinchona. For all of the preceding uses specific podophyllum may also be used, but the dose must be correspondingly larger. For the gastric disorders many prefer it to the resin. Cathartic doses are required in *biliary calculi*, *apoplexy*, *dropsy*, and in some forms of *inflammation*. Younkin advises cathartic doses ($\frac{1}{6}$ grain, every 2 hours, with 10 grains of potassium bitartrate) for the relief of *gonorrhœal epididymitis*. The dose of podophyllin, as a cathartic, is from $\frac{1}{2}$ to 2 grains; as an alterative and stimulant, $\frac{1}{100}$ to $\frac{1}{10}$ grain; as a cholagogue, $\frac{1}{20}$ to $\frac{1}{10}$ grain. A good form in most disorders requiring the small dose, is the following: ℞ Podophyllin trituration (1 in 100), grs. v to xxx; aqua, ℥iv. Dose, 1 teaspoonful, every 1 to 3 hours.

Specific Indications and Uses.—Podophyllin is specifically indicated by fullness of tissues, fullness of veins, sodden, expressionless countenance, dizziness, tongue coated dirty yellowish-white, heavy headaches, indisposition to bodily exertion, intestinal atony, with sense of weight and fullness, full open pulse; "pain deep in ischiatic notches," and as an ideal cholagogue; clay-colored stools, floating upon water; stools, hard, dry, and accompanied with distended abdomen and colicky pain. It is contraindicated by pinched features, and small, wiry pulse, or when the pulse has a sharp stroke.

RESINA SCAMMONII (U. S. P.)—RESIN OF SCAMMONY.

Preparation.—"Scammony, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Digest the scammony with successive portions of boiling alcohol until it is exhausted. Mix the tinctures, and reduce the mixture to a syrupy consistence by distilling off the alcohol. Then add the residue in a thin stream, with active stirring, to twenty-five hundred (2500) cubic centimeters [84 fl℥, 257 ♏] of water, separate the precipitate formed, wash it thoroughly with water, and dry it with a gentle heat"—(*U. S. P.*). The resin of the *British Pharmacopœia* differs in regard to the source, being prepared from the root direct instead of the resin, though the final product is essentially the same, except that, as found by Hess (1875), it contains some tannin (compare *Scammonium*).

Description.—"Yellowish-brown or brownish-yellow masses or fragments, breaking with a glossy, resinous fracture, translucent at the edges; or a yellowish-white or grayish-white powder, having a faint, peculiar odor, and a slight, peculiar taste. Soluble in alcohol in all proportions; also wholly soluble in ether and in oil of turpentine. Ammonia water and solutions of alkalies dissolve it with the aid of a gentle heat; from these solutions the resin is not reprecipitated by acids"—(*U. S. P.*). (For report on commercial resins of scammony, see *Amer. Jour. Pharm.*, 1892, p. 122; and 1882, p. 543.)

Action, Medical Uses, and Dosage.—Uses same as for scammony (see *Scammonium*), the pure resin being about twice the strength of the latter. Dose, 3 to 8 grains, rubbed up with milk, or in combination in pills.

RESORCINUM (U. S. P.)—RESORCIN.

FORMULA: $C_6H_4(OH)_2$. MOLECULAR WEIGHT: 109.74.

SYNONYMS: *Resorcinol*, *Metadioxybenzol*.

"A diatomic phenol. Resorcin should be kept in dark amber-colored vials"—(*U. S. P.*).

Source, History, and Preparation.—This substance was discovered in 1864 by Hlasiwetz and Barth in the process of fusing galbanum resin (see *Galbanum*) with caustic potash, neutralizing with sulphuric acid and extracting with ether. The ethereal extract yielded upon distillation besides fatty acids an oily body which crystallized in the retort. Owing to its similarity to *Orcin*, the mother substance of several lichen coloring matters (see *Lacmus*), discovered in 1829 by Robiquet, the authors named the new substance *resorcin*. This process yielded

6 per cent. Similarly, resorcin may be obtained from other resins, such as ammoniacum, guaiacum, sagapenum, asafœtida, acaroid, etc., and by the dry distillation of *brasilin* or dry extract of brazil wood. It is now prepared on a large scale by fusing the sodium salt of benzene-meta-disulphonic acid ($C_6H_4[SO_3H]_2$) with caustic soda, neutralizing with acid and extracting with ether. The following reaction takes place: $C_6H_4(SO_3Na)_2+2NaOH=C_6H_4(OH)_2+2SO_3Na_2$ (sodium sulphite).

Description and Tests.—Resorcin forms "colorless or faintly reddish, needle-shaped crystals or rhombic plates, having a faint, peculiar odor, and a disagreeable, sweetish and afterward pungent taste. Resorcin acquires a reddish or brownish tint by exposure to light and air. Soluble, at 15° C. (59° F.), in 0.6 part of water, and in 0.5 part of alcohol; very soluble in boiling water, or in boiling alcohol; also readily soluble in ether or glycerin; very slightly soluble in chloroform. When heated to a temperature between 110° and 119° C. (230° and 246.2° F.), resorcin melts, a higher melting point indicating a greater degree of purity. At a higher heat it is completely volatilized. The aqueous solution is neutral or only faintly acid to litmus paper"—(*U. S. P.*). Resorcin is meta-diphenol, *i. e.*, benzene, substituted by two hydroxyl groups in the meta position (1, 3). It is isomeric with *pyrocatechin* (ortho-diphenol, 1, 2) and *hydroquinone* (para-diphenol, 1, 4). The name *resorcinol* was also given to resorcin to indicate its phenol nature; it must not be confused, however, with the noncrystalline, brown substance introduced by Bielaiew (see *Pharm. Centralhalle*, 1892, p. 714) under the same name. This new resorcinol is obtained by heating together resorcin and iodoform, to the point of fusion. It has an unpleasant taste, and somewhat the odor of iodine, and is said to be efficient in certain skin diseases, etc. Resorcin is chemically very active. It reduces both silver nitrate and Fehling's solution upon boiling. When bromine water is added to its aqueous solution, small colorless needles of *tribromresorcin* ($C_6HBr_3[OH]_2$) are precipitated, which are sparingly soluble in cold, more readily in hot water and in alcohol (see analogous reaction with phenol under *Acidum Carbolicum*). Unlike pyrogallol (which see), resorcin is not precipitated by ferrous sulphate, or by neutral lead acetate; it is precipitated, however, by basic lead acetate. *Resorcin black*, a dye for wool and silk, is obtained in the form of a black solution by adding sulphate of copper to an aqueous solution of resorcin, then sufficient ammonia to redissolve the precipitate. *Lacmoid*, a possible substitute for litmus as indicator, is obtained by heating resorcin with sodium nitrite; for use as indicator, dissolve lacmoid (0.5 Gm.) in water (100 Cc.) and alcohol (100 Cc.). Resorcin produces some characteristic color reactions. The *U. S. P.* enumerates the following: "On adding a few drops of ferric chloride T.S. to 10 Cc. of a diluted aqueous solution (1 in 200) of resorcin, the liquid assumes a bluish-violet color. If 0.1 Gm. of resorcin be dissolved in 1 Cc. of potassium hydrate T.S. and a drop of chloroform added, the mixture, upon being heated, will assume an intense crimson color. If a slight excess of hydrochloric acid be then added, the color will change to a pale straw-yellow. On cautiously heating 0.05 Gm. of resorcin with 0.1 Gm. of tartaric acid and 10 drops of concentrated sulphuric acid, a thick, carmine-red liquid will be formed, becoming pale yellow when diluted with water"—(*U. S. P.*). When the latter test is carried out with oxalic acid, a blue mixture is obtained which turns red upon dilution with 10 Cc. of water and 20 Cc. of alcohol of 91 per cent (by volume). Upon now adding aqua ammoniæ, the solution is carmine-red in transparent light, and greenish-yellow in reflected light. Citric acid gives a blue-green fluorescence (Flückiger, *Pharm. Chemie*, Vol. II, 1888, p. 329). These coloring matters are analogous to those known as *phtaleines* (see *Aniline Dyes* and *Fluorescein*, page 1652). Resorcin should wholly volatilize, without residue, when heated in a platinum or porcelain vessel. "A concentrated aqueous solution (1 in 2) of resorcin should be colorless (absence of empyreumatic bodies), and when gently heated should not emit the odor of phenol"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Resorcin has been compared to carbolic acid in physiological effects. Though regarded as less valuable than the latter as an antiseptic, a 1 per cent solution will preserve the normal acidity of the urine for weeks, and will prevent changes in animal structures and solutions of organic material. Applied to the skin in 1 or 2 per cent solutions it does not induce irritation of the integument and is free from the toxic effects which sometimes follow the local use of carbolic acid. It may also be applied to corneal wounds, the conjunctiva and gums and favors the union of wounds by first intention. Upon animals it has proved a narcotic and convulsive poison producing death. No lethal effects have been reported from its use upon man, though it has induced decided narcosis and convulsions. In the case of a woman who took 120 grains (Murrell, 1881) no spasms occurred, the patient first becoming dizzy, and then losing consciousness. Relaxation of the limbs, almost imperceptible pulse and respiration, subnormal temperature, pallor, olive-green urine, and excessive cold sweating were the other symptoms. Complete recovery took place in a day's time. The larger therapeutic doses may occasion a flushed face, tinnitus aureum, dizziness, acceleration of the pulse and respiration, and profuse sweating. Sixty grains have produced the added symptoms of collapse and insensibility. Andeer's two experiments distinctly show the effects of the drug. Deep narcosis was produced by 160 grains of resorcin, in a quart of water, taken in the course of a couple of hours. Upon a second trial a like amount was dissolved in 1 pint of water and taken within 15 minutes. He experienced ocular disturbances, such as light flashes with dimness of sight and palpebral heaviness. Loss of smell and hearing followed; the tongue became thick, extremities cold, a profuse cold sweat bathed his body and he fell in epileptiform convulsions, with irregular respiratory movements; the limbs flexed spasmodically, and finally opisthotonos occurred. Deep unconsciousness prevailed from which he was aroused after five hours' treatment, with the result of absolute lapse of memory as to what had taken place. No after-effects were observed after 24 hours. Alcohol is the antidote for poisoning by resorcin.

Resorcin has been used as an antipyretic but has been abandoned for the purpose by the majority of physicians as a dangerous agent. It is, however, at the present day, given for its antiseptic and healing effects in destructive diseases of the stomach, such as *gastric ulcer*, *cancer*, etc. It is also said to control *vomiting* produced by various causes, such as *sea-sickness*, *gastric ulcers*, *pregnancy*, *drunkenness*, *menstrual disorders* and *renal* and *hepatic colic*. It has also been used in *typhoid fever*, *pneumonia*, *inflammatory fevers* during the pus-forming stage, in *bronchorrhœa*, *gastric catarrh*, and advised in *diphtheria* (Andeer). These uses of the drug (except in gastric ulcer) have not been generally imitated by eclectic practitioners, and about the only internal use of the drug made by them has been the following: In 1 to 2-grain doses every 6 hours in *gastric irritation* from fermentation, in ½ grain doses in *cholera infantum*, and in 2 grain doses in *gastric ulcer*, the drug always being administered well diluted with water.

Locally, however, resorcin is a valued remedy. In spray it may be used in *whooping-cough*, *hay fever*, *laryngeal tuberculosis* and *ulceration of the larynx*. Washes of from 1 to 3 per cent strength have proved useful in catarrhal profluvia, as *ozœna*, *otorrhœa*, *fetid leucorrhœa* and *gonorrhœa*. A 10 per cent solution applied directly to the membrane has been lauded in *non-laryngeal diphtheria*, but probably it possesses no marked advantages over other antiseptic applications, none of which can be relied upon to the exclusion of internal treatment. In *eye diseases* a 3 per cent ointment of resorcin, or an ointment containing an addition of 3 per cent of sulphur, or a 1 to 3 per cent solution is useful in *non-ulcerative blepharitis*, in *corneal wounds*, and in *conjunctivitis* in both the acute and chronic forms. The solutions are beneficial in *suppuration of the middle ear* and have the advantage over many other agents in not causing maceration of the drum membrane (Foltz). A petrolatum resorcin ointment (equal parts) has been reported efficient in *carcinoma*. The chief use that has been made of resorcin is in *skin diseases*. Here it gives its best results. It is used very much in the same disorders as those benefited by carbolic acid. In from 5 to 30 per cent ointment it has been successfully applied in *pityriasis capitis*, *alopecia pityroides*, *squamous eczema of the scalp* and *seborrhœal eczema*. A 10 to 20 per cent ointment has acted well in *psoriasis*. It is useful in *parasitic eczema*, resembling psoriasis and pityriasis versicolor, the papules being depressed and itching severely. *Acneiform eczema*, *eczema flavum* and *lichen circumscriptus*, particularly if facial, are well treated with a weak ointment of resorcin (Thin's *Report;* see *Eclectic Medical Journal*, 1888, p. 37). *Frost-bite*, *fissures*, *erythema*, and *erysipelas* are conditions relieved by resorcin, applied in solution or ointment.

The internal dose of pure resorcin should range from 1 to 5 grains well diluted with water, though larger doses have been given without danger. As a rule its internal employment is contraindicated by cardiac affections, diphtheria, menstrual disorders, pneumonia, pulmonary œdema, last stages of continued fevers, typhoid fever, tuberculosis (last stages), arterio-sclerosis, and all exhaustive and debilitating diseases (Blake, *Ec. Annual*, Vol. IV, p. 18). Solutions may be used from 1 to 20 per cent in strength; ointment, 2 to 50 per cent.

Resorcin, in the form of ointment or solution, has been successfully employed upon diseases about the feet of horses.

Specific Indications and Uses.—Gastric irritation from fermentative food-changes; gastric ulcer. Locally in fetid mucous profluvia; eczematous and parasitic skin affections, with pruritis, and in papules with depressed center and much itching.

Related Compounds.—Thioresorcin ($C_6H_4O_2S_2$), a yellowish amorphous powder soluble in caustic alkalies, and their carbonates and sulphides. It is prepared by heating resorcin (1 molecule), sulphur (3), and sodium hydroxide (3), in the presence of water. It is precipitated from this solution by an acid. This agent is used like iodoform but has not superseded that article, and it is reputed not wholly innocuous.

Resopyrine.—Rhombic crystals produced by severally dissolving antipyrine (30 parts and resorcin (11 parts) in water (3 parts in each case). A crystalline mass results which is dissolved in alcohol and crystallized. It is odorless and has a feebly pungent taste. Alcohol (5 parts), chloroform (30), and ether (100) dissolve it; it is insoluble in water.

Pyrocatechin, *Catechol, Orthodioxy-benzene.*—This substance occurs in the products of the dry distillation of wood and of iron-greening tannins, *e. g.*, catechin, kino, while the iron-bluing tannins yield dioxy-benzene, or pyrogallol. It crystallizes in needles, soluble in alcohol, water and ether. It melts at 104° C. (219.2° F.), and boils at 245° C. (473° F.). It is best prepared from its methyl ether guaiacol (which see) by heating it with hydriodic acid. The reaction is as follows: $C_6H_4(OCH_3).OH+IH=C_6H_4OH.OH+ICH_3$ (methyl iodide). Pyrocatechin strikes emerald-green with ferric chloride, the color changing to a handsome violet-red upon treatment with sodium bicarbonate. Introduced as an antipyretic but discarded on account of its pernicious effects.

Hydrochinone, *Hydroquinone, Hydroquinol, Paradioxy-benzene.* This body is generally prepared by oxidizing aniline with a mixture of potassium bichromate and sulphuric acid, whereby quinone ($C_6H_4O.O$) is formed. The latter is then reduced to hydroquinone by means of sulphurous acid. It was first obtained in 1844 by Wöhler by destructive distillation of quinic (kinic) acid and may be prepared in like manner from oxysalicylic and succinic acids. It is isomeric with resorcin and pyrocatechin. It forms long, dimorphous crystalline leaflets without color or odor. Alcohol, ether and hot water readily dissolve it; cold water less readily. In concentrated solution it forms dark green crystals of *quinhydrone* when ferric chloride is added; if the latter be in excess yellow quinone results, the crystals being redissolved. Hydrochinone is largely employed to develop photographic plates. A 1 per cent solution checks alcoholic fermentation and putrefactive processes. Upon man the symptoms produced by doses of 40 or more grains are cerebral fullness, giddiness and ringing in the ears, accompanied with a reduction of the frequency and force of the heart action. It is decidedly antipyretic in the smaller doses (3 to 10 grains), but larger amounts tend to produce nervous phenomena, chills, and profuse perspiration. Its power of quickly reducing the temperature is marked and has been taken advantage of in the febrile exacerbations of *phthisis* and in the excessive temperature of *septicæmia, erysipelas, acute rheumatism of the joints* and *general tubercular affections.* Its employment in *pneumonia, pleurisy, scarlatina*, etc., is not to be commended. Occasionally it is used as a gastro-intestinal antiseptic. The urine is colored deep brown or greenish-brown by hydrochinone taken internally, and the drug, when mixed with solution of urea rapidly decomposes the latter. Dose, 2 to 20 grains.

Fluorescein, *Fluorescin* ($C_{20}H_{12}O_5$), *Resorcin-phtalein.*—This body is formed when phtalic anhydride (5 parts) and resorcin (7 parts) are melted together. It forms a deep red or brownish powder or crystals. It is not easily soluble in cold water, but dissolves in alcohol with a yellowish-red color and in ammonia with a red color, both solutions exhibiting a beautiful green fluorescence. This substance is analogous to phenolphtalein (see *Aniline Dyes;* also see *Eosin*, below). Used in ophthalmic practice to diagnose *corneal abrasions* and to locate *foreign bodies* imbedded in the surface of the eyeball. It does not affect the corneal epithelium, but wherever this is absent it produces a green spot; and around foreign bodies it shows a green encircling line. Recent corneal abrasions may be differentiated from old ones, the latter taking no stain; also in *corneal infiltration* the stain may be produced, while no discoloration occurs in *hypopyon keratitis* (Foltz).

Eosin, *Tetrabrom-Fluorescein* ($C_{20}H_8Br_4O_5$).—This body is formed by acting upon *resorcin-phthalein* (fluorescein) with bromine, and it is the potassium salt of this substance ($C_{20}H_6Br_4O_5K_2$) that is used under the name *soluble eosin.* It is a bronze-colored crystalline powder with a greenish reflection. In water it dissolves red with a green fluorescence which is destroyed by hydrochloric acid, the fluid assuming a yellow color. Eosin is largely used as a dye material and as a coloring reagent in microscopy. Eosin 5 grains, gum acacia 10 grains, and water 1 fluid ounce make a fine red ink.

RHAMNUS CATHARTICA.—BUCKTHORN.

The fruit (berries) of *Rhamnus cathartica*, Linné (*Cervispina cathartica*, Moench). *Nat. Ord.*—Rhamnaceæ.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 64.

Botanical Source.—Buckthorn is a shrub from 6 to 15 feet in height. Its branches are alternate or nearly opposite, spreading, straight, round, smooth, hard, and rigid, each terminating in a strong spine, after the first year. The leaves are 1 to 2 inches long, about two-thirds as wide, deciduous, bright-green, smooth, simple, and ribbed; the young ones downy; the earlier ones in tufts from the flowering buds; the rest opposite, on the young branches. Petioles downy. Stipules linear. Flowers yellowish-green, on the last year's branches, and numerous; the fertile ones with narrow petals, rudiments of stamens, and a deeply 4-cleft style; the barren ones with an abortive ovary and broader petals. The berries are globular, bluish-black, nauseous, with 4 cells, and as many elliptical, plano-convex seeds (L.).

Fig. 206.

Rhamnus cathartica.

History and Description.—Buckthorn is indigenous to Europe, and has been observed in this country as an introduced plant. It flowers from April to July, and matures its fruit about the middle of autumn. The parts used are the berries; they are globular, 3 or 4 lines in diameter, slightly compressed at the apex, black, glossy, and inclose a green pulp in which the seeds are imbedded. The juice becomes gradually red, owing to the development of acetic acid, and may be preserved long unchanged in the form of a syrup. It is soluble in water. When evaporated to dryness with alum, or lime and gum Arabic, it forms the color called *sap-green*. Carbonate of sodium and caustic potash change the solution of sap-green to yellow. Sulphuric, nitric, and hydrochloric acids turn it red. Hence, paper tinged with sap-green might be used as an indicator in place of litmus.

Chemical Composition.—The cathartic principle of this shrub is *rhamnocathartin*, a bitter, amorphous substance, isolated from the juice of the berries by Binswanger (1849), and previously by Hubert and Winckler. Mr. George W. Kennedy (*Amer. Jour. Pharm.*, 1885, p. 497) observed the same substance as a brownish deposit from a fluid extract of the bark. It was amorphous, soluble in caustic alkali with deep-purplish-red color, reprecipitated by acids, soluble in diluted and strong alcohol, insoluble in chloroform and ether, nearly so in water, and possessing strongly laxative properties in 3-grain doses. The resin, held in solution by the fluid extract, differed from that mentioned, by being soluble in ether and chloroform. *Rhamnotannic acid* was also isolated from the berries by Binswanger. The coloring matters of the berries were frequently investigated, and consist of the crystallizable glucosid *rhamnin* (Stein, 1868 and 1869; *rhamnegin* of Lefort and Schützenberger), and especially its decomposition product, *rhamnetin* (*rhamnin* of Fleury and Lefort), which is also crystallizable. This substance is likewise a constituent of the unripe berries of *Rhamnus infectoria* (see *Related Species*). *Rhamnin* crystallizes in pale-yellow, or golden-yellow, tasteless needles, readily soluble in water, diluted alcohol, and boiling alcohol, nearly insoluble in ether, chloroform, benzol, and carbon disulphide. Soluble, with yellow color, in caustic alkalies. *Rhamnetin* (*methyl quercetin*, J. Herzig, 1891) crystallizes in small, golden-yellow plates, nearly tasteless, hardly soluble in water, soluble in boiling alcohol (58.5 parts), and in ether (76 parts). It is soluble, with yellow color, in alkalies, and reduces Fehling's solution and silver nitrate solution in the cold. (For details regarding the earlier chemistry of the constituents of rhamnus, see Husemann and Hilger, *Pflanzenstoffe*, Vol. II, 1884, pp. 889–896.)

Action, Medical Uses, and Dosage.—Buckthorn berries (*Rhamni baccæ*) are powerfully cathartic; 20 of the recent berries cause brisk, watery purging, with nausea, dryness of the throat, thirst, and tormina. These effects are partly removed by giving the juice (*Rhamni succus*) in the form of syrup, and which formerly enjoyed much reputation as a hydragogue in *gout*, *rheumatism*, and *dropsy;* at present it is seldom employed in practice, but is occasionally employed as an adjunct to other cathartic and diuretic mixtures. Prof. Scudder suggests a trial of small doses of a tincture (berries, ℥viii, to alcohol, 76 per cent, Oj) as a stimulant to the vegetative processes, for its influence on the digestive tract, and in *diseases of the nose, throat, and lungs.* Dose of the syrup, from ½ to 1 fluid ounce. Dose of the tincture, 2 to 30 drops, well diluted with water. A tincture of the bark, made in the same proportions as that of the berries, may be given in doses of from 6 to 30 drops.

Related Species.—*Rhamnus infectoria*, Linné. Berries resemble in appearance buckthorn berries, except that their color is green-brown or brown. They are known as *French berries*, and yield several yellow coloring matters. According to Liebermann and Hörmann (*Jahresb. der Pharm.*, 1878, p. 433; and 1879, p. 195) the berries of *R. infectoria* and *R. tinctoria* contain about 12 per cent of glucosidal coloring matters. One of these glucosids is Kane's *xanthorhamnin* (*rhamnin* of Stein; see *R. cathartica*). Diluted acids split it into *rhamnetin* ($C_{12}H_{10}O_5$) and *isodulcit* ($C_6H_{14}O_{10}$). The decomposition is also brought about by ferments existing in the berries, hence rhamnetin is a prominent constituent of the latter. More recently, J. Herzig (*Chem. Centralblatt*, Vol. II, 1891, p. 306) established rhamnetin to be the *methyl ether of quercetin*, and to have the formula $C_{16}H_{12}O_7$, or $C_{15}H_9O_6(OCH_3)$.

Persian Berries, the fruit of several species of Rhamnus (*R. amygdalina*, Desfontaines; *R. saxatalis*, Linné, etc.) skirting the Mediterranean, also yield these color pigments.

RHAMNUS PURSHIANA (U. S. P.)—CASCARA SAGRADA.

The bark of *Rhamnus Purshiana*, De Candolle (*Rhamnus alnifolius*, Pursh; *Frangula Purshiana*, Cooper).

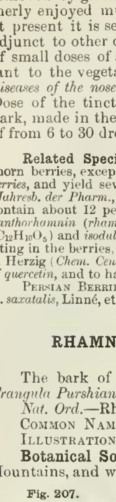
Nat. Ord.—Rhamnaceæ.

Common Names: *Chittem bark, Sacred bark.*

Illustration: Hooker, *Flora Bor. Amer.*, Vol. I, Plate 43.

Botanical Source and History.—This is a small tree, found in the Rocky Mountains, and westwardly to the Pacific Ocean, and extending north into British America. According to Mr. James G. Steele, the country producing the tree extends over 1000 miles in length. The branches are round and pubescent. The leaves are from 3 to 5 inches long, about one-half as broad, and are borne on leaf-stalks nearly an inch in length. When young they are covered with a dense pubescence on the under surface, but become glabrous and bright-green when old. In outline, they are broadly elliptical, obtuse, and entire at the base, and generally with a blunt, acute apex. The margin of the leaf is regularly dentate, with numerous small, serrate teeth, except at the base. The lateral veins are many, subparallel, prominent underneath, and proceed from the midrib at an acute angle. The leaves closely resemble, but are not so slender as those of the Alder buckthorn, or Southern buckthorn, of our southern states (*Frangula caroliniana*, Gray, or *Rhamnus caroliniana*, Walter). The flowers are small, white, and appear after the leaves have matured; they are borne in close, umbellar clusters, on pubescent peduncles, slightly longer than the leaf-stalks. The pedicels are short, about ¼ inch in length when in flower, but, in fruit, elongate to an inch or more. The calyx is small, 5-cleft, and pubescent on the outer surface. The petals are 5, minute, white, shorter than the calyx lobes, and 2-cleft at the apex. The stamens are 5, opposite, and embraced by the concave petals. The pistil, which is much shorter than the calyx-tube, consists of a free, 3-celled, and 3-ovuled ovary, a short style, and a 3-lobed stigma. The fruit is a small black drupe, obtusely 3-angled, about the size of a large pea, and contains 3 black, shining seeds. The genus Rhamnus is represented by 6 native species, and all, excepting *R. lanceolata*, Pursh, and *R. alnifolia*, L'Heritier, are found on the Pacific coast.

Fig. 207.



Genuine Cascara sagrada.

A few of the western species have evergreen coriaceous leaves. *Rhamnus californica*, Eschscholtz (*Frangula californica*, Gray), known as California buckthorn, or California coffee tree, probably furnishes a portion of the Cascara sagrada of commerce (see *Related Species*). The bark of *California mountain holly* (*Rhamnus crocea*) is aromatic and bitterish, and has both tonic and laxative qualities.

Cascara sagrada was discovered by an Eclectic physician, Dr. J. H. Bundy, its virtues being first extolled in "*New Preparations*," Detroit, 1877. Parke, Davis & Co. introduced the fluid extract to the medical profession and gave it great conspicuity. It may be confidently said that to their efforts is due the widespread celebrity of this drug and its preparations.

Description.—The bark is the part used in medicine, and has long been known in domestic practice among western people as a mild cathartic. Cascara sagrada is officially described as "in quills or curved pieces, about 3 to 10 Cm. (1⅕ to 4 inches) long, and about 2 Mm. ($\frac{1}{12}$ inch) thick; outer surface brownish-gray and whitish; the young bark having numerous, rather broad, pale-colored warts; inner surface yellowish to light brownish, becoming dark-brown by age; smooth or finely striate; fracture short, yellowish, in the inner layer of thick bark somewhat fibrous; inodorous; taste bitter"—(*U. S. P.*).

Chemical Composition.—Prof. Prescott (*Amer. Jour. Pharm.*, 1879, p. 165) described the microscopical structure and the chemical composition of the bark, which he finds to contain: (1) A *brown resin*, bitter to the taste, soluble in alcohol, chloroform, benzol, and carbon disulphide; insoluble in ether; slightly soluble in water. Solution of caustic alkalies dissolve it with purple-red color, from which solution acids precipitate it. Charcoal removes it from its alcoholic solution. It occurs chiefly in the middle and inner layers of the bark. (2) A *red resin*, nearly tasteless, insoluble in water; slightly soluble in ether, chloroform, and carbon disulphide; soluble in alcohol, and in caustic alkali with a brown color. Animal charcoal does not remove it from its solution in alcohol. It occurs in the corky layer of the bark. (3) A *light-yellow resin*, neutral, tasteless, insoluble in water; soluble in hot alcohol, chloroform, and carbon disulphide; not colored by potassium hydroxide solution.

In addition, Prof. Prescott obtained a tannic acid, oxalic acid, malic acid, a yellow fixed oil, volatile oil, wax, starch, and a neutral crystallizable body. The latter substance, from solution in absolute alcohol, crystallized in the form of white, double pyramids, which were almost insoluble in ether, chloroform, and petroleum ether; soluble in benzol. They melt and sublime, unchanged, at a temperature little above the heat of a water-bath, condensing into crystalline form. The substance does not give alkaloidal reactions. Prof. Prescott believes that some of these substances are closely related to constituents of *Rhamnus frangula*. P. Schwabe (*Archiv der Pharm.*, 1888, p. 591) found the bark to contain *emodin* ($C_{15}H_{10}H_5$) (see *Rhubarb*), but was unable to confirm the statement of Prof. W. T. Wenzell (1886), that a crystallizable glucosid (not identical with *frangulin*) is present in the bark (see *Frangula*). A. R. L. Dohme and H. Engelhardt (*Proc. Amer. Pharm. Assoc.*, 1897, p. 198) succeeded, however, in isolating from cascara sagrada a glucosid, which they named *purshianin*. Leprince, in 1892, obtained an orange-red substance, which he named *cascarin* ($C_{12}H_{10}O_5$), and which F. L. Phipson (*Comptes Rendus*, 1892) believes identical with *rhamnoxanthin* of Buchner (see *Frangula*). Messrs. H. F. Meier and J. LeRoy Webber (*Pharmacology of the Newer Materia Medica*, Detroit, 1892) found the bark to contain a ferment, occurring especially in recent bark, and being destroyed by heat. To this principle, it is claimed, the unpleasant griping and vomiting effects of recent bark are due. The authors also state that a glucosid is present, which is not bitter, but yields a bitter principle upon hydrolysis with acids or the gastric juice. Dr. R. G. Eccles (*Druggists' Circular*, 1888, p. 54) reported the presence of an alkaloid in cascara bark.

Action, Medical Uses, and Dosage.—Cascara sagrada, when introduced as a medicine, was highly recommended as a certain remedy in cases of *habitual constipation*, and in some forms of *indigestion*. Further trial has substantially sustained these assertions, and it is, undoubtedly, a valuable addition to our list of therapeutical agents. It does not, however, succeed in all cases, but acts best where a tonic to the intestines is required. As it tones the whole intestinal tract, it is valuable in doses of 10 drops, after meals, for that dyspeptic condition which depends most largely upon constipation, and is due to intestinal weakness. Administered in large doses, it has served us nicely in *sick headache*, due to like causes. Loss of tone in the rectum, with constipation, giving rise to *hemorrhoids*, is benefited by it. In *chronic constipation* it may be necessary to begin with the larger doses, and gradually reduce the quantity to a few drops, 3 times a day, though, as a rule, it is better to give repeated small doses, gradually increased, until the desired action is obtained, and then to gradually withdraw the drug. It acts kindly without irritating or griping, and produces stools of a semifluid consistence. Occasionally, but rarely, have reports of harsh action been made, such as cramps, colic, vomiting, and inordinate catharsis, while a soreness of the bowels, persistent in character, has been attributed to it. These effects, however, are not common. The remedy, in 10 to 15-drop doses, has been used with asserted success in *rheumatism*. *Chronic diarrhœa*, when due to hepatic sluggishness, has been checked by this agent, and it is said to be of some value in *gastric*, *duodenal*, and *biliary catarrh*, with *jaundice*. It is commonly prepared in the form of a fluid extract, the dose of which is from 10 to 60 minims, repeated, as required, 2 or 3 times a day. The powder may be given in 5-grain doses; the solid extract in 2 or 3-grain doses.

Specific Indications and Uses.—Constipation, due to neglect or to nervous and muscular atony of the intestinal tract; lesser ailments, depending solely upon constipation, with intestinal atony.

Related Species and Pharmaceutical Preparations.—*Rhamnus californica*, Eschscholtz (*Frangula californica*, Gray), *California coffee tree*, *California buckthorn*. This agent constitutes a portion of some commercial lots of cascara sagrada. (For its differentiation from other species of Rhamnus, in powder, see *Amer. Jour. Pharm.*, 1897.) It was introduced as a remedy for *rheumatism* by Prof. H. T. Webster, M. D., of California, who contributed an article—"*Rhamnus Californica in Rheumatism*"—to the *Eclectic Medical Journal*, in July, 1895. Prof. Webster (*Ec. Ann. of Med. and Surg.*, 1895, p. 30) says of it: "Rhamnus californica is commonly known as the *California coffee tree*. It is a shrub, which grows to the height of 20 feet in some instances, and bears a berry which is first green, then red, and finally, when ripened, black in color. This berry contains 2 seeds, resembling coffee-beans in shape, the flattened and grooved sides of the two lying in apposition, and being covered with a thin, sweetish-bitter pulp, resembling the choke cherry in taste, though the berry is as large as a marrowfat pea. It grows in the Sierras, in the coast range, and along the coast from Santa Barbara as far north as southern Oregon." In this connection, Dr. Rusby states (*Amer. Jour. Pharm.*, 1890, p. 532) that *Rhamnus californica* grows sparingly in northern California, but becomes more abundant southward and eastward, through Mexico and Arizona, while *Rhamnus Purshiana* is abundant from northern California northward, so that the place of collection forms presumptive evidence of the botanical origin of the bark. "It has been used in domestic practice as a substitute for *Rhamnus Purshiana*, and it has, doubtless, been a common practice to sophisticate the latter with the bark of *Rhamnus californica*, the resemblance between the two barks being very great, except that the bark of Rhamnus californica is thinner. California wholesale druggists designate the bark of the Rhamnus californica as '*thin cascara bark*.' Rhamnus californica (the bark) seems to me to be the most positive remedy for *rheumatism* and *muscular pain of rheumatoid character* that I have ever employed. A saturated tincture of the fresh bark, made in alcohol, may be administered in 15 or 20-drop doses, every 3 or 4 hours, in ordinary cases of *acute rheumatism*; 3 or 4 doses a day will answer in chronic cases. The preferable form of administration is that of a decoction of the recently dried bark. A heaping tablespoonful of the finely-broken bark is covered with a pint of cold water and steeped over a slow fire, it being allowed to simmer 15 or 20 minutes after reaching the boiling point. Of this 1 or 2 tablespoonfuls may be administered every 3 or 4 hours. If a laxative effect follows this dose, the amount to be administered must afterward be reduced until the cathartic effect is avoided. Catharsis is not necessary for its effective action. I have found it very effectual in long-standing and obstinate *dysmenorrhœa* (not requiring surgical interference). It may be administered in the manner already described, and should be continued 3 or 4 months, about 4 times a day. The dose of specific Rhamnus californica ranges from 10 to 30 drops. A variety of this plant, with white, tomentose leaves, is said to grow in New Mexico and Arizona" (Webster).

KASAORA.—This is a palatable preparation of cascara sagrada (a mild laxative), prepared exclusively by Messrs. Frederick Stearns & Co., Detroit, and was introduced by this firm under the name of "Cascara Aromatic."

ELIXIR PURGANS.—This compound is prepared exclusively by Eli Lilly & Co., Indianapolis, Ind., and is extensively used as a pleasant purgative and laxative. It contains and fully represents Rhamnus Purshiana, Euonymus atropurpureus, Cassia acutifolia (purified), Iris versicolor, and Hyoscyamus leaves combined with aromatics.

Colubrina reclinata, Brongn., *Mabee bark*.—South America. Contains 9.7 per cent of a bitter glucosid (W. Elborne and H. Wilson, *Pharm. Jour. Trans.*, Vol. XV, 1885, p. 831), and is employed in the West Indies as a gastric stimulant.

Colubrina asiatica, Brongn. (*Ceanothus asiatica*, Linné; *Rhamnus lævigatus*, Sol.).—Fiji Islands and Australia. The leaves are used by natives of the Fijis to cleanse the hair and destroy vermin (Maiden).

Alphitonia excelsa, Reissek (*Colubrina excelsa*, Fenzl), *Red ash*, *Leather jacket.*—Australia. Used occasionally in tanning (Maiden).

RHEUM (U. S. P.)—RHUBARB.

"The root of *Rheum officinale*, Baillon"—(*U. S. P.*).

Nat. Ord.—Polygonaceæ.

COMMON NAMES: *Rhubarb root* (*Rhei radix, Br.*).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 213, 214, 215.

Botanical Source and History.—The botanical origin of the species which yielded the best rhubarb, formerly known in commerce as the Russian rhubarb, imported from China via Kiachta, in Siberia, is not known; no competent observer has ever been able to see the growing plant in its native habitat, the mountainous country Tangut, in Chinese Tartary, near the source of the Hoang-ho River. Chinese rhubarb is probably derived from more than one species; the closest approach to it is that described by Baillon, in 1872, as *Rheum officinale*, the description being taken from a plant successfully grown at Montmorency. This originated from leaves and cuttings forwarded to Dr. Soubeiran, of Paris, in 1867, by the French Consul at Hankow, China, Mr. Dabry de Thiersant, who obtained them from southeastern Thibet through French missionaries. Offsets of the French plant were also forwarded to England, in 1876, and cultivated with success by Rufus Usher, in Bodicote, in Oxfordshire. The common garden rhubarb (from *R. rhaponticum* and *R. undulatum*) had been in cultivation in England since 1608. The official rhubarb is that from *Rheum officinale*, which grows in southeastern Thibet, and probably other localities of the Chinese Empire.

RHEUM OFFICINALE, Baillon, according to *Pharmacographia*, is a "perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars. The leaves spring from a distinct crown, rising some inches above the surface of the ground; they have a sub-cylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short, erect hairs. The lamina, the outline of which is orbicular, cordate at the base, is shortly 5 to 7-lobed, with the lobes coarsely and irregularly dentate. It attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display, before expanding, the peculiar, metallic-red hue of copper" (p. 492).

In addition, we quote from Mr. W. Elborne (*Pharm. Jour. Trans.*, Vol. XV, 1884–85, p. 136): "The best distinguishing character of *Rheum officinale* is the strong development of the sympodium or root-stalk, a large portion of which projects conically above the ground, being provided with a few lateral roots, about the thickness of a finger. Also the first epidermis of the radical portion is remarkable for the bright brownish-red color, the roots of the other species being yellowish-brown."

The *microscopical structure* of the official root is described by Mr. W. Kirkby (see W. Elborne, *loc. cit.*) as follows: "The outer layer, immediately beneath the epidermal portion, consists of about 8 rows of the tabular parenchyma, extended tangentially. Within this is a broad zone of loose parenchyma, containing starch, into which the medullary rays entered about half way across. Next comes the dark cambial line, made up of several rows of closely compacted, oblong parenchyma, exhibiting the radial arrangement of the medullary rays. Between the medullary rays are seen groups of large, reticulated vessels, consisting of from 1 to 5 vessels, arranged, for the most part, in a radial manner. They are surrounded by unthickened, elongated parenchyma. The coloring matters are found in the medullary rays. The center of the root shows no definite arrangement of the tissues, being a mass of parenchymatous cells, interspersed irregularly by the medullary rays. The whole root is loaded with starch. The granules are generally compound. The larger single granules have a diameter of about 20 micro-millimeters. The hilum is generally, but only slightly, eccentric, and is seen as a small, black dot. When mounted in Canada balsam, the black cross is distinctly visible with polarized light. Raphides (crystals of calcium oxalate) are fairly numerous, and vary considerably in size. In the loose tissue of the root, just within the zone of radial medullary rays, are found scattered the stars so characteristic of Chinese rhubarb; these exhibit all the anatomical features of the root. *R. officinale* differs chiefly from Chinese rhubarb in that it contains more starch, and from *R. rhaponticum* in the vessels and cells of the medullary rays being larger, and the arrangement of the various tissues being less distinct and regular." (Also see microscopical study of several species of Rhubarb, by Prof. L. E. Sayre, *Amer. Jour. Pharm.*, 1898, pp. 129–135.)

Cultivation and Collection.—Little is known about the cultivation and collection of Chinese rhubarb, the best of which seems to be obtained from wild varieties (Flückiger, *Pharmacognosie des Pflanzenreichs*, 3d ed., 1891, p. 399). According to Pereira, "the method of curing or preparing Asiatic rhubarb for the market varies somewhat in different localities. In China it is as follows: The roots are dug up, cleansed, cut in pieces, and dried on stone tables, heated beneath by fire. During the process, the roots are frequently turned. They are afterward pierced, strung upon cords, and further dried in the sun. In Tartary the roots are cut in small pieces, in order that they may dry the more readily, and a hole is made in the middle of every piece, through which a cord is drawn, in order to suspend them in any convenient place. They hang them, for the most part, about their tents, and sometimes on the horns of their sheep. Sievers, however, states that the roots are cut in pieces, strung upon threads, and dried under sheds, so as to protect them from the rays of the sun. He also tells us that sometimes a year elapses from the time of their collection until they are ready for exportation." The best grade is that known as *Shensi rhubarb*.

As regards cultivation in Europe, Mr. Elborne remarks (*loc. cit.*) that, as a general principle, forced cultivation produces a plant inferior in medicinal value, because it is chiefly inert tissue which is benefited by such cultivation. Propagation is effected from offsets or lateral shoots of 4-year-old plants, set at distances of 6 to 8 feet apart, and left to grow from 5 to 7 years, then the roots are ready for collection. They are dug up in dry weather, between July and September, peeled, sliced into pieces, known in trade as "flats" and "rounds." The rootlets furnish "small rounds," or "sticks." They are then exposed to a current of dry air in an open bedding for several days, and the drying is completed by exposure to artificial heat of 90° F., or, preferably, 80° F. for *Rheum officinale*.

Description and Commercial History.—As described by the *U. S. P.*, rhubarb occurs "in cylindrical, conical, or flattish segments, deprived of the dark-brown, corky layer, smoothish or somewhat wrinkled, externally covered with a bright, yellowish-brown powder, marked with white, elongated meshes, containing a white, rather spongy tissue, and a number of short, reddish-brown or brownish-yellow striæ; compact, hard; fracture uneven; internally white, with numerous red, irregularly curved and interrupted medullary rays, which are radially parallel only near the cambium line; odor somewhat peculiar, aromatic; taste bitter, somewhat astringent. When chewed, rhubarb feels gritty between the teeth, and imparts a yellow color to the saliva. Rhubarb which is very porous, or has a prominently mucilaginous taste, or is of a dark-brown color internally, should be rejected"—(*U. S. P.*). The grittiness observed when rhubarb is chewed is due to the oxalate of calcium present. Commercial rhubarbs, according to their geographical and botanical origin, may be classed as follows (Elborne, *loc. cit.*):

ASIATIC RHUBARBS.—*Chinese* (Russian, Muscovy or Turkey; Canton or East Indian; Batavian or Dutch-trimmed), yielded by *R. palmaticum* var. *tanguticum* and *R. officinale* (?). *Siberian*, from *R. rhaponticum*. *Himalayan* (*large*), from *R. Emodi*; *small*, from *R. Webbianum*. *Bucharian*, from *R. undulatum*.

EUROPEAN RHUBARBS.—*English*, from *R. rhaponticum* and *R. officinale*. *French*, from *R. rhaponticum*, *R. compactum*, and *R. undulatum*. *Austrian* (*Moravian*), from *R. rhaponticum*.

The former trade in *Russian rhubarb* was a government monopoly and the article, called *crown rhubarb*, has disappeared from commerce. It was collected in Chinese Tartary and sold to the Russian government, at the frontier town of Kiachta, where it was sorted by especially appointed apothecaries, and only the best grade accepted, the inferior grade being destroyed. It came to Europe by way of Asia Minor, and for this reason the term, *Turkey rhubarb*, established itself.

Since the opening of the Chinese ports to European commerce in the '60s, the trade via Kiachta rapidly declined. (For interesting details regarding Russian rhubarb and its trade, see A. Fero, *Amer. Jour. Pharm.*, 1867, p. 212; also *Druggists' Circular*, 1897, p. 278.) *Chinese* or *East Indian rhubarb* is that now mostly in use. It is the official kind of rhubarb. It was formerly brought from Canton, but is now collected in Hankow and exported from Tien-Tsin (see *Amer. Jour. Pharm.*, 1866, p. 153, for details regarding this grade). The *European rhubarb* (see *English Rhubarb* above) is produced in quite considerable quantity. Mr. Elborne (1884) reports that 12,000 pounds of English rhubarb were being gathered annually.

In selecting rhubarb, roots only should be taken which are sound and hard, of a bright-yellow color, of a strong rhubarb-aromatic smell, of a bitterish, slightly astringent taste, without viscidity, which feel gritty under the teeth, and which communicate a bright-yellow color to the saliva; they should present, when fractured, a marbled appearance of red and whitish veins, and be easily reduced to a bright-yellow powder, sometimes tawny-tinged (*Ed.*—T.). Inferior rhubarb is sometimes colored with turmeric, which may be detected by placing the rhubarb in powder on filtering paper, and moistening with chloroform, drop by drop. The turmeric color is thus transferred to the paper; dry the latter, moisten with solution of borax, then with hydrochloric acid. A brown-red tinge is formed if turmeric is present (see E. L. Howie, *Amer. Jour. Pharm.*, 1874, p. 16).

Rhubarb, if boiled in water till it becomes soft, then crushed and agitated in the water, deposits pale-gray sandy crystals of oxalate of calcium. Continued boiling injures its virtues. Proof-spirit is a more ready solvent of the active ingredients of rhubarb than water. Solution of caustic potash is colored blood-red by rhubarb. Lime-water causes at first a pale cherry-red haze, which slowly gives place to a red precipitate. Ferric chloride produces a green precipitate, and solution of isinglass a yellow, curdy deposit, owing to the presence of tannin.

Chemical Composition.—G. Dragendorff (*Jahresb. der Pharm.*, 1878, p. 74) analyzed 5 species of rhubarb, partly historical specimens, and found them to contain moisture (8.7 to 11.3 per cent), ash (3.2 to 24 per cent), mucilaginous matters (11 to 17 per cent), starch (6.2 to 16.5 per cent), sugar (3.7 to 5.5 per cent), cellulose, pectose, lignin, etc. (21 to 30 per cent), *cathartic acid* (2.03 to 5.25 per cent), oxalic acid (occurring as calcium oxalate, 1.12 to 4.6 per cent), malic acid (a trace to 1.24 per cent), free *chrysophanic acid* soluble in petroleum ether, absent or traces—in one instance 1.01 per cent—*chrysophan* and *tannin* (4.8 to 17.1 per cent), *emodin*, and resins soluble in alcohol, *e. g.*, *erythroretin*, *phæoretin*, etc. (1.15 to 6.29 per cent), white crystalline resin soluble in ether, insoluble in alcohol (0.15 to 2.32 per cent), fatty matter (traces, to 0.32 per cent), albuminous bodies (3.17 to 4.39 per cent). The results of an analysis of the species *Rheum officinale*, *R. rhaponticum* (both being *English rhubarbs*) and *East Indian* and *Russian rhubarbs*, by Mr. William Elborne (*Pharm. Jour. Trans.*, Vol. XV, 1884, p. 137) practically agree with those of Dragendorff. The latter considers *cathartic acid*, a glucosidal, nitrogenous substance, to be the purgative principle of rhubarb, greatly resembling that occurring in the leaves of senna and the bark of frangula. Quite recently, A. B. Stevens (*Proc. Amer. Pharm. Assoc.*, 1898, p. 339) again laid stress upon cathartic acid, and gave a method for its preparation. The tonic action of rhubarb, Dragendorff considers due to the tannin present (*rheo-tannic acid* [$C_{26}H_{26}O_{14}$] of Kubli), and the unmistakable antiseptic action, in cases of catarrhal affections of the intestines, due to the coloring matters *chrysophanic acid*, *emodin* and allied substances. Tschirch, however, finds the action of even chrysophanic acid to be decidedly purgative (*Archiv der Pharm.*, 1899, p. 632). *Chrysophanic acid* ($C_{15}H_{10}O_4$) was first isolated by Rochleder and Heldt, in 1843, from the wall-lichen *Parmelia parietina*. In 1844 its presence in rhubarb was recognized by Schlossberger and Dœpping, who also isolated several resins, *aporetin*, *phæoretin*, and *erythroretin*, all soluble in alkalies. Chrysophanic acid likewise occurs in the roots of certain species of Rumex (which see) and in goa powder (see *Acidum Chrysophanicum*). It crystallizes from alcohol in orange-yellow needles, soluble with yellow color in ether, alcohol (in 224 parts of 86 per cent); in petroleum benzin and amylic alcohol, almost insoluble in cold water. It dissolves in caustic alkali with beautiful dark-red color, but is insoluble in solution of sodium carbonate. According to M. Kubli (*Amer. Jour. Pharm.*, 1885, p. 614), chrysophanic acid usually does not exist as such in rhubarb, but occurs in the form of a glucosid called *chrysophan* (also see Dragendorff, previous page). Treatment of rhubarb with water seems to dissolve a ferment capable of converting chrysophan into chrysophanic acid. The same conversion with liberation of sugar in both cases, takes place upon boiling with diluted acids. Chrysophan is soluble in warm water, insoluble in ether and benzin. Chrysophanic acid is gradually deposited when a tincture of rhubarb weak in alcohol is allowed to stand. Warren de la Rue and Müller, in 1857, discovered in rhubarb a substance analogous to chrysophanic acid which they called *emodin* (compare *Frangula* and *Rhamnus Purshiana*). It crystallizes in long, red, monoclinic prisms, more easily soluble in alcohol than chrysophanic acid, but less soluble in benzol. It also differs by being soluble in solution of sodium carbonate. It has the formula $C_{15}H_{10}O_5$, and is *trioxy-methyl-anthra-quinone*, while chrysophanic acid is *dioxy-methyl-anthra-quinone*, both derivatives of the hydrocarbon *anthracene* ($C_{14}H_{10}$) (Liebermann and Waldstein, 1876).

In addition, J. O. Hesse (*Amer. Jour. Pharm.*, 1895, p. 615) obtained a third crystallizable principle *rhein* ($C_{15}H_{10}O_6$), which seems to be *tetra-oxy-methyl-anthraquinone.* Like emodin, it dissolves in sodium carbonate solution at ordinary temperature with deep purple-red color, but differs from it in being insoluble in hot toluene. It is physiologically inert. Hesse finds the purgative principle of rhubarb to reside in that portion of its ether extract which is dissolved by 80 per cent alcohol and from the latter extract dissolved by a weaker alcohol. The principle thus obtained is resinous, non-glucosidal, not yielding chrysophanic acid upon boiling with acids. It is somewhat acrid and bitter, acid in alcoholic solution, and strongly purgative.

These results, however, do not seem to be final (see J. O. Hesse, *Lieb. Annalen* Vol. CCCIX, 1899, p. 32; also A. Tschirch, *Archiv der Pharm.*, 1899, p. 632). Tschirch takes the ground that in the group of Frangula, Rheum, Senna and Aloe the purgative action is due to the presence of glucosids which are decomposed by the alkaline fluid of the intestines, whereby sugar and oxy-methyl-anthraquinones are formed. Of the latter, *emodin* in particular is decidedly active. In rhubarb, this glucosid is *chrysophan* (see above), the presence of which is confirmed also by Gilson (1898).

Action, Medical Uses, and Dosage.—Rhubarb is cathartic, astringent and tonic; as a cathartic, it acts by increasing the muscular action of the intestines, rather than by augmenting their secretions, and affects the whole intestinal canal, especially the duodenum. Its cathartic effect is succeeded by a mild astringency, which has gained for rhubarb the reputation of being secondarily a calmative, as well as a stimulant of the digestive canal; with its astringent influence, it likewise exerts for the most part, a tonic action on the stomach, improving the appetite and digestive powers. It is absorbed in the course of its operation, making the serum of the blood yellow, the sweat tawny, and the urine red, which may be distinguished from bloody urine by heating it. If blood be present it will coagulate, and remove the red color, which will not happen if the tint be owing to rhubarb. Rhubarb applied moist to the skin, or when used to dress ulcers, as it sometimes is, has produced its peculiar purgative effects. Rhubarb is much used as a laxative for infants, in many infantile diseases; its mildness and tonic qualities rendering it peculiarly applicable, especially when enfeebled digestion and irritation of the alimentary canal are present. In *acute* or *chronic diarrhœa* or *dysentery*, in convalescence from exhausting diseases, and in some irritable habits, where the mildest of all other laxatives are apt to excite hypercatharsis, rhubarb is an appropriate medicine. Its combination with soap or an alkali tends to counteract its astringent effects, and it thus becomes valuable in cases of *constipation.* It is useful in all cases of *fecal accumulations*, as it produces fecal, more than watery discharges. Sometimes it produces griping, which may be obviated by aromatics. The following pill I have found very beneficial in *dyspepsia* attended with constipation, *chronic diarrhœa* and *dysentery*, *habitual constipation*, *hepatic derangements*, *piles*, etc.: Take extract of rhubarb, extract of leptandra, hydrochlorate of berberine, and castile soap, of each, $\frac{1}{2}$ drachm. Mix them well together, and divide into 30 pills. Of these, 1, 2, 3, or 4 may be taken daily, sufficient to keep the bowels regular, without causing catharsis. When more than 1 are required daily, they should be given in doses of 1 pill at a time at regular intervals through the day (J. King). Prof. Locke recommends it in the *constipation of dyspeptics* with hepatic torpor, combining the neutralizing cordial with specific podophyllum or aloes. He also recommends it in *gout* and *rheumatism* with constipation, and as a gentle laxative after parturition. The cordial is recommended in the *nursing sore mouth of infants*. Rhubarb is efficient in the bowel disorders following the excessive use of alcoholics. The following is efficient during convalescence from *delirium tremens*: ℞ Leptandra, rhubarb, gentian āā, in powder, ℥i; ginger, ʒii; diluted alcohol, Oj. Macerate. Sig. Dose, 1 teaspoonful (Locke). Rhubarb is generally contraindicated in severe febrile or inflammatory affections. Toasting dissipates its purgative property considerably, but without diminishing its astringency, and it is, thus prepared, recommended by some practitioners in *diarrhœa*, *dysentery*, *cholera morbus*, and other diseases where astringents are indicated. In the ordinary *summer diarrhœa* of both children and adults, and particularly when an acid condition presents, the neutralizing cordial (Locke's formula preferred) is a most excellent corrective.

Specifically rhubarb is employed for a different action from that given above which represents the old but excellent uses of the drug. The specific object sought is the control of *gastro-intestinal irritation*, and this is nicely accomplished by the use of small doses of specific rheum. The red-pointed tongue, evidencing gastro-intestinal irritation, is the direct indication for its use. Add to this vomiting, nervous irritability as manifested by restlessness, screaming and convulsive muscular contractions, and the specific field of rhubarb is clearly set forth. The common method of administration is as follows: ℞ Specific rheum, ʒi; water, ℥iv. Dose, a teaspoonful every ½ or 1 hour. The same doses given less often act as an excellent gastro-intestinal tonic, giving better digestion and controlling the *papescent diarrhœa of indigestion* when present. In *chronic constipation* with a sense of constriction in stomach and bowels and contraction of the abdominal muscles, 10 drops of specific rheum may be given in a full glass of cold water in the morning. Fatty inunction of the abdomen adds to its efficacy. In conjunction with cod-liver oil and phosphorus preparations Prof. Scudder administered rhubarb where an "increased nutrition of nerve tissue" was demanded.

Dose of the powder as a purgative, from 10 to 30 grains; as a laxative, from 5 to 10 grains; as a tonic, from 1 to 5 grains; of the tincture or syrup, 1 or 2 fluid drachms; of neutralizing cordial, 1 to 4 fluid drachms. For specific effects, from $\frac{1}{10}$ to 5 drops of specific rheum.

Specific Indications and Uses.—Gastric irritation, nausea, vomiting, elongated tongue reddened at tip and edges; irritative diarrhœa with tenderness on pressure; sour smelling discharges imparting to the child a sour odor; gastro-intestinal irritation with nervous irritability, restlessness, screaming and convulsive muscular contractions; constipation, with a sense of intestinal constriction and abdominal contraction; light-colored fecal discharges.

Related Species.—*Rheum Emodi*, Wallich (*R. australe*, Don.) *R. Moorcroftianum*, *R. speciforme* and *R. Webbianum* are Himalayan species of rhubarb. (For description of these and the following species see Lindley, *Flora Medica*, p. 354.)

Rheum palmatum, Linné.—This plant inhabits the country near the great wall of China. It was cultivated in Russia soon after 1750, when a Tartarian merchant supplied Dr. Boerhaave, physician to the emperor of Russia, with what were believed to be the seeds of genuine rhubarb. Guibourt strongly held that *R. palmatum* was the botanical sonrce of genuine rhubarb of China, a view supported by the Russian Colonel Przewalski, who observed this species and collected specimens thereof in 1872-73 in the Chinese province of Kansu. The specimens, however, by analysis of Dragendorff (see *Rheum*) proved to be different from authentic specimens of the genuine root.

Rheum hybridum, Murray, and its variety *Colinianum* are cultivated, the former in Europe and the latter in Asia. Their roots agree with rhubarb.

Rheum undulatum (*Bucharian rhubarb*) and *R. compactum* are two species cultivated in France. The petioles of the latter species are used for pies.

Rheum rhaponticum, Linné, *Common garden rhubarb.*—This plant inhabits the borders of the Black Sea and is more abundant north of the Caspian, in the deserts between the Volga and the Yaik; also on the mountains of Krasnojar in Siberia. This has a more disagreeable smell than rhubarb, and is not so gritty to the taste. It is cultivated in this country and Europe, for pies, etc. The prepared root has the resemblance of true rhubarb, but not its medicinal properties. R. Otto believes the continued use of the petioles of rhubarb for pies, etc., to be injurious to health owing to the oxalic acid (0.2 to 0.3 per cent) it contains in soluble form in addition to insoluble calcium oxalate (*Drug. Cir.*, 1895, p. 150).

Perezia adnata, Gray (*Trixis Pipitzahoac*, Schaffner) (*Nat. Ord.*—Compositæ.—The rhizome of this plant is employed as a laxative and contains a violently purgative acid, which also imparts to the urine a greenish color. *Pipitzahoic acid* ($C_{15}H_{10}O_3$) is obtained by extracting the roots with alcohol of 82 per cent and precipitating with water. It forms beautiful yellow or reddish scales (*vegetable gold*) soluble in alcohol, ether, chloroform and carbon disulphide, nearly insoluble in water. It is sublimable. In alkali it dissolves with beautiful violet color. It has also been obtained from *Perezia Wrightii*, Gray, and *Perezia nana*, Gray, both from southwestern Texas. As a drastic cathartic the dose is from 4 to 8 grains. The acid is an oxyquinone (Anschütz).

Rhinacanthus communis, Nees (Acanthaceæ).—India and China. Root-bark of this shrub contains viscous, tasteless, *rhinacanthin* ($C_{14}H_{18}O_4$), not a glucosid (Liborius). In some respects it resembles chrysophanic acid. The leaves and woody root have been employed in *ringworm* and other *skin affections* (see complete analysis, by P. Liborius, in *Jahresb. der Pharm.*, 1883-84, p. 152).

RHODODENDRON.—ROSEBAY.

The leaves of *Rhododendron chrysanthum*, Linné.

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Yellow-flowered rhododendron*, *Rosebay*, *Snow rose.*

Botanical Source.—This is a small bush, with the stem from 1 to 1½ feet high, spreading, very much branched, often almost hidden among moss, from which the tips only of its shoots are protruded. The leaves are alternate, of the texture of a laurel leaf, ovate, somewhat acute, tapering into the stalk, reticulated and very rough above, and paler and smoother underneath. The flowers are large, showy, nodding, and borne on clustered, terminal, loose peduncles, emerging from among large downy scales. Corolla campanulate, 5-cleft, with rounded segments, of which the three upper are rather the largest, and streaked with livid dots next the tube, the lower unspotted. Stamens 10, unequal, and deflexed; the anthers oblong, incumbent, and without appendages, opening by two terminal pores. Capsule ovate, rather angular, 5-celled, 5-valved, and septicidal; seeds numerous and minute (L.).

History, Description, and Chemical Composition.—Rhododendron is an elegant evergreen shrub, inhabiting the mountains of Siberia, with large, yellow flowers, which appear in June and July. The leaves are the parts used in medicine, and should be gathered as soon as the capsules have ripened. They have a faint odor when recent, which is lost by drying; their taste is somewhat bitter, slightly acrid and astringent. Water or alcohol extracts their properties. Besides tannic acid and the other usual plant constituents, a small amount of essential oil is present, as well as the poisonous *andromedotoxin* (Plugge and De Zaayer, *Amer. Jour. Pharm.*, 1889, p. 361).

Action, Medical Uses, and Dosage.—Yellow rhododendron contains a stimulant, narcotic principle; for it increases the heat of the body, excites thirst, and produces diaphoresis, or an increased discharge of the other secretions or excretions, and which are generally followed by a decrease of action of the arterial system. With some persons it causes emeto-catharsis, inebriation, and delirium. The Siberians use a decoction of it in *chronic rheumatism* and *gout*. They put about 2 drachms of the dried shrub in an earthen pot, with about 10 ounces of boiling water, keeping it near a boiling heat for a night, and this they take in the morning. Beside its other effects, it is said to produce a sensation of prickling or creeping in the painful parts; but in a few hours the pain and disagreeable symptoms are relieved, and 2 or 3 doses generally complete the cure. The use of liquids is not allowed during its operation, as this is apt to induce vomiting (*Ed.*—Coxe). It is a valuable remedy, used in Russia, Germany, and sometimes in France and England, but scarcely at all in this country. That it possesses a decided control over the circulation, acting like the special sedatives, slowing the quickened pulse by giving increased heart power and removing capillary obstruction, seems well established. *Myalgic pains*, whether rheumatic or not, but especially of the facial and ocular region, appear to be the special indication for its use. It has been employed in *acute testicular*, and *ovarian affections*, as well as in *chronic orchitis* and *hydrocele*. The dose should be minute, from a fraction of a drop to a drop of a saturated tincture. Probably our native species would be fully as effective.

Specific Indications and Uses.—Myalgic pain, particularly of the face; "face-ache;" pain in the ocular muscles.

Related Species.—Our native species, the *R. maximum* and *R. punctatum*, according to Barton, possess properties similar to the *R. chrysanthum*, but milder. According to Bigelow, they are astringent, but not narcotic.

Rhododendron maximum, Linné, *Rosebay tree*, or *Great laurel*, is a tall, evergreen shrub, or small tree, found growing along mountainous streams in the eastern section of the United States. The leaves are very thick and leathery, entire, oblong, acute, smooth, and borne on short wrinkled stalks. The flowers appear in midsummer, and are very large and showy, in terminal, umbellate clusters. Tannin, gallic acid, wax, resin, albumen, a little essential oil, and several bodies peculiar to the Ericaceæ—viz.: *arbutin, ursone, ericolin*, etc.—were found in the leaves by Kuehnel (*Amer. Jour. Pharm.*, 1885, p. 164). *Andromedotoxin* was isolated by Plugge, in 1889. This agent was introduced to the profession by Dr. J. M. Mulholland, of Pennsylvania, in 1877, as a remedy for *obstinate cough* in elderly persons, in *diphtheritic croup*, and for the cure of those *cutaneous affections* in which arsenic is frequently prescribed. In cough, he found it more efficacious, when this was severe without expectoration, and was accompanied with a sweetish or mawkish odor of the breath, and a tremulous pulse. The dose is a teaspoonful every hour, of a mixture of 20 minims of the fluid extract with 4 fluid ounces of water.

Rhododendron ferrugineum, Linné, of Europe, has bitter, astringent leaves, which contain tannin as well as *ericolin* and *arbutin*. Said to contain no andromedotoxin (Dragendorff, *Heilpflanzen*).

RHŒADOS PETALA.—RED-POPPY PETALS.

The fresh petals of *Papaver Rhœas*, Linné.

Nat. Ord.—Papaveraceæ.

Common Names and Synonym: *Corn poppy*, *Corn rose; Flores rhœados.*

Illustration: Bentley and Trimen, *Med. Plants*, 19.

Botanical Source.—This is an annual, herbaceous plant, growing to a height of about 2 feet, beset with diverging hairs, and having deeply 5-cleft leaves, the segments being cut-toothed and lance-shaped. The flowers are red and showy. The capsules are truncate at the top, smooth, short, obovate in shape and contain many, very small, blackish seeds.

History and Description.—The red poppy grows in Europe, North Africa, and western half of Asia, thriving in grain fields. The petals are the parts employed, being used in the preparation of syrup of red poppy. They are 2 or more inches in width, roundish, and in 2 pairs, one of which is always larger than the other, a rich-scarlet in color, and, when dry, becoming purplish. They are thin, marked near their base with a deeper-colored spot, and are attached by a short claw. When dried the heavy, rather narcotic odor is dissipated. They are feebly bitter and mucilaginous to the taste.

Chemical Composition.—Red-poppy petals contain dark-red, amorphous *rhœadic acid*, which is dissolved by water and alcohol, but not by ether, dissolving with violet color in alkaline liquids; and bright-red, deliquescent *papaveric acid*, soluble in water and diluted alcohol, insoluble in strong alcohol and ether. With alkalies, the latter acid likewise produces a violet solution (L. Meier, 1846). The alkaloid, *rhœadine*, was found in the fresh petals by Hesse, in 1865 (see *Opium*). One kilo of old and dry petals yielded Hesse no alkaloid whatever (*Amer. Jour. Pharm.*, 1890, p. 179), while the expressed juice of 300 grammes of fresh petals yielded a small quantity of crystallized alkaloid, not morphine, and containing but little *rhœadine*.

Uses.—Used in preparing syrup of red poppy.

RHUS AROMATICA.—FRAGRANT SUMACH.

The bark of the root of *Rhus aromatica*, Aiton.

Nat. Ord.—Anacardiaceæ.

Common Name: *Fragrant sumach*, *Sweet sumach.*

Illustration: Gray's *Genera*, Plate 160.

Botanical Source.—This is a small, bushy shrub, growing from 2 to 6 feet high, and found in clumps throughout sections of the eastern United States, in rocky situations. The leaves are trifoliate, and on stalks about 1 inch in length. The 3 leaflets are sessile, and covered with a short velvety pubescence when young. The terminal leaflet is considerably larger than the lateral leaflets, from 1 to 2 inches in length, and about two-thirds as wide. They are entire and tapering at the base, acute, and have 8 or 10 crenate teeth at the apex. The flowers are small, greenish-yellow, and open in April before the leaves; they are in stalked, spiked, ament-like clusters, and, before flowering, have the appearance of an unexpanded catkin. The sepals, petals, and stamens are in fives, and the pistil is a 1-ovuled ovary, with 3 short styles. The fruit is a small red drupe, about the size of a pea, covered with dense, white pubescence. They are produced in clusters of about a dozen, and are on stalks about ½ inch long; each one contains a single flattened seed. A variety (var. *trilobiata*, Gray) with small, smooth leaflets, generally less than an inch in length, is common throughout Texas and the western states and territories.

History, Description, and Chemical Composition.—The part employed in medicine is the root, or the bark of the root. It has attained some little local reputation heretofore, but was unknown to the medical profession until introduced by Dr. McClanahan, in 1879. When dry, the root is from ¼ to 1 inch in diameter, and appears in the market in pieces of from 6 inches to 2 feet in length. The bark is of a dark, rusty-brown color externally, and a pink or walnut color below the cork. It is about ⅛ of an inch in thickness, and throughout the inner bark of a prime article are little cavities containing a transparent balsam, somewhat resembling balsam of fir. The wood is white or yellowish. When fresh, the wounded bark exudes a turpentine-like balsam, or solution of a resin in some volatile oil, which dries to a glossy tear or layer. The bark is astringent, but, undoubtedly, the turpentine-like balsam likewise possesses considerable medicinal value. Alcohol extracts this substance, and the addition of water to the tincture produces a milkiness. In making the tincture of either the fresh or dry bark, alcohol alone should be used, and any addition of water is objectionable. Quantitative analysis of the drug by H. W. Harper (*Amer. Jour. Pharm.*) showed the presence of volatile and fixed oils, several resins and wax, butyric acid, tannin, glucose, gum, starch, oxalates, etc., and 13.8 per cent of ash. The berries were examined for acids by Edo Claassen (*Pharm. Rundschau*, 1890, p. 262), and yielded 10.65 per cent of citric and a small quantity of malic acids.

Action, Medical Uses, and Dosage.—This exceedingly valuable medicine was introduced by J. T. McClanahan, M. D., Booneville, Mo. (*Ec. Med. Jour.*, 1879, p. 317). At first, the use of this remedy was confined to the treatment of *diabetes*, and other excessive discharges from the kidneys and the bladder, as well as to cases of *incipient albuminuria.* More recently, in addition to the above-named diseases, it has been largely employed with advantage in *urethral irritations*, *uterine leucorrhœa*, *cholera infantum*, *diarrhœa*, *dysentery*, *chronic laryngitis*, *chronic bronchitis*, and especially in the *enuresis of children and of aged persons*.

While it is of undoubted value in many *hemorrhagic states*, particularly in *chronic hematuria*, a malarial form of which is quite common in the southern states, its chief value is in *enuresis*, with marked atony and chronic irritability of the urinary passages, whether in young or old subjects. The favorite remedies for "bed-wetting" are Rhus aromatica, belladonna, and thuja. Sometimes this affection yields to Rhus aromatica alone; sometimes a combination, as indicated, must be used. Fragrant sumach is indicated in all cases of over-activity of the kidneys, but is always contraindicated when there is active inflammation. A patient suffering, for several years, from *catarrh of the bladder* and *hypertrophy of the prostate*, with excruciating pain during micturition, necessitating the continued use of a soft catheter, the introduction of which invariably proved painful, was relieved by fragrant sumach. After exhausting the employment of all recognized remedies for the patient's condition, together with the use of the water at the Hot Springs of Arkansas, etc., without the least benefit, as a *dernier ressort*, the patient was placed upon teaspoonful doses, 3 or 4 times daily, of the fluid extract of Rhus aromatica. In 3 weeks' time the symptoms were all removed, and the prostate so far reduced that the use of the soft catheter became unnecessary. The patient was 65 years old and subsequently voided urine as freely and as painlessly as a boy of 18 years (J. King).

Inflammatory symptoms being absent, it may be employed in *passive uterine hemorrhage*, *hemorrhage of the bowels*, as in *chronic bloody-flux* (not in acute dysentery), *chronic painful vesical catarrh*, and in *phthisis*, to control hemorrhage when small in amount, and to restrain the accompanying *diarrhœa* and *night-sweats*. In *bronchitis*, with profuse, blood-streaked expectoration, it may be given with confidence. A good form of administration is as follows: ℞ Specific fragrant sumach, ʒss; glycerin, ʒiijss. Mix. Sig. Dose, from ½ to 1 teaspoonful every 3 or 4 hours. This remedy is reputed useful in *purpura hemorrhagica*. The forms of administration now preferred are specific fragrant sumach and the fluid extract, of which the dose of either varies from 5 to 60 minims, repeated every 3 or 4 hours. It may be taken in water, in glycerin and water, and in solution of pure gelatin, or in syrup, when these vehicles are not contraindicated.

Specific Indications and Uses.—Not the remedy for active conditions. As given by its introducer, Dr. McClanahan, the specific indications are: "Stools profuse, skin cool and sallow, pulse small and feeble, loss of flesh, abdomen flabby, tongue pale, trembling and moist, trembling in lower limbs; general sense of lassitude and languor. Dose for infants, 10 to 20 drops in a half-glass of water, teaspoonful as often as necessary; for children, perhaps 5 drops of the first dilution" (*Ec. Med. Jour.*, 1879, p. 317). To these may be added large, painless diarrhœal discharges; nocturnal enuresis, from weakness of spincter vesicæ; prostatic enlargement; and malarial hæmaturia.

RHUS GLABRA (U. S. P.)—RHUS GLABRA.

The fruit of *Rhus glabra*, Linné.

Nat. Ord.—Anacardieæ.

Common Names: *Smooth sumach, Upland sumach, Pennsylvania sumach.*

Illustration: Willdenow, *Sp. Plant*, I, 1478.

Botanical Source.—Great care is necessary in the selection of the several species of Rhus, as many of them are extremely poisonous. Rhus glabra, or Smooth sumach, is a shrub 6 to 15 feet high, consisting of many straggling, glabrous branches, with a pale-gray bark, having occasionally a reddish tint. The leaves are alternate, odd-pinnate, of from 6 to 15 leaflets, about 3 inches long and one-fourth as wide, lanceolate, acuminate, acutely serrate, smooth, shining, and green above, whitish beneath, and sessile, except sometimes the terminal odd one; during the fall they become red. Flowers greenish-red, in terminal, thyrsoid, dense panicles. Calyx of 3 sepals, united at base; petals 5; stamens 5, inserted into the edge or between the lobes of a flattened disk in the bottom of the calyx; styles 3; stigmas capitate. The fruit is a small red drupe, hanging in clusters, and, when ripe, is covered with a crimson down, which is extremely sour to the taste, owing to the presence of malic acid in combination with calcium (W.—G.).

Fig. 208.

Rhus glabra.

History and Description.—Rhus glabra, sometimes called *Upland* or *Pennsylvania sumach*, is common to the United States and Canada, growing in thickets and waste grounds, and on rocky or barren soil, flowering in June and July, and maturing its fruit in September and October. The drupes or berries only are official. They should be gathered before the rains have removed their external downy efflorescence, for when this is washed off the berries are no longer acid. The bark is likewise used to some extent in medicine. The berries are officially described as "subglobular, about 3 Mm. (⅛ inch) in diameter, drupaceous, crimson, densely hairy, containing a roundish-oblong, smooth putamen; inodorous; taste acidulous"—(*U. S. P.*).

Sumach leaves have been used in tanning, and a concentrated decoction of the bark is used as a mordant for dyeing red colors. Sumach root bark is of a light-gray color, with a tinge of red externally, yellowish-white internally, and of a very astringent and slightly sweet taste. When broken on the plant, a milky fluid exudes from the bark as well as from the leaves, which subsequently forms a solid, gum-like body. Both the bark of the branches and root are used. Both the bark and berries of sumach yield their active properties to water. The excrescences (*galls*) which form upon the leaves are reddish-brown externally, grayish-white internally, varying in size and appearance, being usually very irregular in their outline, hollow, and sometimes consist of a mere shell, of a line or less in thickness. Their taste is slightly bitter, and very astringent.

Chemical Composition.—Sumach berries have an agreeably acid, slightly styptic taste, which is due, according to W. J. Watson, to malic acid and tannic acids, beside which they contain malate of calcium, gallic acid, fixed and volatile oils, red coloring matter, etc. The bark of the root contains albumen, gum, starch, tannic and gallic acids, caoutchouc, soft resin, coloring matter, and probably a volatile odorous principle (*Amer. Jour. Pharm.*, 1853, p. 193). The leaves of Rhus glabra, collected in Iowa, contained, according to Jos. A. Palen (*ibid.*, 1888, p. 389), about 16 per cent of tannin. Virginia-grown leaves usually yield 20 to 25 per cent. The excrescences upon the leaves contain tannic and gallic acids, albuminous and coloring matter, and are fully equal to nutgalls in medicinal power. Prof. Trimble (*The Tannins*) found one specimen to contain 61.7 per cent of tannin.

Action, Medical Uses, and Dosage.—Sumach bark is tonic, astringent, antiseptic, and decidedly alterative; the berries are refrigerant and diuretic. In decoction or syrup, the bark of the root has been found valuable in *gonorrhœa*, *leucorrhœa*, *diarrhœa*, *dysentery*, *hectic fever*, *scrofula*, and in *profuse perspiration from debility*. Combined with the barks of slippery elm and white pine, in decoction, and taken freely, it is said to have proved highly beneficial in *syphilitic ulcerations*. Externally, the bark of the root in powder, applied as a poultice to *old ulcers*, forms an excellent antiseptic. A decoction may also be used in injection for *prolapsus uteri* and *ani*, and *leucorrhœa*, and as a wash in many *cutaneous diseases;* simmered in lard it is valuable in *scald head*. A decoction of the inner bark of the root is serviceable in the *sore mouth* resulting from mercurial salivation, and was formerly much used internally in *mercurial diseases*. A saturated tincture is useful in *ulcerative stomatitis*, and for *spongy gums* attending *purpura hemorrhagica* and *scorbutus*. *Diarrhœa* and *dysentery*, with intestinal ulceration, seem to be well controlled by it. Dose of the tincture, from 5 to 20 drops. The berries may be used in infusion in *diabetes*, *strangury*, *bowel complaints*, *febrile diseases* (as a pleasant acidulous drink where acids are indicated), etc., as a gargle in *quinsy* and *ulcerations of the mouth and throat;* and as a wash for *ringworm*, *tetter*, *offensive ulcers*, etc. Excrescences are frequently formed on the leaves of this plant, and which are very astringent; when powdered and mixed with lard or linseed oil, they are said to prove useful in *hemorrhoids*. In hot weather, if the bark be punctured, a gummy substance flows out, which has been used with advantage in *gonorrhœa* and *gleet*, and several urinary affections. Dose of the decoction of sumach bark, or infusion of the berries, from 1 to 4 fluid ounces. A free use of the bark will produce catharsis.

Specific Indications and Uses.—Relaxation of mucous tissues, with unhealthy discharges; mercurial ulcerations; aphthous stomatitis; spongy gums; ulcerative sore throat, with fetid discharges; flabbiness and ulceration of tissues.

Related Species.—There are several species of Rhus, as the *Rhus typhina*, *Staghorn* or *Velvet sumach;* and the *Rhus copallina*, *Mountain* or *Dwarf sumach*, which possess similar virtues, and which must be carefully distinguished from those which possess poisonous properties. The non-poisonous species have their fruit clothed with acid crimson hairs, and their panicles are compound, dense, and terminal; the poisonous varieties have axillary panicles and smooth fruit (see also *Rhus Toxicodendron* and *Related Species;* and *Coriaria*, p. 607).

RHUS TOXICODENDRON (U. S. P.)—RHUS TOXICODENDRON.

The fresh leaves of *Rhus radicans*, Linné (*Rhus Toxicodendron*, Linné).
Nat. Ord.—Anacardieæ.
Common Names: *Poison ivy*, *Poison oak*, *Poison vine*.
Illustration: Johnson, *Medical Botany of North America*, Fig. 117.

Botanical Source.—*Rhus Toxicodendron*, or *Poison oak*, is a creeping shrub from 1 to 3 feet high, with long cord-like shoots, emitting strong lateral fibers; the stems are either erect or decumbent. The bark is brownish-gray. The leaves are ternate, on long, semi-cylindrical petioles; the leaflets are broadly oval or rhomboidal, 2 to 6 inches long, ⅔ as wide, petiolate, acuminate, smooth and shining above, slightly downy beneath, especially on the veins; the margin is sometimes entire, and sometimes variously toothed and lobed, in the same plant. The flowers are small, greenish-white, diœcious, and grow in axillary, subsessile, racemose panicles on the sides of the new shoots. Barren flowers have a calyx of 5 erect, acute segments, and a corolla of 5 oblong recurved petals; stamens erect with oblong anthers; in the center is a rudiment of a style. Fertile flowers about half the size of the preceding, with calyx and corolla similar, but more erect. They have 5 small abortive stamens, and a roundish ovary, crowned by a short, erect style bearing 3 small capitate stigmas. The fruit is a roundish, smooth, dry berry, of a pale-green color, approaching to white, and contains a solitary bony seed (L.—W.—G.).

Fig. 209.

Rhus Toxicodendron.

History.—*Rhus radicans*, or *Poison ivy*, and sometimes called *Poison vine*, is considered by botanists to be merely a variety of the above species; it has a climbing stem from 3 to 20 or more feet in length, and climbs trees, fences and neighboring objects, to which it becomes attached by its myriads of radiating tendrils. The leaflets are quite entire, smooth and shining on each side, with the exception of the veins beneath. These plants grow throughout the United States and Canada along fence-rows, in thickets, etc., flowering from May to August. They yield an abundance of yellowish narcotic acrid milky juice, which becomes black when exposed to the air, and forms an indelible ink when applied to linen; it is soluble in ether. The genus Rhus belongs to an interesting family of plants—the *Anacardieæ* (*Anacardiaceæ*) or *Cashew family*, a group of frequent occurrence in the tropical sections of both the eastern and western worlds, diminishing in distribution, however, as we approach the northern and southern sections of the temperate zones. Species of this family produce some of the most valued of tropical fruits, yet the group is chiefly distinguished for its gum-resinous juices, that from the majority of the species being caustic, becoming black on exposure to the air, and charged with an acrid, poisonous principle. This family includes not only the species of Rhus but also the plants yielding the *Pistachia nut* (*Pistachia vera*) *Cashew-nut* (*Anacardium occidentale*), *Marking fruit* or *Oriental cashew-nut* (*Semecarpus Anacardium*), *Mango* (*Mangifera indica*), the *Mastich tree* (*Pistachia Lentiscus*) and other products interesting from a medicinal or economic standpoint. As before intimated, several species of Rhus have been used in medicine and in the arts. Many of these are now obsolete as medicines. However, a brief enumeration of them and their chief characteristics and uses may not be out of place. The bark of the *Wild olive* or *Venetian sumach* (*Rhus Cotinus*) is both astringent and aromatic. It was at one time employed as a substitute for cinchona. Under the name of *Smoke tree* it is frequently observed in cultivation for ornament in American yards and gardens. The wood of this species is known as *young fustic* and is much used in Greece to impart a beautiful yellow hue to woolen fabrics. In Italy, where it is known as *scotino*, the whole plant is used for tanning leather. *Doctor's gum* or *Gum hog* of Jamaica, is one of the substances once considerably used as a plaster-base, and substituted, in some instances, for copaiba balsam. It has been referred to *Rhus Metopium*, though as is often the case, the same common names have been applied to the products of widely different species, therefore there seems to be no certain evidence that the species of Rhus referred to produces it. Doctor's gum, when dissolved in water, is powerfully cathartic and emetic, and was formerly in great repute as a diuretic. The most poisonous species of Rhus is the recently rediscovered *Rhus Michauxii*, Sargent

(*Rhus pumila*, Michaux). Occupying a second place in toxic power is the *Rhus venenata*, well known as *Poison dogwood*, *Poison sumach*, or *Poison elder*. The *Rhus vernix* of Japan yields a whitish resinous varnish in small amount, which turns black on exposure to air. An oil, known as *Japanese wax*, is expressed from the seeds of *Rhus succedaneum*, which is employed by the Japanese in the making of candles to be used in times of special pagan festivities and in preparing certain kinds of food (Thunberg). A like oil is obtained from the fruit of the *Lacquer tree*. The *Japan varnish* or *Lacquer tree* is the *Rhus vernicifera* of De Candolle. From this plant exudes the gum-resinous substance used in making the celebrated *Japanese lacquer-work.* At first this juice is of a light color, and about as thick as cream. It is, however, so transparent that when laid unmixed with any other material upon wood even the faintest natural marking of the wood is plainly discernible through it. Generally a dark or reddish surface is first prepared and upon it the varnish is spread. This gives a mirror-like effect. The gum, when hardened, is difficultly soluble, even withstanding treatment with boiling water, but on the other hand is so brittle as to be very easily destroyed by striking it against any hard body. The *Rhus Coriaria* is powerfully astringent, and is much employed in tanneries. According to Lindley, its acid fruit is eaten by the Turks, who also employ it to add sharpness to vinegar. In Tripoli the seeds are sold as appetizers. The leaves are reputed astringent, tonic, cooling, and styptic, and boiled with broom (*Genista tinctoria*) were formerly employed by the Russians in hydrophobia. *Smooth sumach* (*Rhus glabra*) leaves are sufficiently astringent to be of importance in an economic sense, as in tanning. The fruit is employed as a mordant in dyeing red. The under surfaces of smooth sumach leaves produce excrescences which contain an abundance of tannic and gallic acids, and are considered equal in value to common galls. *Staghorn* or *Virginian sumach* (*Rhus typhina*) is sometimes called *Vinegar plant* from the fact that vinegar may be produced from it, and that when added to vinegar it increases its strength. Boiled with alum, the ripe fruit formerly furnished a hat dye. Yellow, green and black are the colors that may be produced from it. With green vitriol it forms a black ink. All parts of the plant are valued for tanning white glove-leather. The milky juice is said to furnish a varnish comparing favorably in value with that from Japan. It has been stated that honey-bees gather more honey from its flowers, when accessible, than from those of any other species of plants. The leaves were used like tobacco by the American Indians.

Indigenous Species.—The medicinal species of Rhus indigenous to North America are distributed as follows:

I. NON-POISONOUS SPECIES.

Rhus glabra, Linné.—A smooth shrub, known as *Smooth* or *Upland sumach*, found throughout the United States and Canada, flourishing in dry, barren or rocky situations, fence corners, etc. (see *Rhus glabra*).

Rhus typhina, Linné, *Staghorn* or *Virginian sumach*.—A shrub or small tree of Canada and the United States, growing in the rich soil of uplands.

Rhus copallina, Linné, *Dwarf* or *Mountain sumach*.—A small shrub found throughout Canada and the United States, growing in rocky and barren places.

Rhus aromatica, Aiton, *Sweet* or *Fragrant sumach*.—Eastern United States. A variety (*R. aromatica* var. *trilobiata*, Gray) is found in Texas and in the western states and territories (see *Rhus aromatica*).

II. POISONOUS SPECIES.

Rhus Michauxii, Sargent (*Rhus pumila*, Michaux).—A rare shrub, recently rediscovered in North Carolina, regarded by Prof. C. S. Sargent as our most poisonous species of Rhus. Grows from North Carolina to Georgia (Wood).

Rhus venenata, De Candolle, *Poison sumach*, *Poison dogwood*, or *Poison elder*.—Grows in swamps and other wet situations from Canada southward to Florida and thence westward.

Rhus diversiloba, Torrey and Gray.—Closely allied to *Rhus Toxicodendron*, and growing on the Pacific coast.

Rhus Toxicodendron, *Poison ivy*, or *Poison oak*.—Either a small shrub or a tall climbing vine growing from 10 to 100 feet high, found plentifully from Canada to the Mexican Gulf and from thence westward. Dr. Asa Gray, in his essay on

"*Sequoia and Its History*," says: "Our *Rhus Toxicodendron*, or *Poison vine*, is very exactly repeated in Japan, but is found in no other part of the world, although a species much like it abounds in California. Our other poisonous Rhus (*R. venenata*) commonly called Poison dogwood is in no way represented in western America, but has so close an analogue in Japan that the two were taken for the same by Thunberg and Linnæus, who called them both *Rhus vernix*." This explains why our older writers on the American *Rhus venenata* called it *R. vernix*. The species often spoken of as *Rhus radicans*, from the fact that it is a tall climber clinging by means of its numerous radicles to any object of support, is probably identical with *Rhus Toxicodendron*, or *Poison vine*, and is so considered in this article.

Description.—FOLIA TOXICODENDRI. The *U. S. P.* thus describes the drug: "Long-petiolate, trifoliolate; the lateral leaflets sessile or nearly so, about 10 Cm. (4 inches) long, obliquely ovate, pointed; the terminal leaflets stalked, ovate or oval, pointed, with a wedge-shaped or rounded base; the leaflets entire and glabrous, or variously notched, coarsely toothed or lobed, more or less downy; when dry, papery and brittle; inodorous; taste somewhat astringent and acrid. The fresh leaves abound with an acrid juice, which darkens when exposed to the air, and, when applied to the skin, produces inflammation and swelling. The leaves should, therefore, not be touched with bare hands. Rhus Toxicodendron should not be confounded with the leaves of *Ptelea trifoliata*, Linné (*Nat. Ord.*—Rutaceæ), which are similar in appearance, but have all the leaflets sessile"—(*U. S. P.*). The leaves of the R. Toxicodendron are the only parts of the plant used, although the whole plant is highly active. When dried they have no odor, and an insipid taste with acridity. Water or alcohol extracts their properties.

Chemical Composition.—Dr. Joseph Khittal (Wittstein's *Vierteljahrsschrift*, 1858, p. 348) found the leaves to contain chlorophyll, wax, resin, starch, tannin (*rhus-tannic acid*), etc., and a volatile alkaloid which exists in the plant combined with acids, and to which, he asserts, the toxic properties of the leaves are due. This opinion is contradicted, however, by Prof. Maisch. According to this authority, the exhalations of vigorous leaves redden blue litmus paper previously moistened, and contain volatile *toxicodendric acid*, the active principle. Its reactions do no coincide with those of formic acid (*Amer. Jour. Pharm.*, 1866, p. 6). Dr. Pfaff and S. S. Orr, however, state this acid in pure condition to be non-toxic, and that the real active principle is a non-volatile oil, *toxicodendrol*, allied to cardol, from cashew-nut. The oil is soluble in alcohol and forms an insoluble lead compound. Thus the authors recommend the use of an alcoholic solution of lead acetate as a wash in cases of poisoning (*Pharm. Jour. Trans.*, 1894-95, Vol. XXV, p. 818; also see V. K. Chesnut, in *Yearbook U. S. Dept. Agr.*, 1896, p. 139). The efficiency of this antidote has long been known (see Maisch, *loc. cit.*); among other remedies suggested are ammonium chloride, washing soda, sodium hyposulphite, potassium permanganate, aqua ammoniæ, or the bruised plant of *Pilea pumila* (*Amer. Jour. Pharm.*, 1888, p. 390), fluid extract of serpentaria (*ibid.*, 1884, p. 355), etc. Also compare interesting article, by G. M. Beringer, on Rhus poisoning (*ibid.*, 1896, p. 18).

Early Medical History of the Species of Rhus.—Medical interest, in the species of Rhus, during the early history of this genus, seems to have centered chiefly in two species—*R. Toxicodendron* and *R. glabra*. *Rhus venenata* (as *R. vernix*), was quite fully considered, more however, with a view to studying its juice from an economic view, and its poisonous qualities and the remedies therefor. We are not aware that it has been medicinally employed, to any extent at least. Rhus glabra received a good share of attention from the profession and probably had its medicinal starting point from its aboriginal and domestic uses. One of the most interesting accounts of some species of Rhus is "*An Experimental Dissertation on the Rhus vernix* (*venenata*), *Rhus radicans*, and *Rhus glabrum;* commonly known in Pennsylvania by the names of *Poison ash*, *Poison vine*, and *Common sumach*, by Thomas Horsfield, of Bethlehem, Pa.," published in 1798. This interesting 88-page book gives a most excellent résumé of the knowledge of those species acquired up to that date, and we might add that the description of the effects of the poisonous species has not, in our opinion, been excelled to this day.

Rhus Toxicodendron is almost universally admitted to have been introduced to the profession, in 1793, by Dr. I. Alderson, of Hull, England, that gentleman first using it as a remedy in paralytic states. Dr. Du Fresnoy, of France, however, previous to this had employed *Rhus radicans* in paralytic and herpetic disorders. This was in 1788, and if we consider *Rhus radicans* and *Rhus Toxicodendron* as identical, this gives Du Fresnoy priority. It further seems that Gleditsch, in 1782, wrote an article (in French) on "*Novel Effects Concerning a Dangerous American Plant*," referring to Rhus. Du Fresnoy first experimented on himself before administering the leaves to his patient. His experience with an infusion of 12 leaves he thus records: "At this dose I observed a slight pain in my stomach, and my perspiration and urine were increased in quantity." Alderson observed that when the drug acted beneficially in paralysis, "the first signs of improvement were an unpleasant feeling of pricking and twitching in the paralytic limbs" (Thacher's *Dispensatory*, 1821). Du Fresnoy's dissertation was the first publication in regard to the medical uses of Rhus. Horsfield (1798) experimented on consumptives with the infusion. In some cases benefit seemed to be derived from its use, while other cases were aggravated by it. He states of the wife of a consumptive patient that, "invited by the agreeable odor of the infusion, she drank a teacupful. It produced an unusual degree of cheerfulness, and a copious discharge of urine" (*Diss.*, p. 87). In a case of anasarca, it relieved the patient by "producing copious perspiration" (*ibid*). He concluded from his results that it "acts slightly as an incitant and diuretic." A tincture was used by Baudelocque in scrofulous chronic ophthalmia of infants (Porcher).

Rhus glabra was used early by American practitioners as an astringent in diarrhœa, dysentery, and in ulceration of the throat, etc. The fruit (*sumach bobs*) infused in water, was employed as a cooling drink in febrile affections. The whitish substance covering the berries, known as *Indian salt*, has acid properties, rendering the infusion pleasantly sour. *Rhus copallina* and *Rhus typhina* were used for like purposes, while the first was valued by the Chippewa Indians in gonorrhœa, and the gall-like excrescences on the leaves, powdered and made into an ointment, afforded the white settlers a remedy for piles (see *Rhus Glabra*).

Rhus diversiloba appears to have been effectual in dysmenorrhœa. A case (in California) is reported (*Ec. Med. Jour.*, 1865, p. 314) of an anemic girl, who usually suffered greatly during menstruation, the flow being scanty, cured by having been poisoned at the menstrual epoch by contact with this plant. An easy menstruation followed. When the next monthly period was due a return of the eruption came also, and with it again an easy catamenial flow. This, so far as we are aware, is the extent to which this plant has been known to act medicinally, though nearly all old works state that its properties are similar to those of *Rhus Toxicodendron* and *Rhus venenata*. The latter, we believe, has not been employed in medicine (see *Related Species*).

Rhus aromatica was introduced to the profession by an Eclectic physician, Dr. J. T. McClanahan, of Booneville, Mo., in 1879, who stated that the remedy had been employed by members of his family, several of whom were doctors, for a quarter of a century, for the relief of urinary, bowel, and hemorrhagic disorders, with uniform success (see *Rhus Aromatica*).

Action, Medical Uses, and Dosage.—Locally, rhus is a powerful irritant poison. The toxic manifestations produced from the different species is of precisely the same nature, differing only in degree of intensity. *Rhus Toxicodendron* ranks next to poison dogwood in point of virulence. Whilst locally poisonous to some persons, some individuals are totally unaffected by it. Many are but mildly poisoned by it; many more, however, show serious evidence of its great activity. Contact is not always necessary to obtain its effects. Indeed many individuals are poisoned merely by exposure to an atmosphere contaminated with the toxic exhalations of the plant. This is especially true when the air is heavy and humid, or when the susceptible individual is freely perspiring. Alcoholic solution of the toxic principle retains its virulence for many years (Johnson). The dried leaves are, as a rule, inert. A young lady in the employ of Prof. J. U. Lloyd, is always notified to remain at home—not even being allowed in the building—on the days when specific rhus is being bottled, so intense are poisonous effects in this case that mere exposure to the emanations is sufficient to cause the individual to be confined to her bed. Peter Kalm, the Swedish traveler, who visited this country during its colonial days—a man who investigated our plant resources and made large collections of the same—writes: "I was acquainted with a person, who, merely by the noxious exhalation of the *Rhus vernix* (*venenata*), was swelled to such a degree, that he was as stiff as a log of wood, and could only be turned about in sheets."

A singular feature connected with rhus poisoning is its recurrence from month to month, and from year to year, even when the affected individual is far remote from all exhalations of the plant. This was early noted by Barton, who personally experienced such recurrence for 5 successive years—a portion of which time was passed in Europe far from proximity to the plant in question. We have also observed this phenomenon. The smoke from burning rhus wood, was noticed as early as 1720, by Sherard, Wangenheim, and Kalm, to produce poisonous effects. It appears (Barton) that horses eat the plant with impunity. According to William Bartram, they are very fond of the leaves. Cows are wholly unaffected by the ingestion of the plant. Thunberg observed that sheep ate of the leaves of *Rhus lucidum*, a similar species, without harm. To dogs and guinea pigs, on the other hand, poison vine is fatal. The statement that the infusion of the leaves was administered to consumptives with non-poisonous results, may seem contradictory, but we can not but believe that a portion of the poisonous principle is volatile, in spite of the assertion that non-volatile *toxicodendrol* is the toxic agent, and consequently driven off in heating. The poisonous properties are likewise, in a measure, dissipated in drying the plant, hence the necessity of preparing the fluid preparations from fresh material. It is not surprising, therefore, that certain individuals—"eminent therapeutists"—have decried the use of rhus as of no value, when fluid extracts and tinctures from dried materials had failed to give good results.

The nature of poisoning by rhus has always partaken somewhat of the mysterious, and it has been the subject of much speculation. Various reasons have been assigned as to why it poisons at all, and as to why it affects only certain individuals. It has been customary to attribute the deleterious effects to emanations from the living plant. Later, Prof. Maisch announced a volatile substance of acid character as the offender, and named it *toxicodendric acid*. Still later, a bacterium was charged with creating the mischief. The latter cause, however, has now been satisfactorily disproved. An oil has now been isolated, and this, even when purified, excites exactly the same form of dermatitis as the growing plant. This discovery was made, in 1895, by Dr. Franz Pfaff, of Harvard University. It is present in every part of the ivy plant, and even the dried wood is said to retain it. It has been named *toxicodendrol*, and is asserted to be in reality the only tangible substance found thus far to which may be attributed the toxic effects of the vine. Still, this does not explain why individuals are poisoned when not in contact with the plants. Alcohol freely dissolves this oil, but water, as with oily bodies, does not, nor does it wholly remove it from the skin; hence the reason why washing after contact with ivy does not prevent the appearance of the characteristic eruption. Experimentation (see V. K. Chesnut, *United States Yearbook of Department of Agriculture*, 1896, p. 141) has shown that if the oil be placed upon the skin, and immediately removed with alcohol, but slight effects are observed. The longer the interval, however, the more pronounced the effects become. In all, the effects were less marked than when no such treatment was given. From the fact that several portions of the skin could be impressed without coalescence of the areas, it has been concluded that the action of the oil is wholly local, and that the poison does not enter the blood. We are not, however, satisfied with this view of the matter, for if so, how are we to explain the recurrence of the trouble after weeks and months, and even years, in persons who have not for some time been near the plants or in the neighborhood of their growth? There are many agents that might be used for the relief of this species of dermatitis, as lobelia, grindelia, sulphate of iron or copper, both of which have served us well, and the more recently recommended echafolta.

The *local* effects of rhus are well known. Briefly stated, it occasions an eczematous, sometimes erysipelatoid, inflammatory eruption, characterized by intense itching, redness, and tumefaction, followed by burning pain, sympathetic febrile excitement, and vesication. The vesicles are at first small and filled with a watery fluid; sometimes they become yellow, as if pus were present. Finally, as they mature, they rupture, when a yellow scab forms. The tongue is coated white, and headache and delirium are often symptoms. The effects are observable a short time after exposure to the poison, the affection usually spending its force in the course of 4 or 5 days, and is followed by desquamation of the cuticle. The face and genitalia seem to be favorite localities for the most pronounced swelling to appear. One case of poisoning by *Rhus venenata* came under our observation, in which the swelling of the face was so great as to wholly obliterate the features, giving to the individual a swine-like, rather than human, appearance. Domestic medication, in the shape of bruised *Impatiens pallida* and *fulva* (Jewel weeds) gave great relief in this instance. Lack of space forbids more than the partial enumeration of the many remedies that have been extolled for the cure of this malady. The chief, however, are lobelia (infusion), veratrum, gelsemium, hamamelis, grindelia, stramonium, eupatorium, serpentaria, lindera, sassafras bark, dulcamara, oak bark, tannic acid, alnus (boiled in buttermilk), carbolized olive oil, sodium bicarbonate, borax, alum curd (especially to be used near the eyes), and, perhaps the best of all, solution of ferrous sulphate (green vitriol). Sugar of lead (lead acetate) has long been a favorite agent for the relief of this trouble, but as it has most frequently been applied with water, it has very often failed to give relief. It has now been shown that a solution in weak alcohol (50 to 75 per cent) gives immediate and permanent relief. Occasionally, zinc and copper sulphates, oxalic acid, potassium chlorate, and other salts are effectual. Echafolta has recently been extolled in this affection.

All treatment should be accompanied with a light, cooling regimen, and cooling purgatives or diuretics. The bruised leaves of the *Collinsonia canadensis*, externally, and an infusion of the *Verbena urticifolia*, internally, have been successfully used in internal or external poisoning by these plants. A solution of caustic potash, sufficiently strong to render the skin soapy, has been advised as a local application. Sodium carbonate, sodium sulphite, chlorinated lime, weak ammonia solution, and lime-water have been similarly employed.

Internally, administered in small doses, Rhus Toxicodendron is slightly stimulant, increasing the renal and cutaneous secretions, and proving feebly laxative. Employed in *paralytic states* it is reputed to have effected a return of sensation and power of movement, the good effects being ushered in with a sensation of pricking and burning, with twitchings of the affected parts. Large doses occasion stupefaction, or a sort of intoxication, exhibited by vertigo, impairment of the special senses, pupillary dilatation, chilliness, sickness at the stomach with thirst and burning pain, and a feeling of constriction in the temporal regions. The pulse becomes slow, irregular and small, the activity of the skin and kidneys increases, weakness, trembling, and fainting occur, and sometimes convulsions ensue. A pint of rhus berries induced drowsiness, stupor, delirium, and convulsions in two children who partook of them. The infusion of the root taken internally is asserted to have produced the characteristic local eruptions besides producing a harsh cough, scanty urine, and severe gastro-intestinal symptoms. Rhus Toxicodendron is one of our best medicinal agents. Its range of application, specifically considered, is only excelled by few drugs. It is an ideal sedative, controlling the circulation, and acting primarily and most pronouncedly upon the nervous system. Fortunately specific medication does not require the enumeration of special diseases to show when and where a remedy should be employed. Indeed, the action of rhus is best understood by its fitness for conditions rather than for certain *disease-condition groups* which we know as particular diseases. The general specific indications and uses for rhus are: The small, moderately quick and vibratile pulse, especially exhibiting sharpness in stroke and associated with burning sensations. There is a peculiar nervous erethism which always indicates it. The sick infant requiring rhus, sleeps disturbedly, frequently starting suddenly from out its slumbers, and uttering a shrill cry (*cry encephalique*) as if from fright. Many of these conditions are met with in the cerebral irritation of children suffering from *cholera infantum* and other summer bowel troubles and in *cerebro-spinal meningitis*. The circulatory disturbance requiring rhus upon which the nervous phenomena chiefly depend is usually localized and not general; small areas of the brain or nerve centers only may have a disturbance of the blood supply. As a rule the marked restlessness is all out of proportion to the apparent circulatory derangement. Frontal pain, and more especially if confined to the left orbit, and sharp in character, is a prominent indication for this drug. The rhus tongue is reddened on the tip and edges, and even may take on the strawberry character, typical of gastric irritability, typhoid, and scarlatinal states. Associate with the kind of pulse mentioned, and with tympanites, brown sordes and reddened mucous surfaces, and the indication is still more direct. Discharges of an acrid character, and ichorous flow from tissues which seem to disappear by mere drainage, are further guides to its use. It is a certain remedy for *vomiting* when the tongue is of the kind above referred to. In fact, great unrest with vomiting is one of the most direct indications for its selection. *Pain* of a burning character, whether deep or superficial, is relieved by rhus quicker than by any other agent. It may be of the head, abdominal or thoracic viscera, of the urinary organs, of the eyes, or of the skin, no matter where the pain or what the name may be, *neuralgia*, *rheumatism*, *erysipelas*, *pleurisy*, or *cystitis*, etc. If there be burning, and if of the surface an erysipelatoid redness, rhus will cure. Rheumatic pain, aggravated by the warmth of the bed, is usually relieved by it. It is more valuable in acute than chronic rheumatism and is serviceable in *rheumatic paralysis* and *articular stiffness* after rheumatic attacks. It is particularly useful to control the feeling of restlessness of rheumatic subjects. *Rheumatic toothache*, aggravated by warmth or warm liquids, is relieved by it. It is a valuable drug in the bowel disorders of infants, as *diarrhœa* and *typhoid dysentery*, with head symptoms, and in *typhoid and other fevers*, such as *remittent* and *intermittent gastric fever*, and especially when typhoid symptoms are present. It is a fine remedy in *cholera morbus*.

Rhus is a valuable agent in *pneumonia*, *bronchitis*, *la grippe*, and *phthisis*, when the patient is extremely irritable and suffers from gastric irritation. With the small wiry pulse as a guide it controls that restlessness and delirium in *adynamic fevers*, which is probably caused by irritation and local hyper-vascularization of limited areas in the cerebral and other nerve centers. It is indicated in *typhoid pneumonia*, with red, glazed tongue, and offensive muco-purulent expectoration. Uncontrollable, dry, spasmodic, and tickling *cough* is frequently relieved by it. Rhus is an extremely useful remedy in the various *disorders of the skin* presenting the characteristic rhus indications. Redness, intumescence, and burning are the indications in cutaneous diseases.

For vivid, bright-red, glistening *erysipelas*, especially when confined to the upper part of the face, with marked puffiness, it is one of the most successful of remedies. In fact in *acute inflammations of the skin* it is often more serviceable than aconite and veratrum. It is of great service in *herpes* where there are burning, itching, and exudation of serum. *Eczema*, *pemphigus*, and many irritable and inflammatory skin affections are relieved by it when redness, intumescence, and burning are prominent symptoms. Associated with iron it has proved useful in *purpura hemorrhagica*. *Erythematous and erysipelatous inflammation of the vulva*, with burning pain, and the itching and vulval irritation following micturition, are permanently relieved by rhus. In the *exanthemata*, as in all zymotic diseases, rhus appears to exert a special antizymotic influence, for which it may be given in *scarlatina* and *measles* where the vital powers are greatly depressed, and in *variola*, with livid color of the surface and foul discharges. Tumid, reddened, and glistening enlargements, and *ulcerations* with red glistening margins, syphilitic or non-syphilitic, likewise call for rhus. In the ulcerative forms the parts seem to melt away without sloughing. It is of much value in *parotitis*, and in *swelling of the submaxillary gland* with great induration few remedies are better (Locke). Its constitutional effects are often manifested in *carbuncle* and *carbunculous furuncles*. In ocular therapeutics rhus is an important drug. It is sometimes administered to prevent inflammatory action after *cataract operations*. *Palpebral œdema*, with marked redness is relieved by it, while *neuralgic and other pains in the globe of the eye*, and aggravated by motion and warmth are often banished under its use. Acute and subacute forms of *conjunctivitis* are relieved by it on account of its special affinity for the blood vessels of the orbit. In the *catarrhal ophthalmia* of scrofulous children with strongly inflamed palpebral edges and conjunctivæ and marked photophobia and burning lachrymation, the action of the remedy is decided and prompt. There is usually a sensation as of foreign particles, such as sand, etc., in the eye. Rhus has been employed successfully in *paraplegia* without any actual organic lesion, and in *paralysis of the bladder and of the rectum.* In paralytic states, however, it is of little value except in those conditions which follow attacks of rheumatism. Its efficiency in *sciatica*, however, is admitted by some who think the drug practically valueless as a medicine.

The proper dose for specific effects, and it is scarcely employed in any other manner, is the fraction of a drop of specific rhus, thus: ℞ Specific rhus, gtt. v to xv; aqua, fl℥iv. Mix. Dose, 1 teaspoonful every hour in acute disorders; 4 times a day in chronic affections.

Specific Indications and Uses.—Small, moderately quick, *sharp* pulse, sometimes vibratile or wiry; great restlessness; child starts from sleep with a sharp, shrill cry as if from fright; great restlessness with vomiting; tongue red and irritable, showing red spots; strawberry tongue; burning pain; pain in or above left orbit; rheumatic pain aggravated by warmth; bright, superficial redness of the skin with burning, itching, or tingling; bright-red, glistening erysipelas with burning pain; pinched countenance; burning urethral pain with dribbling of urine; redness of mucous tissues; brown sordes; tympanites; acrid discharges from bladder or bowels; inflammation with bright-red tumid surfaces and deep-seated burning pain; inflammation with ichorous discharges, the tissues seemingly melting away; tumid red swellings; old ulcers with shining red edges; induration of submaxillary gland; conjunctival inflammation with burning lachrymation, pain, and photophobia.

Related Species.—*Rhus venenata*, De Candolle (*R. vernix*, Linné), or *Poison sumach*, also known as *Poison wood*, *Swamp sumach*, *Poison ash*, and inappropriately as *Poison elder* and *Poison dogwood*, has been confounded with the *Rhus vernix* of Linné, a species which grows in Japan. It is a shrub or small tree, 10 to 20, and even 30 feet in height, with the trunk 1 to 5 inches in diameter, branching at the top, and covered with a pale grayish bark, which is reddish on the leaf-stalks and young shoots. Leaves pinnate, with 3 to 6 pairs of opposite leaflets, and an odd terminal one, which are oblong or oval, entire or slightly sinuated, acuminate smooth, paler underneath, and nearly sessile, except the odd terminal one; they are about 3 inches long, and nearly half as wide. Flowers diœcious and polygamous, very small, green, and in loose, axillary, pedunculate panicles. Panicles of the barren flowers are downy, the largest most branched. Sepals 5, ovate; petals 5, oblong; stamens longer than the petals, and projecting through their interstices; the rudiment of a 3-cleft style in the center. In the fertile flowers the panicles are much smaller, sepals and petals resemble the last, while the center is occupied by an oval ovary, terminated by 3 circular stigmas. Fruit a bunch of dry berries or drupes, about the size of peas, smooth, greenish-yellow or greenish-white, sometimes marked with slight purple veins, and becoming wrinkled when old; roundish, a little broadest at the upper end, and compressed, containing 1 white, hard, furrowed seed (L.—G.—W.).

Rhus venenata grows in low meadows and swamps from Canada to the Gulf of Mexico, flowering from May to August. The milky juice which flows when the plant is wounded, is similar in its action to that of *Rhus Toxicodendron*, and may, according to Bigelow, be made into a beautiful, shining and permanent varnish, by boiling, very analogous to that obtained in Japan from the *Rhus vernix*. It is much more poisonous than *Rhus Toxicodendron*, and its volatile principle taints the air for some distance around with its pernicious influence, producing in many persons severe swellings of an erysipelatous nature; sometimes the body becomes greatly swollen, and the person unable to move. Some persons are hardly, or not at all, affected even by handling it. The affection caused by it generally abates after several days, and may be treated in the same manner as named for the poisonous effects of the *Rhus Toxicodendron*.

Rhus Michauxii, Sargent (*Rhus pumila*, Michaux).—This is the most poisonous Rhus in this country. It is an extensively procumbent, villous-pubescent shrub, about 1 foot high, with pinnate leaves; leaflets about 11, oval or oblong, slightly acuminate, coarsely toothed, with a velvety pubescence, the 3 upper leaflets often confluent, the terminal one when distinct attenuate at base. Panicles terminal, thyrsoid, nearly sessile; drupes covered with a red silky pubescence (T.—G.). It is a rare shrub, confined to the south, and is found in North Carolina and Georgia, and was recently rediscovered.

Rhus diversiloba, Torrey and Gray.—Dr. C. A. Canfield describes a very poisonous shrub, growing in California, which is very similar in appearance and poisonous qualities to our *Rhus Toxicodendron.* It is the *Rhus diversiloba* of Torrey and Gray, or *Rhus lobata* of Hooker. The remedy that he has found invariably successful as an antidote to its local poisonous effects is another plant of California, of the composite family, and somewhat resembling a small sunflower, the *Grindelia hirsutula*. A strong decoction of the herb may be used as a wash to the poisoned surfaces, or the bruised fresh herb may be rubbed over the affected parts. One application often cures, but in obstinate cases several days may be required (*Amer. Jour. Pharm.*, 1860, p. 412).

Rhus Metopium, Linné, is found in the south of Florida, and more abundantly in the West Indies. It is known variously as *Coral sumach*, *Mountain manchineel*, or *Bum wood*. It is a tree about 30 feet high, and its wood contains an abundance of tannin. Its leaves are composed of 5 leaflets, which are entire and smooth, and borne on long petioles. An acrid, red fruit is produced upon the tree. A gum-resin, known as *Hog gum*, or *Doctor's gum*, of Jamaica, is said to be yielded by this tree. In aqueous solution, it is reputed purgative and diuretic, and is an ingredient of strengthening plasters (Hogg, *Nat. Hist. of Veg. King.*, p. 241).

For further interesting matter regarding the Rhus family, consult Thomas Horsfield's *Experimental Dissertation on R. vernix, R. radicans, and R. glabrum*, published in 1798; see also paper on *Rhus Family in Medicine*, by H. W. Felter, M. D., in *Annual of Ec. Med. and Surgery*, Vol. V, a portion of which is included in this article.

Comocladia dentata, Jacquin (*Nat. Ord.*—Anacardiaceæ), *Guao, Bastard Brazil wood, Tooth-leaved maiden plum.* A small tree, 6 to 8 feet high, common in Cuba, thriving in stony and barren soils. The leaves are a beautiful deep-green, with a brownish margin. The bluish-brown flowers are small and borne in clusters. The branches and trunk contain a milky juice, which, upon exposure to sunlight, becomes black, and leaves a stain upon clothing and the skin. It is a native superstition that if one sleeps in the shade of this tree, death will be the penalty. The bark is the part employed, preferably when fresh. The action of this agent upon the skin is said to resemble Rhus, and it has some reputation as a remedy for *leprosy*.

Fustic.—Under this name several woods, from diverse sources, have entered commerce. Thus *Young fustic*, or *Hungarian fustic*, is derived from *Rhus Cotinus*, while *Old fustic* is the wood of *Morus tinctoria* (*Broussonetia tinctoria*). The latter contains the dye-stuff, *morin* ($C_{15}H_{10}O_7$), or *moric acid*, and *moritannic acid* ($C_{13}H_8O_6$); the former contains *fisetin* ($C_{23}H_{10}O_3[OH]_6$), which, in combination with sugar (the glucosid, *fustin*) and tannic acid, forms the yellow coloring matter of the wood. Some of the West Indian Xanthoxylums and allied species enter commerce under the name *fustic*. Fustic is not used in medicine and pharmacy, but as a dyeing material in the arts.

RIBES.—CURRANT.

The fruit of *Ribes nigrum*, Linné, and *Ribes rubrum*, Linné.

Nat. Ord.—Saxifragaceæ.

Common Names: (1) *Black currant*, (2) *Red currant*.

Botanical Source.—*Ribes Nigrum.* The Black currant is a woody bush or shrub, from 3 to 5 feet in height, with stems unarmed, and leaves 3 to 5-lobed, punctate beneath, dentate-serrate, and longer than their petioles. The racemes are lax, hairy, and somewhat nodding. Calyx campanulate, with reflexed segments; petals oblong, yellowish; bracts minute, subulate, or blunt, nearly as long as the pedicels. The fruit is large, roundish-ovoid, and nearly black (W.—L.).

Ribes Rubrum, or common *Red currant*, has unarmed, straggling, or reclined stems, with leaves obtusely 3 to 5-lobed, smooth above, pubescent beneath, subcordate at base, with margin mucronately serrate. The racemes are from lateral buds, distinct from the leaves, pendulous, and nearly glabrous. Bracts blunt, shorter than the pedicels. Calyx flattened out, short, spreading, with obtuse lobes; petals obcordate and green. Fruit globose, smooth, and red (W.—L.).

History and Chemical Composition.—The *Black currant* is a native of Europe and Siberia, growing in woods, cultivated in Europe and this country, and flowering in May. The *Red currant* grows in cold, damp woods and bogs in this country and Europe, and is extensively cultivated in gardens. It also flowers in May. The fruit of these two plants is the part used, and imparts its virtues to water. The juice of *Red currants* contains free acids (malic, citric, and tartaric acids, 1.5 to 3 per cent), sugar (4 to 7 per cent), vegetable jelly (pectin matter), gum, etc. That of *Black currants* contains the same, with the addition of a peculiar volatile principle, and a violet coloring matter.

Action, Medical Uses, and Dosage.—The juice of these berries, especially of the black currant, is said to be diuretic and diaphoretic. They may be made into a jelly, a jam, paste, etc., and are very useful in *febrile* and *inflammatory diseases*, and in *hoarseness* and *affections of the throat*. The raw juice is an excellent refrigerant beverage in *febrile diseases*. A decoction of the bark of the black currant has proved useful in *calculous affections*, *dropsy*, and *hemorrhoidal tumors*. It may be freely used. The French prepare from the berries an aromatized, fermented liquor called *cassis* (*Amer. Jour. Pharm.*, 1888, p. 337).

Related Species.—*Ribes floridum*, L'Heritier, the *Wild black currant* of this country, possesses similar properties. It is a handsome shrub, growing from 3 to 5 feet high, with leaves 1 or 2 inches long, and somewhat wider, subcordate, from 3 to 5-lobed; lobes acute, spreading, sprinkled on both sides with yellowish, resinous dots, just visible to the naked eye. Flowers greenish-yellow, subcampanulate, in pendulous, pubescent, many-flowered racemes. Calyx cylindrical; bracts linear, longer than the pedicels; petioles 1 or 2 inches long. Fruit obovoid, smooth, black, insipid. It flowers in May and June (W.—G.).

Shepherdia argentea, Buffalo berry, Bull berry.—This shrub produces an acidulous fruit, resembling currants, being a little more acid (Trimble). The fruit is largely used as a food along the Upper Missouri, where it occurs in abundance.

ROBINIA.—LOCUST TREE.

The bark and leaves of *Robinia Pseudacacia*, Linné.

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Locust tree, Black locust, Yellow locust, False acacia.*

Botanical Source.—This is a tree from 50 to 80 feet in height, and from 1 to 4 feet thick; the bark is rough and dark. The branches are numerous, smooth, and armed with stipular prickles. The leaves are unequally pinnate; the leaflets in from 8 to 12 pairs, ovate and oblong-ovate, thin, nearly sessile, and very smooth; the stipules minute, bristle-form, and partial. The flowers are white, fragrant, showy, and borne in numerous, axillary, pendulous racemes. Calyx 5-cleft, short, campanulate, slightly 2-lipped. Standard large and rounded, turned back, scarcely longer than the wings and keel. Stamens diadelphous; style bearded inside. The fruit is a legume, or linear, compressed pod, 2 to 4 inches in length, and about 6 lines wide, margined on the seed-bearing edge. Seed several, small, brown, and reniform (G.—W.). When young, the tree is armed with thorns, which disappear in its maturity.

History.—This tree, known by the names of *Black locust* and *Yellow locust*, is found in several parts of the United States, principally west of the Allegheny Mountains, being seldom found north of Pennsylvania, or in the Atlantic southern states; it blossoms in May. It is valued for the durability, hardness, and lightness of its wood. The bark and leaves are used, and yield their properties to water or alcohol. The bark of the root is the most active. The seeds are slightly acrid, and contain much oil, which may be obtained by expression. By steeping in water, their acridity is removed, and a very mild, useful meal may be then prepared from them. The inner bark is tough and fibrous

Chemical Composition.—From the root of this plant Hlasiwetz (1852) isolated *asparagin*. The flowers, according to Zwenger and Dronke (1861; see Husemann and Hilger, *Pflanzenstoffe*, p. 1046), contain a yellow, crystallizable glucosid, *robinin* ($C_{25}H_{30}O_{16}$), which, upon hydrolysis, is split into *quercetin* and a non-fermentable sugar. The bark of the locust tree, when chewed, produced violent emeto-catharsis (*Amer. Jour. Pharm.*, 1887, p. 153; F. B. Power and Jacob Cambier, *Pharm. Rundschau*, 1890, pp. 29–38). The latter authors, searching for the poisonous principle, found it in an albuminous body (*phytalbumose*, 1.66 per cent), which is tasteless, soluble in water, insoluble in alcohol, and coagulated by heat, with complete loss of its toxic properties; for this reason some declare a decoction of the bark is inert. It is precipitated by tannic acid and by solution of potassium bismuth iodide. It is allied to *ricin*, the poisonous, albuminous constituent of the castor-oil seed. (For further reactions, see the original paper.) The authors, in addition, found an inert albumin (*globulin*, characterized by being insoluble in concentrated salt solution); small quantities of the poisonous alkaloid, *choline* (of the class known as *ptomaïnes*), fatty matter, inert resin, cane sugar (4.57 per cent, referred to air-dry bark), starch, gum, some tannin, coloring matter, and probably *asparagin*. The poisonous principle, in the form of an albuminous body, was likewise obtained by R. Kobert (*Jahresb. der Pharm.*, 1891, p. 146).

Action, Medical Uses, and Dosage.—A decoction of the bark of the root is tonic in small doses, but emetic and purgative in large ones. An ounce of the bark boiled in 3 gills of water, operates as a cathartic in doses of $\frac{1}{2}$ ounce, given morning and evening. The bark is supposed to possess some acro-narcotic properties, as the juice of it has been known to produce coma and slight convulsions. An overdose has produced symptoms very similar to those resulting from an improper dose of belladonna, and at the same time cured a case of *fever and ague*. The flowers possess antispasmodic properties, and form an excellent and agreeable syrup. The leaves, in doses of 30 grains, every 20 minutes, operate mildly and efficiently as an emetic. The drug should be tested for its effects upon *gastro-intestinal* and *nervous affections*.

ROSA CANINA.—DOG ROSE.

The recent ripe fruit of *Rosa Canina*, Linné, and other related indigenous species.

Nat. Ord. Rosaceæ.

COMMON NAMES AND SYNONYMS: *Dog rose, Hip-tree, Wild brier; Cynosbata, Fructus cynosbati.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 103.

Botanical Source.—Dog rose is a soft, branched, smooth bush, with long green curved root-shoots, covered with equal, remote, strong, compressed, falcate prickles. The leaflets, 5 to 9 in number, are ovate, firm, without glandular pubescence, and have acute, incurved and often double serratures. Flowers with leafy bracts. Sepals partly pinnated, and usually naked as well as the tube of the calyx. Petals white or pink, obcordate, and fragrant; throat of the calyx thick and quite closed up. Fruit red, succulent, ovoid, truncated, in consequence of the fall of the sepals (L.—W.).

History, Description, and Chemical Composition.—This plant is indigenous to Europe, and introduced into this country; it usually attains the height of 6 or 10 feet, and flowers in June and July. The flowers are succeeded by a scarlet fruit called *hip*. The fruit (*Rosæ Caninæ Fructus*) was official in *Br. Pharm.*, 1885. It is inodorous, but possesses a rather pleasant, sweetish, acidulous taste, which is increased by the action of frost. The hip or fruit (not a true fruit) consists of the developed tube of the calyx, inclosing within its cavity numerous carpels or true fruits; these must be carefully removed before it is used for pharmaceutical purposes. After having been dried it contains gum, citric acid, malic acid, a large proportion of uncrystallizable sugar, various salts, and traces of wax, resin, and volatile oil. Its properties are preserved by beating the pulp with sugar (C.). The vanilla-like fragrance of the fruits is due to the presence of *vanillin* (Schneegans, *Jahresb. der Pharm.*, 1890, p. 148).

Pharmaceutical Uses.—The conserve made by beating the pulp with sugar, is called conserve of dog rose, or conserve of hips (*Confectio Rosæ Caninæ, Br.*), and is tenacious, retaining its softness for a long time, even under exposure to the air. It is a useful material for forming pill masses, and, as it contains less tannic acid, may be used as a substitute for the conserve of red roses, when preparations of iron are to enter into the pill mass.

ROSA CENTIFOLIA (U. S. P.)—PALE ROSE.

"The petals of *Rosa centifolia*, Linné"—(*U. S. P.*).

Nat. Ord.—Rosaceæ.

COMMON NAMES AND SYNONYM: *Hundred-leaved rose, Cabbage rose-petals; Flores rosarum incarnatarum.*

ILLUSTRATION. Bentley and Trimen, *Med. Plants*, 105.

Botanical Source.—This is an erect shrub, 3 to 6 feet in height, having the branches closely covered with nearly straight prickles, scarcely dilated at base, and glandular bristles of various forms and sizes; the large ones are falcate. Shoots erect. Leaves unequally pinnated; leaflets 5 to 7, oblong or ovate, glandular-ciliate on the margin, and subpilose beneath. The flowers are large, usually of a pink color, but varying in hue, form, size, etc., through 100 known varieties, several together, and drooping, with leafy bracts; flower-bud short and ovoid. Sepals leafy, compound, viscid, and spreading in flower. Petals 5, and usually pale-red. Fruit ovoid; calyx and peduncles glandular-hispid, viscid, and fragrant (L.—W.).

History, Description, and Chemical Composition.—The native country of this rose-bush is unknown; but it is extensively cultivated in nearly all parts of the world, forming a valuable ornament to gardens. There are many varieties, the most fragrant of which are the best adapted for use. (For some accounts of the cultivation of roses, see *Amer. Jour. Pharm.*, 1887, p. 33, and 1893, p. 603.) The parts employed are the petals, which are "roundish-obovate and retuse, or obcordate, pink, fragrant, sweetish, slightly bitter and faintly astringent"—(*U. S. P.*).

They should be gathered before they are fully blown, freed from the calyx cups and stamens, and dried in the air. To preserve them they are frequently salted. The petals contain volatile oil (*otto of roses*, see *Oleum Rosæ*), tannic acid, coloring matter, saccharine matter, mineral salts, salts of malic and tartaric acids, etc. (J. B. Enz, Wittstein's *Vierteljahrsschrift*, 1867, p. 53).

Pharmaceutical and Medical Uses.—This rose, on account of its delightful fragrancy, is principally employed in France for the distillation of rose-water, so much used in collyria and other lotions; taken internally, it is said to be gently aperient, but is seldom, if ever, administered for this purpose.

ROSA GALLICA (U. S. P.)—RED ROSE.

"The petals of *Rosa gallica*, Linne, collected before expanding"—(*U. S. P.*).

Nat. Ord.—Rosaceæ.

Common Names and Synonyms: *Red rose petals*, *French rose*, *Provence rose; Flores rosarum rubrarum*, *Rosæ gallicæ petala* (*Br.*).

Illustration: Bentley and Trimen, *Med. Plants*, 104.

Botanical Source.—The *Red*, *French* or *Provence rose* is a dwarfish, short-branched bush, 2 to 3 feet high, with the stem and petioles armed with numerous fine, nearly equal, uniform prickles and glandular bristles intermixed; the leaflets, mostly 5, are stiff, elliptical, and rugose. The flowers are large, erect, and several together, with leafy bracts; sepals ovate, leafy, and compound. Petals 5 or more, obcordate, large, spreading, and of a rich crimson color. The fruit is oblong or ovoid, glossy, and very coriaceous (L.—W.).

History and Description.—This plant is indigenous to Austria and other parts of the middle and south of Europe, and is common in the gardens of that country and the United States. There are a great many varieties known in cultivation. With this plant as with other species, cultivation multiplies the petals very much, by the conversion of stamina. The official parts are the petals. They should be collected previous to the expansion of the flowers, freed from their calyces and claws or heels, and speedily dried in the sun or by artificial heat. When dried they are sifted to remove the stamens and insects, and should be kept in a dry place, as for instance, in well-covered tin canisters or bottles. "When dried they have a velvety appearance; their color is purplish-red; their odor is much improved by desiccation" (Pareira). As officially described they are "usually in small cones, consisting of numerous imbricated, roundish, retuse, deep purple-colored, yellow-clawed petals, having a roseate odor and a bitterish, slightly acidulous and distinctly astringent taste"—(*U. S. P.*).

Chemical Composition.—Infusion of red rose yields a black precipitate with ferric salts, and is changed to a scarlet color by sulphuric acid. Water takes up their properties. Cartier found in the petals volatile oil, coloring matter, tannic and gallic acids, fatty matter, albumen, soluble potassium salts (the ash containing 42 to 44 per cent of potassa, Niederstadt), calcareous insoluble salts, silica, and oxide of iron. Filhol found a notable quantity of *quercitrin* in them, to which he attributes their astringency, also a large amount (20 per cent) of non-crystallizable sugar. Bowman (*Amer. Jour. Pharm.*, 1869, p. 194) finds 5.4 per cent of tannin present. The coloring matter, according to H. Senier (1877), is insoluble in ether which dissolves quercitrin and fat, soluble in much alcohol, precipitated by lead acetate. Acids color it a more vivid red, while alkalies turn it dark-red with green reflection, then yellow. Adulteration sometimes consists in artificially dyeing rose leaves with aniline colors (*Amer. Jour. Pharm.*, 1881, p. 314).

Action and Medical Uses.—Red roses are tonic and mildly astringent. They have been used in *passive hemorrhages*, and *excessive mucous discharges*. They have also been found beneficial in *bowel complaints*, and are more commonly used in *ophthalmic diseases* as a poultice, or, the pith of sassafras and infusion of roses as a collyrium in *acute ophthalmia*. The infusion is also used as a vehicle for various other remedies. The confection is mostly employed as a basis for making pills. If iron be added to the confection, or any of its preparations, it forms a hard black pill, which passes through the alimentary canal unchanged.

ROSMARINUS.—ROSEMARY.

The tops and leaves of *Rosmarinus officinalis*, Linné.

Nat. Ord.—Labiatæ.

Common Name and Synonyms: *Rosemary; Folia rosmarini, Folia roris marini, Folia anthos.*

Illustration: Bentley and Trimen, *Med. Plants*, 207.

Botanical Source.—Rosemary is an erect, perennial, evergreen shrub, 2 to 4 feet high, with numerous branches of an ash color, and densely leafy. The leaves are sessile, opposite, linear, over an inch in length, and about 2 lines broad, entire, obtuse at the summit, revolute at the margins, of a firm consistence, dark-green and shining above, and downy and sometimes whitish beneath. The flowers are few, bright-blue or white, subsessile, and borne in short, opposite, axillary, and terminal racemes; the bracts are shorter than the calyx; the calyx purplish, campanulate, and villose; the corolla not ringed in the inside, somewhat inflated in the throat, with 2 equal lips, the upper of which is erect and emarginate, the lower trifid, with the middle lobe very large, concave, and hanging down. Stamens 2; filaments minutely toothed near the base; anthers linear, with 2 divaricating, confluent cells. Upper lobe of style very short. Seeds 4, oblong, naked at the base of the calyx (L.—W.).

Fig. 210.

Rosmarinus officinalis.

History.—Rosemary is a native of the countries surrounding the Mediterranean, and is cultivated in nearly every garden for its beauty and fragrance, flowering in April and May. The parts used in medicine are the flowering tops, which have a powerful, diffusive, camphoraceous odor, and an aromatic, bitter taste; they yield their properties to water or spirits, but more effectually to alcohol. The leaves are likewise used. Age and drying impair their odor and virtues, which are due to a volatile oil (*Oleum Rosmarini*), and which may be procured by distillation. On standing for some time, the oil deposits crystals of stearopten (*rosemary camphor*). Tannin, a bitter body, and resin are also constituents.

Action, Medical Uses, and Dosage.—Rosemary is stimulant, antispasmodic, and emmenagogue; seldom used in this country, except as a perfume for ointments, liniments, embrocations, etc. The oil is principally employed. Dose, internally, from 3 to 6 drops.

RUBIA.—MADDER.

The root of *Rubia tinctorum*, Linné.

Nat. Ord.—Rubiaceæ.

Common Names: *Madder, Dyer's madder.*

Botanical Source.—Dyer's madder has a perennial, long, cylindrical root, about the thickness of a quill, branched, externally deep, reddish-brown. The stems are several in number, herbaceous, diffuse, brittle, branched, tetragonal, and very rough, with sharp hooks. The leaves are 4 to 6 in a whorl, lanceolate or oblong-lanceolate, mucronate, somewhat membraneous, with pinnated veins, 2 or 3 inches long, and nearly one-third as wide. Flowers small and yellow. Corolla rotate and 5-parted; lobes ovate-lanceolate, apiculate. Stamens 5, short; styles 2 short; anthers ovate-oblong; stigmas conical. Fruit didymous, globose, baccate, shining, and juicy (L.—Wi.).

History and Description.—Madder is a native of the Mediterranean and southern European countries, and was extensively cultivated for the use of the dyer in various parts of that continent. The drug was chiefly imported from Holland and France, but its use is now largely supplanted by that of the artificial alizarin dye-stuffs. The root is collected in the third year of the plant, is freed from its epidermis and then dried. It consists of a dark, easily separable cortex, whose epidermis is thin, and of a ligneous meditullium, which, in the fresh state, is yellow, but becomes reddish by drying. It has a feeble odor, and a bitter and astringent taste, which properties, together with its color, are communicated to alcohol or water. The microscope discovers numerous needle-shaped crystals, or raphides, in the cells of the root-bark (P.).

Chemical Composition.—The color-producing principles of madder root are chiefly *alizarin* ($C_{14}H_8O_4$) and *purpurin* ($C_{14}H_8O_5$), which exist in the root partly free, but mostly combined with sugar, in the form of more or less easily decomposable glucosids. Decomposition is effected through the agency of the water-soluble, nitrogenous ferment, *erythrozym*, when solutions of madder extract are exposed to the air (Schunck, 1851). The alizarin-glucosid is the *ruberythric acid* of Rochleder (1851) (*rubianic acid* of Schunck), and is itself probably a decomposition product of *rubian* (Schunck). In the formation of purpurin from the glucosid, an intermediary product is *pseudo-purpurin* (*purpurin-carbonic acid*), which also exists in the root in free condition. Upon exposure to the air, it loses carbonic acid, and becomes purpurin. Additional constituents of madder root are sugar (10 to 15 per cent), pectin, albuminous bodies, yellow *xanthine* of Kuhlmann (1824), and *rubichloric acid* of Rochleder (*chlorogenine* of Schunck), which is a glucosid yielding an undesirable brownish-green coloring matter. Xanthine and chlorogenine can be removed with cold water, which dissolves from dried madder a total of 55 per cent, while boiling water abstracts about 3 per cent, consisting of nearly all the valuable color-giving constituents of madder.

ALIZARIN ($C_{14}H_8O_4$) was discovered in madder, in 1826, by Colin and Robiquet, and was obtained synthetically from the hydrocarbon, *anthracene* ($C_{14}H_{10}$), by Graebe and Liebermann, in 1869. According to these chemists, it is *dioxyanthraquinone*. Alizarin crystallizes in dark-yellow or red prisms, or in scales, is freely soluble in alcohol, ether, wood alcohol, benzol, carbon disulphide, oil of turpentine and glycerin, very little soluble in boiling water (1 in 2940). It is insoluble in cold, very little soluble in hot solution of alum, differing in this respect from purpurin. At a temperature of 237.7° C. (460° F.), it sublimes in the form of orange-colored prisms. It dissolves in caustic alkali with purple-blue color; with calcium, barium, aluminum salts, also with the salts of heavy metals, it forms insoluble colored compounds. With alumina, fixed in fabrics, it yields red and pink; with ferric salts, purple and black colors; calico impregnated with oil and alum produces, with alizarin, *Turkey-red*.

PURPURIN ($C_{14}H_8O_5$) is *oxyalizarin* or *trioxy-anthraquinone*. It was formerly designated as *madder-purple*. It crystallizes from alcohol in red needles, is more soluble in boiling water than alizarin, and dissolves readily in hot solution of alum with cherry-red color. By heating purpurin in sealed glass tubes to about 215° C. (400° F.), it is converted into alizarin (Bolley).

As to other coloring principles of madder, *e. g.*, *munjistin* ($C_{15}H_8O_6$) and *purpuro-xanthine* ($C_{14}H_8O_4$), see A. Wurtz, *Amer. Jour. Pharm.*, 1883, p. 365; and Husemann and Hilger, *Pflanzenstoffe*. Also see admirable paper on madder by Dr. Crace-Calvert, *Pharm. Jour. Trans.*, Vol. II, 1871–72, pp. 394 and 414; and by W. J. Russell, *ibid.*, Vol. IV, 1873–74, pp. 346 and 382.

Action, Medical Uses, and Dosage.—Madder is supposed to promote the menstrual and urinary discharges, and has been recommended for such purposes by various practitioners. However, it is not in general use, as the profession lack confidence in its action. The dose is 30 grains, 3 or 4 times a day. Animals fed upon madder have their bones colored red by it.

ALIZARIN INK.—Leonhardi obtained a patent for "*Alizarin Ink*" which does not contain gum, is prevented from becoming moldy by its indigo and acetate of iron, and in which the sulphate of indigo prevents the tannate of iron from separating. It is prepared by digesting 24 parts of aleppo galls and 3 parts of Dutch madder with 120 parts of water. The liquid is filtered and mixed with 1.2 parts solution of indigo, 6.2 sulphate of iron, and 2 parts crude acetate of iron solution. It is said to be a superior ink.

RUBUS (U. S. P.)—RUBUS.

The bark of the root of *Rubus villosus*, Aiton; *Rubus canadensis*, Linné; and *Rubus trivialis*, Michaux.

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Blackberry*, etc. (see next page).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 100.

Botanical Source.—*Rubus villosus* is a perennial, half shrubby plant, pubescent and prickly. Its root is woody, knotty, and horizontal, and sends up a tall, branching, slender, prickly, more or less furrowed and angular stem, recurved at top, and from 3 to 6 feet high. The leaves are mostly in threes, sometimes fives, often solitary, on a channeled, hairy petiole; leaflets ovate, acuminate, sharply and unequally serrate, covered with scattered hairs above, and with a thick, soft pubescence underneath; terminal stalked; 2 side ones sessile; petiole and back of the midrib commonly armed with short, recurved prickles. Branchlets, stalks, and lower surface of the leaves hairy and glandular; leaflets from 2½ to 4 inches long, by 1½ to 2½ inches wide. Flowers large, in erect racemes, with a hairy, prickly stalk; pedicels slender, 1 or 2 inches long, with glandular hairs and lanceolate bracts. Petals 5, white, ovate or oblong, concave, contracted into a short claw at base. Calyx short, with ovate, hairy segments, ending in an acuminate point, or a lanceolate leaflet. Stamens numerous, inserted on the calyx along with the petals; filaments slender; anthers small. The fruit is large, at first green, then red, and, when matured, black; it consists of about 20 roundish, shining, black, fleshy carpels, closely collected into an ovate or oblong head, subacid, well flavored, and ripening in August and September (L.—W.—G.).

Rubus canadensis, sometimes called *Low* or *Creeping blackberry*, has a slender, prickly stem, procumbent, or trailing several yards upon the ground. The leaves are petiolate, of three (or pedately 5 or 7) leaflets, which are elliptical, or rhomboidal-oval, acute, thin, membranaceous, sharply and unequally cut-serrate, often somewhat incised, somewhat pubescent, 1 to 1½ inches long, and about one-half as wide. The flowers are large, white, nearly solitary, on slender, elongated, prickly, somewhat corymbed pedicels, with leafy bracts; lower peduncles distant; upper crowded. Petals obovate and twice as long as the calyx. The fruit is large, black, very sweet, and juicy (W.—T.—G.).

Rubus trivialis, or *Low-bush blackberry*, of the southern states (*Southern dewberry*). has a procumbent, shrubby stem, armed with both prickles and bristles. The leaves are trifoliate, or pedately 5-parted, evergreen, leathery, and almost smooth. The leaflets are sharply serrate, and of the ovate-oblong or lanceolate form. Flowers large, and from 1 to 3 to the peduncles. They blossom in March.

History, Description, and Chemical Composition.—The *Dewberry* grows wild in dry, stony fields, gravelly soil, and neglected grounds, and is common from Canada to Virginia, flowering in May, and ripening its fruit in July and August. The root is the official part; it is generally smaller than the blackberry root, with its external covering transversely cracked, of a dark, brownish-gray color, odorless, and woody internally. The *Southern dewberry* blooms in March, and matures its fruit in May. It is found in sandy soils from Virginia to Florida, and from thence westward. *Blackberry* grows abundantly in most parts of the United States, in old fields, by the roadside, and on the borders of thickets, flowering from May to July, and maturing its fruit in August. The bark of the root is the part used. As demanded by the *U. S. P.*, it is "in thin, tough, flexible bands, outer surface blackish, or blackish-gray, inner surface pale-brownish, sometimes with strips of whitish, tasteless wood adhering; inodorous; taste strongly astringent, somewhat bitter"—(*U. S. P.*).

These plants possess astringent medicinal properties, and may be substituted the one for the other. The bark of the old roots, or the smaller roots, of dewberry and blackberry, should always be preferred, as the woody portion is inert. Their properties are similar, and they impart their virtues to water, alcohol, or port wine. The fruits of these plants (and *Rubus strigosus*) are much esteemed as an article of diet, and have been manufactured into cordials, jams, jellies, and syrups. They contain volatile oil, coloring matters, citric and malic acids, sugar, mucilage, etc. The root-bark of Rubus villosus, according to analysis by G. A. Krauss (*Amer. Jour. Pharm.*, 1889, p. 605, and 1890, p. 161), contains a crystallizable, bitter glucosid, *villosin*, sparingly soluble in water and petroleum benzin; freely soluble in alcohol, insoluble in chloroform, nearly so in ether. It is rather unstable, being readily hydrolyzed into sugar and resinous *villosic acid*, soluble in alcohol, ether, and chloroform. Herman Harms (*ibid.*, 1894, p. 580) believes villosin to be allied to *saponin*. This author found the dry bark to contain from 12 to 19 per cent of tannin.

Action, Medical Uses, and Dosage.—These plants are useful as astringents. An infusion or decoction of the leaves of raspberry (see *Rubus Idæus*), or the bark of the roots of the other two, has been found an excellent remedy in *diarrhœa*, *dysentery* (chronic), *cholera infantum*, *relaxed conditions of the intestines* of children, *passive hemorrhage from the stomach*, *bowels*, or *uterus*, and in *colliquative diarrhœa*. The decoction, used as an injection, is useful in *gonorrhœa*, *gleet*, *leucorrhœa*, and *prolapsus uteri* and *ani*. In *prolapsus uteri*, it may be used either alone or combined with the internal use of a decoction of equal parts of black cohosh and blackberry roots, taken freely. Rubus villosus is especially adapted to *children's diarrhœas*, the stools being copious, watery, and clay-colored. Such children are pale, fretful, without appetite, there is deficient glandular activity, and the gastro-intestinal tract shows evidence of enfeeblement and relaxation. The leaves of raspberry, in decoction with cream, will allay nausea and vomiting, and, combined with aromatics, have been found useful in *diarrhœa*, *cholera morbus*, and *cholera infantum*. It is said that raspberry will, during *labor*, increase the activity of the uterine contractions when these are feeble, even in instances where ergot has failed, and that it has been found serviceable in *after-pains*. The fruit, especially that of the blackberry, makes an excellent syrup, which is of much service in *dysentery*, being pleasant to the taste, mitigating the accompanying tenesmus and sufferings of the patient, and ultimately effecting a cure. The fruit of the raspberry contains very little nourishment, but is an agreeable acidulous article, rarely disturbing the stomach, and, when eaten freely, promotes the action of the bowels. Raspberry syrup, added to water, forms a refreshing and beneficial beverage for *fever patients*, and during convalescence. The jelly or jam may likewise be used in similar cases; that of the blackberry being more astringent, is better adapted to cases of *diarrhœa*, *dysentery*, and *cholera infantum*. Dose of the decoction of these plants, from 1 to 4 fluid ounces, several times a day; of the pulverized root-bark, 20 to 30 grains.

Specific Indications and Uses.—(*Rubus villosus.*) Gastro-intestinal atony, with copious, watery, and pale alvine discharges.

RUBUS IDÆUS (U. S. P.)—RASPBERRY.

"The fruit of *Rubus Idæus*, Linné"—(*U. S. P.*), and fruit and leaves of *Rubus strigosus*, Michaux.

Nat. Ord.—Rosaceæ.

Common Names: (1) *Raspberry*, (2) *Red raspberry*.

Botanical Source.—*Rubus Idæus*. This plant grows to a height of 6 feet. The young branches are glaucous, somewhat bristly and spinous, with odd-pinnate leaves, bearing 1, 2, or 3 pairs of serrate, ovate, sessile, whitish, pubescent leaflets. The flower-petals are white, about the length of the calyx-lobes, and 5 in number. The plant is believed to be derived from the following plant.

Rubus strigosus, Michaux, is a shrubby, strongly hispid plant, about 4 feet in height. The leaves are pinnately 3 or 5-foliate; the leaflets oblong-ovate or oval, obtuse at base, pointed, coarsely and unequally serrate, green above, canescent tomentose beneath, lateral ones sessile, odd one often subcordate at base, and distinctly petiolate, 1½ to 2½ inches long, and about one-third to two-thirds as wide. The flowers are white, and borne in panicled corymbs. Corolla cup-shaped, about the length of the calyx. Fruit a red berry, hemispherical, composed of many juicy, 1-seeded acini, on a dry receptacle, of a rich, delicious flavor (W.).

History and Description.—*Rubus Idæus*, or cultivated raspberry, is indigenous to Europe and to Asia, eastward to Japan, where the red raspberry is likewise found. The *Red raspberry* grows wild, and is common to Canada and the northern United States, growing in hedges, neglected fields, thickets, and hills, flowering in May, and ripening its fruit from June to August. The leaves and fruit are the medicinal parts. The leaves impart their properties to water, giving to the infusion an odor and flavor somewhat similar to that of some kinds of black tea. The *U. S. P.* describes Rubus Idæus fruit as follows: "Deprived of the conical receptacle, and, therefore, hollow at the base; hemispherical, red, finely hairy, composed of from 20 to 30 coalesced, small drupes, each one crowned with the withered style; juice red; of an agreeable odor, and a pleasant, acidulous taste.

The closely allied, light-red fruit of *Rubus strigosus*, Michaux, and the purplish-black fruit of *Rubus occidentalis*, Linné, may be employed in place of the above"—(*U. S. P.*). The *Rubus occidentalis* is the *Black raspberry*, or *Thimbleberry*, common in waste places and fence corners from Canada to Georgia, and west. Its fruit is inferior to that of the preceding varieties.

Chemical Composition.—According to analysis by Seyffert (*Archiv der Pharm.*, 1879, p. 324), garden raspberries yielded 9 per cent more juice than a wild-growing variety. Acidity was about equal in both specimens (1.4 per cent). The cultivated variety contained 4.5 per cent of sugar, while the other had only 2.8 per cent (referred to fresh berries). According to Papst (see Dragendorff's *Heilpflanzen*, p. 278), the acids of raspberry juice are chiefly malic and citric acids; the sugar consists of *lævulose* (4.6 per cent) and *dextrose* (2.5 per cent). *Raspberry camphor* is a volatile solid, which forms in an aqueous distillate from pressed raspberries (Bley; see Husemann and Hilger, *Pflanzenstoffe*, p. 1005).

Action, Medical Uses, and Dosage.—Same as for *Rubus*. A syrup is prepared from *R. Idæus.*

Related Species.—*Rubus odoratus*, Linné, *Rose-flowering raspberry*, or *Mulberry*, has an erect or reclining, unarmed, glandular-pilose, shrubby stem, from 3 to 5 feet in height. Leaves 4 to 8 inches long, nearly as wide, cordate at base, palmately 3 to 5-lobed, unequally serrate; lobes acuminate, the middle one prolonged; petioles 2 or 3 inches long, and with the peduncles, calyx, and branches clothed with viscid hairs. Flowers many, large, nearly 2 inches in diameter, in terminal corymbs. Petals orbicular, purple-rose color; stamens numerous, whitish. Fruit broad and thin, bright-red, sweet. This plant grows on rocky banks and in upland woods in the United States and Canada, flowering in June and July, and ripening its fruit in August. A decoction of it is said to be powerfully diuretic, and may be used freely in *affections of the urinary organs*, and *dropsy* (W.—G.).

Rubus Chamæmorus, Linné, or *Cloudberry*, is a small, herbaceous plant, found in our White Mountains. Mr. C. O. Cech found the berries to contain much sugar, citric acid, and an orange-yellow coloring matter. In Russia, where it is indigenous, the infusion of the leaves is successfully employed in *cystic debility* and *dropsy.*

RUMEX (U. S. P.)—RUMEX.

"The root of *Rumex crispus*, Linné, and of some other species of Rumex"—(*U. S. P.*).

Nat. Ord.—Polygonaceæ.

Botanical Source and History.—*Rumex crispus*, Linné, or *Yellow dock*, is the species of dock most commonly used by physicians. It has a deep spindle-shaped, yellow root, with a stem 2 or 3 feet high, angular, furrowed, somewhat zigzag, smooth to the touch, panicled, and leafy. The leaves are lanceolate, acute, strongly undulated, and crisped at the edges, of a light-green color; radical ones on long petioles, truncate, or subcordate at base; uppermost narrower, and nearly sessile. Flowers numerous, pale-green, drooping, in a large panicle consisting of many wand-like racemes of half-whorls, interspersed with leaves below. Inner sepals, or valves, much larger than the outer, veiny, waved, entire, ovate, each bearing a large ovate-brown grain or tubercle on the back. Nut contracted at each end, with three blunt or tumid angles. This plant is introduced into this country from Europe, growing in cultivated grounds, waste grounds, about rubbish, etc., flowering in June and July (L.—G.—W.).

Rumex aquaticus, Pursh (*R. orbiculatus*, Gray), or *Great water dock*, has a stout black root, whitish internally, with a thick, erect stem, 3 to 5 feet high. Leaves 1 foot or more in length, 3 to 5 inches wide, smooth, lanceolate, and pointed; lower ones cordate, on long petioles. Flowers verticillate, in a terminal, leafy panicle. Pedicels capillary, drooping. The 3 petals, or as termed by some botanists, the 3 inner divisions of the calyx, which form a kind of triangle, and are termed valves, are large, broadly-ovate, obtuse, entire, and minutely granular along the center. This is an European plant, but introduced into this country, growing in wet places, ditches, etc., and flowering in July (W.—G.).

Rumex britannica, Linné, or *Yellow-rooted water dock*, has a large root, externally dark, internally yellowish, with an angular, furrowed, branching stem, 2 or 3 feet high. Leaves broad-lanceolate, acute at both ends, 3 to 5 inches long, petiolate, flat, smooth, with the sheathing stipules slightly rent. Flowers perfect, in verticillate fascicles collected into a large, terminal panicle, the spikes of which are nearly leafless; pedicels capillary and nodding in fruit. Calyx valves large, cordate, entire, graniferous, 2 of the grains small or abortive. This is an indigenous plant, growing in muddy places, along banks of streams, etc., in various parts of the United States, and bearing flowers from May to August (W.—G.—Wi.).

Rumex obtusifolius, Linné, or *Blunt-leaved dock*, has its root brown outside and yellow within; the stem is 2 or 3 feet high, furrowed, somewhat roughish, branching, and leafy. Radical leaves about 1 foot long, and 5 or 6 inches in width, ovate-cordate, obtuse, rather downy on veins underneath, somewhat wavy margined, often with stock and veins red; upper ones oblong-lanceolate, and acute. Flowers in long, nearly naked racemes; whorls loose and distant; valves ovate-halbert-shaped, sharply denticulate at the base, strongly reticulated, one of them principally bearing a granule on the back. This is a common weed, introduced from Europe, growing about houses and fields, and flowering from May to August (G.—W.).

History and Description.—These four species of dock possess similar medicinal properties. The roots of several other species have been medicinally employed, and may be used indiscriminately with the above, as the *R. patientia* and *R. alpinus* of Europe, and the *R. acutus* and *R. sanguineus* of this country. These various dock-roots have hardly any odor, an astringent, bitterish taste, and yield their virtues to alcohol, or boiling water. The young leaves of some of the species are sometimes used as greens. Yellow dock root varies in length from 4 to 6 inches, or more, and has an epidermis easily removed, beneath which are the bark layers, the woody part, and the medulla. The bark of Yellow dock root is the most active part, though the whole root is generally employed. Occasionally the root is divided longitudinally into halves or quarters; it is sometimes called *Sour dock*, *Narrow dock*, or *Curled dock*. The term *Sour dock* has been given to it probably on account of the sourness of the petioles, and which is due to the oxalic acid they contain. As officially described rumex is "from 20 to 30 Cm. (8 to 12 inches) long, about 10 to 15 Mm. ($\frac{2}{5}$ to $\frac{3}{5}$ inch) thick, somewhat fusiform, fleshy, nearly simple, annulate above, deeply wrinkled below; externally rusty brown, internally whitish, with fine, straight, interrupted, reddish, medullary rays, and a rather thick bark; fracture short; odor slight, peculiar; taste bitter and astringent"—(*U. S. P.*).

Chemical Composition.—*Yellow dock root* has been found to contain a small amount of sugar, gum, albuminous substance, starch, tannin forming green precipitates with iron salts, etc. Riegel (1841) found in the root of *R. obtusifolius* (*Radix lapathi acuti*) resin and the aforenamed substances, and a principle which he named *rumicin*, and which Karl von Thann (*Amer. Jour. Pharm.*, 1859, p. 152) believed to be identical with *chrysophanic acid* of rhubarb (see *Related Species*, next page). Rumicin was first obtained in an impure condition by Buchner and Herberger in 1831. Oxalic acid is present in the petioles of Yellow dock. Prolonged boiling injures the properties of the roots.

Action, Medical Uses, and Dosage.—The dock roots are decidedly alterative, tonic, mildly astringent, and detergent, and are eminently useful in *scorbutic*, *cutaneous*, *scrofulous*, *scirrhous* and *syphilitic affections*, *leprosy*, *elephantiasis*, etc.; for which purpose we prefer the *Rumex crispus*, which is principally employed for its alterative and tonic influences in all cases where these are desired. Preparations from old material are worthless, but very efficient medicines are produced from the green root. The drug induces retrograde metamorphosis, increases innervation, and improves nutrition. In *bad blood* with *skin disorders* it is exceedingly efficient, acting decidedly upon the glandular system, removing *chronic lymphatic enlargements*, and especially influencing those conditions in which there is a tendency to *indolent ulcerations* and *low inflammatory deposits*. The most direct indication for its use is a scrofulous condition with low deposits in the cellular tissues and glands with a tendency to break down and but little tendency to repair. It should be used both locally and internally. Small doses of specific rumex are useful in *nervous dyspepsia*, with epigastric fullness and pain, and aching or darting pain in the left chest, with flatulent distension of the stomach and eructations of gas. It is said to check *painless watery diarrhœal discharges*. Rumex is employed for "*cough* with a sensation of fullness in the chest, with sighing, yawning, and efforts to take a full inspiration." It is most valuable in respiratory affections showing impoverished and vitiated blood. It may be employed in *laryngeal*, *tracheal*, and *bronchial catarrh*, and in *chronic sore throat* with hypersecretion, and is not without good effects in *incipient phthisis*. *Summer coughs*, of a dry and stubborn character have yielded to it (Webster). The fraction of the drop acts best here. Internally in doses of from $\frac{1}{10}$ to $\frac{1}{5}$ drop specific rumex may be employed for the relief of *army itch* (*contagious prurigo*).

The fresh root bruised in cream, lard, or fresh butter, forms an excellent ointment for *scrofulous ulcers*, *scrofulous ophthalmia*, *itch*, and a discutient for *indolent glandular tumors*. An ointment of the root of R. crispus, and the root-bark of Celastrus scandens, with gunpowder, is said to prove a certain cure for the *itch*, as well as being of value in other *cutaneous diseases* and *ulcers*. Its efficacy (of the ointment) in *itch* is probably chiefly due to the sulphur in the gunpowder. The powdered root is recommended as a dentifrice, especially when the gums are spongy. Dose of the decoction or syrup, from 1 to 4 fluid ounces, 3 times a day; specific rumex, fraction of a drop to 30 drops.

Specific Indications and Uses.—Bad blood with chronic skin diseases; bubonic swellings; low deposits in glands and cellular tissues, and tendency to indolent ulcers; feeble recuperative power; irritative, dry laryngo-tracheal cough; stubborn, dry, summer cough; chronic sore throat, with glandular enlargements and hypersecretion; nervous dyspepsia, with epigastric fullness and pain extending through left half of chest; cough, with dyspnœa and sense of præcordial fullness.

Related Species.—*Rumex nepalensis*, Wallich. This plant grows abundantly in Madras and other parts of India, and is used by the natives for its astringent qualities, and for dyeing purposes. According to O. Hesse (*Amer. Jour. Pharm.*, 1896, p. 443), this root contains a series of homologous substances (differing by multiples of the group, CH_2). The author found *rumicin* ($C_{15}H_{10}O_4$) differing from chrysophanic acid (see *Rheum*) chiefly in melting point; *nepalin* ($C_{17}H_{14}O_4$) in largest quantity, and *nepodin* ($C_{18}H_{16}O_4$). (Compare the series *chrysophanic acid*, *emodin*, and *rhein*, under *Rheum*.)

Rumex hymenosepalus, Torrey.—This species of dock is plentiful in sandy soils along the Rio Grande in Mexico, western Texas, New Mexico and California. The root, called *Canaigre*, has come into prominence in recent years, on account of the large amount of tannin it contains. It was used by the Indians as a tanning material and a dye-stuff; its Mexican name is *Raiz del Indio*. The root contains 23.16 per cent of tannin (Voelcker, *Amer. Jour. Pharm.*, 1876, p. 49) and 18 per cent of starch (Clifford Richardson, *ibid.*, 1886, p. 265). The coloring matters isolated by both chemists are analogous to those of rhubarb (see *Rheum*). Prof. Trimble (*The Tannins*) found the tannin to agree with that from mangrove, rhatany and perhaps mimosa.

RUMEX ACETOSA.—SORREL.

The leaves of *Rumex Acetosa*, Linné.
Nat. Ord.—Polygonaceæ.
COMMON NAME: *Sorrel*.

Botanical Source.—Rumex Acetosa has a long and tapering, somewhat woody root, with an erect, simple, leafy, striated stem, 1 or 2 feet high. The lower leaves are petiolate, somewhat ovate, and narrow-shaped, with 2 lateral teeth; the upper ones sessile, more oblong, and narrower. The stipule is tubular, membranous, and fringed. Clusters erect, compound, whorled, and leafless. Flowers diœcious; males green, with a reddish tinge; inner sepals ovate, rather larger than the outer; females rather redder; inner sepals ovate, obtuse, red, entire, each bearing an oblong, pale tubercle. The whole herb is smooth and powerfully and agreeably acid. The root is astringent. The plant is common to England, and is sometimes cultivated in this country (L.).

History and Chemical Composition.—The leaves of this and the following plant (see *Rumex Acetosella*, next page) are the parts used in medicine. They are inodorous, and have an agreeable, acid, slightly astringent taste. The leaves chiefly contain acid oxalate (binoxalate) of potassium, tannic acid, and nitrogenous matter. By drying, their acidity is lost. They are used alone, or in the form of an infusion of the fresh leaves. The root contains a substance allied to

Fig. 211.

Rumex Acetosa.

crysophanic acid, and an iron-greening tannin. In the early stage of its growth, it abounds in oxalic acid (5 per cent soluble, and about 9 per cent insoluble). (As to the distribution of oxalic acid at different seasons of the growth of the plant, see Berthelot and André, *Amer. Jour. Pharm.*, 1886, p. 500.)

Fig. 212.

Rumex Acetosella.

Action, Medical Uses, and Dosage.—Fresh sorrel leaves are refrigerant and diuretic. An infusion is useful in *febrile* and *inflammatory diseases*, and in *scorbutic diseases*. They may likewise be used as a salad, or boiled like spinach. The leaves, eaten freely, have produced poisonous effects, owing to the potassium binoxalate they contain (see *Amer. Jour. Pharm.*, 1887, p. 7). In poisoning by this agent the same treatment should be pursued as for poisoning by oxalic acid, viz.: the free administration of chalk suspended in an abundance of water; this should be followed by an emetic or stomach-pump, and subsequently by lenitives. Wrapped up and roasted, the leaves form an excellent application to *indolent tumors, wens, boils*, etc., hastening suppuration. The inspissated juice, applied on leather, is said to form an effectual but painful cure for *tumors*, and the improbable claim has been made that it will cure *incipient cancers*. Acting upon this hint, the following preparation has been used as a remedy in *cutaneous cancers*, viz.: Take of burnt alum, 1 drachm; citric or tartaric acid, 2 drachms; oxalic acid, 2 drachms; rain-water, ½ pint. Mix. To be applied by means of a camel's-hair pencil.

Related Species.—*Rumex Acetosella*, Linné, *Field* or *Sheep sorrel*, has a leafy stem, from 6 to 12 inches in height, with lanceolate-hastate, pleasantly-acid leaves. The flowers are small, reddish, in panicled racemes. Valves ovate, scarcely enlarging in fruit, destitute of granules. Stamens and styles on separate plants; styles adherent to the angles of the ovary. This weed is found in abundance throughout the United States, growing in pastures, waste grounds, and worn fields, flowering all summer (G.—W.). A strong tincture of the fresh plant (℥viii to alcohol, 76 per cent, Oj , in doses ranging from 1 to 30 drops, has been suggested by Dr. Scudder (*Spec. Med.*) as a remedy where there is a "tendency to degeneration of tissue," and he states that whether "in *syphilis, scrofula*, or *cancer*, the indication for its use is the replacement of tissue with lower organizations." The urinary apparatus and renal secretions are influenced by it.

RUTA.—RUE.

The leaves and unripe fruit of *Ruta graveolens*, Linné.

Nat. Ord.—Rutaceæ.

Common Name: *Garden rue.*

Illustration: Bentley and Trimen, *Med. Plants*, 44.

Botanical Source.—Rue is a glaucous, hairless, erect, suffruticose, perennial plant, with branching stems, 2 or 3 feet in height, woody below, with a grayish, rough bark; herbaceous and smooth above. The leaves are alternate, 2 and 3-pinnately divided; leaflets sessile, oblong, obtuse, dotted, glaucous, or bluish-green, 6 to 10 lines long, by 2 to 4 wide; terminal ones obovate-cuneate. The flowers are yellow, or pale greenish-yellow, in terminal, corymbose racemes; peduncles subdividing. Petals 4, yellow, unguiculate, concave, wavy, and a little irregularly toothed. Stamens 8, longer than the petals; filaments subulate; anthers ovate, obtuse, and yellow. Styles 4, distinct at the base, where they spring from the inner angle of the carpels above the common axis; united upward into a single pistil, which is attenuated toward the apex; stigma 4-furrowed. Carpels terminal, leafless, trichotomous, and cymose. The fruit is a roundish capsule, warted, and 4-lobed, each lobe opening into 2 valves (L.—W.). It is remarkable that the anthers move in turns to the pistillum, and after having shed their pollen retire.

Fig. 213.

Ruta graveolens.

History, Description, and Chemical Composition.—Rue is a well-known evergreen, half-shrubby plant, common to southern Europe, and introduced into this country as a garden plant. It flowers in July and August. The whole plant has a strong, heavy, unpleasant smell, and a bitter, acrid, pungent taste, which is due to its volatile oil. The leaves are the parts used, and, when fresh, are said to irritate and even vesicate the surface to which they are applied. They should be gathered when the seed-vessels are well developed, yet still green; the seed-vessels of the unripe fruit are covered with large oil vesicles, and may likewise be used for medicinal purposes. Rue yields its properties to boiling water in infusion, but alcohol is its best solvent. The plant loses much of its activity by drying. Its chief constituents are volatile oil (see *Oleum Rutæ*), *coumarin*, the crystallizable, yellow glucosid, *rutin* (*rutic acid*), and a volatile alkaloid (Dragendorff's *Heilpflanzen*, 1898, p. 351).

Rutin ($C_{42}H_{50}O_{25}$) was discovered, in 1842, by Weiss, in the leaves of the garden rue, and also occurs in the flower-buds (*capers*) of *Capparis spinosa*, Linné, *Sophora japonica*, Linné, and other plants. Boiling with diluted acids converts it into *quercetin* (1 molecule) and *isodulcite* (3 molecules). (For further details, see Husemann and Hilger, *Pflanzenstoffe*, p. 830; and Watt's *Dictionary of Chemistry*, Vol. IV, 1894, p. 419.)

Action, Medical Uses, and Dosage.—Rue is emmenagogue, ecbolic, anthelmintic, and antispasmodic. In large doses it seems to be a narcotico-acrid poison. It is asserted to cause abortion, and such effect is accompanied with inflammation of the stomach and bowels, with cerebral disturbance. Among the symptoms are retching and vomiting, violent pain in the stomach, headache, cerebral oppression and fullness, heat flushes, uncertain locomotion, somnolence, prostration, pulse feeble, at first rapid, then slow, coldness and twitching of the extremities, and frequent desire to pass urine, which is strongly impregnated with the peculiar odor of rue. Its action is chiefly directed upon the uterus, and is capable of exciting *menorrhagia*, *inflammation*, and *miscarriage*. It has been successfully used in *flatulent colic*, *hysteria*, some *nervous complaints*, *epilepsy*, and as an excellent vermifuge. Rue is a stimulant to the genito-urinary tract, and, in small doses, might prove a remedy in atonic conditions of these parts. Owing to its affinity for the nervous system, it relieves irritation and pain when administered in small amounts. It deserves study; and from 1 to 10 drops of the strong tincture (fresh herb, ℥viii to alcohol, 98 per cent, Oj) may be given, well diluted with water, at a single dose. Dose of the leaves, from 10 to 20 grains; of the decoction, from 1 to 4 fluid ounces; of the oil, from 2 to 6 drops.

SABADILLA.—CEVADILLA.

The seeds of *Schœnocaulon officinale*, Asa Gray (*Veratrum officinale*, Schlechtendal; *Sabadilla officinarum*, Brandt; *Helonias officinalis*, Don; *Asagræa officinalis*, Lindley), deprived of and unmixed with their pericarps.

Nat. Ord.—Melanthaceæ.

COMMON NAMES: *Cevadilla*, *Sabadill*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 287.

Botanical Source and History.—The precise origin of this remedy is yet somewhat obscure; by some cevadilla is referred entirely to *Veratrum officinale*, with the synonyms as given above, while others consider it the product of *V. Sabadilla*, Retzius, with other plants of allied species. It is not probable, however, that *Veratrum Sabadilla* furnishes much of the commercial seed. The *British Pharmacopœia* (1885) gave *Schœnocaulon officinale* (*Asagræa officinalis*) as the only plant from which the seeds are procured. It is not official in the edition of 1898. The following is a description of two plants from which the seeds are reputed to be obtained:

Veratrum Sabadilla of Retzius, is a plant 3 or 4 feet high, with a simple, erect, round scape. The leaves are numerous, spreading on the ground, all radical, ovate-oblong, and obtuse, with from 8 to 14 ribs, glaucous underneath. The flowers are blackish-purple, rather nodding, on spreading, simple, or a little branched panicles; pedicels very short, approximated in twos and threes; those of the fertile flowers eventually becoming turned to one side; those of the sterile flowers deciduous, and leaving a scar. Segments of the perianth ovate-lanceolate, and veinless. Ovaries 3, oblong, connate, and obtuse; styles acute, and dilated downward; stigmas simple. Capsules 3, in form resembling those of Larkspur, occupying only one side of the stem, opening at the apex inside. Seeds 3 in each cell, imbricated, curved, blunt on one side, sooty, and acrid. This plant inhabits Mexico and the West Indian Islands (L.).

Schœnocaulon officinale, Gray (*Asagræa officinalis*, Lindley, *Veratrum officinale*, Schlechtendal, and *Helonias officinalis* of Don), is a cæspitose plant, bulbous, with the leaves linear, tapering to a point, even, smooth, entire, channeled above, carinate at the back, and about 4 feet long, by 3 lines broad. The scape is naked, the height of a man, quite simple, and terminated by a raceme 18 inches long. Perianth deeply 6-parted, spreading, yellowish-white, permanent, with linear, thick, veinless, obtuse segments, 3 of which are rather broader than the others. Filaments 6, somewhat clavate, those opposite the broad segments of the perianth longer than the others, and all longer than the perianth. Anthers large, yellow, cordate, and obtuse. Ovary formed of 3 cells, united by their sutures, with an obscure stigma. Fruit tricapsular; the carpels united by their suture separable. Seeds winged, and wrinkled. The lower flowers are hermaphrodite and fertile; the upper male and sterile. This plant is a native of the eastern side of the Mexican Andes, near Barranca de Tioselo, by the Hacienda de la Laguna, in grassy places (L.).

Description.—Cevadilla seeds are said to be brought from the Antilles, from Mexico (ripe capsules), and from Venezuela (seeds only), and are generally associated with the tri-follicled fruit, each division of which is composed of a slender elastic, membranous follicle, and from 1 to 3 black, shining, flat, shriveled, winged, elastic seeds. The seeds are odorless, but have a bitter, acrid, tingling taste, which is intense, persistent, and disagreeable; and their powder excites violent sneezing and discharge from the nostrils. They yield their properties with difficulty to water, but readily to alcohol. They are used as a source of the alkaloid *veratrine*, of which the yield is one-third of 1 per cent.

Chemical Composition.—Sabadilla seeds contain fixed oil (24.6 per cent), resin (10 per cent, of which 8.5 per cent is insoluble in ether), the alkaloid *veratrine* (Meissner, 1818) (see *Veratrina*), a peculiar volatile and crystallizable fatty acid called *sabadillic* or *cevadic acid* (Pelletier and Caventou, 1819), etc.

The alkaloidal constituents have been frequently investigated. C. R. A. Wright and A. P. Luff (*Amer. Jour. Pharm.*, 1878, p. 489, from *Lond. Jour. Chem. Soc.*, Aug., 1878, p. 358) come to the following conclusions: The seeds of Veratrum Sabadilla contain: (1) amorphous *veratrine* ($C_{37}H_{53}NO_{11}$), first isolated by Couerbe (1834); upon saponification it splits into *veratric acid* (*dimethylprotocatechuic acid*) and a new base, *verine* ($C_{28}H_{45}NO_8$); (2) crystallizable *cevadine* ($C_{32}H_{49}NO_9$), the principal alkaloid, first isolated by Merck (1855) and named by him *veratrine*. It melts at about 205.5° C. (402° F.), and upon saponification splits into the base *cevine* ($C_{27}H_{43}NO_8$) and *methylcrotonic acid* ($C_5H_8O_2$) with which the above cevadic acid is identical. The authors could not obtain the crystallizable, non-sternutatory (3) *sabadilline* of Couerbe (1834), Hübschmann (1852), and Weigelin (*Jahresb. der Pharm.*, 1871, p. 34), the existence of which, however, is upheld by Masing (*ibid.*). Wright and Luff found instead a similar body, likewise insoluble, or nearly so, in ether, but amorphous and insoluble in water, and named it *cevadilline*. The amorphous alkaloid *sabatrine* of Weigelin (*loc. cit.*) is believed by the authors to be a mixture. They likewise disbelieve the statements of former authors (Weigelin, E. Schmidt and R. Köppen, *Archiv der Pharm.*, 1877, p. 1) that cevadine (veratrine) occurs in two isomeric modifications, one crystalline, the other amorphous. Bosetti, however (*Archiv der Pharm.*, 1883, pp. 81–106), differentiated commercial veratrine into a crystallizable base, nearly insoluble in water, soluble in alcohol and ether, and identical with *cevadine* ($C_{32}H_{49}NO_9$), which he names veratrine, and an isomer of the latter, soluble in water, which he calls *veratridine* (also see *Veratrina*). E. Merck (*Amer. Jour. Pharm.*, 1891, p. 338) isolated from cevadilla seeds two new alkaloids *sabadine* ($C_{29}H_{51}NO_8$) and *sabadinine* ($C_{27}H_{43}NO_8$, or $C_{27}H_{45}NO_8$). Both are crystallizable and non-sternutatory. Wright and Luff believe the sabadilla alkaloids to be closely related to the alkaloids of aconite. Sabadilla seeds, when assayed by Keller's method (*Jahresb. der Pharm.*, 1892, p. 14), yield from 4.25 to 4.35 per cent of total alkaloid, while the yield is usually stated to be only from 1 to 2 per cent.

Action, Medical Uses, and Dosage.—Cevadilla seeds have been used as a vermifuge, and to destroy *vermin* in the hair, but their dangerous drastic and irritating properties have caused them to be dismissed from practice. They are principally used in the manufacture of veratrine; and rarely, but with great caution, in some *nervous diseases*, *tapeworm*, etc. The dose is from 5 to 15 grains, for the expulsion of *tænia*, and other *worms*. An extract has proved beneficial in painful *rheumatic* and *neuralgic affections*. Cevadilla is now used only as a source of veratrine, to which all of its activity and toxic properties are due.

SABBATIA.—AMERICAN CENTAURY.

The herb of *Sabbatia angularis*, Pursh (*Chironia angularis*, Linné).

Nat. Ord.—Gentianeæ.

COMMON NAMES: *American centaury*, *Rose-pink*.

Botanical Source.—This plant, also called *Rose-pink*, has a yellow, fibrous, biennial root, with an erect, smooth, quadrangular stem, the angles of which are winged, having many opposite branches, and 1 to 2 feet in height. The leaves are opposite, sessile, ovate, cordate at base, clasping the stem, 5-veined, smooth, entire, 1 or 2 inches in length, by ½ to 1½ inches in width. The flowers are numerous, 1¼ to 1½ inches in diameter, of a rich-rose color, terminal, on elongated peduncles, greenish or whitish in the center, forming a large corymbose panicle. Calyx with 5 lanceolate segments; tube of calyx angular. Corolla rotate, 5-parted, with oval segments twice as long as the calyx. Stamens 5; filaments slender; anthers yellow, oblong, slightly recurved when the flower first opens, after shedding their pollen, they become revolute and curl up. Ovary ovate; style longer than the stamens, and declined. Stigma 2 parted, the segments separate at first, but gradually become twisted spirally together. The capsule is 1-celled and 2-valved, with numerous seeds (L.—W.).

History and Chemical Composition.—This plant is common in most parts of the United States, growing in moist meadows, among high grass, on the prairies, and in damp, rich soils, flowering from June to September. The whole plant is used. It has a very bitter taste, and yields its virtues to water or alcohol. The best time for gathering it is during its flowering season. It is preferable to the European centaury (*Erythræa Centaurium*, Persoon). M. Mehu obtained, in 1866, crystallizable *erythrocentaurin* from European centaury. It is neutral, colorless, odorless, tasteless, and dissolves in 1630 parts of cold, 35 parts of boiling water, in 48 parts of alcohol, of 86 per cent strength, at 15° C. (59° F.), in 245 parts of ether, and 13 parts of chloroform; it is easily soluble in fixed and volatile oils. Direct sunlight causes it to turn red (*Jahresb. der Pharm.*, 1866, p. 70). Mr. J. F. Huneker (*Amer. Jour. Pharm.*, 1871, p. 207) detected a probably analogous substance in the American plant. As obtained in an impure form, it was soluble in water, alcohol, and ether, but insoluble in fixed and volatile oils, of a sharp, acrid taste, and an odor resembling that of nicotine. The crystals turn red when exposed to sunlight. Mr. William T. Hankey (*ibid.*, 1891, p. 335) made a complete analysis of the herb, and obtained the same substance, and, in addition 3.75 per cent of a bitter principle.

Action, Medical Uses, and Dosage.—Tonic. Used in autumn *periodic febrile diseases*, both as a preventive and as a remedy. It is also serviceable as a bitter tonic in *dyspepsia*, and *convalescence from fevers*. When administered in warm infusion, it is a domestic remedy for *worms*, and to restore the menstrual secretion. Dose of the powder, from ½ to 1 drachm; of the cold infusion, 4 fluid ounces, every 2 or 3 hours; of the tincture, 1 to 2 fluid drachms; and of the extract, from 2 to 6 grains.

Related Species.—*Sabbatia Elliottii*, Steudel (*Sabbatia paniculata*, Elliott), *Quinine flower*. This is an erect herb, about 12 inches in height, and is common to the pine barrens of the southern United States. It does not, probably, occur farther north than the Carolinas. The stem is smooth, slender, round, with but few leaves, and alternately branched. The leaves are small, opposite, entire, without leaf-stalks, and from ½ to 1 inch in length; the upper leaves are very narrow and linear, the lower are broader; they are attached at nearly a right angle to the stem. The flowers are white, nearly an inch broad, and quite showy; they are borne on slender peduncles, and appear late in the summer. The calyx has a short tube, and 5 linear lobes, about one-third the length of the corolla segments. The corolla is flat, rotate, and has 5 obtuse lobes. The stamens are 5, and attached to the corolla tube. The fruit is a dry, 1-celled capsule, opening by 2 valves, and containing many small seeds. This plant was noticed in the *Amer. Jour. Pharm.*, 1876, p. 455, by Dr. Palmer, of Monticello, Florida. It had been previously used in domestic practice, and during the civil war. Some little demand was created after the publication of Dr. Palmer's article, but the remedy has since almost fallen into disuse. This plant, as the name "quinine flower" would show, was supposed to possess tonic and antiperiodic properties, somewhat analogous to those of quinine. It was lauded as a remedy for all *malarial fevers*, as a tonic during convalescence from exhausting diseases, and in various forms of *debility*. It is seldom, if ever, employed at the present day. The dose of the fluid extract is from 5 to 60 minims, repeated every 1, 2, 3, or 4 hours, according to circumstances.

Erythræa Centaurium, Persoon (*Gentiana Centaurium*, Linné), *European centaury*.—A bitter tonic (see *Sabbatia*, preceding page). Several South American and Mexican species are employed as bitter tonics under the name of *Canchalagua*. Among them are *Erythræa chilensis*, Persoon; *E. jorullensis*, Kunth; *E. stricta*, Schiede, etc.

Pleurogyne rotata, Grisebach.—Japan and the Pacific states. A bitter tonic.

SABINA (U. S. P.)—SAVINE.

The tops of *Juniperus Sabina*, Linné"—(*U. S. P.*) (*Sabina officinalis*, Garcke).
Nat. Ord.—Coniferæ.

COMMON NAME: *Savin-tops.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 254.

Botanical Source.—Juniperus Sabina is an evergreen, very compact shrub, growing from 4 to 16 feet in height, with a disposition to spread horizontally rather than to form a stem. Its branches are slender, round and tough, with the bark of the young branches pale-green, of the trunk rough. The leaves are very small, ovate, convex, dark-green, densely imbricated, erect, decurrent, and opposite; the oppositions pyxidate. Flowers diœcious. The fruit is a deep-purple, almost black, ovoid berry, about the size of a whortleberry, and smaller than that of *J. communis* (L.—W.).

History, Description, and Chemical Composition.—This plant is indigenous to middle and southern Europe, Siberia, and in the northern United States, in rocky situations. The parts used are the tops and leaves. They have a powerful, peculiar, rather disagreeable odor, a bitter, acrid, biting taste, and yield their properties to alcohol, or hot water in infusion. Desiccation renders them of a lighter color. The drug is officially described as "short, thin, subquadrangular, branchlets; leaves rather dark-green, in 4 rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, on the back with a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste nauseous, resinous, and bitter"—(*U. S. P.*). Gardes found them to contain volatile oil (see *Oleum Sabinæ*), resin, gallic acid, chlorophyll, extractive, lignin, and calcareous salts. In addition to these, Mr. C. H. Needles found fixed oil, gum, and salts of potassium (*Amer. Jour. Pharm.*, Vol. XIII, 1841, p. 15).

Action, Medical Uses, and Dosage.—Savin is emmenagogue, diuretic, diaphoretic, and anthelmintic. In large doses it will produce gastro-enteritis. Care must be taken in its administration, as it has, in several instances, produced fatal results. It should never be given when there is any general or local inflammation present, and it should never be used during pregnancy, on account of its tendency to cause abortion, and yet, notwithstanding this effect, it is reputed efficient in checking the tendency to abort, and to be beneficial in *menorrhagia*, when carefully exhibited in small doses. It is also serviceable in *atonic leucorrhœa*, *amenorrhœa*, with torpor, *irritative urethral diseases*, and *vesical catarrh*, in all cases being contraindicated by an excited circulation. The oil (*Oleum Sabinæ*), given 2 or 3 times a day, in doses of from 10 or 15 drops on sugar, will, in most cases, cause abortion, but it is apt to violently affect the stomach and bowels at the same time, bringing life into extreme danger. It is sometimes combined with oils of tansy, pennyroyal, or hemlock, as an emmenagogue and abortivant, and given in doses of 2 to 5 drops. Sometimes the leaves of savin are combined with pink and senna and given to remove *worms*. Savin oil will also frequently remove them, but we have more efficient and much safer remedies for this purpose. Externally, the leaves, made into a cerate, have been used as a stimulant to *indolent ulcers*, and to promote a discharge from blistered parts. Mixed with an equal weight of verdigris, the powdered leaves have been used for destroying *venereal warts*. Dose of the powdered leaves, from 5 to 15 grains in syrup, 3 times a day; of the fluid extract, from 5 to 10 drops; of the strong tincture (℥viii to alcohol, 76 per cent, Oj), from 1 to 5 drops; of the infusion, from ½ to 2 fluid ounces.

Specific Indications and Uses.—"Suppressed menses, with colicky pains, general fullness of veins, headache" (Watkins, *Ec. Comp. of Prac. of Med.*).

Related Species.—*Juniperus virginiana*, Linné, is a tree which attains the height of 35 feet, or even more. Its trunk varies from 10 to 14 inches in diameter, is straight, and decreases rapidly from the ground, giving off many horizontal branches; its surfaces are generally unequal, and disfigured by knots, and by the crevices and protuberances they occasion. Small twigs, covered with minute, densely imbricated leaves, which are fleshy, ovate, concave, rigidly acute, with a small depressed gland on the middle of their outer side, growing in pairs which are united at the base to each other, and to the pairs above and below them. (A singular variety sometimes appears in the young shoots, especially those which issue from the base of the trees; this consists in an elongation of the leaves to 5 or 6 times their usual length, while they become spreading, acerose, remote from each other, and irregular in their insertion, being either opposite or ternate; such shoots are so dissimilar to the parent tree, that they have been repeatedly mistaken for individuals of a different species.) Barren flowers, in small oblong aments, formed by peltate scales with the anthers concealed within them. Fertile flowers form a small roundish galbus, with 2 or 3 seeds, covered on its outer surface with a bright-blue powder (L.—B.). The red cedar is a tree which inhabits almost all parts of the United States, especially the southern, preferring dry, rocky situations, and barren soils. It is evergreen, growing very slowly, and flowering in April and May. The internal wood is of a dull-reddish hue, fine-grained, and compact, very light and durable, and is much used for tubs, pails, lead-pencils, fences, etc. The parts used are the leaves and twigs. They have a characteristic, rather agreeable odor, and a peculiar, somewhat acrid and amarous taste. Their virtues are taken up by alcohol or ether, and partly by hot water, and are due to essential oil (see *Oleum Juniperi Virginianæ*). The leaves are often confounded with those of *Juniperus Sabina*, which have an entirely different smell. According to Jenks, the leaves yield gum, albumen, volatile oil, tannic acid, resin, bitter extractive, chlorophyll, fatty matter, woody fiber, etc. (*Amer. Jour. Pharm.*, Vol. XIV, p. 235). Excrescences known as *cedar apples*, are frequently formed on the branches, and occasioned, like galls, by the pricking of an insect; they have a somewhat agreeable odor, and an austere taste. These are sometimes powdered and administered successfully as a vermifuge, the dose being from 10 grains to ½ drachm, in some convenient vehicle, and repeated every 4 hours through the day. The medical properties and uses are the same as for the *Juniperus Sabina;* less energetic, but used in the same diseases; also with spearmint and marshmallows, in *scalding of urine*, and derangements of the kidneys and bladder. The oil makes a valuable external stimulating application for *rheumatic pains, bruises*, etc. Dose of the leaves, from 1 to 2 drachms; of the oil, from 10 to 15 drops. The excrescences, or *cedar apples*, are decided anthelmintics. The following makes a pleasant and excellent vermifuge and tonic for pale, sickly children; I have used it with much success: Take of cedar apples, 1 pound; of black alderberries (*Prinos verticillatus*), 1 pint, by measure. Digest these, for 14 days, in 1 quart of alcohol and 1 pint of molasses. The more recent the articles, the better. Dose, 1 fluid drachm, 3 times a day, for a child 1 or 2 years old; it is a laxative, tonic, and vermifuge (J. King).

SACCHARINUM.—SACCHARIN.

FORMULA: $C_6H_4COSO_2NH$. MOLECULAR WEIGHT: 168.65.

SYNONYMS: *Glusidum, Gluside, Glucusimide, Benzoyl-sulphonimide* (all in *Br. Pharm.*, 1898); *Benzoic sulphimide, Benzoic sulphinide, Orthosulphamine-benzoic anhydride.*

Source and History.—The sweet taste of saccharin (gluside) was discovered by Constantin Fahlberg in his researches on this substance (see Fahlberg and Remsen, *Amer. Chem. Jour.*, 1879 and 1880). It is the anhydride of *orthosulphamido-benzoic acid* (C_6H_4 COOH.SO$_2$NH$_2$) and has the formula C_6H_4:(CO)(SO$_2$):NH. It is prepared from the benzene hydrocarbon *toluene* (C_6H_5 CH$_3$) by a series of reactions, for which see explanatory details in *Pharm. Jour. Trans.*, Vol. VII, 1898, p. 593. Commercial saccharins, when first introduced, were frequently a mixture of saccharin (the *ortho* compound) with *para-sulphamido-benzoic-acid* (see *Tests*, next page; and dissertation by Dr. A. R. L. Dohme, on *Ortho-Sulpho-Benzoic Acid*, etc., Baltimore, Md.). In recent years, purified saccharins are being obtained, which consist of the ortho compound only (see *Chem. Centralblatt*, Vol. II, 1896, p. 690).

Description and Tests.—The most characteristic feature of this substance is its intense sweetness, hence the names gluside, saccharin, although the latter name properly belongs to another substance previously so named, a bitter, crystallizable derivative of the sugar group, of the formula $C_6H_{10}O_5$.

Saccharin (gluside) is a light, white, minutely crystalline powder having an intensely sweet taste in dilute solutions. A solution of 1 in 10,000 is said to be still decidedly sweet. The sweetening power of the absolutely pure ortho compound is stated to be from 500 to 550 times that of sugar. According to the *British Pharmacopœia*, gluside is "soluble in 400 parts of cold water, in 24 parts of boiling water, in 25 parts of alcohol (90 per cent), and but slightly in ether or chloroform." It is sufficiently soluble in ether, however, to enable its abstraction, for analytical purposes, from its acidulated aqueous solution. "It is very soluble in diluted solution of ammonia; also in solution of sodium bicarbonate, with evolution of carbonic anhydride. A warm solution of sodium bicarbonate, when neutralized with gluside and evaporated to dryness, yields 'soluble gluside' or 'soluble saccharin,' which is very soluble in water, 100 parts of gluside yielding nearly 113 parts of neutral 'soluble gluside'"—(*Br. Pharm.*, 1898). When saccharin is heated, it melts and then sublimes with partial decomposition, the vapors possessing an intensely sweet taste. When saccharin is heated with caustic soda to about 250° C. (482° F.) salicylic acid is formed which may be detected by dissolving the mass in acidulated water, shaking out with ether, evaporating to dryness and producing the characteristic violet-blue coloration by adding ferric chloride. If saccharin and salicylic acid are simultaneously present in a liquid (*e. g.*. beer), the amount of saccharin may be determined, according to A. H. Allen (*Amer. Jour. Pharm.*, 1888, p. 360), by igniting the isolated mixture of the two, with addition of caustic alkali and a little nitre, and determining the sulphate formed by means of barium chloride. By another method, salicylic acid may be separated from saccharin in acidulated solution by means of bromine water which precipitates all the salicylic acid as a bromine compound; from the supernatant liquid, saccharin may be conveniently extracted with ether, after the excess of bromine is removed by a current of air (Hairs, *Amer. Jour. Pharm.*, 1893, p. 554). Saccharin is distinguished from sugar by not being charred by sulphuric acid even when warmed with it for a short time. To test for para-sulphamido-benzoic acid which melts at about 288° C. (536° F.), the *British Pharmacopœia* (1898) directs that a solution of 0.5 gramme of gluside in 80 cubic centimeters of warm water, set aside for 12 hours, should deposit tabular crystals which melt between 218.8° and 220° C. (426° and 428° F.), and it should not, even when briskly shaken, deposit crystals melting at a higher temperature (absence of sulphamido-benzoic acid).

Action, Medical Uses, and Dosage.—Saccharin has come into use somewhat as a sweetening agent to replace sugar where the latter is for any reason contraindicated. It has been demonstrated that even in large doses it does not affect the system in the least. It does not augment or diminish the secretions, disturb the respiratory or circulatory functions, nor interfere with nutrition. Elimination takes place almost wholly by the kidneys, and the urine. while not increased in quantity is rendered decidedly sweet and its putrefactive tendency is markedly delayed. Saccharin passes from the system unchanged. Owing to its power over putrefaction it has been employed in *fermentative disorders of the stomach and bowels*, with distension, in *suppurative otitis*, and in *disorders of the urinary tract* with purulent urine. On account of retarding the digestive action of the pancreatic and salivary fluids in experiments conducted without the body it has been concluded by some physicians that it may retard or disorder stomachic and intestinal digestion, but clinical experience does not appear to support such a view. It is employed principally in lieu of sugar and milk sugar in *saccharine diabetes*, *fermentative dyspepsia*, *obesity*, and other disorders in which the sugars are contraindicated. Its sweetening power is exceedingly great. from 1 to 1½ grains of saccharin in combination with sodium bicarbonate being sufficient to sweeten an ordinary cup of coffee. For sweetening purposes it should be mixed with sodium bicarbonate in the proportion of 2 parts of the saccharin to 3 parts of the sodium salt. A glycerin solution prepared by heating together saccharin. 30 grains, and glycerin, ℥viij (by weight), is an efficient sweetening preparation for lemonade and acid fruits. The dose of saccharin is from 1 to 4 grains, in capsules. 4 or 5 times a day. The taste of many disagreeable medicines may be disguised by saccharin; among them are quinine, cod-liver oil, guaiacum, etc.

Related Preparation.—DULCIN, *Sucrol*, or *Paraphenetol-carbamide* ($C_6H_4.OC_2H_5.NH.CONH_2$). Colorless needles of a sweet compound prepared synthetically by acting with ammonia upon the product of the reaction between the gaseous carbonyl chloride ($COCl_2$) (1 molecule), and paraphenetidin ($C_6H_4[OC_2H_5]NH_2$) (2 molecules), both in toluene solution. The crystals fuse at 160° C. (320° F.) (see *Jahresb. der Pharm.*, 1892, p. 407; and *Amer. Jour. Pharm.*, 1893, p. 288).

SACCHARUM (U. S. P.)—SUGAR.

FORMULA: $C_{12}H_{22}O_{11}$. MOLECULAR WEIGHT: 341.2.

"The refined sugar obtained from *Saccharum officinarum*, Linné, and from various species or varieties of *Sorghum* (*Nat. Ord.*—Gramineæ); also from one or more varieties of *Beta vulgaris*, Linné (*Nat. Ord.*—Chenopodiaceæ)"—(*U. S. P.*).

COMMON NAMES AND SYNONYMS: *Cane-sugar*, *Sucrose*, *Refined sugar*, *Saccharum purificatum*, *White sugar*.

History, Source, and Preparation.—Sugar, which at present constitutes so important an article in the food of all civilized nations, seems to have been known at a very early period to the inhabitants of India and China. It was used only as a medicine for ages after its introduction into the West. But it was not until after the discovery of America, and the introduction of the sugar-cane into the West Indies by the Spaniards, that its use as an article of food became common. About one-half of the total sugar production of the world is from sugar-cane; another equally important source is the sugar-beet (*Beta vulgaris*, Linné) cultivated chiefly in Germany and Austria, and now to some extent also in this country. The occurrence of sugar in the beet was demonstrated by Marggraf, as early as 1747, but only since about 1840, the manufacture from this source began to flourish. Minor quantities of cane-sugar (sucrose) are produced from several species of Sorghum (*e.g.*, *Sorghum saccharatum*, Persoon, and *Holcus saccharatus*, Linne), a Chinese plant, and from the sap of the sugar-maple (*Acer saccharinum*, Linné, and other species), as well as the sap of the date palm (*Phœnix dactylifera*), and other palm trees. The crude sugar obtained in India, from the latter source, is called *jaggery*. Cane-sugar also occurs in corn-stalks, and in the roots of many plants, *e.g.*, parsnips, carrots, and such drugs as ipecacuanha, scopolia, etc.; in the nectar of flowers, and, together with other sugar, in ripe fruits, such as pineapples, pears, apples, bananas, dates, strawberries, etc., while it is entirely replaced by other sugars in figs, grapes, gooseberries, and sweet cherries.

Saccharum officinarum, Linné, *Sugar-cane*, is a plant having an articulated, juicy root, from which proceed several erect, solid stems, 10 or 12, sometimes 15 or 20 feet high, 1 or 2 inches in diameter, of a hard, shining rind, which is green, while the cane is immature, but turning yellow, purple, red, or striped when the cane ripens. Internally it is whitish, juicy, saccharine, and pithy. The leaves are situated at the joints, at intervals of about 2 or 3 inches, flat, sheathing at the base, 2 to 4 feet in length, about one-fourth as wide, the margins being armed with numerous small, sharp teeth. The panicle is terminal, spreading, erect, oblong, 1 to 3 feet in length, and grayish from the quantity of long, loose hairs surrounding the florets; the branches are alternate and very spreading. Rachis striated. Florets diœcious in pairs. Glumes smooth. Paleæ smooth, membranous, and of a pink color. This plant, a native of tropical and subtropical climates, is cultivated in the East and West Indies, Mauritius, Tahiti, the Sandwich Islands, and in some of the southern United States.

In cultivation, the canes are not allowed to flower, because the yield of sugar is greatest from non-flowering canes. (For interesting details regarding the cultivation of sugar-cane, and connected matters, see Henry Pocklington, *Pharm. Jour. Trans.*, Vol. V, 1875, p. 746.) When the canes turn yellow, they are cut and transported to the sugar-mills, where the juice is obtained by crushing the canes between revolving cylinders of stone or, preferably, iron. The resultant cane-straw is called *bagasse*, and is used as fuel. Sugar-cane, when matured, contains about 90 per cent of juice, which holds, on an average, 18 per cent of cane-sugar, with small quantities of uncrystallizable (invert) sugar. The latter kind occurs mostly in the upper part of the stem; it is more abundant in rapidly-growing cane than in cane of slower growth. Cane-juice also contains about 9 per cent of a peculiar albuminous matter, which readily undergoes putrefaction; likewise, small quantities of organic acids, *e. g.*, oxalic and malic acids, and *aconitic acid* (A. Behr, 1877), a derivative of citric acid, are present. These constituents cause cane-juice to be rapidly decomposed in warm climates; the acids tend to convert sucrose into uncrystallizable invert sugar. Hence, the juice must be immediately worked for sugar, by neutralizing the free acid with a calculated quantity of milk of lime; after boiling and removing the scum *(defecating)*, the juice is gradually evaporated in a series of open pans (old method), or by means of *vacuum pans*, *i. e.*, under diminished pressure at a lower temperature (modern method). By the old method, the *raw*, *brown*, or *muscovado sugar* is separated from the mother liquor, or *molasses*, by simple draining in perforated vessels; by the modern method, the molasses is separated from the sugar in centrifugal machines, and the raw sugar thus obtained is frequently pure enough for many purposes. From molasses additional quantities of sugar are frequently obtained; the residual, impure molasses is fermented and used in the distillation of *rum*. To produce *refined*, *white* or *loaf-sugar*, the raw sugar is sent to refineries, where it is dissolved in water, purified by means of bullock's blood and bone-black, and decolorized by passing the syrup through filters of animal charcoal. It is then evaporated in vacuum pans to crystallization, and the mass is run into conical molds, wherein the molasses *(treacle)* is either allowed to drain or is separated by centrifugal force. According to Dr. S. P. Sadtler (*Indust. Org. Chem.*, 2d ed., 1895, p. 152), the hard commercial sugars (dried by artificial heat) contain over 99 per cent of pure sucrose, while the softer sugars (merely centrifugated) hold about 4 per cent of water, due to traces of mother liquor adhering to the crystals.

The SUGAR-BEET contains from 12 to 15 per cent of sucrose. Unlike sugar-cane, it is free from uncrystallizable invert sugar, but contains the sugar *raffinose*. The presence of about 1.25 per cent of nitrogenous matter (*betaïne*, *asparagin*, etc.) and a comparatively large amount of salts, make the purification of the raw beet-sugar a more complicated operation than that of the sugar from sugar-cane. The molasses from beet-sugar, unlike that from cane-sugar, can not be used for table syrups, on account of its bad taste and smell. It contains about 50 per cent of sucrose, which can be recovered for the most part by precipitating the sugar in the form of calcium sucrate, or strontium sucrate (*strontium process*). (For further details, we must refer the reader to special works on technology—*e. g.*, see S. P. Sadtler, *loc. cit.*, pp. 119–166.)

Description and Tests.—Cane-sugar (sucrose), as demanded by the *U. S. P.*, occurs in "white, dry, hard, distinctly crystalline granules, odorless, and having a purely sweet taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 0.5 part of water, and in 175 parts of alcohol; in 0.2 part of boiling water, and in 28 parts of boiling alcohol; also soluble in 80 parts of boiling, absolute alcohol, but insoluble in ether, chloroform, or carbon disulphide. The aqueous solution, saturated at 15° C. (59° F.), has the specific gravity 1.345, and is miscible with water in all proportions. The aqueous or alcoholic solution of sugar is neutral to litmus paper"—(*U. S. P.*).

An aqueous solution of 850 parts of sugar in water, sufficient to make 1000 Cc., has a specific gravity of 1.317; this solution is the official *syrup* (formerly called *Syrupus Simplex*). Cane-sugar melts at about 160° C. (360° F.), and solidifies on cooling, forming a glossy, amorphous mass, called *barley sugar;* its specific gravity is only 1.509, while that of cane-sugar is 1.606. When heating cane-sugar to about 200° C. (392° F.), a brown-coloring matter, called *caramel*, is formed. Cane-sugar, upon dry distillation, yields acetone, aldehyde, acetic acid, formic acid, carbonic dioxide, some monoxide, methane, tarry products, etc. Concentrated sulphuric acid converts sugar into a charred mass, sulphurous acid being evolved. Boiling with nitric acid produces *saccharic acid* ($C_4H_4[OH]_4.[COOH]_2$), tartaric and oxalic acids. By the action of concentrated nitric and sulphuric acid upon sugar, explosive *nitro-sugars* are formed, analogous to nitro-cellulose (see *Pyroxylin*). With bases, as calcium and strontium oxide, sugar forms characteristic compounds, called *saccharates*, or *sucrates*, *e. g.*, tri-calcium sucrate ($C_{12}H_{22}O_{11}.3CaO$), which are technically important (see *Preparation*, preceding page).

Cane-sugar is optically dextro-rotatory, but upon warming with diluted acids, it is converted into *invert sugar*, which is a mixture of equal molecules of dextrose and lævulose, the combination of which is slightly lævo-rotatory. Measurement of the optical rotation by means of especially devised instruments, is of great importance in the analysis of the various sugars. (For details on this subject, with index of literature, see H. W. Wiley, *Principles and Practice of Agricultural Analysis*, Vol. III, Easton, Pa., 1897.) Cane sugar (sucrose) does not reduce Fehling's solution, nor ammoniated silver nitrate, except in traces; reduction takes place freely after inversion by means of acids. Cane-sugar as such ferments, only after it is transformed by the action of yeast into invert sugar; the latter is capable of being fermented.

The *U. S. P.* gives the following tests for the purity of cane-sugar: "Both the aqueous and the alcoholic solution of sugar should be clear and transparent. When kept in large, well-closed and completely filled bottles, the solutions should not deposit a sediment on prolonged standing (absence of *insoluble salts*, *ultramarine*, *Prussian blue*, etc.). If 1 Gm. of sugar be dissolved in 10 Cc. of boiling water, the solution mixed with 4 or 5 drops of silver nitrate T.S., then about 2 Cc. of ammonia water added, and the liquid quickly brought to the boiling point, not more than a slight coloration, but no black precipitate, should appear in the liquid after standing at rest for 5 minutes (absence of *grape-sugar*, or of more than a slight amount of *inverted sugar*)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Sugar is nutritive, alterative, demulcent, diuretic, and topically antiseptic. It belongs to the class of "elements of respiration," contributes to the formation of fat and lactic acid, and, by its oxidation, furnishes heat. It has been detected in the tissue of the liver. As it is void of nitrogen, it can not sustain life alone, and only becomes eminently nutritive when combined with other alimentary proximate principles. Used in large quantities, it is injurious to digestion. In relation to both vegetable and animal matters, it acts powerfully in preventing putrefaction; the former of which may be preserved indefinitely in syrup, so long as the syrup is secured against fermentation; while the latter, after long immersion in syrup, or in moistened sugar, may be perfectly mummefied. On this account it is now used considerably in the preservation of fish, and various meats, instead of salt, to which it is superior, requiring a smaller amount, and not materially affecting the flavor nor the nutritive properties of these meats. Sugar or molasses, when freely eaten by children, prove excellent anthelmintics, and have also proved efficient in *scorbutic affections.* Powdered white sugar is sometimes sprinkled over *ulcers* to remove fungus or proud flesh, and has been blown upon the ball of the eye to remove *specks on the cornea.* As a local application in *aphthæ*, it is quite efficient, and cures have been wrought with it in *trachoma.* It favors the detachment of *diphtheritic membranes*, and may be employed as an antiseptic dressing for various kinds of *wounds.* On account of its property of correcting fetor, a snuff of finely-powdered sugar has been used in *ozæna.* As a demulcent, sugar may be employed in various forms, in *cough*, *hoarseness*, *soreness of the throat*, etc. When taken to the extent of 12 or 16 ounces per day, dissolved in water, sugar is said to powerfully increase the sexual passion. It has long been supposed that the teeth are injured or acted upon by sugar, in a manner calculated to cause their decay, but this opinion is erroneous; if particles of sugar become lodged between the teeth, and are allowed to decompose, decay will inevitably ensue, but if the particles be removed at an early period, sugar will be found to exert a beneficial influence upon the teeth and gums. The use of it, however, is mainly confined to the preparation of syrups, to conceal the unpleasant taste of several drugs, to render water and oils miscible, to suspend certain medicines in the form of mixture or emulsion, to prevent the oxidation of some chalybeate compounds, and also for converting some agents into the state of conserve, confection, electuary, pill, or lozenge. For pills, molasses is most generally preferable to syrup, as it does not so readily harden, and preserves them in a soft, moist state, for a long time, while its antiseptic properties prevent them from becoming moldy.

Sugar, in solution, absorbs a very large quantity of lime. A *saccharate of lime* has been found very beneficial in the *chronic diarrhœas* of children, as well as to prevent acidity of the stomach, and the disposition to diarrhœa so common in children of a certain age at particular seasons. It is made by saturating simple syrup with lime, and then filtering it. It forms a transparent mixture of an extremely alkaline taste, and may be added to water or milk. It is altogether superior to the bicarbonate of sodium. Dose for an infant, from ¼ to ½ drachm, given in some of the mother's milk; for an adult, from 1 to 2½ drachms.

Related Sugars.—GLUCOSE, or GRAPE-SUGAR ($C_6H_{12}O_6$=179.58), known also as DEXTROSE, or STARCH-SUGAR, is found in grapes, cherries, plums, figs, honey, always associated with lævulose and sometimes cane-sugar (which see). Dextrose is the sugar of diabetic urine, and frequently occurs combined in the form of *glucosids*, such as *amygdalin*, *salicin*, *phloridzin*, *quercitrin*, etc. (which see). Chemically pure dextrose may be obtained by adding finely powdered cane-sugar, in small portions, to a mixture of 15 parts of alcohol (80 per cent) and 1 part of fuming hydrochloric acid, until the cane sugar is no longer dissolved. *Invert-sugar* is formed, and from the solution obtained, dextrose ($C_6H_{12}O_6+H_2O$) crystallizes, while lævulose remains in solution. On a commercial scale, grape-sugar is obtained from starch by boiling it under pressure with diluted sulphuric acid until the conversion of the starch into dextrin and finally into sugar (dextrose and some maltose) is complete. The acid solution is neutralized with calcium carbonate, the solution decolorized with animal charcoal and concentrated in vacuo, either to form commercial "grape-sugar," or the syrup known as "glucose." Commercial grape-sugar contains from 72 to about 73.5 per cent dextrose, from 0 to 3.5 per cent maltose, and from about 4 to 9 per cent dextrin; "glucose syrup" contains from 34 to 42 per cent dextrose, from 0 to 19 per cent maltose, and from 30 to 45 per cent dextrin. *Maltose* ($C_{12}H_{22}O_{11}$) is the sugar formed when *diastase*, the ferment of malt extract, is allowed to act upon solution of starch. Grape-sugar (dextrose) is soluble in water and diluted alcohol, insoluble in ether and chloroform, and crystallizes without combined water, in the form of warty masses, from hot absolute, and from methyl alcohol, also from aqueous solution at 30° to 35° C. (86° to 95° F.; otherwise it crystallizes with 1 molecule of water. In solution, it is optically dextro-rotatory (see *Cane-sugar*). Pure dextrose is less sweet than sucrose (cane-sugar), 1½ parts of the former being equivalent to 1 part of the latter. Unlike cane-sugar, dextrose is not charred by concentrated sulphuric acid, and is permanent toward acids, while sensitive toward warm alkalies; the latter darken and decompose it, with formation of lactic, formic, acetic, glucic, and saccharic acids (*Moore's Test*). Solutions of grape-sugar (dextrose) easily ferment when yeast is added, chiefly alcohol and carbonic acid being formed, according to the equation: $C_6H_{12}O_6 = 2CO_2+2C_2H_5OH$. Upon this reaction Dr. Wm. C. Alpers (Merck's *Report*, 1898, p. 468) bases a gravimetric method for determining the quantity of grape-sugar present in diabetic urine, by allowing it to ferment by means of yeast, and collecting the carbonic acid formed, in a weighed quantity of caustic potash. One Gm. of carbonic acid is equivalent to 2.0458 Gm. of dextrose.

Grape-sugar forms a crystallizable compound with sodium chloride ($2C_6H_{12}O_6.2NaCl+H_2O$) which has been incidentally obtained in the isolation of dextrose from diabetic urine. Grape-sugar (dextrose) in alkaline solution is a strongly reducing agent. It reduces Fehling's solution, ammoniated silver solution and alkaline mercuric cyanide (Knapp's) solution, etc. In these and other reactions it behaves as an aldehyde, and is believed to have the graphic formula $CH_2OH.(CHOH)_4.CHO$, while lævulose is considered to be a ketone, $CH_2OH.(CHOH)_3.CO.CH_2OH$. Both sugars are reduced to the alcohol *mannit* with nascent hydrogen in alkaline solution. An important test for dextrose is that with *phenylhydrazine* ($C_6H_5NH.NH_2$). With 2 molecules of the latter it forms *dextrosazone* which crystallizes in yellow needles, is almost insoluble in water, crystallizable from warm alcohol, and can be identified by its melting point which lies at 204° C. (399.2° F.). It is prepared by prolonged heating of 1 part of dextrose, 2 parts of the hydrochlorate of phenylhydrazine, and 3 parts of sodium acetate on the water-bath, and recrystallizing the precipitate formed. (For an exceedingly interesting summary of the more recent chemistry of the sugar group, see *Amer. Jour. Pharm.*, 1893, p. 32, from *Pharm. Jour. Trans.*, 1892.)

DETECTION OF SUGAR IN URINE.—A rapid, qualitative test for sugar, if much is present, consists in adding to the warmed suspected liquid a warmed saturated solution of potassium bichromate mixed with sulphuric acid in slight excess. A brisk effervescence ensues if sugar is present, the chromate being reduced to green chromium salt. The presence of albumen, urea, or uric acid does not interfere with this test. The most certain test for sugar is undoubtedly that by means of the optical method, but can be practically employed only in rare cases, since a polarizing apparatus is not always available (see remarks under *Saccharum*).

Fermentation of the slightly acid specimen with pure yeast at a temperature of about 30° C. (86° F.), and collecting the gas over mercury (or water), in qualitative analysis is a good test for sugar in urine. A parallel experiment with yeast and a sugar-free urine should always be made. Also compare the gravimetric method, mentioned above. A good qualitative test consists in the formation of the crystals of *dextrosazone* which must show the melting point 204° C. (399.2° F.) (see above). The best-known test which still gives much satisfaction, is that with Fehling's solution. For the preparation of the latter, see *U. S. P. Volumetric Solutions*. When testing for sugar, mix in a test-tube equal volumes of the copper and the tartrated alkali solution, and heat to boiling; no reduction must take place. Then add to the deep-blue liquid a few drops or more, of the suspected urine. Mix, and boil again. If a small quantity of sugar is present, the liquid becomes fluorescent, and upon standing deposits a *copper-red* precipitate; if much sugar is present, the liquid upon warming rapidly turns bright yellow, then cinnabar red, and precipitates at once a *copper-red* precipitate of cuprous oxide (Cu_2O). If uric acid or urates occur in the urine, these must be removed by the addition of a few drops of hydrochloric acid, setting aside for 12 hours and filtering. For the quantitative determination of sugar by means of this and other tests, see for example, Hammarsten and Maudel, *A Text-book of Physiological Chemistry*, 2d ed., New York, 1898.)

LÆVULOSE, UNCRYSTALLIZABLE OR FRUIT-SUGAR ($C_6H_{12}O_6$ = 179.58), called by Soubeiran *Chylariose*, is found in sweet fruits and honey, along with grape-sugar; it is likewise obtained with dextrose grape-sugar by subjecting cane-sugar to the action of acids. From invert-sugar it may be isolated by means of its calcium saccharate which is less soluble in cold water than that of dextrose. It is not usually crystallized, but it has been obtained in long silky needles, has a very sweet taste, is dissolved in water or alcohol, and wholly parts with its water when heated upon the water-bath. Its solution in water rotates the plane of polarized light to the left. Like grape-sugar, it is capable of direct vinous fermentation (see *Honey*).

INOSIT, OR PHASEO-MANNIT, is a peculiar sugar found in muscle and other organs of the body. The fruits of several leguminous, and other plants, when green, also yield this sugar. It is not fermentable, is very sweet, soluble in water (1 in 6), not soluble in absolute alcohol or ether, crystallizing easily from the first two. With diluted nitric acid, oxalic acid is formed; with concentrated nitric acid explosive nitrates result.

SACCHARUM LACTIS (U. S. P.)—SUGAR OF MILK.

FORMULA: $C_{12}H_{22}O_{11}+H_2O$. MOLECULAR WEIGHT: 359.16.

SYNONYMS: *Milk-sugar, Lactin, Lactose.*

"A peculiar, crystalline sugar, obtained from the whey of cow's milk by evaporation, and purified by recrystallization"—(*U. S. P.*).

Preparation and Description.—Remove from milk its fat and casein by precipitation with rennet. The residual thin fluid is called "whey;" this, evaporated to the consistence of molasses, clarified by white of eggs, strained and evaporated, forms sugar of milk crystals on cooling. To purify them, redissolve in boiling water, decolorize by animal charcoal, and recrystallize, repeating the process as often as may be necessary. Or, the whey is decolorized by running it through animal charcoal and concentrated in vacuum pans. Neutralization of the free acid is stated to increase the yield of milk-sugar. It is met with in commerce in powder form, or in crystallized cylindrical pieces of various lengths, and from 2 to 4 inches in diameter. Until about 1890, most of the milk-sugar in the American market came from Switzerland; since then, sugar of milk is being manufactured in America on a large scale and is competing even in the European markets (see *Amer. Jour. Pharm.*, 1897, p. 161, 1892, p. 386, and 1893, p. 158). As described by the *U. S. P.*, it is "in white, hard, crystalline masses, yielding a white powder feeling gritty on the tongue, odorless, and having a faintly sweet taste. Permanent in the air. Soluble in about 6 parts of water at 15° C. (59° F.), and in 1 part of boiling water; insoluble in alcohol, ether, or chloroform. The aqueous solution of sugar of milk is neutral to litmus paper"—(*U. S. P.*). Milk-sugar loses its water of crystallization, without melting, when heated to 130° C. (266° F.), leaving a white hygroscopic mass. A higher heat causes it to become yellow. At 170° C. (338° F.) or above it is converted into *lacto-caramel* ($C_6H_{10}O_5$).

Milk-sugar, by boiling with diluted acids, is converted into *galactose* ($C_6H_{12}O_6$) and *dextrose* ($C_6H_{12}O_6$), hence, like cane-sugar, belongs to the compound group called *saccharobioses*. Milk-sugar as such is probably not capable of undergoing vinous fermentation; it ferments, however, after conversion by acids, *e. g.*, lactic acid which is formed in the presence of lactic ferments. Alcohol and mannit are additional products of milk-sugar fermentation. Sugar of milk reduces Fehling's solution more slowly than grape-sugar. "On adding to a few Cc. of a hot, saturated aqueous solution of sugar of milk an equal volume of sodium hydrate T.S., and gently warming, the liquid will turn yellow and brownish-red. On the further addition of a few drops of copper sulphate T.S., a brick-red precipitate will appear"—(*U. S. P.*).

To test milk-sugar for cane-sugar, the *U. S. P.* directs the following test: "If about 1 Gm. of powdered sugar of milk be sprinkled upon about 5 Cc. of cold sulphuric acid contained in a flat-bottomed capsule, the acid may acquire a greenish or reddish but no brown or brownish-black color within half an hour (absence of *cane-sugar*)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The principal medicinal use of sugar of milk is in the trituration of drugs; to aid in rendering them finer and more energetic, as well as to assist in more easily dividing active agents which are to be given in minute doses; thus, if we wish to divide 1 grain of strychnine into 20 doses, it may be thoroughly triturated with 19 grains of sugar of milk, and 1 grain of the mixture gives the required dose. Or, 1 grain of resin of podophyllum, which, in general, is a cathartic dose, by long trituration with 10 grains of sugar of milk, will form several purgative doses. In these cases, the trituration should always continue for from 1 hour to 1½ hours. As a medicinal agent, sugar of milk is thought to be practically inert, yet Germain Sée and others declare it a powerful hydragogue diuretic, and have employed it in doses of 1 to 6 ounces well diluted with water, or milk, and in a concentrated syrup in *dropsies of cardiac origin.* Though being a non-nitrogenous substance, it has been employed as an article of diet in *pulmonary and other affections* where such diet is desirable; also, as a nutrient in *excessive gastric irritability.* On account of its lesser liability to fermentation in the stomach it is preferable to cane-sugar for sweetening infant foods.

SAGO.—SAGO.

The prepared farina from the pith of the *Metroxylon Rumphii*, Martius (*Sagus Rumphii*, Willdenow; *Sagus genuina*, Blume), and other species of palm.

Nat. Ord.—Palmæ.

Botanical Source.—*Metroxylon Rumphii*, or *Sago palm*, has an erect stem, of middling height, with large, pinnately-divided leaves, and prickly petioles, rachides, and spathes; the prickles scattered or confluent. The flowers are polygamomonœcious, on the same spadix. The spadix is much branched, and sheathed by many incomplete spathes. The amenta are terete; the calyx 3-cleft; the corolla tri-partite. Stamens 6, with anthers affixed by the back. The fruit is a 1-seeded, globose berry, coated by reversed scales, and depressed on both sides.

History and Preparation.—This tree is common to New Guinea and the Molucca Islands, growing spontaneously in low, swampy lands, and the sago is obtained from its pith, or spongy medullary substance, of which it contains a large quantity when the tree is sufficiently developed. Several species of palm are known to produce fine sago, among which may be named *Metroxylon Sagu*, Rottboell (*Sagus lævus*, Blume; *Metrorylon Sago*, Koenig; *Metroxylon læve*, Martius; *Sagus inermis*), which is the *Spineless* or *Unarmed sago palm*, a native of Borneo and Sumatra; the *Arenga saccharifera*, Labillardière (*Saguerus Rumphii*, Roxburgh), the sugar palm, abounding in all the isles of the Indian Ocean; and the *Sagus farinifera*, Lamarck, and other palms.

As soon as the palm has arrived at a sufficient degree of maturity, which is from 5 to 7 years, it is cut into pieces of 5 or 6 feet in length; the woody part is cut off on one side, exposing the pith lying, as it were, in the hollow of a canoe. Cold water is poured in, and the pith well stirred, by which means the starch is separated from the fibrous part and passes through with the water, when the whole is thrown on a sieve. The sago, thus separated, is allowed to settle; the water is poured off, and, when it is half dry, it is granulated by being forced through a kind of funnel. It is then either air-dried (*sago flour*), or it is granulated by mechanical means, and dried by artificial heat, which causes part of the starch to become gelatinous (*pearl sago*). A single tree of some species, will yield no less than from 200 to 500 pounds. (For an interesting description of the cultivation of sago in north Borneo, see *Amer. Jour. Pharm.*, 1895, p. 331.)

Description and Chemical Composition.—Sago occurs in commerce either in the form of a fine amylaceous powder, called *sago meal* or *sago flour*, or as *pearl sago.* Sago meal is whitish, with a reddish tint, of a feeble, somewhat unpleasant, moldy odor, and has the general characters of starch. The microscope shows it to consist of irregularly elliptical or oval, more or less ovate, usually isolated particles, often narrowed or tapered at one extremity, and appearing as if truncated, or more or less mullar-shaped; most of them have an irregular surface as if eroded (see illustration of sago-starch grains, in *Amer. Jour. Pharm.*, 1876, p. 297). *Pearl sago* occurs in white or brownish, pearl-like grains, which vary in size from that of a poppy seed to that of a white mustard seed, or even larger. It is the kind usually met with in commerce, and contains about 86 per cent of starch, 13 per cent of water, and small amounts of mineral and nitrogenous matters. A factitious sago is frequently prepared from potato starch.

Action, Medical Uses, and Dosage.—Sago is nutritive and demulcent, and is a convenient and agreeable article for making puddings, gruel, and diet drinks for the sick-room. It should always be long boiled before it is used. It is not so much used as formerly, being superseded by the purer arrow-root and tapioca. For common uses, half an ounce of sago may be boiled in a pint of water (in some cases milk is preferred), the solution strained, and flavored with sugar and spices, lemon, or even with a little white wine, when there are no contraindications to their use.

Castillon's Powders, a popular article of diet for invalids, in cases of *indigestion, chronic dysentery*, etc., is composed of sago, salep, tragacanth, each, in powder, 4 drachms; powdered prepared oyster shells, 1 drachm. These are to be well mixed, and divided into 12 powders; sometimes it is colored with a small quantity of cochineal. For use, each powder is to be boiled with a pint of milk, which may be sweetened and flavored to suit the patient's taste.

SALEP.—SALEP.

The dried tubers of several species of *Orchis* and related genera.

Nat. Ord.—Orchidaceæ.

Botanical Source and History.—Formerly, the tubers derived from *Eulophia campestris* and *E. herbacea*, Lindley, and related species, growing in Persia and the Levant, constituted the drug salep. South and central Europe now furnish salep, and the only kinds admitted in the *German Pharmacopœia* are those unbranched tubers derived from *Orchis mascula*, Linné; *Orchis ustulata*, Linné; *Orchis Morio*, Linné; *Platanthera bifolia*, Reichenbach; *Anacamptis pyramidalis*, Richard; and other related species. The tubers are gathered, scalded, and dried quickly, which process removes their bitterness and disagreeable odor, as well as renders them somewhat translucent. The Oriental salep is less translucent than that from Europe. Oriental salep is dark in color. Among other species, the *Orchis maculata*, Linné; *Orchis latifolia*, Linné; *Orchis sambucina*, Linné; and *Gymnadenia conopsea*, Robert Brown, furnish the flattish, palmately-divided tubers, having 3 to 5 divisions. They resemble the commercial grades, excepting that they contain less mucilage. They were once called *Radix Palmæ Christi*.

Description and Chemical Composition.—European salep is never so large as Oriental salep, which ranges from 1 to 1⅝ inches in length, ovoid, oval, oblong, or pyriform, more or less flattened and corrugated, and marked at the apex with a terminal bud-scar. It is yellowish and translucent, hard, and horn-like, and without odor, but has a mucilaginous and somewhat insipid taste. In commerce it occurs mostly as a yellowish powder. The chief constituents of salep, according to Dragendorff (1865), are *mucilage* (48 per cent), starch (27 per cent), albuminous bodies (5 per cent), etc. The mucilage of salep is soluble in cold water, this solution being precipitated by alcohol, and by basic lead acetate.

Action, Medical Uses, and Dosage.—Salep is nutrient and demulcent. Administered in milk, water, broth, or jelly, it is useful in the *summer diarrhœas* of infants and children, and in the *chronic diarrhœa* of adults, particularly that form associated with *tuberculosis*. A good mucilage may be prepared by macerating 40 grains of salep in some cold water, and subsequently adding boiling water until 8 fluid ounces of water have been used. The jelly may be prepared by rubbing 30 grains of salep with water until the powder has swollen fourfold, and gradually adding, with continual stirring, 8 fluid ounces of boiling water; boil until but 4 ounces remain. Like tapioca and similar products, it may be freely administered.

Related Species.—*Asphodelus bulbosus*. The corm of this plant, under the term "*Tsiniss*," is used in eastern countries as a mucilage, and to adulterate powdered salep.

SALICINUM (U. S. P.)—SALICIN.

Formula: $C_{13}H_{18}O_7$. Molecular Weight: 285.33.

"A neutral principle obtained from several species of *Salix* and *Populus* (*Nat. Ord.*—Salicaceæ)"—(*U. S. P.*).

Source, History, and Preparation.—Salicin was discovered, in 1830, by Leroux, and its glucosidal nature recognized by Piria. It occurs in the bark of most of the willows and poplars (see *Salix* and *Populus*), and in smaller quantity in the leaves, young twigs, and pistillate flowers of the willows, and in the leaves of the poplar. The barks of *Salix Helix*, Linné; *S. pentandra*, Linné; and *S. præcox*, Hoppe, are richest in salicin, containing from 3 to 4 per cent of this glucosid (Herberger).

Salicin may be prepared by concentrating an aqueous decoction of willow bark, adding litharge to the hot liquid until it is nearly colorless; this precipitates tannin, gum, and extractive. From the filtrate remove the lead by sulphuric acid and barium sulphide (BaS), filter again, and evaporate to crystallization. By this process, Merck obtained from Salix Helix a yield of 3.2 per cent. (For additional methods, see this *Dispensatory*, preceding edition.)

Description.—Salicin is described by the *U. S. P.* as occurring in "colorless, or white, silky, shining, crystalline needles, or a crystalline powder, odorless, and having a very bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 28 parts of water, and in 30 parts of alcohol; in 0.7 part of boiling water, and in 2 parts of boiling alcohol; almost insoluble in ether or chloroform. When heated to 198° C. (388.4° F.), salicin melts, yielding a colorless liquid, which, on cooling, congeals to a crystalline mass. Upon ignition, it is consumed, leaving no residue. Salicin is neutral to litmus paper"—(*U. S. P.*). Salicin is optically lævo-rotatory.

When salicin ($C_{13}H_{18}O_7$) is carefully warmed with diluted sulphuric or hydrochloric acid, or treated with the ferment emulsin (see *Amygdala*), it splits into *dextrose* ($C_6H_{12}O_6$) and crystallizable *saligenin* ($C_7H_8O_2$ or $C_6H_4OH.CH_2OH$), the alcohol of salicylic acid ($C_6H_4OH.COOH$). With ferric chloride, the aqueous solution of saligenin produces an indigo-blue color. Upon warming saligenin with diluted acids, it loses water, and is converted into resinous *saliretin* ($C_{14}H_{14}O_3$). When *salicin* is carefully oxidized with concentrated nitric acid (in the cold), a new glucosid, *helicin* ($C_7H_8O_2$), is formed, which, upon hydrolysis, yields dextrose and *salicylic aldehyde* ($C_6H_4OH.CHO$) (compare *U. S. P. Tests*, below). The glucosid *populin* (see *Populus*) is benzoyl-salicin.

Tests.—"On heating a small portion of salicin, in a test-tube, until it turns brown, then adding a few Cc. of water, and afterward a drop of ferric chloride T.S., a violet color will be produced. Cold, concentrated sulphuric acid dissolves salicin with a red color; the solution, after the addition of water, becomes colorless, and deposits a dark-red powder, insoluble in water or alcohol"—(*U. S. P.*). This substance has received the name *rutilin*, by Braconnot. "On heating a small portion of salicin with 1 Cc. of potassium dichromate T.S., and 2 Cc. of sulphuric acid, the odor of salicylic aldehyde (or of oil of meadow sweet, *Spiræa Ulmaria*, Linné (*Nat. Ord.*—Rosaceæ), will become noticeable. The aqueous solution of salicin is not precipitated by tannic or picric acid, nor by mercuric potassium iodide T.S. (absence of, and difference from, *alkaloids*)"—(*U. S. P.*). (For further details regarding salicin, see Husemann and Hilger, *Pflanzenstoffe*, p. 475.)

Action, Medical Uses, and Dosage.—Salicin is not regarded as poisonous to man. However, large doses have produced unpleasant symptoms, among which may be mentioned a dusky countenance, severe headache, nervous irritability, extreme weakness, tinnitus aurium, hurried breathing, tingling of the extremities, and huskiness of the voice. As a rule, the temperature in a healthy individual is uninfluenced by it. In its passage through the system, salicin undergoes oxidation, and is converted into salicylous, salicylic, and salicyluric acids, which are found in the urine. Their presence is detected by a ferric salt, which strikes an intense violet color with urine containing it. Salicin is tonic, antiperiodic, and febrifuge, and may be used as a substitute for quinine, to which, however, it is slightly inferior. It is, however, less likely to irritate the stomach and excite the nervous system, for which properties it may be administered in cases where cinchonism would be produced by the exhibition of quinine. The *intermittents* cured by salicin are those showing distinct periodicity, together with rheumatic pain. Give from 10 to 30 grains in divided doses. It has been successfully employed in *periodical neuralgia*, *lumbago*, *diarrhœa of phthisis*, and som forms of *rheumatic fever*. It is often employed to adulterate quinine, and may detected by sulphuric acid, which will turn the salicin red, even in minute quantity. Salicin is frequently effectual in controlling various forms of pelvic pain. The dose of salicin is from 2 to 10 grains, to be repeated 3 or 4 times a day; 3 doses of 6 grains each, have been known to cut short intermittent fevers in 1 day. Salicylous acid (salicylic aldehyde) and salicylite of potassium, in 4-grain doses, have been found useful sedatives in acute maladies, acting without causing any primary excitement.

Specific Indications and Uses.—Periodicity, with severe pain, rheumatic in character, or simulating rheumatism; anti-rheumatic, associated with the special sedatives to control the fever.

SALIX.—WILLOW.

The bark of *Salix alba*, Linné.

Nat. Ord.—Salicaceæ.

COMMON NAMES: *Willow, White willow, European willow.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 234.

Botanical Source.—The white willow is a tree 30 to 80 feet in height, with many round, widely spreading branches, silky when young, and a thick, brown bark, full of cracks; that of the smaller branches smooth and greenish. The leaves are alternate, on short petioles, lanceolate, or elliptic-lanceolate, broadest a little above the middle, pointed, tapering toward each end, acutely serrate, with the lower serratures glandular; both sides of a grayish, somewhat glaucous, green, beautifully silky, with close-pressed, silvery hairs, especially on the under surface, and which is very dense and brilliant on the uppermost, or youngest leaves; the lowermost on each branch, like the bracteas, are smaller, more obtuse, and greener. Stipules variable, either roundish or oblong, small, and often wanting. The flowers and leaves appear coincidently. The aments are borne on short stalks, with 3 or 4 spreading, leafy bracteas, and are terminal, cylindrical, and elongated. Scales brown, elliptical, lanceolate, pubescent at the margin; those of the barren aments narrower toward the base; of the fertile, dilated and convolute in that part. Stamens 2, yellow, rather longer than the scales, with 1 obtuse gland before and 1 behind; filaments hairy in their lower part. Anthers roundish and yellow. The ovary is very nearly sessile, green, smooth, ovate-lanceolate, bluntish, and longer than the scale. Style short; stigmas short, thick, 2-parted, recurved, and nearly sessile. Capsule ovate, brown, smooth, and rather small (L.—W.—G.).

History and Description.—The white or European willow is a large tree of rapid growth, native of Europe, and introduced into this country. Its flowers appear from March to June. The bark, which is the medicinal part, is readily removed from the stem during the months of July, August, and September. The dried bark is met with more or less quilled, pliable and tough, with a faint odor, and a bitter taste, combined with some astringency. Water takes up its medicinal properties, the decoction having a dark-reddish color, and which is precipitated abundantly by gelatin, carbonates of potassium, and ammonium. Limewater gives at first a blue, and then a buff-colored precipitate. Ferric chloride throws down a dark-green tannate of iron. If the decoction contains much salicin, concentrated sulphuric acid reddens it. This species belongs to the group of willows known as the *crack willows*. A species much resembling it is the *Salix fragilis*, Linné. There are numerous species of Salix, many of which, undoubtedly, possess analogous medicinal virtues. The best rule to follow is to select those whose barks possess great bitterness, combined with astringency. Among those which have been used are the *S. alba*, *S. caprea*, *S. russelliana*, *S. purpurea*, *S. nigra*, and *S. pentandra*. The Weeping willow, or Babylonian willow (*Salix babylonica*) is cultivated as an ornamental tree.

Chemical Composition.—White-willow bark, according to Pelletier and Caventou, consists of bitter, yellow coloring matter, green fatty matter, tannic acid, resin, etc. The chief constituent, however, as with all the willows, is the glucosid *salicin* (see *Salicinum*). Tannin is also prominent, and is more abundant in the crack willows, while salicin seems to predominate in the purple willows. Johanson (1875) showed the presence of *benzohelicin* ($C_{20}H_{20}O_8$), a glucosid previously obtained (Piria, 1851) by acting upon populin with nitric acid (compare *Salicinum*).

Robert W. Beck (*Amer. Jour. Pharm.*, 1891, p. 581) obtained from the bark of *Salix lucida*, 1.09 per cent of salicin; from the leaves, 0.3 per cent. The bark of *S. alba* yielded 0.56 per cent, that of *S. nigra*, 0.73 per cent of salicin. The leaves of *S. alba* contained 6.48 per cent of tannin, while the quantity of tannin in the barks of *S. alba* and *S. nigra* varied from 3.3 to 4.3 per cent.

Action, Medical Uses, and Dosage.—Willow bark is tonic, antiperiodic, and an astringent bitter. It has been given in *intermittents*, *dyspepsia*, connected with debility of the digestive organs, *passive hemorrhages*, *chronic mucous discharges*, in *convalescence from acute diseases*, and in *worms*. Although occasionally substituted for the cinchona bark, it is inferior in activity. In *chronic diarrhœa* and *dysentery*, the tonic and astringent combination of the willow renders it very eligible. It may be given in substance, in doses of 1 drachm of the powder, repeated as indicated; or of the decoction, 1 or 2 fluid ounces, 4 or 5 times a day. The decoction has also proved efficient as a local application to *foul* and *indolent ulcers*.

SALIX NIGRA.—BLACK WILLOW.

The bark and aments of *Salix nigra*, Linné.

Nat. Ord.—Salicaceæ.

Common Names: *Black willow*, *Pussy willow*.

Botanical Source.—*Salix nigra*, Black or Pussy willow, is a tree growing from 15 to 25 feet high, covered with a rough, blackish bark, and found on the banks of rivers, especially in New York and Pennsylvania. The leaves are narrowly lanceolate, pointed and tapering at each end, serrulate, smooth and green on both sides; the petioles and midveins, tomentose. The stipules are small, deciduous, and dentate; the aments erect, cylindric, and villous; the scales oblong, and very villous. Sterile aments 3 inches long; glands of the sterile flowers 2, large, and deeply 2 or 3-cleft. Stamens 4 to 6, often but 3 in the upper scales; filaments bearded at base. The ovary is pedicellate, smooth, and ovoid; the style very short; the stigmas bifid. The branches are pale-yellow, and brittle at base, and are much used for the manufacture of baskets and other kinds of wickerwork (G.—W.).

History.—The medicinal part of the black willow, according to the older authors, and particularly Michaux, is the bark of the root. The bark of the tree has also been employed (compare *Salix Alba*). But the value of salix nigra bark as a remedy has been shown by Eclectic physicians to be of little value as compared with preparations of the *fresh aments*. It is these preparations that have given salix nigra its place as a remedy for sexual disorders. The greatest of care is necessary in the production of the fluid preparations of the aments, absolutely fresh aments, gathered about the first of May, being requisite to produce a preparation of any medicinal value. Dried aments produce inferior, if not worthless, products, and especial care should be exercised by the physician that he procure the preparations of the *fresh aments* and not of the *bark* when a sexual sedative and tonic is demanded.

Action, Medical Uses, and Dosage.—The bark of black willow is recommended as a poultice in *gangrene*, and as an external application to *foul* and *indolent ulcers* and *rhus poisoning*, in which it stands unrivaled. It is made by simmering the powdered bark in cream. It has also been successfully used in *various swellings of the neck*. Internally, the root is a bitter tonic, effectual in *intermittents*. Some have highly recommended it in *asthma* and *gout*. At the present day the bark is seldom employed and the aments now furnish the preferred drug. A decoction of the black willow buds or aments, taken internally and applied locally, is useful in *gangrene;* and drank freely it proves a powerful anaphrodisiac, suppressing venereal desires for a long time, and is highly recommended in the treatment of *spermatorrhœa*. The last statement, written years ago by Prof. King, has been abundantly verified in the last few years by practitioners of all schools of medicine. The drug is not only anaphrodisiac, but by controlling genital irritability it becomes a marked sexual sedative and tonic. As Prof. Bloyer has aptly remarked, it is not a remedy for physiological losses nor is a beneficial action to be expected in cases requiring operative measures at the hands of the orificial surgeon. Its field of action is in those functional wrongs of the reproductive organs due most largely to undue irritability of the parts, and thought to be less due to mental or emotional causes. However, sexual passion from any functional cause is moderated by it, and it is especially adapted to the disorders of the sexually intemperate male or female, and of the youth, subject day or night to libidinous suggestions and lascivious dreams terminating in pollutions, while for those extreme forms of sexual perversion, *satyriasis*, *erotomania*, and *nymphomania*, it is more nearly specific than any other agent. Not only does salix nigra act as a check to sexual passion and misuse, but it proves a useful tonic and sedative to many conditions following in the wake of sexual intemperance, among which may be mentioned *spermatorrhœa* in its varied forms, *prostatitis*, *cystitis*, and *ovaritis*. Specific Salix nigra is the preparation most largely used by Eclectic practitioners, and is to be preferred, for the fresh aments can not be procured at all times for the preparation of the decoction. The dose is from 10 to 60 drops, 3 or 4 times a day.

Specific Indications and Uses.—To moderate sexual erethism, irritability, and passion; lascivious dreams; libidinous thoughts; nocturnal emissions; nymphomania and satyriasis; cystitis, urethral irritation, prostatitis, cystitis, ovaritis, and other sexual disorders arising from sexual abuse or excesses.

SALOL (U. S. P.)—SALOL.

FORMULA: $C_6H_5C_7H_5O_3$. MOLECULAR WEIGHT: 213.49.

"The salicylic ether of phenol"—(*U. S. P.*).

SYNONYM: *Phenyl salicylate.*

History and Preparation.—Phenyl salicylate, or salol, was brought into use as a medicine by Dr. Sahli (1886), of Basel, though previously prepared by Prof. Nencki (1883), of Berne. Salicylic acid and phenol are heated together in the presence of phosphorus oxychloride ($POCl_3$); the elements of water are abstracted, and phenyl salicylate is produced as follows: $C_6H_4OH.COOH+C_6H_5OH=H_2O+C_6H_4OH.COOC_6H_5$. A more recent, patented process consists in heating salicylic acid in an atmosphere of carbonic acid gas; carbonic acid and water are given off, and phenyl salicylate (salol) is formed. Salol contains about 60 per cent of salicylic acid and 40 per cent of phenol.

Description and Tests.—Salol is "a white, crystalline powder, odorless, or having a faintly aromatic odor, and almost tasteless. Permanent in the air. Almost insoluble in water; soluble in 10 parts of alcohol at 15° C. (59° F.), very soluble in boiling alcohol; also soluble in 0.3 part of ether, and readily in chloroform, and in fixed or volatile oils. When heated to 42° to 43° C. (107.6° to 109.4° F.), salol melts. When heated on platinum, it takes fire, and is consumed, leaving no residue. Salol is neutral to litmus paper moistened with alcohol. On warming a small portion of salol with enough sodium hydrate T.S. to dissolve it, and then supersaturating the liquid with hydrochloric acid, salicylic acid will separate, and the odor of phenol will become perceptible. In an alcoholic solution of salol, bromine water, added in excess, produces a white precipitate. On adding a few drops of diluted ferric chloride T.S., made by diluting the test-solution with 20 volumes of water to 10 Cc. of an alcoholic solution (1 in 50) of salol, the liquid will acquire a violet tint. If, however, a few drops of the alcoholic solution of salol be added to 10 Cc. of the diluted ferric chloride T.S., a whitish cloudiness, but no color, will be produced on shaking. On shaking 1 Gm. of salol with 50 Cc. of water, the filtrate should not be affected by ferric chloride T.S. previously diluted with 2 volumes of water (absence of uncombined carbolic or salicylic acid); nor by barium chloride T.S. (absence of sulphate or phosphate); nor by silver nitrate T.S. (absence of chloride)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Salol, in proper doses, is an important medicine, but if the dose be large, toxic symptoms may be expected from it. Through the agency of the pancreatic juice, it is split up in the small intestines into carbolic and salicylic acids, and its toxic action may partake of the symptoms common to both of these agents. Undoubtedly, the chief agent in poisoning by it is the phenol. Circumstances seem to control the action of the drug;

if the pancreatic fluid be abundant, or the dose be large, the toxic symptoms are quicker to manifest themselves. Carboluria (black or smoky urine) is a prominent symptom of poisoning by salol. As a rule, the drug is rather slowly absorbed and slowly eliminated (kidneys), on which account doses of it should not be too rapidly repeated, lest a cumulative effect be produced. Other symptoms which have been observed from its administration are urticaria, herpes, vomiting, persistent anorexia, sweating, and the intoxicating effects of salicylic acid. The kidneys are extremely susceptible to the drug, which should never be administered where there are known acute or chronic structural diseases of those organs. Death, with the symptoms of phenol poisoning, is reported, by Hesselbach, to have been caused by 120 grains of salol. Albuminuria has resulted from large doses of the drug. In view of its evident power over the kidneys, the drug should be very cautiously employed. The toxic renal symptoms are less likely to be produced if diarrhœa be present.

Externally, salol has been applied as an antiseptic in substance (triturated with starch), and in an aqueous dilution of its alcoholic solution. For this purpose it has been used in *wounds*, *erysipelas*, *burns*, *diphtheria*, *otorrhœa*, *ozœna*, *venereal diseases*, *gangrenous* and other *ulcers*, and in *sycosis*, *impetigo contagiosa*, and other skin affections. It is chiefly used internally, as an antirheumatic and intestinal antiseptic. As an antipyretic, it has not met with favor in our school. It may serve a useful purpose in all forms of *rheumatism*, but particularly in chronic cases and the articular varieties, when the kidneys are functionally inactive and no organic renal trouble exists. The same is true in *lumbago* and *sciatic neuralgia*. Salol is useful in *fermentative and putrefactive disorders of the gastro-intestinal tract*, particularly in *fetid diarrhœa*, *fermentative*, *gastric* and *intestinal dyspepsia*, and *dilatation of the stomach*. It may be useful in *typhoid fever* for its effects as an intestinal antiseptic, but is of no value here for its antipyretic action. Signal success has attended the use of salol in urinary disorders requiring an agent to prevent decomposition of the urine. For this purpose it has given excellent results in *cystitis*, with turbid, ammoniacal urine. As the urine becomes clear and acid in reaction, the dysuria is relieved and the catarrhal symptoms vanish. It is of some value in *pyelitis*, but care should be taken that the kidneys are in a condition to act, though there is manifest renal torpor. Salol, in divided doses, may be given to the extent of 20 or 30 grains a day. From 5 to 15 grains may be given at a single dose, though it is far preferable to give from 2 to 5 grains, every 3 hours. It may be administered in milk, emulsion, trituration with milk-sugar, or in capsules. When given in trituration, it imparts to the teeth a sensation as if biting upon rubber. As a dressing for irritated and inflamed parts, it is best triturated with an equal bulk of starch.

Specific Indications and Uses.—Turbid, ammoniacal urine, with renal torpor, when the kidneys are not structurally diseased; gastro-intestinal fermentative disorders; some cases of rheumatism, associated with renal inactivity.

Related Compounds.—SALOL CAMPHOR, *Camphol.* Gradually and completely melt a mixture of camphor (2 parts) and salol (3 parts). A colorless or light-colored fluid is obtained, which readily decomposes when exposed to air or light, therefore it is directed to preserve it, hermetically sealed, in yellow-glass tubes or vials. This fluid mixes with alcohol, ether, and oils, but is not soluble in water. It is a local anæsthetic.

DIIODOSALOL, *Phenyl diiodosalicylate* ($C_6H_2I_2[OH]CO_2C_6H_5$). This compound is produced by acting upon diiodosalicylic acid with phenol. It is a crystalline powder, devoid of odor or taste, and melts at 133° C. (271.4° F.).

CRESALOL, *Cresol salicylate* ($C_6H_4[OH]CO_2C_6H_4CH_3$).—This compound is prepared like salol, except that *meta-* or *para-cresol* ($C_6H_4[CH_3].OH$) is substituted for the phenol employed in the case of salol. Accordingly, either the meta- or para-compound is obtained. Alcohol and ether dissolve these bodies, which are crystalline, but they are not soluble in water. They are local and internal antiseptics, and are reputed useful in correcting and checking fetid discharges. They are less toxic than salol, and are sometimes substituted for it.

SALICYLAMIDE ($C_6H_4[OH]CONH_2$). This compound is formed by the action of dry ammonia gas upon oil of wintergreen (methyl salicylate). It is a colorless, or faintly yellowish powder, is soluble in alcohol, chloroform, ether, and less readily in water (250 parts). It is nearly tasteless, and produces a sensation of grittiness between the teeth. In from 2 to 5-grain doses this compound has been proposed as a substitute for salicylic acid, being favored on account of its tastelessness, greater solubility, and more powerful analgesic powers. Its superiority, however, has not yet been satisfactorily established. Large doses are poisonous.

Salophen, *Acetylpara-amidophenol-salicylate* ($C_6H_4[OH]CO_2.C_6H_4NH.COCH_3$).—A substance, introduced in 1891, and intended to replace salol, because the intestinal fluid does not convert it into a poisonous phenol as it does salol, but resolves it into salicylic acid and acetyl-para-amidophenol, which is comparatively harmless. It is a neutral compound, containing about 51 per cent of salicylic acid. It is odorless and tasteless, insoluble in cold, but partially soluble in boiling water, and is readily dissolved by alkaline solutions, ether, and warm alcohol. *Salophen* should not be confused with *saliphen* (*salicyl-phenetidin*, $C_6H_4[OC_2H_5]NHC_6H_4[OH]CO$), a compound of phenetidin ($C_6H_4[OC_2H_5]NH_2$) and salicylic acid. *Acute articular rheumatism, neuralgia, hemicrania*, and other *headaches* are reputed to yield promptly to this drug, and no ill effects are said to follow its use. It is also an intestinal antiseptic. Dose, 5 to 10 grains, every 2 hours.

Salacetol, *Acetonyl-salicylate* ($C_6H_4[OH]COOCH_2.CO.CH_3$), is intended to replace salol, for the same reason as that given under *Salophen*, above. It is prepared by heating monochloracetone with salicylate of sodium. Salacetol crystallizes from alcohol in needles, slightly soluble in cold water and cold alcohol, easily soluble in ether, chloroform, benzol, benzin, is somewhat bitter, and melts at 71° C. (159.8° F.).

SALVIA (U. S. P.)—SALVIA.

The leaves of *Salvia officinalis*, Linne.

Nat. Ord.—Labiateæ.

Common Names: *Sage, Garden sage.*

Illustration: Bentley and Trimen, *Med. Plants*, 206.

Botanical Source.—Salvia officinalis, or Garden sage, is a plant with a pubescent, 4-sided stem, with erect branches, hoary with down, leafy at the base, those bearing flowers 1 foot or 1½ feet long, and tomentose. The leaves are opposite, entire, petioled, ovate-lanceolate, crenulate, rugose, the lowermost being white with wool beneath. The flowers are blue, in whorls, and in long, terminal, nearly simple racemes; whorls few-flowered, and distinct; floral leaves or bracts sessile, ovate, acuminate, membranous, and striated at the base. The calyx is campanulate, membranous, colored, striated, downy, and bilabiate; the upper lip 3-toothed; the lower bifid; and all the teeth subulate and acuminate. The corolla is 2 or 3 times as long as the calyx, with a large projecting tube, ringed in the inside, and bilabiate; the upper lip is arched, the lower one tri-lobed, the lateral lobes being reflexed. The stamens are affixed to short pedicels transversely about their middle (L.—W.).

Fig. 214.

Salvia officinalis.

History, Description, and Chemical Composition.—Sage is a native of southern Europe, and has been naturalized in this country as a garden plant; the leaves and tops should be gathered and carefully dried during its flowering season, which is in June and July. As described by the *U. S. P.*, the leaves are "about 5 Cm. (2 inches) long, petiolate, ovate-oblong, obtuse or subacute at the apex, rounded or somewhat heart-shaped at the base, finely crenulate, thickish, wrinkled, grayish-green, soft-hairy, and glandular beneath; odor aromatic; taste aromatic, bitterish, and somewhat astringent"—(*U. S. P.*). The odor and aromatic taste of sage are due to its volatile oil. Sage imparts its virtues to boiling water in infusion, but more readily to alcohol. The infusion becomes black on the addition of sulphate of iron, which is due to the presence of tannin. Oil of sage is obtained by distilling the leaves with water; the yield from Dalmatian leaves ranges from 1.3 to 2.5 per cent. Oil of sage is "a yellowish or greenish-yellow liquid, having the penetrating, characteristic odor of sage. Specific gravity, 0.915 to 0.925; optically dextrogyrate. The oil contains small amounts of pinene and cineol, but its chief constituent (50 per cent) is *thujone* ($C_{10}H_{16}O$) (formerly termed *salviol*), which also occurs in the oils of thuja, tansy, and wormwood" (Prof. Power, *Descrip. Cat. of Essential Oils and Org. Chem. Preparations*, 1894; also see Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899).

Action, Medical Uses, and Dosage.—Sage is feebly tonic, astringent, expectorant, and diaphoretic, and has properties common to aromatics. An infusion is beneficial in *flatulence* connected with *gastric debility*, and will, when the skin is soft and relaxed, the extremities cold, and the circulation enfeebled, prove efficient in restraining *exhausting sweats*. Should the sweating be preceded by hectic fever, and dry harsh skin, it is less likely to prove beneficial. The infusion may be taken cold throughout the day; it may likewise be used warm, as an anthelmintic, and for the purpose of causing diaphoresis in some *febrile diseases.* The warm infusion will cause active diuresis by checking its diaphoretic tendency. Dr. James Anton, of Lebanon, Ohio, considered it an excellent remedy for *spermatorrhœa;* also a valuable anaphrodisiac to check excessive venereal desires. It may be used in connection with moral, hygienic, and other aids, if necessary. Van Swieten stated that a vinous infusion forms an excellent fomentation to the breasts, when it is desirable to check the flow of milk. The infusion, either alone or combined with vinegar, honey, alum, or sumach berries, is much used as a gargle for *inflammation and ulceration of the throat,* and *relaxed uvula.* The oil may be used in small doses as a carminative and stimulant; and externally, applied with friction in *rheumatism.* Dose of the infusion, from 2 to 4 fluid ounces, 3 or 4 times a day; of the powdered leaves, 20 to 30 grains. A strong tincture (℥viij to alcohol, 76 per cent, Oj) may be given in from 1 to 60 drop doses.

Specific Indications and Uses.—Skin soft and relaxed; extremities cold, and circulation enfeebled; colliquative sweating; urine of low specific gravity.

Related Species.—Numerous other species of Salvia have similar properties, as the *S. sclarea,* or *Clarry,* a native of southern Europe, which is said to be antispasmodic and balsamic. The foregoing and *S. pratensis,* Linné, have been official in Europe. *S. Horminum, S. bengalensis* of India, *S. pomifera* of Greece, etc., have also been used. The seeds of *S. verticillata* and *S. verbenacea* are mucilaginous.

Salvia lyrata, Linné, variously named *Wild* or *Meadow sage, Lyre-leaved sage,* or *Cancer-weed,* is a perennial plant, growing from Canada to Florida in shady woods and meadows, and flowering in May and June. It has an erect, quadrangular, nearly leafless stem, 1 or 2 feet high, branching and covered with hairs pointing downward. Radical leaves obovate, lyre-shaped or sinuate-pinnatifid, sometimes almost entire, and petiolate; cauline leaves mostly, but 1 or 2 pairs, just below the raceme, smaller and narrower than the radical. Flowers blue, in loose and distant whorls of about 6, forming a long, interrupted raceme; bracts oblong-linear, not longer than the calyx. Upper lip of the blue-purple pubescent corolla, short, straight, not vaulted; tube much exserted (W.—G.). The fresh radical leaves will, it is positively asserted, when bruised and applied to *warts,* generally destroy them; the application to be continued for a day or two, and renewed every 12 hours. It is also reputed to have cured *cancers,* hence one of its names.

Salvia lanceolata, Willdenow, or *Rocky Mountain sage,* is reputed diaphoretic and diuretic, and is employed domestically in the *eruptive, malarial,* and *rheumatic fevers.*

Chia Seeds.—The seeds of some Mexican species are known as *Chia seed.* The true chia seed is yielded by *Salvia polystachya,* Ortega (*Salvia Chian,* La Slave). These seeds are used in sweetened decoction by the Mexicans for *sore throat, fevers,* etc., and the cold decoction is applied to *inflamed eyes.* The fruit of *Salvia Columbariæ,* Bentham, is also known as *Chia seed* (Gray and Rothrock).

SAMBUCUS (U. S. P.)—SAMBUCUS.

"The flowers of *Sambucus canadensis,* Linne"—(*U. S. P.*). In Eclectic medicine, the fresh inner bark is preferred.

Nat. Ord.—Caprifoliaceæ.

Common Names: *Elder, American elder.*

Illustration: Bentley and Trimen, *Med. Plants,* 138.

Botanical Source.—Sambucus canadensis is a common, well-known native plant, from 5 to 12 feet high, with a shrubby stem, filled with a light and porous pith, especially when young. The bark is rather scabrous and cinerous. The leaves are nearly bipinnate, and antiposed; leaflets in 3 or 4 pairs with an odd one, oblong, oval, acuminate, smooth, serrate, with the lower ones often 2 or 3-parted. Petioles smooth. Flowers numerous, white, in very large, level-topped, 5-parted cymes, and have a heavy odor. Calyx small and 5-parted; corolla 5-cleft, with segments obtuse; stamens 5; stigma obtuse, small, and sessile. The fruit consists of numerous purplish-black berries (W.).

History.—Sambucus canadensis is an indigenous shrub, growing in all parts of the United States, in low, damp grounds, thickets, and waste places, flowering in June and July, and maturing its berries in September and October. *S. nigra* (see *Related Species*) is indigenous to Europe, growing in situations similar to those of the American variety. The two plants possess similar medicinal properties. The medicinal parts are the flowers, the berries, and the inner bark

Description and Chemical Composition.—The *U. S. P.* recognizes the flowers only, giving the following description: "The flowers, when fresh, about 5 Mm. (⅕ inch) broad, and, after drying, shrivelled; calyx superior, minutely 5-toothed; corolla originally cream-colored, after drying pale brownish-yellow, wheel-shaped and 5-lobed, with 5 stamens on the short tube; odor peculiar; taste sweetish, somewhat aromatic and bitterish. The peduncles and pedicels of the inflorescence should be rejected"—(*U. S. P.*). The odor of the *flowers* is characteristic and heavy, quite powerful when fresh, but faint when dried; they are slightly aromatic and bitterish, and impart their virtues to hot water. Boiling dissipates a volatile oil, which may be obtained by distillation with water; when cold it has the consistence of butter. Mr. F. F. Lyons (*Amer. Jour. Pharm.*, 1892, p. 1) found the bitterness of the flowers to be due to an amorphous, yellow, glucosidal substance, soluble in chloroform. The *berries* have little or no odor, an acid-saccharine taste, and yield by expression a purple juice, called *elder-rob*, which turns a dark-lilac color with alkalies, and a scarlet with acids; acetate of lead added to the juice causes a blue deposit of its coloring substance. It contains malic acid, some citric acid, and, according to J. B. Metzger (*Amer. Jour. Pharm.*, 1881, p. 553), a dark-brown resin, fat, sugar, gum, tannin, etc. The *inner bark* is whitish, with a green tint, odorless, of a saccharine taste, but subsequently bitterish, with some acrimony, and imparts its properties to water or alcohol. Mr. Charles G. Traub (*Amer. Jour. Pharm.*, 1881, p. 392) found the bark to contain valerianic acid, volatile oil, fat, resin, tannin, sugar, coloring matter, etc. Also see quantitative analysis, by C. Otto Moosbrugger (*ibid.*, 1895, p. 520), who found tannin, starch, alkaloids, and glucosids to be absent.

Fig. 215.

Sambucus canadensis.

Action, Medical Uses, and Dosage.—Sambucus is stimulant to all of the emunctories, increasing secretion. In warm infusion, elder flowers are diaphoretic and gently stimulant; in cold infusion, they are diuretic, alterative, and cooling, and may be used in all diseases requiring such action, as in *hepatic derangements of children*, *erysipelas*, *erysipelatous diseases*, etc. In infusion, with maidenhair and beech-drops, they will be found very valuable in all erysipelatous diseases. The expressed juice of the berries, evaporated to the consistence of a syrup, is a valuable aperient and alterative; 1 ounce of it will purge. An infusion of the young leaf-buds is likewise purgative, and sometimes acts with violence. The flowers and expressed juice of the berries have been beneficially employed in *scrofula*, *cutaneous diseases*, *syphilis*, *rheumatism*, etc. The inner green bark is cathartic; an infusion of it in wine or cider, or the expressed juice, will purge moderately, in doses of from ½ to 1 fluid ounce; large doses produce emesis; in small ones, it proves an efficient deobstruent, promoting all the fluid secretions, and is much used in *dropsy*, especially that following *scarlatina*, and other *febrile* and *exanthematous diseases*, as well as in many chronic diseases. Specific sambucus is largely used as an alterative where there is a tendency to unhealthy deposits in, or depravation of the tissues. The chief indication for sambucus is a fullness or œdematous condition of the parts, giving them a watery and flabby appearance. In these conditions it is a valuable agent in dropsy. Webster asserts that small doses of specific sambucus are valuable in the *catarrhal nasal obstructions of infants*. The juice of the root in ½ ounce doses, daily, acts as a hydragogue cathartic and diuretic, and will be found valuable in dropsical affections requiring purgation.

Externally, sambucus is a valuable agent, especially for eruptions which appear upon the full, flabby, œdematous tissues as described above, and particularly when attended with abundant discharge of serum. Beaten up with lard or cream, it forms an excellent discutient ointment, which is of much value in *burns*, *scalds*, and some *cutaneous diseases*, such as *eczema*, *milk-scall*, *old ulcers*, with soft, œdematous edges and free secretion of serum, and in *mucous patches*, with free discharges. The dose of specific sambucus ranges from 1 to 60 drops; decoction (inner bark, 2 ounces, to water, 1 quart, boiled down to 1 pint), from 2 to 4 fluid ounces.

Specific Indications and Uses.—In skin affections, when the tissues are full, flabby, and œdematous; epidermis separates and discharge of serum is abundant, forming crusts; indolent ulcers, with soft, œdematous borders: mucous patches, with free secretions; post-scarlatinal dropsy; low deposits in, or depravation of tissues.

Related Species.—*Sambucus nigra*, Linné, is the species official in the *British Pharmacopœia*. It grows in northern Africa and southern Siberia, and throughout the larger part of Europe. *Sambucus nigra*, or *European elder*, is much larger than the *S. canadensis*. The stem is much and irregularly, though always oppositely branched, and of quick growth; after a year's growth, the branches become filled with a light, spongy pith, and covered with a smooth, gray bark. The bark of the stem is rough and whitish. The leaves are usually two pairs of smooth, deep-green leaflets, with an odd one, all smooth, ovate-lanceolate, and serrate. The flowers are numerous, cream-colored, in large, smooth, 5-parted cymes, with a sweet but faint smell; some in each cyme are sessile. Calyx 5-cleft; corolla rotate and 5-cleft; lobes obtuse. The fruit is a globular, purplish-black berry, having reddish stalks (L.—De Cand.). H. Kramer (1846) found the bark to contain *viburnic acid*, proved, by Monro, to be *valerianic acid;* a trace of volatile oil, albumen, tannic acid, fatty matter, resin, gum, wax, sugar, starch, etc. *Chemical Gazette*, May, 1846). The inner bark of Sambucus nigra is hydragogue and emeto-cathartic. It has been successfully employed in *epilepsy*, by taking it from branches 1 or 2 years old, scraping off the gray outer bark, and steeping 2 ounces of it in 5 ounces of cold or hot water for 48 hours. Strain, and give a wineglassful every 15 minutes when the fit is threatening; the patient fasting. Resume it every 6 or 8 days. Simon (*Amer. Jour. Pharm.*, 1840, p. 250) states that the active principle of the bark of the root is a soft resin, which may be obtained by treating an evaporated, syrup-like, alcoholic tincture with ether, which separates an inert, hard, and takes up the soft resin; filter, and make into an extract by evaporation. Twenty grains produced vomiting 4 or 5 times, and as many stools.

Sambucus Ebulus, Linné, *Dwarf elder*.—The fruit of this plant is 4-seeded, and bears some resemblance to elderberries. Its taste, however, is considered more agreeable, and the fruit is sometimes employed medicinally.

Lonicera caprifolium, *Italian honeysuckle*, *Honeysuckle*.—Europe. A syrup of the flowers of this well-known garden vine has been successfully employed in *asthma* and other *respiratory disorders*, and the juice of the plant is said to give relief to *bee-stings*. The fruit, like all species of this genus, is emeto-cathartic.

SANGUINARIA (U. S. P.)—SANGUINARIA.

The rhizome of *Sanguinaria canadensis*, Linné, gathered in autumn after the leaves and scape have died to the ground.

Nat. Ord.—Papaveraceæ.

Common Names: *Bloodroot*, *Puccoon*, *Red puccoon*, *Indian paint*, *Tetterwort*.

Illustrations: Bentley and Trimen, *Med. Plants*, 20; Johnson's *Med. Bot. of N. A.*, Pl. III.

Botanical Source.—Bloodroot is a smooth herbaceous, perennial, indigenous plant, with a horizontal, truncate or premorse, creeping rhizome covered with scattered fibers, and emitting an acrid bright orange-colored juice when cut or bruised. It is frequently crooked, 2 or 3 inches long, 3 to 6 lines in diameter, brownish-red externally, and red internally. From each bud of the root-stalk there springs a single leaf, and a round, erect scape about 6 inches high, with a single flower; and as they arise, the folded leaf incloses the flower-bud, and rolls back as the latter amplifies. The leaf is smooth, on long, channeled petioles, reniform or cordate, with large roundish lobes separated by rounded sinuses; the underside strongly reticulated by orange-colored veins, paler than the upper, and at length glaucous. The flowers are white, scentless, of a quadrangular outline, and of short duration. The calyx is formed of 2 concave, ovate, obtuse sepals, falling off when the corolla expands; the corolla has 8 (or more by cultivation) petals, which are spreading, concave, obtuse, the external ones the longer; sometimes they have a purple or rose tint. Stamens short, numerous,

Fig. 216.

Sanguinaria canadensis

with oblong, yellow anthers. Ovary oblong, and compressed, style none; stigma thick and somewhat 2-lobed. Capsule oblong, acute at both extremities, and 2-valved. The seeds are numerous, roundish, compressed, dark shining red, half-surrounded by a white vermiform raphe (L.—W.—B.).

Description.—The root of sanguinaria is the official part, although the whole plant is actively medicinal. The fresh root is from 1 to 4 inches in length, fleshy, round, about as thick as the finger and tolerably stout in the middle, abrupt at the end, often contorted and truncated, somewhat curved at each end, covered with orange-colored fibers 2 or more inches in length, of a reddish-brown color externally, brighter blood-red within, and containing an abundance of orange-colored juice, which flows out when the root is cut. The end of the root always appears as if broken or cut off by a dull instrument in removing it from the ground.

A horizontal section of the fresh root is a most beautiful object under the microscope; it is found to consist of numerous cells throughout its central part, somewhat oval or hexagonal, of nearly equal diameter, and containing: (1) a large proportion of the orange-colored resin peculiar to the plant, presenting the most beautiful shades of transparent amber; (2) a magnificent transparent, garnet hue, not seen, however, in every cell, resembling dots of garnet scattered over the field, with lateral facets, like a precious stone; and (3) a scarcity of white, transparent substance, consisting of a colorless, fixed oil. The juice when examined under the microscope, presents numerous transparent milk-like globules, and many colored granules, free and in clusters; with a power of 740 diameters, multitudes of transparent monads are seen in active motion. These globules and granules are rendered thinner and more transparent by liquor potassæ, and are mostly dissolved by ether; acetic acid dissolved most of the granules. The juice forms a fine dye of an orange color, the color being fixed by various mordants, as perchloride of tin, and sulphate of aluminum (G. D. Gibb).

As found in commerce, the dried root, considerably shrunken, is dark brown externally, bright yellow internally, but becoming dark-brown by the action of the air, more or less crooked, compressed, corrugated, having a short, uneven, pith-like fracture, a peculiar faintly virose odor, and a bitter, acrid, and pungent taste, leaving an impression in the fauces for some time after it has been chewed. "Of horizontal growth, about 5 Cm. (2 inches) long, and 1 Cm. (½ inch) thick, cylindrical, somewhat branched, faintly annulate, wrinkled, reddish-brown; fracture short, somewhat waxy, whitish, with numerous small, red resin-cells, or of a nearly uniform, brownish-red color; bark thin; odor slight; taste persistently bitter and acrid"—(*U. S. P.*). It is readily reduced to brownish-red powder, which causes sneezing when stirred. Boiling water or alcohol takes up its active properties, the latter, however, being the best menstruum; the root should be kept in a dry place; age or moisture impairs its activity. The seeds are about the size of barley grains, of a shining dark reddish-brown color, half surrounded with a peculiar white vermiform appendage, projecting at the lower end; they contain a bland, nutritious, and colorless fixed oil.

History.—Sanguinaria is one of the best known of our vernal-flowering-plants, making its appearance very early in the spring, usually in this climate in April, frequently covering the ground with large patches of beautiful white flowers. It usually grows in open woods, but may also be found along fences, around old stumps, and in recent clearings. Though extremely common throughout the eastern half of the union it is rapidly becoming scarce in the New England states, where it formerly grew in abundance. It thrives best in clayey soils, and rich loam, and is not usually found in wet places, as swamps and marshes, nor is it fond of sand, consequently it is not found near the ocean and lakes, nor in the swamps of the south. Otherwise it is encountered from Quebec and Ontario on the north to the Gulf of Mexico on the south, and from the Atlantic to the western boundary of the tier of states bordering on the west bank of the Mississippi River. It is commonly known as Bloodroot and Red puccoon, and less familiarly as Bloodwort, Red-root, Puccoon, Turmeric, and Indian paint. By the middle of summer the whole plant dies to the ground. The rhizome is fleshy, fibrous rooted, and breaks abruptly with a transverse fracture. The first botanical mention of bloodroot was made by Cornuti, in 1635, who placed it in the genus

Chelidonium. The name sanguinaria was first applied to it by a French botanist, Pierre Morin (Morinus), who published, in 1651, a catalogue of plants in his garden, and through John Jacob Dillenius, an eminent English botanist (of German birth and education, however), became established as the generic name, though it remained for Linnæus to define the genus. The name *sanguinaria* is from the Latin *sanguis*, blood; so named because the plant when wounded throws out the copious blood-like sap before referred to. The name sanguinaria, or "herba sanguinalis" had previously been used by both Greek and Latin writers, but was probably applied to other plants, as the name had reference to such plants as had the property of stopping the flow of blood—acted as hemostatics—and not on account of any red coloring possessed by them. This plant was well known to the American Indians, who used it as a dye. Through them the Virginians became acquainted with it. Strachey, who lived in Jamestown in 1610, states that it was called by the natives "*Musquaspenne*."

Perhaps no indigenous plant created greater interest among the early botanical physicians than the bloodroot. While nearly every writer on materia medica and botany gave full descriptions of the plant, and commended it for its beauty and usefulness, yet it never obtained the prominence that a drug of its class merits. In fact, while used to a considerable extent in domestic and botanical practice, it remained for the "Eclectic fathers" to take it up and develop its use as a remedy. Schoepf was among the earliest to notice it as a medicine. He speaks of 15 or 20 grains of the powdered root producing powerful emesis, and further notices its irritating action on the fauces, when given in powder. He advised a decoction or pill form of administration. Both Schoepf and Mérat used it for gonorrhœa, and Colden employed it in jaundice. Thacher mentions it, stating that it was the chief ingredient of a nostrum known as "Rawson's Bitters." The younger Barton employed a spirituous tincture in connection with the tinctures of bitter plants as a tonic, and used it locally as a wash for indolent ulcers, with hardened edges and ichorous discharges. He also applied the pulverized root to fungoid growths and nasal polypi. Bigelow and Smith used it for the same purpose. Thacher speaks of its use for coughs and pneumonic complaints, being used in place of digitalis. It was also used for "peripneumonia trachealis, cynanche maligna, and cynanche trachealis." Barton and Downey pointed out that the leaves and seeds were possessed of a narcotic power similar to that possessed by stramonium seeds, which fact was confirmed by the celebrated Dr. Bard (in an inaugural address), who used the root in croup, pneumonia, whooping-cough, phthisis, and jaundice. In 1831, Dr. Daniel B. Smith published in the *Journal of the Philadelphia College of Pharmacy* a dissertation on bloodroot, giving the natural and botanical history, and called attention to Dr. Dana's experiments, in 1824, when the latter possibly first obtained *sanguinarine*. Prof. Tully, who carefully experimented with bloodroot, classed it therapeutically with squills, seneca, digitalis, guaiacum, and ammoniacum. About the middle of the present century Dr. Fell, of England, was permitted to make a trial of a secret method of treating cancer, in the Middlesex Hospital of London, an act which was severely condemned by the *London Lancet*, consequently it led Dr. Fell to publish a work on "*Cancer and Its Treatment*," in which he said that he used the "bruised bloody pulp of the white flowering puccoon" (*Drugs and Medicines of North America*). *The Western Medical Reformer*, the pioneer Eclectic medical journal, in October, 1836, gave a description of bloodroot and its uses, and from that time on it has been a favorite remedy with our practitioners. The salts of sanguinarine were introduced into commerce by the late William S. Merrell, M. D.

Specific sanguinaria, the preparation principally employed by Eclectic physicians, has a deep ruby-red color and little odor. The taste is sharp and acrid, or as some might contend peppery, the after-taste being disagreeable, especially the sensation that remains in the throat and fauces. When ammonia is added to specific sanguinaria the red color disappears, a buff, purplish hue resulting. Acids restore the red color. When specific sanguinaria is dropped into water it imparts a yellow color if in small amount, which deepens to red as the proportion increases. A slight opalescence also results owing to precipitation of resin in a finely divided condition, and if the specific be in large amount the mixture becomes turbid and ultimately precipitates.

Chemical Composition.—G. König (*Amer. Jour. Pharm.*, 1891, p. 457) isolated from the root of sanguinaria the following alkaloids: *Chelerythrine* ($C_{21}H_{17}NO_4$), occurring in largest quantity, and forming lemon-yellow salts with acids; *sanguinarine* ($C_{20}H_{15}NO_4$), forming red-colored salts with acids; *gamma-homochelidonine* (probably $C_{22}H_{21}NO_4$); and *protopine* ($C_{20}H_{17}NO_5$), which is also a constituent of opium and chelidonium. *Sanguinarine* (formerly also called *chelerythrine*) was discovered in bloodroot by Dana, in 1829, and, afterward, in Chelidonium majus (see *Chelidonium*) by Probst (1838). It crystallizes in colorless needles, melting at 211° C. (411.8° F.) (G. König); insoluble in water, soluble in alcohol and ether, and in acids, forming red-colored salt-solutions of acrid taste (see *Sanguinarine*, page 1713). The bases above-named are combined in the root with *sanguinaric acid* (Newbold, 1866), which L. C. Hopp showed to be a mixture of citric and malic acids (*Amer. Jour. Pharm.*, 1875, p. 193). Mr. F. L. Slocum (*ibid.*, 1881, p. 275) found the root to contain about 3.5 per cent of resin, soluble in alcohol, insoluble in water. Sanguinaria seeds were analyzed by John Culley (*ibid.*, 1894, p. 189); petroleum ether extracted fixed oil and alkaloids (28.2 per cent), ether then took up resin and alkaloids (4.47 per cent), and absolute alcohol finally removed 2.9 per cent of resin. Mr. Charles H. LaWall (*Amer. Jour. Pharm.*, 1896, p. 305) recommends an assay of sanguinaria by abstracting the powdered root with petroleum benzin and aqua ammoniæ, an average of 1.5 per cent of total alkaloids being uniformly obtained. Other solvents extracted as much as 5 or 6 per cent.

Action, Medical Uses, and Dosage.—I. SANGUINARIA. The physiological action of sanguinaria is pronounced. The powder, when inhaled, is exceedingly irritating to the Schneiderian membrane, provoking violent sneezing, and free and somewhat prolonged secretion of mucus. To the taste, bloodroot is harsh, bitter, acrid, and persistent, and, when swallowed, leaves an acridity and sense of constriction in the fauces and pharynx and induces a feeling of warmth in the stomach. In small doses, it stimulates the digestive organs, and increases the action of the heart and arteries, acting as a stimulant and tonic; in larger doses it acts as a sedative to the heart, reducing the pulse, causing nausea, and, consequently, diaphoresis, increased expectoration, and gentle diuresis, at the same time stimulating the liver to increased action. If the dose be large, it provokes nausea, with violent emesis, vertigo, disordered vision, and great prostration. It also increases the broncho-pulmonary, cutaneous, and menstrual secretions. It is a systemic emetic, very depressing, causing increased salivary and hepatic secretions, and hypercatharsis may result. When an emetic dose has been taken, the heart's action is at first accelerated and then depressed. Poisonous doses produce violent gastralgia of a burning and racking character, which extends throughout the gastro-intestinal canal. The muscles relax, the skin becomes cold and clammy, the pupils dilate, there is great thirst and anxiety, and the heart's action becomes slower and irregular. Spinal reflexes are reduced and paralysis of the spinal nerve centers follow. Lethal doses produce death by paralysis of medullary, respiratory, and cardiac centers, death being sometimes preceded by convulsions.

Sanguinaria fulfils a variety of therapeutic uses according to the size of the dose employed. Though an emetic, it is seldom employed alone, but in combination with lobelia, as in the acetous emetic tincture, it forms one of our most efficient systemic agents of this class, and may be employed in *inflammatory* and *febrile states*, where it is thought necessary to thoroughly cleanse the stomach, and to excite the hepatic and general glandular system to activity. Upon the liver it acts as a gentle but reliable cholagogue, and may be employed in torpor of that viscus, or in congestive states and subacute as well as *chronic hepatitis*. Its action on the stomach is kindly. It promotes secretion and improves the appetite. It is a good remedy for *atonic dyspepsia*, administering drop doses of specific sanguinaria every 2 or 3 hours. By its stimulant action on the mucous surface, it proves valuable in the treatment of *gastric* and *duodenal catarrh*, and in *catarrhal jaundice*. It is applicable in all cases of *hepatic debility*, especially where the biliary product is suppressed, deficient or vitiated, and the general circulation is feeble, with cold extremities and *sick headaches*. Its value is often increased when combined with either podophyllin or specific iris. Bloodroot has proven serviceable in *rheumatism*, *dysentery*, and *scrofula*, with imperfect circulation.

Bloodroot is useful in many troubles of the genital system. *Amenorrhœa*, especially in anemic and chlorotic patients, with chilliness and headache, is benefited by it, as well as *dysmenorrhœa* in debilitated females. *Hysteria*, when due to moral causes, or pain, has likewise yielded to sanguinaria. *Hemorrhage of the lungs*, depending on vicarious menstruation, has been controlled by bloodroot. In the male, it is a remedy for *genital debility* and *seminal weakness*, *impotence*, with seminal incontinence and relaxed sexual organs.

Sanguinaria is "a neglected drug in respiratory disorders. Its action upon the pulmonary organs is somewhat similar to that of lobelia. It is important as a stimulating expectorant, to be used after active inflammation has been subdued. It may be employed in atonic conditions. It restores the bronchial secretions when scanty, and checks them when profuse. It is indicated in burning, smarting, itching conditions of the throat, larynx, and nares; tickling or burning in the nasal passage with abundant secretion, and an irritative, tickling cough; or when from atony the secretions are checked, it restores them, and removes the dry, harsh cough. It is useful in both *acute* and *chronic bronchitis*, *laryngitis*, *sore throat*, and *acute* or *chronic nasal catarrh*. It acts as a sedative to the irritable mucous surfaces, promotes expectoration, and stimulates their functions. It has proved very valuable as a cough remedy in *phthisis pulmonalis*. It is further a valuable alterative. It has been successfully employed in various forms of *croup*, particularly *mucous croup*. It is serviceable in *humid asthma* and *whooping-cough*. *Pharyngitis*, with red and irritable mucous membranes, and burning, smarting, or tickling, is cured by it. As an expectorant, it may be combined with other agents, as lobelia, etc. It enters into the composition of the 'acetous emetic tincture,' and, in powder form, is contained in the 'compound powder of lobelia and capsicum.' It is too harsh to use as an emetic, still good results have come from its use in *pseudo-membranous croup*, first giving small doses until profound nausea is produced, then carrying it to emesis. In *pneumonia*, after the inflammatory stage has passed, it may be given in 1 or 2-drop doses, frequently repeated, or it may be combined with wild cherry, lycopus, or eucalyptus. The vinegar of sanguinaria is a very efficient pectoral agent. The nitrate of sanguinarine is, with many, a favorite remedy to fulfil the indications for bloodroot. It may be administered in water, syrup, or in trituration with milk-sugar. The specific indications are a sense of burning in the fauces, pharynx, larynx, or nasal tissues, with redness of surface, and thin, acrid burning, smarting discharge; post-sternal constriction, or at the supra-sternal notch, with difficult breathing. A decoction of bloodroot is of service in *scarlatinal sore throat*" (Felter, *Ec. Med. Jour.*).

Sanguinaria is of value in *syphilitic skin eruptions*, and, as an ointment, has been employed, locally, in *tinea*. The powder, made into a cataplasm with slippery-elm, has been used in domestic practice as a local dressing for *frozen feet*. An infusion, made in vinegar, has been found valuable in several cutaneous diseases, as *eczema*, *ringworm*, and *warts*. At one time the root was extensively employed in the treatment of *carcinomata*, and was also applied to *exuberant excrescences* for its escharotic action, and to *ill-conditioned ulcers*, to create a healthy energy in the sores. Bloodroot, with bayberry, was formerly popular as an errhine in *catarrhal affections of the nose*, *cephalalgia*, *neuralgic affections of the head*, and to destroy *nasal polypi*. Prof. W. Byrd Scudder (*Ec. Med. Jour.*, 1892, p. 86) reports a case of *hypertrophic rhinitis*, caused by irritating dust in a seed-house, promptly relieved by $\frac{1}{10}$-grain doses of sanguinarine nitrate. The patient complained of a "dryness of the naso pharynx and throat, attended with sharp lancinating pain, and a sensation as if one side of the throat rubbed against the other." We have employed the nitrate of sanguinarine when the only symptom was an irritating cough, with tickling low in the larynx, with marked benefit. The preparations of sanguinaria in use are the powder, fluid extract, tincture, specific sanguinaria, vinegar of sanguinaria, syrup of sanguinaria, sanguinarine, and sanguinarine nitrate. The latter should be given in milk-sugar, or in syrup, on account of its acridity. Dose of the powder, as an emetic, from 10 to 20 grains; of the tincture, from 20 to 60 drops; as a stimulant or expectorant, from 3 to 5 grains; as an alterative, from $\frac{1}{2}$ to 2 grains. The dose of sanguinarine is $\frac{1}{24}$ to $\frac{1}{12}$ grain; of sanguinarine nitrate, $\frac{1}{30}$ to $\frac{1}{10}$ grain; specific sanguinaria, from 1 to 10 drops. For chronic respiratory troubles the syrup may be combined with wild cherry and liquorice.

II. SANGUINARINE NITRATE.—The action of this agent is practically that ascribed to sanguinaria (which see), though for respiratory affections it is to be preferred to that drug. The usual methods of administration are the syrup (½ to 2 grains to 4 fluid ounces of water and syrup), the dose of which is a teaspoonful every 1 to 3 hours; and the 2 x trituration, the dose of which ranges from 1 to 10 grains.

Specific Indications and Uses.—I. SANGUINARIA. For its specific indications, Prof. J. M. Scudder gives a "sensation of burning and itching of mucous membrane, especially of fauces, pharynx, Eustachian tubes and ears; less frequently of larynx, trachea, and bronchia, occasionally of stomach and rectum, and rarely of vagina and urethra. The mucous membrane looks red and irritable. Sometimes the redness will be of the end of the nose." Added to this he gives "nervousness, redness of nose, with acrid discharge, burning and constriction in fauces of pharynx, with irritative cough and difficult respiration." Prof. Locke gives also feeble circulation, with coldness of extremities.

II. SANGUINARINE NITRATE.—Tickling or irritation of the throat, with cough, burning or irritative sensation in the fauces, pharynx, larynx, or nasal tissues, with red surface and thin, acrid, burning, or smarting discharges; dryness of the nasopharynx and throat, with sharp, lancinating pain, and a feeling as if the walls of the throat were rubbing against each other; post-sternal constriction, or sense of uneasiness at the supra-sternal notch, with difficulty in breathing; sense of uneasiness and burning in the stomach, with nervousness.

Related Species.—*Stylophorum diphyllum*, Nuttall. United States. E. Schmidt (*Amer. Jour. Pharm.*, 1888) found the plant to contain *chelidonine* and another alkaloid, probably *chelerythrine*. This plant was first analyzed by J. U. Lloyd at the suggestion of C. G. Lloyd, who argued that its botanical relationship suggested an alkaloidal constituent. The product, a white alkaloid, was obtained in considerable amount, but no attempt at identification was made. Subsequently, the alkaloid was sent to Prof. Eykman, of Tokio, Japan, who reported in detail concerning it.

The following agent, though not related botanically, is also used for antispasmodic purpose. It may be well to state here that under the subheads *Related Species* and *Related Preparations*, we have frequently placed plants or drugs usually according to botanical or chemical relationship to the subject of the main article, but in several instances physiological or therapeutic relationship only has been taken into consideration.

Adhatoda Vasica, Nees (*Justicia Adhatoda*, Linné) (*Nat. Ord.*—Acanthaceæ).—India, "in the sub-Himalayan tract, from Nepal westward." The *Malabar nut-tree*, also known as *Arusa* (Hindu), *Adulsa* (Bombay), *Bàkas* (Bengalese), and *Adatodai* (Tam.). Of this plant, Ainslie long ago made the following statement: "The flowers, leaves, and roots are supposed to possess antispasmodic qualities; they are bitterish and subaromatic" (Lindley's *Medical Flora*). This shrub is largely employed in India as an antispasmodic and expectorant, particularly in *asthma* (leaves smoked also in this complaint), and in *phthisis* and *bronchitis*, and in other *catarrhal* and *pectoral complaints*, with cough and hectic. There is a saying in the East, according to Dutt, "that no man suffering from phthisis need despair as long as the *Vasaka* (Sanscrit) plant exists." The flowers are also used to purify the blood, and in *gonorrhœa*; the wood makes a fine charcoal for gunpowder (Dymock, *Mat. Med. of Western India*). Adhatoda contains *adhatodic acid* and the alkaloid, *vasicine*, in combination. Frogs and leeches, and fleas, mosquitoes, and many other insects are destroyed by a solution of vasicine. Adhatoda has been advised in this country in the treatment of *diphtheria* and *intermittent* and *typhoid fevers*. The leaves are the parts chiefly employed, of which a fluid extract may be given in doses of from 5 to 60 drops. Adhatoda leaves are said to be used in rice cultivation, being spread over the recently-flooded districts to kill the lower orders of aquatic plants (green scum), which interfere with the growth of the rice; they also serve as fertilizers to the soil.

Sanguinarine, Its Salts, and Sanguinarin.—The Eclectic name *Sanguinarine* was affixed to the mixed alkaloids thrown down by ammonia from an aqueous solution of the drug. When purified, this mixture, while free from extraneous matter, was still a mixture of alkaloidal educts and never free from decomposition or oxidation products. Change rapidly occurs, the ammoniacal precipitate if white, soon changes to buff and then to blue, drying dark. The salts are, when first thrown out of ethereal solution, of a yellow color; they darken soon, and on drying become of a deep-red color. These salts have long been used in Eclectic medicine.

SANGUINARINÆ.—*Sanguinarine* ($C_{19}H_{17}NO_4$, Limpricht; $C_{20}H_{15}NO_4$, G. König), the alkaloid of bloodroot. Dr. T. L. A. Greve, of Cincinnati, proposed the following formula for an impure alkaloid: "It may be obtained by adding aqua ammoniæ to the liquor from which the resin (*sanguinarin*) has been precipitated. It is then separated from the liquid by straining or filtering, washing the mass on the filter with water, then drying and powdering it. It may also be procured by treating ground bloodroot with water acidulated with sulphuric acid, and then precipitating with aqua ammoniæ, as above named." We have found that a purer form of sanguinarine may be obtained by triturating the sanguinarine nitrate with an ethereal solution of ammonia gas, which yields the alkaloid to ether which may then be evaporated to dryness. Sanguinarine ($C_{19}H_{17}NO_4$) is a white or pearl-gray body, having a bitter taste with some acrimony, is hardly dissolved by water, but readily by ether or alcohol, and possesses well-marked alkaline characters, rendering turmeric paper brown or red, and forming red-colored salts with the acids. So intensely irritating is it that even a very minute amount of the dust in the room will render the air irrespirable. It is a strong base and readily combines with even the weaker organic acids to form salts. All that is necessary to produce the salt is to simply neutralize the alkaloid with a weak solution of the desired acid, and evaporate to dryness. The uses of sanguinarine are similar to those of preparations of bloodroot. One grain of this alkaloid may be thoroughly triturated with 20 or 30 grains of sugar of milk, and divided into 10 or 30 doses, according to the effect desired. A very excellent cough preparation may be made, composed of chloride of ammonium, 2 drachms; extract of liquorice, 2 drachms; extract of hyoscyamus, ½ drachm; syrup of tolu, 1 fluid ounce; water, 6 fluid ounces; acetate or sulphate of sanguinarine, 1 or 2 grains. Mix. The dose is a tablespoonful, repeating it 3 or 4 times a day.

Sanguinarinæ Sulphas, *Sanguinarine Sulphate.*—Prof. E. S. Wayne recommends the following mode of obtaining sulphate of sanguinarine, which is Dr. Schiel's process: Exhaust bloodroot, in coarse powder, in a percolator, with diluted sulphuric acid, and then add ammonia; a deep purple precipitate occurs, which must be washed with water upon the filter, dried, and treated with ether, which dissolves out the sanguinarine. Treat this solution with animal charcoal, and the alkaloid is obtained as a sulphate of a bright vermilion color, on the addition of a solution of sulphuric acid in alcohol (*Amer. Jour. Pharm.*, Vol. CXXV, p. 521).

Sanguinarinæ Nitras, *Sanguinarine Nitrate.*—The nitrate of the alkaloids obtained from *Sanguinaria canadensis*, Linné. Prepare an alcoholic extract of sanguinaria, evaporate to a syrupy consistence, mix it with water, filter, and to the filtrate add ammonia water in slight excess. A bluish precipitate falls which must be filtered out and dried. Cautiously powder the dried mass, exhaust with ether, and filter. To prepare the nitrate, cautiously add nitric acid to the ether solution, being careful to avoid an excess, when sanguinarine nitrate will have formed, and not being soluble in ether precipitates as a yellow-red magma which, when dried, assumes a crimson hue. This substance is a salt of the mixed alkaloids of sanguinaria. It forms a powder of a crimson or brick color (according to process employed), almost entirely soluble in water, of an acrid taste, and a slight odor like that peculiar to the root, intensely irritating to the nasal mucous surfaces, and is employed as an expectorant, and likewise used where the root is indicated, in doses of from ⅛ to ¼ grain. (For *Action*, and *Specific Indications and Uses*, see *Sanguinaria.*)

Sanguinarin.—The alka-resinoid principle of bloodroot. Under the above name the early Eclectics used an impure resinous product of sanguinaria made after the manner of making resin of podophyllum. It possessed the qualities, largely, of the sanguinaria alkaloids which were mixed mechanically therewith. When used alone it should be triturated with sugar, sugar of milk, or some other article. As a tonic, the dose is from ¼ to 1 grain, 3 or 4 times a day; as a hepatic and alterative, from ½ to 2 grains. It may be proper for me to state here that I consider the *resin* of sanguinaria nearly, if not quite, devoid of medicinal principles, and that all the effects stated, as above, to have occurred from its administration, are entirely owing to its containing a greater or less amount of the alkaloid. Consequently, it would be better, both in a therapeutical and economical view, to dispense with this resin altogether, and employ sanguinarine only (J. King).

SANGUIS.—BLOOD.

Description.—Blood is an animal fluid somewhat of the character of an emulsion. It is the fluid which flows through the circulatory system of animals, that passing through the arteries in the vertebrate animals being bright red, and that returning to the heart by the veins, of a darker color and loaded with impurities. In the lower animals blood is white. This emulsion-like fluid, holding in suspension the blood corpuscles, is composed of a liquid and solid portion; the *corpuscles*, red and white, form the visible solid constituent, and the *liquor sanguinis*, or *plasma*, the fluid in which they float. These portions must not be confused with the fluid and solid portions of blood seen when drawn blood is allowed to stand. The solid portion is the "*clot*," or "*coagulum*," and contains a solid, colorless material—*fibrin*—enclosing the blood corpuscles, while the yellowish fluid in which the clot floats is the *serum*, which contains the salts and albumen. Blood has a faint but characteristic odor, a clammy somewhat viscid feel, is salty to the taste and of alkaline reaction. The coloring of blood corpuscles is due to a complex proteid compound known as *hæmoglobin*. This is crystallizable, and is capable of entering into a loose molecular combination with oxygen, called *oxyhæmoglobin*, and into a more stable compound with carbon-monoxide. Hæmoglobin is converted by acids or alkalies into a crystallizable red-coloring matter, *hæmatin*. The saline constituents of blood are iron, sodium and potassium chlorides, sulphates, and phosphates, and magnesium and calcium phosphates. The sodium chloride predominates. When ox-blood is evaporated to the consistence of an extract, it is known as *extractum sanguinis;* when pulverized, *pulvis sanguinis;* when defibrinated and dried as *sanguis bovinus exsiccatus.*

Action, Medical Uses, and Dosage.—Outside of its nutritive value blood has been employed as a medicine. Blood was introduced by Vacher (1873) as a remedy for *scrofulous conditions* of children and for the expulsion of *entozoa*, being found most efficient for *rectal ascarides.* Liquid blood has been administered in *chlorosis*, but the form generally employed is defibrinated blood, being administered chiefly by rectum and hypodermatically, the latter method being unattended with inflammatory or other ill-results. The conditions in which it has been found to exert a favorable and permanent influence are: *Debility* of infants and children, due to *dyspepsia*, *anemia*, debilitating discharges and various chronic affections; by the subcutaneous method in *anemia* from *hemorrhage*, *leukæmia*, *pernicious anemia*, and *anemia from exhausting discharges.* By rectum from 2 to 3 ounces may be injected several times a day.

SANICULA.—SANICLE.

The root of *Sanicula marilandica*, Linné.

Nat. Ord.—Umbelliferæ.

Common Names: *Sanicle, Blacksnake root, Pool-root.*

Botanical Source.—Sanicle is an indigenous, perennial herb, sometimes known by the name of *Blacksnake root*, with a stem from 1 to 3 feet high, smooth, furrowed, and dichotomously branched. The leaves are 3 to 5-parted, digitate, mostly radical, on petioles 6 to 12 inches long; the segments 2 to 4 inches long, half as wide, oblong, and irregularly and mucronately toothed. Cauline leaves few and nearly sessile. The flowers are mostly barren and white, sometimes yellowish; the sterile flowers are borne on slender pedicels; the fertile ones sessile. Segments of the calyx entire. Involucre 6-leaved and serrate. Umbels often proliferous; umbellets capitate. Fruit several in each umbellet, and densely clothed with hooked bristles (W.—G.). A variety (*S. canadensis*) has short-pedicelled, sterile flowers.

History and Chemical Composition.—Sanicle is common to the United States and Canada, and is found in low woods and thickets, flowering in June. The fibrous root is the medicinal part. Its taste and odor are somewhat aromatic. An alcoholic tincture contains its medicinal properties. Resin, essential oil, tannin, coloring matters, and ash (9 per cent) were obtained from the root by C. J. Houck (*Amer. Jour. Pharm.*, 1884, p. 463).

Action, Medical Uses, and Dosage.—Sanicle very much resembles valerian in its action on the system, possessing nervine and feebly anodyne properties, together with some astringency. It has been used with advantage as a domestic remedy in *intermittent fevers*, *sore throat*, *cynanche trachealis*, *erysipelas*, and some *cutaneous diseases.* It is very efficient in *chorea*, in doses of ½ drachm of the powdered root, 3 times a day, to children 8 or 10 years of age. It has also been beneficially employed in various other *nervous affections.* The decoction of it, administered in doses of from 2 to 4 fluid ounces, and repeated 3 or 4 times a day, is said to be valuable in *gonorrhœa*, *dysentery*, *passive hemorrhages*, and *leucorrhœa.* The decoction used freely, at the same time bathing the wound with it, is reputed a certain cure for the bites of *poisonous snakes* (J. King).

Related Species.—*Sanicula europæa*, Linné. The root of this plant is astringent, and possesses an acrid, bitter taste. In the Old World it is a domestic remedy for *hemorrhages* of a profuse character, such as from the lungs, uterus, etc.; *leucorrhœa*, *dysentery*, and *diarrhœa* are likewise treated with it. Externally, it is applied to *wounds.* An infusion in wine, or the fresh juice, is generally administered in ½-ounce doses.

Astrantia major, Linné. This plant has a root similar to the sanicles, and is employed sometimes as *Black imperatoria* (*Radix imperatoriæ nigræ*). This root is commonly known as *Black sanicle.*

SANTALUM RUBRUM (U. S. P.)—RED SAUNDERS.

The wood of *Pterocarpus santalinus*, Linné filius.

Nat. Ord.—Leguminosæ.

Common Names and Synonym: *Red saunders, Ruby wood, Red sandal-wood; Lignum santalinum rubrum.*

Illustration: Bentley and Trimen, *Med. Plants*, 82.

Botanical Source.—This is a lofty forest tree. The leaves are alternate, stalked, ternate, and rarely pinnate; the leaflets alternate, petiolate, the uppermost larger, ovate-roundish or oblong, entire, emarginate or retuse, smooth above, and hoary beneath; the stipules wanting. The flowers are yellow, with red veins, papilionaceous, and borne in axillary, simple or branched, erect racemes. Bracts none. Calyx brown and 5-cleft. Stamens 10, combined into a sheath, split down to the base on the upper side, and half-way down on the lower. The legume is roundish, long-stalked, falcate upward, compressed, smooth, and keeled on the lower edge; the keel is membranous and undulated. Seed solitary (L.).

History and Description.—This is a large forest tree inhabiting Ceylon and the mountains of the opposite Coromandel coast on the Indian continent. Only in the Madras Presidency does it grow wild. The wood is the official *Red saunders*, or *Red sandal-wood*. It is "a hard, heavy, dark reddish-brown, coarsely splintery wood, deprived of the light-colored sap-wood; usually met with in chips, or as a coarse, irregular, brownish-red powder, nearly inodorous and nearly tasteless. Red saunders does not impart any red color to water when macerated with it"—(*U. S. P.*). Other dye-woods generally communicate their color to water, which is not the case with red saunders; the latter, however, imparts to alkaline solutions, ether, and alcohol, a scarlet color. The alcoholic solution produces with solutions of lead a violet-colored, with corrosive sublimate a scarlet, and with sulphate of iron a deep-violet, precipitate.

Chemical Composition.—The coloring principle of red saunders is *santalic acid* (*santalin*), discovered by Pelletier. It is a red, tasteless, and odorless, crystalline powder, insoluble in water, soluble in ether, with yellow color, and in alcohol, with blood-red color (L. Meyer, 1848). It likewise dissolves in alkalies and acetic acid, but not in essential oils. H. Weidel (1869) obtained a similar substance, *santal* ($C_8H_6O_3$), by extracting the wood with boiling alkaline water, precipitating with hydrochloric acid, and recrystallizing from alcohol. The yield was 0.3 per cent. Cazeneuve and Hugounenq (*Jahresb. der Pharm.*, 1887, p. 159; and 1889, p. 127) digested the powdered wood with milk of lime, extracted the coloring substance with ether, and crystallized from alcohol. Carbon disulphide differentiated the product obtained into insoluble *pterocarpin* ($C_{20}H_{16}O_6$) and soluble *homo-pterocarpin* ($C_{24}H_{24}O_6$). Both substances are probably orcin-derivatives (see *Lacmus*). A small amount of tannin is contained in red saunders.

Action and Medical Uses.—Tonic and astringent. Formerly used for these indications, but at present employed only for coloring tinctures, etc.

Related Wood.—Cam Wood. Red dye-wood from *Baphia nitida*, De Candolle (*Nat. Ord.*—Leguminosæ). Western Africa. It scarcely colors water, but readily gives its red color to alkalies and alcohol. The coloring principle is thought to be identical with *santalin*.

SANTONICA (U. S. P.)—SANTONICA.

"The unexpanded flower-heads of *Artemisia pauciflora*, Weber"—(*U. S. P.*) (*Artemisia Lercheana*, Karel et Kirel; *Artemisia maritima*, var. *a pauciflora*, Ledebour; *Artemisia maritima*, var. *a Stechmanniana*, Besser).

Nat. Ord.—Compositæ.

Common Name and Synonyms: *Levant wormseed; Semen cinæ, Semen sanctum, Semen contra, Semen santonici.*

Illustration: Bentley and Trimen, *Med. Plants*, 157.

Botanical Source and History.—The plant furnishing santonica is one of the many forms of *Artemisia maritima*, a plant having a wide distribution, especially in salty soils of marshes in the northern hemisphere of the Old World. "It is found in the salt marshes of the British Islands, on the coasts of the Baltic, of France and the Mediterranean, and on saline soils in Hungary and Podolia; thence it extends eastward, covering immense tracts in southern Russia, the regions of the Caspian, and central Siberia, to Chinese Mongolia. The particular variety which furnishes at least the chief part of the drug, is a low, shrubby, aromatic plant, distinguished by its very small, erect, ovoid flower-heads, having oblong, obtuse, involucral scales, the interior scales being scarious. The stem in its upper half is a fastigiate, thyrsoid panicle, crowned with flower-heads. The localities for the plant are the neighborhood of the Don, the regions of the lower Volga, near Sarepta and Zaretzyn, and the Kirghiz deserts"—(*Pharmaeographia*). The great fair of Nishnei-Novgorod is the chief mart for Levant wormseed, the drug being conveyed there from Moscow, St. Petersburg, and the western ports of Europe. Two commercial varieties of the drug are known in Europe, the one under consideration being called *Aleppo*, *Levant* or *Alexandria wormseed*, the other is known as *Barbary wormseed*, and is the product of other Artemisiæ, growing in Arabia and Palestine, the exact species being yet undetermined.

Description.—"From 2 to 4 Mm. ($\frac{1}{12}$ to $\frac{1}{6}$ inch) long, oblong-ovoid, obtuse, smooth, somewhat glossy, grayish-green, after exposure to light, brownish-green, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales, with a broad midrib, enclosing 4 or 5 rudimentary florets; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter"—(*U. S. P.*).

Chemical Composition.—Levant wormseed contains resin, essential oil (about 2 per cent), and the crystalline, active principle, santonin ($1\frac{1}{2}$ to 2 per cent) (see *Santoninum*). *Oil of Levant wormseed* "has a yellowish color and a penetrating, disagreeable odor; specific gravity 0.930. It consists chiefly of *cineol* ($C_{10}H_{18}O$), with some dipentene" (see *Essential Oils*, by Prof. F. B. Power, 1894). *Cineol* is identical with *eucalyptol* and *cajuputol*.

Action, Medical Uses, and Dosage.—Levant wormseed is seldom used in substance in medicine, but is the official source of *santonin*. In small doses, it is a gastric stimulant, and, in larger amounts, a nervous and circulatory stimulant. Very large doses have produced a sense of depression at the stomach, nausea, emesis, purgation, and congestion of the brain. Wormseed is a vermicide, and is less apt than santonin to produce yellow vision. It is a remedy for the expulsion of *lumbricoides* and *rectal ascarides*, and less efficient for *tænia*. The dose of the powder is from 10 to 40 grains, 3 times a day, in syrup, honey, or similar fluid, in combination with a purgative, such as jalap, etc.

SANTONINUM (U. S. P.)—SANTONIN.

FORMULA: $C_{15}H_{18}O_3$. MOLECULAR WEIGHT: 245.43.

"A neutral principle obtained from Santonica. Santonin should be kept in dark, amber-colored vials, and should not be exposed to light"—(*U. S. P.*).

History and Preparation.—Santonin, the vermifuge principle of santonica, was discovered, in 1830, by Kahler and Alms, simultaneously. The *British Pharmacopœia* (1885) gives detailed directions for its preparation, which consists in boiling the bruised santonica seeds in water with addition of slaked lime, concentrating the solution of calcium santonate, adding hydrochloric acid, and allowing it to stand for 5 days. Wash the precipitated santonin (santonic anhydride) with water and ammonia water, which removes resin, and recrystallize from alcohol after treating the solution with animal charcoal. Another method consists in boiling out a mixture of santonica seeds and slaked lime with alcohol of 50 per cent (by volume), and decomposing the calcium santonate with carbonic acid (see Flückiger, *Pharmacognosie des Pflanzenreichs*, 3d ed., 1891, p. 822). (Also see detailed *Bibliography on Santonin*, by A. Van Zwaluwenburg, *Pharm. Arch.*, 1899, pp. 1–11.)

Description.—Santonin occurs "in colorless, shining, flattened, prismatic crystals, odorless and nearly tasteless when first put in the mouth, but afterward developing a bitter taste; not altered by exposure to air, but turning yellow on exposure to light. Nearly insoluble in cold water; soluble in 40 parts of alcohol at 15° C. (59° F.), in 250 parts of boiling water, and in 8 parts of boiling alcohol; also soluble in 140 parts of ether, in 4 parts of chloroform, and in solutions of caustic alkalies. When heated to 170° C. (338° F.), santonin melts, and forms, if rapidly cooled, an amorphous mass, which instantly crystallizes on coming in contact with a minute quantity of one of its solvents. At a higher temperature, it sublimes partly unchanged, and, when ignited, it is consumed, leaving no residue. Santonin is neutral to litmus paper moistened with alcohol. Santonin yields, with an alcoholic solution of potassium hydrate, a bright pinkish-red liquid, which gradually becomes colorless. From its solution in caustic alkalies, santonin is completely precipitated by supersaturation with an acid"—(*U. S. P.*).

Santonin ($C_{15}H_{18}O_3$) is the anhydride of *santonic acid* ($C_{15}H_{20}O_4$), which is a derivative of *dimethyl-naphtalene* ($C_{10}H_6[CH_3]_2$). Santonin dissolves in alkalies with formation of salts of this acid. Santonin, in acetic acid solution, when exposed to sunlight for about a month, is converted into (colorless) *photosantonic acid* ($C_{15}H_{22}O_5$). The ethyl-ester of the latter is obtained when an alcoholic solution of santonin is exposed to sunlight (Sestini). The yellow coloration developed upon exposure of santonin to light, is believed to be due to a red resin. Santonin is optically lævo-rotatory.

Adulterations and Tests.—Santonin has been adulterated by boric acid: this substance may be recognized by being insoluble in chloroform, or by not being volatilized when heated on platinum foil. If the residue is dissolved in water, and the solution acidulated with hydrochloric acid, a strip of yellow turmeric paper is colored brown by it. Santonin, turned yellow from exposure to light, has been mistaken for picric acid; the latter is easy of detection, being soluble in cold and hot water with yellow color (J. M. Maisch, *Amer. Jour. Pharm.*, 1874, p. 52); or the white crystals of santonin might be mistaken for strychnine, the latter, however, may readily be distinguished by the violet coloration it produces with sulphuric acid and potassium dichromate (see *Strychnina*). Other substitutions, *e. g.*, salicin, may be recognized by the following *U. S. P.* directions for santonin: "Its solution in cold, concentrated sulphuric acid is at first colorless (absence of easily carbonizable, organic substances), but, after some time, turns yellow, then red, and finally brown. If water be added, immediately after it is dissolved without color in sulphuric acid, it will be completely precipitated, and the supernatant liquid should not have a bitter taste, nor should it be altered upon the addition of potassium dichromate T.S. (absence of brucine or strychnine), or of mercuric potassium iodide T.S. (absence of alkaloids in general)"—(*U. S. P.*). D. Lindo's test for santonin is as follows: Dissolve, in a test-tube, a small quantity of santonin in strong sulphuric acid, add a few drops of a highly-diluted solution of ferric chloride; upon warming in the flame of a Bunsen burner, a beautiful violet coloration is developed.

Action, Medical Uses, and Dosage.—Santonin is an active agent, and, in improper doses, is capable of producing serious symptoms, and even death. As small a dose as 2 grains is said to have killed a weakly child of 5 years, and 5 grains produced death in about ½ hour in a child of the same age. Among the toxic effects may be mentioned gastric pain, pallor and coldness of the surface, followed by heat and injection of the head, tremors, dizziness, pupillary dilatation, twitching of the eyes, stertor, copious sweating, hematuria, convulsive movements, tetanic cramps, stupor, and insensibility. Occasionally symptoms resembling cholera morbus have been produced, and in all cases the urine presents a characteristic yellowish or greenish-yellow hue. We have observed convulsions caused by the administration of "worm lozenges." Death from santonin is due to respiratory paralysis, and post-mortem examination revealed in one instance a contracted and empty right ventricle, and about an ounce of liquid, black blood in the left heart, an inflamed duodenum, and inflamed patches in the stomach (Kilner). The chief form of treatment of poisoning by santonin is by artificial respiration. Internal and external stimulation should also be resorted to, inhalations of ether or chloroform, to control the convulsions, should be given, and a purgative administered to remove remaining traces of the poison from the bowels. Santonin often produces a singular effect upon the vision, causing surrounding objects to appear discolored, as if they were yellow or green, and occasionally blue or red; it also imparts a yellow or green color to the urine, and a reddish-purple color if that fluid be alkaline. Prof. Giovanni was led to believe that the apparent yellow color of objects observed by the eye, when under the influence of santonin, did not depend upon an elective action on the optic nerves, but rather to the yellow color which the drug itself takes when exposed to the air. Santonin colored by the air does not produce this effect, which only follows the white article. The air gives the yellow color to santonin, to passed urine containing it, and to the serum of the blood when drawn from a vein, and, according to Giovanni, it is owing to its direct action upon the aqueous humor, where it is carried by absorption, that objects present this color. The view now held, however, is that of Rose, that the alkaline serum dissolves the santonin, which then acts upon the perspective centers of the brain, producing the chromatopsia or xanthopsia. Santonin has been advantageously given in *amaurosis* following acute inflammation of some of the internal parts of the eye; also in *subacute* and *chronic retinitis* and *choroiditis*. It is said to have materially benefited cases of *non-congenital color-blindness*, being administered in $\frac{1}{20}$ or $\frac{1}{10}$ grain doses (Foltz).

Santonin is the chief remedy now used for the expulsion of the *roundworm* or *ascaris lumbricoides*. It acts less effectually upon *rectal ascarides*, and not at all upon the tapeworm. As a rule, when a single dose is to be given, it should be administered upon an empty stomach, and the patient should refrain from eating for a short time afterward. A purgative should precede and follow its use. Another method, which has found much favor in the Eclectic school, is that of giving santonin, in divided doses, as follows: ℞ Santonin, grs. v; podophyllin, grs. j; milk-sugar, ʒi. Mix. Divide into 10 powders, and administer 1 powder 3 times a day.

Santonin is an important nerve stimulant. It relieves many of those nervous phenomena which simulate the conditions produced by worms—picking at the nose, starting in sleep, intestinal irritation, etc. Its effects upon troubles of the urinary apparatus, due to disordered or deficient innervation, make it one of our best specific remedies. In *retention of urine*, due to atony of the bladder, no remedy surpasses it, and when this occurs as a symptom of the advanced stage of acute diseases of children, indicating an unfavorable prognosis, unless the urinary function can be restored, santonin may be given in $\frac{1}{4}$ to $\frac{1}{2}$-grain doses (triturated with sugar), every hour, until a free urinary flow is established. Retention of urine, caused by opium preparations, is corrected by it. Being strongly diuretic, it may be administered in *renal colic*. It relieves *urethral irritation*, *dysuria*, *strangury*, *nocturnal enuresis*, *chronic vesical catarrh*, and *vesical tenesmus*. It acts promptly in the urethral irritation, with pain and scalding, associated with *uterine disorders*, and in large, but unsafe, doses (10 grains), it has been recommended in *uterine colic* and *amenorrhœa* (Berthey). It relieves the difficult micturition and urinal retention following parturition, when not due to long-continued pressure of the child's head upon the parts. Many of the unpleasant urinary symptoms of *albuminuria* and *chronic nephritis* are relieved by santonin, and it is a remedy for impaired breathing and tympanitis due to deficient spinal innervation. The dose of santonin for an adult ranges from $\frac{1}{10}$ to 4 grains; for a child, $\frac{1}{20}$ to 2 grains, always avoiding the larger dose when possible; 2 x trituration, 2 or 3 grains, for its effects upon the urinary apparatus.

Specific Indications and Uses.—To remove all kinds of intestinal worms but the tapeworm; retention of urine from atony; nocturnal enuresis from atony; urethral irritation, with pain and scalding, accompanying uterine disorders; retention of urine in fevers; deficient spinal innervation, as evidenced by impaired respiration and tympanitis; vesical tenesmus and strangury; retention of urine from the use of opiates.

Related Products.—SANTONINOXIME ($C_{15}H_{19}NO_3$, or $C_{15}H_{18}O_2:N.OH$). Said to be a safe substitute for santonin, and the dose given may be 3 times as large. P. Guici (1889) prepared it by the interaction of santonin (5 parts), hydroxylamine hydrochloride (4 parts), strong alcohol (50 parts), and precipitated calcium carbonate (4 parts). These were digested for 3 or 4 days at about 80° C. (176° F.). It forms white silky, lævogyre needles, very sparingly soluble in hot water. It fuses at near 217° C. (442.6° F.).

Santolina chamæcyparissus (Compositæ).—Popular in Scotland as a remedy for *roundworm*. Half ounce of the plant may be boiled with 1 pint of water for 30 minutes, strained, and brought to the measure to 1 pint when finished. Of this decoction, 2½ ounces may be given to children, or 5 ounces to adults for 4 successive days, and may be followed with an active cathartic. Maben finds in the plant a bitter body, which he believes to be the active substance, resin, and an essential oil (*Pharm. Jour. Trans.*, Vol. XVI).

SAPO (U. S. P.)—SOAP.

"Soap prepared from soda and olive oil"—(*U. S. P.*).

COMMON NAMES AND SYNONYM: *Soap*, *White castile soap*, *Castile soap*, *Hard soap*; *Sapo durus*, *Br.*

Source and Preparation.—Soaps in general are the sodium or potassium salts of the higher fatty acids (lauric, stearic, palmitic, oleic acids, etc.) occurring in fats or fixed oils, these being glycerin esters of the acids named (see *Olea Fixa* and *Adeps*). Sodium and potassium soaps are readily soluble in water, while calcium soaps and the soaps formed with heavy metals are insoluble. The latter are called *plasters, e. g.*, lead plaster (see *Emplastrum Plumbi*).

Commercial soaps are broadly classed as *hard soaps* and *soft soaps*. As a rule, sodium soaps are hard soaps, while potassium soaps are soft. The nature of the higher fatty acid with which the alkali is combined, has a secondary influence on the consistency of the soap. Fats in which the solid stearic acid is preponderant, *e. g.*, mutton and beef suet, yield a harder soap than those in which the fluid oleic or related acids are predominant, *e. g.*, olive oil, linseed oil, fish oils. The fats from which soaps are prepared are chiefly tallow and lard, palm oil, olive oil, cocoanut oil, for hard, partly also for soft soaps, and hempseed oil, linseed oil, cotton-seed oil, and fish oils, for soft soaps; castor oil for transparent toilet soaps, and commercial oleic acid both for hard and soft soaps. In the case of oleic acid, soap-making consists simply in the neutralization of the free acid by caustic alkali or by the carbonate of an alkali. The carbonic acid evolved in the latter case is liable to be a disturbing element in the manufacture. With neutral fats, decomposition into the fatty acid and glycerin may be effected in several ways (see *Glycerinum*); of these, saponification by caustic alkalies is still the prevailing method of making soap. Taking *stearin* (glyceryl-tristearate) as a type of a solid fat, the reaction with caustic soda will be as follows: $C_3H_5(C_{18}H_{35}O_2)_3+3NaOH=$ $3C_{18}H_{35}O_2Na$ (sodium stearate) $+C_3H_5(OH)_3$ (glycerin). White castile soap is officially recognized and is made from olive oil.

HARD SOAPS.—In practical soap-making, saponification of the fat must be started with a weak lye, because soap being insoluble in strong alkali, the first soap formed would envelop the fatty particles and prevent them from being further attacked. The heating is done in copper boilers provided both with indirect and direct steam. After adding stronger lye, the mixture is boiled until a sample becomes firm on cooling; the soap is then "salted out," *i. e.*, common salt or concentrated brine is added, in which the soap is insoluble. The latter rises to the top, while the liquid below ("spent lye") contains all the glycerin, salt solution and various impurities, but should not contain either soap or free alkali. It is drawn off, and the supernatant soap boiled with another quantity of strong soda-lye, which completes the saponification. A small quantity of weak lye is now added and the mass boiled for several hours by direct steam. This produces *curd soap*, composed of hard, granular particles. The soap is taken out and allowed to harden in wooden or iron frames. *Mottled soap* is obtained when ferrous sulphate (about 0.25 per cent) is incorporated into the cooling mass which causes greenish streaks of ferrous hydrate to form, turning red on the surface of the soap. Other substances are also used for this purpose. *Yellow* or *resin soap*, is formed by adding a certain quantity of resin (see *Resina*) (as much as 50 per cent and more, of the fat employed) to the mass in the soap boiler toward the end of the process; a yellow soap of uniform texture, not curdy and granular, is produced. When unbleached palm oil is saponified, the soap that is formed is also yellow.

Filled Soaps.—These are the cheapest soaps made. As they are not salted out they represent the total contents of the soap boiler, including the glycerin. The fats usually receive an addition of a large percentage of cocoanut oil, which has the remarkable property of being readily saponifiable with a strong soda-lye at a lower temperature producing a hard soap which can not be separated from the liberated glycerin, and in addition is capable of taking up large amounts of extraneous matters, soluble silicate of sodium being especially used for this purpose Thus, 100 kilogrammes of cocoanut oil, 75 to 80 kilogrammes of rosin, 300 kilogrammes of waterglass, and 100 to 150 kilogrammes of tallow, yield, with 240 kilogrammes of soda-lye of 33° Beaumé, a total of 800 kilogrammes of finished soap (S. P. Sadtler, *Indust. Org. Chem.*, 2d ed., 1895, p. 62).

Saponification of cocoanut oil, even when mixed with twice its quantity of tallow, takes place with soda-lye of the above strength at a temperature as low as 50° C. (about 120° F.) (*cold process*). The soap known as *marine soap* is made from cocoanut oil by boiling with the calculated quantity of caustic soda. It retains all the glycerin of the fat, and has the property of forming a lather with sea-water which ordinary soap does not do. *Toilet soaps* are prepared from *grained* (*curd*) *soap*, and according to the process of treatment are distinguished as transparent soaps, remelted soaps, and milled soaps. The latter are produced by slicing and drying the stock soap, grinding the material, mixing in the ingredients, *e. g.*, perfumery, etc., and pressing into cakes. Transparent soaps may be obtained by making an alcoholic solution of soap and distilling off the alcohol.

SOFT SOAPS.—These are made by saponifying hempseed, linseed (*U. S. P.*) or cotton-seed oil (*Nat. Form.*, 1st ed.), fish oils, etc., with caustic potash. They can not be salted out with potassium chloride, hence contain glycerin and any excess of alkali that may have been employed. The *U. S. P.* gives the following directions for making *soft soap* (SAPO MOLLIS): Take of "linseed oil, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; potassa, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]; alcohol, forty cubic centimeters (40 Cc.) [1 fl℥, 169 ♏]; water, a sufficient quantity. Heat the linseed oil in a deep, capacious vessel, on a water-bath or steam-bath, to a temperature of about 60° C. (140° F.). Dissolve the potassa in four hundred and fifty cubic centimeters (450 Cc.) [15 fl℥, 104 ♏] of water, add the alcohol, and then gradually add the mixture, constantly stirring, to the oil, continuing the heat until a small portion of the mixture is found to be soluble in boiling water without the separation of oily drops. Then allow the mixture to cool, and transfer it to suitable vessels. The potassa used in this process should be of the full strength directed by the *Pharmacopœia* (90 per cent). Potassa of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 8100 by the percentage of absolute potassa (potassium hydrate) contained therein"—(*U. S. P.*). (Also see formula for *Sapo mollis* from olive oil, *Amer. Jour. Pharm.*, 1895, p. 485; and comment on this and the official formula, by S. A. Sicker, *Pharm. Review*, 1898, p. 15.)

Description, Chemical Composition, and Tests.—Dr. S. P. Sadtler (*loc. cit.*) broadly classifies the many commercial varieties of soaps as follows: (1) *Compact soaps*, including curd soaps (tallow soap or *Sapo animalis*, *S. domesticus*, and toilet soaps), mottled and yellow (palm oil and rosin) soaps; they contain from 10 to 25 per cent of water; (2) *smooth* or *cut soaps*, which are curd soaps, allowed to take up more water; they contain from 25 to 45 per cent; (3) *filled* or *padded soaps* (see previous page), from 45 to 75 per cent of water, and glycerin, spent lye, etc.; (4) *soft* or *potash soaps*.

Two classes of medicinal soaps are recognized by the *U.S.P.*: I. SAPO (*U.S.P.*), *Soap; White castile soap*.—This soap, prepared from olive oil, is also known as *Hard soap* (*Sapo durus*), *Sapo oleaceus*, *Sapo venetus*, *Sapo Hispanicus*, or *Spanish soap*. As described by the *U. S. P.*, it is "a white or whitish solid, hard, yet easily cut when fresh, having a faint, peculiar odor free from rancidity, a disagreeable, alkaline taste, and an alkaline reaction. Soluble in water and in alcohol, more readily with the aid of heat"—(*U. S. P.*).

Soap is insoluble in petroleum ether; this permits the quantitative extraction of any unaltered fat that may be present in soap. Soap is incompatible with all acid liquids, with the salts of heavy metals, with alum, and the solutions of the alkaline earths and their salts, *e. g.*, with lime-water, chloride of calcium, sulphate of magnesium, etc. Hard waters do not form a lather with soap, because soap forms granular compounds with the calcium salts of the water. Previously boiling the water with sodium carbonate will precipitate the calcium salts, and the water thus purified will foam with the soap. Or, sodium or potassium carbonate incorporated with the soap, is said to produce the same effect.

The *U. S. P.* directs the following tests for hard soap: "On placing a small, weighed portion of soap, together with about 10 Cc. of alcohol, in a tared beaker containing sand, evaporating the resulting solution of the soap to dryness, and drying the residue at 110° C. (230° F.), the loss of weight should not exceed 36 per cent (absence of an undue amount of water). A 4 per cent alcoholic solution of soap should not gelatinize on cooling (absence of animal fats). An aqueous solution of soap should remain unaffected on the addition of hydrogen sulphide or ammonium sulphide T.S. (absence of metallic impurities). On dissolving 20 Gm. of soap in alcohol, with the aid of heat, transferring the undissolved residue, if any, to a filter, and washing it thoroughly with boiling alcohol, it should, after drying, weigh not more than 0.6 Gm. (limit of sodium carbonate, etc.); and at least 0.4 Gm. of this residue should be soluble in water (limit of silica and other accidental impurities). If a solution of 5 Gm. of soap in 50 Cc. of water be mixed with 3 Cc. of decinormal oxalic acid V.S., the subsequent addition of a few drops of phenolphtalein T.S. should produce no pink or red tint (limit of alkalinity)"—(*U. S. P.*). The presence of free alkali in soap may be qualitatively ascertained by adding to a concentrated solution of the soap either calomel or solution of mercurous nitrate. A black precipitate is formed if free alkali is present.

The adulterants that have been found in hard soap are China clay, fuller's earth, chalk, pumice stone, gypsum, sand, bran, etc. They all remain undissolved when the soap is treated with alcohol or water.

II. SAPO MOLLIS (*U. S. P.*), *Soft soap*, *Sapo viridis* (*Pharm.*, 1880), *Green soap.*—"A soft, unctuous mass, of a yellowish-brown or brownish-yellow color. Soluble in about 5 parts of hot water to a nearly clear liquid; also in 2 parts of hot alcohol, without leaving more than 3 per cent of insoluble residue"—(*U. S. P.*). This soap has been found adulterated with starch to the extent of 25 per cent. The adulteration may be recognized by iodine in slightly acidulated solution. (For a tabulated scheme of systematic soap analysis, we refer the reader to S. P. Sadtler, *Handbook Indust. Org. Chem.*, 2d ed., 1895, p. 82; or to A. H. Allen, *Commercial Organic Analysis*, 3d ed., Vol. II, Part I, 1899, p. 277. An interesting account of the analysis of five samples of castile soap and four samples of soft soap, with comment on the above *U. S. P.* requirements, is given by F. A. Sieker, *Pharm. Review*, 1898, pp. 15, 94, and 267; also see S. R. Knox, *Proc. Amer. Pharm. Assoc.*, 1894, p. 174; and article by Alfred Smethan, on "Soap Manufacture and Soaps of Commerce," in *Pharm. Jour. Trans.*, Vol. XIV, 1883–84, p. 534.)

The following table, from Dr. S. P. Sadtler's *Handbook*, p. 73, gives the results of some analyses performed by M. Dechan (*Pharm. Jour. Trans.*, Vol. XV. 1884–85, p. 870), of the soaps chiefly employed in pharmacy:

NAME OF SOAP.	Fatty Acids.	Combined Alkali.	Free Alkali.	Silica.	Sulphates and Chlorides.	Insoluble Matter.	Water.	Insoluble in Alcohol.
Hard soap (*Sapo durus*)................	81.5	9.92	.08	.00	.28	0.20	10.65	0.50
White castile soap................	76.7	9.14	.09	.00	.36	0.90	13.25	0.60
Mottled castile soap................	68.1	8.9	.19	.15	.63	0.80	21.70	1.30
Tallow soap (*Sapo animalis*)	78.3	9.57	.28	.00	.47	0.40	12.50	1.10
Soft soap (*Sapo mollis*)................	48.5	12.6	.38	.17	.93	1.00	39.50	1.60

Action, Medical Uses, and Dosage.—Soap taken internally is slightly laxative, and, externally, it is detersive. Its action is very much like that of the alkalies, but less energetic; hence it may be administered in considerable doses without producing inflammation, though it readily disturbs digestion. As an antacid, it is useful in strong solution, in cases of *poisoning by mineral acids*, and also in *acid conditions of the stomach*. It has likewise been found serviceable in those cases of *gravel* in which uric acid prevails, but it does not dissolve the uric acid formations. In cases of poisoning by acids, it may be used until more effective agents can be procured, as chalk, lime, magnesia, or the alkaline bicarbonates. It is seldom used alone as a purgative, but is usually combined with aloes, gamboge, resin of podophyllum, or other resinous cathartics, whose irritating properties are thereby modified. United with rhubarb, it forms a pill of much service in *obstinate costiveness* and *biliary derangements*. It lessens the astringent action of rhubarb. Externally, it has been found serviceable in *tinea capitis*, *itch*, *boils*, and other *cutaneous diseases*, and as a discutient in *glandular enlargements*, *abscesses*, *contusions*, etc., in which it is used either in form of liniment or plaster. Soft soap, especially, has been found efficient in these cutaneous affections, used either alone, or in combination with other suitable agents. An excellent injection is formed by making a strong soap-water from soft soap, which will be found useful in obstinate costiveness, or where it is desirable to produce a prompt discharge from the bowels. In the preparation of pills, liniments, or plasters, we must be particular not to add agents which are chemically changed by the soap. Soap may be administered in a dose of 5 to 30 grains, and is commonly used in the pilular form; in poisoning by mineral acids, ½ pint of a strong solution should be promptly administered and be repeated every few minutes, if necessary.

Special Soaps.—As such we consider soaps containing certain ingredients intended to impart to the soap special medicinal or economic characters. This includes the multitude of *medicated soaps*. The following special soaps may be mentioned:

Transparent Glycerin Soap may be made by melting together 10 kilogrammes of tallow, 10 kilogrammes of cocoanut oil, 6 kilogrammes of castor oil, 10 kilogrammes of glycerin, heating to about 50° C. (122° F.), adding 13 kilogrammes of soda-lye of 40 per cent, and 12 kilogrammes of 96 per cent alcohol, stirring the mixture until the soap becomes transparent, then add sugar solution (2 kilogrammes of sugar boiled with ½ kilogramme of water), 100 grammes of cassia oil, 50 grammes of bergamot oil, and pour the finished soap into tin molds (*Amer. Jour. Pharm.*, 1879, p. 566). It is stated by Dr. Sadtler, however, that the addition of sugar is harmful to sensitive hands.

Opodeldoc is the camphorated soap liniment (*Linimentum Saponato Camphoratum*) of the *German Pharmacopœia* (also see p. 1143).

Sapo Medicatus of the *German Pharmacopœia* (which enters into the composition of the preceding) is a neutral soda soap, prepared on the steam-bath, with the aid of alcohol, from a mixture of equal amounts of lard and olive oil.

Sapo Jalapinus (*Ger. Pharm.*).—Dissolve jalap resin (4 parts) and medicinal soap (4 parts) in diluted alcohol (8 parts), evaporate on the steam-bath to 9 parts, with constant stirring.

Tannin Soap.—Saponify cocoanut oil (9 kilogrammes) with soda-lye (4.5 kilogrammes); add solution of tannin (250 grammes) in alcohol; finally add balsam of Peru (30 grammes), oil of cassia, oil of cloves (each, 10 grammes).

Iodine Soap.—Cocoanut oil (10 kilogrammes), lye of 38° Beaumé (5 kilogrammes), potassium iodide (500 grammes), dissolved in water (250 grammes).

Gall Soap.—Cocoanut oil (25 kilogrammes) is mixed with galls (1.5 kilogrammes) and saponified in the cold with 12.5 kilogrammes of soda-lye of 38° Beaumé. The soap is colored with 350 grammes of ultramarine green, and perfumed with 75 grammes each of oil of lavender and caraway.

Camphorated Sulphur Soap.—Cocoanut oil (12 kilogrammes), soda-lye of 38° Beaumé (6 kilogrammes), potassium sulphide (1 kilogramme), dissolved in water (0.5 kilogramme); camphor (160 grammes) is to be dissolved in melted cocoanut oil (*Amer. Jour. Pharm.*, 1882, p. 64).

Petroleum Soap.—Heat white beeswax (40 parts), petroleum (50 parts), alcohol of 90 per cent (50 parts) on a water-bath; when melted, add hard Marseille soap (100 parts), agitate and pour into molds. The soap is said to be firm, emulsifies easily and does not leave the washed parts impregnated with petroleum (*Amer. Jour. Pharm.*, 1889, p. 287).

Sand Soap may be prepared from curd soap and cocoanut oil soap, each, 7 pounds; sifted sea-sand, 28 pounds; oils of thyme, cassia, caraway, and French lavender, each 2 ounces.

Asepsin Soap is a milled tallow soap medicated with asepsin and borax (also see *Asepsin*).

Antiseptic Soap (*ethereal*, Johnston) is a medicinal soap in liquid form introduced and manufactured by Parke, Davis & Co., Detroit.

Shaving Cream.—The *Pharm. Jour. Trans.*, Sept. 19, 1896, p. 248, recommends the following formula: Curd soap, 2 ounces; fresh butter, 4 drachms; tincture of quillaja, 2 ounces; carbonate of potassium, 2 drachms; otto of rose, 10 minims; oil of lavender, 10 minims, oil of myrcia acris, 5 minims. Dissolve the soap, shredded fine, in 10 ounces of water by the aid of heat; melt the butter, and mix in a warm mortar with the carbonate of potassium dissolved in 1 ounce of water; gradually add the soap solution, and stir until a paste is formed, then add the quillaja tincture in which the oils have been dissolved.

Mollin.—An ointment base in use in German dermatological practice, and is classed as a soft soap containing 17 per cent of free fat. It is a smooth, soft, yellowish-white, non-rancid body not easily altered in the air, and readily washed from the skin with water, hot or cold. To prepare it, fresh fat, or cocoanut oil, 100 parts is first saponified with caustic potash solution (specific gravity 1.145), 40 parts. Glycerin, 30 parts, is then intimately mixed with it and carefully heated.

Pulverulent Medicinal Soaps.—This form of soap is recommended by Dr. P. J. Eichhoff. A *neutral* soap-powder base (anhydrous, hygroscopic) is obtained from beef tallow; *superfatted* soap powder is obtained from the preceding by adding oleic acid (2 per cent) and lanolin (3 per cent). An *alkaline* soap-powder base is obtained by adding to the neutral base potassium and sodium carbonates (2.5 per cent of each). A number of medicinal soaps have been prepared from the three bases named, by incorporating with them certain medicinal constituents, *e. g.*, sulphur (10 per cent), balsam of Peru, chrysarobin, chlorinated lime; or carbolic acid, salicylic acid, pyrogallol, iodoform, aristol, quinine sulphate, etc, etc. (see *Amer. Jour. Pharm.*, 1893, p. 68, from *Pharm. Zeitung*, 1892; also see *Amer. Jour. Pharm.*, 1891, p. 360).

SAPONARIA.—SOAPWORT.

The root and leaves of *Saponaria officinalis*, Linné.
Nat. Ord.—Caryophyllaceæ.
Common Names: *Soapwort*, *Soaproot*, *Bouncing Bet*, *Fuller's-herb.*

Botanical Source.—This is a stout, perennial herbaceous plant, sometimes known by the name of *Bouncing Bet*, with a stem 1 to 2 feet in height. The leaves are lanceolate, inclining to elliptical, very acute, smooth, 2 or 3 inches long, and about one-third as wide. The flowers are many, large, flesh-colored or pale pink, often double, and borne in paniculate fascicles. Calyx cylindrical and slightly downy. Petals 5, and unguiculate; crowns of the petals linear. Stamens 10; styles 2; capsule oblong and 1-celled (G.—W.).

Fig. 217.

Saponaria officinalis.

Description and Chemical Composition.—Soapwort is found growing in Europe and the United States, by roadsides and in waste places, flowering in July and August. The parts used medicinally are the root and leaves; they are without odor, and of a bitterish, slightly saccharine taste, with a subsequent persistent pungency and a benumbing sensation. With water they become frothy, like soap-suds; water or alcohol extracts their active properties. The active principle of this root was discovered in 1808 by J. C. C. Schrader, who named it *saponin*, and obtained it by extracting the powdered root with boiling alcohol and allowing to crystallize. Closely allied substances have since been found in the roots of *Polygala Senega*, *Gypsophila Arrostii* (not *Struthium;* see Flückiger, *Archiv der Pharm.*, 1890, p. 192), in the barks of *Quillaja Saponaria* and *Chrysophyllum glycyphlœum*, in the seeds of *Agrostemma Githago*, *Sapindus Saponaria*, and in many other plants, *e. g.*, the fruit of horse-chestnut, the root of the common pink, etc. (see complete enumeration by N. Kruskal, *Dissert.* Dorpat, 1891). Christophson (1874) found *Gypsophila* to yield the largest quantity of saponin (13 to 15 per cent). According to C. Schiaparelli (*Amer. Jour. Pharm.*, 1884, p. 273), *saponin* ($C_{32}H_{54}O_{18}$) from *Saponaria officinalis* is a white, amorphous powder which excites sneezing when inhaled through the nostrils; it has a pungent taste and is poisonous. It dissolves freely in water, but is insoluble in ether, benzene, and chloroform, only slightly soluble in alcohol. A diluted aqueous solution forms a persistent froth upon shaking. Saponin is a glucosid, and is hydrolyzed by boiling with diluted acids into sugar and *saponetin*, which is insoluble in water, alcohol and ether. W. Von Schulz (*Jahresb. der Pharm.*, 1896, p. 516) states that the active principle of white soaproot is *sapotoxin* (see *Quillaja*); that of red soaproot is *sapo-rubrin* (3.45 per cent), a glucosid which he finds to be *methyl-sapotoxin*.

Action, Medical Uses, and Dosage.—Soapwort is tonic, diaphoretic, and alterative; and forms a remedy in the treatment of *syphilitic*, *scrofulous* and *cutaneous diseases*, also in *jaundice*, *liver affections*, *rheumatism*, and *gonorrhœa*. It is generally used in decoction; although an extract or the inspissated juice will be found equally efficient. Saponin has been advised as a substitute for the root, but this is not satisfactorily established; it will likewise be found a powerful sternutatory. Dose, from 2 to 6 grains. E. Pelikan believes that saponin is destined to play a different part from that which is now given to it, and that it should be submitted to further investigations. According to his experiments he finds that saponin and identical substances produce a local paralysis followed by rigidity of the muscles and paralysis of the nerves of sensation; and also that between saponin and agents that act upon the pupil, as atropine and physostigmine, there exists considerable analogy (*Gaz. Méd. de Paris*, 1867). Decided emmenagogue properties are attributed to saponaria. Dose of the decoction ℥i to Oj), from 2 to 4 fluid ounces, 3 or 4 times a day; of the extract or inspissated juice, from 10 to 20 grains.

Related Drugs. SOAPBERRIES. A tree of the American tropics, the *Sapindus Saponaria*, Linné, of the natural order *Sapindaceæ*, yields an orange-colored, spherical or ovoid fruit about the size of our common cherry, containing a tough endocarp yielding tartaric and formic acids, and *saponin* (*sapindus-sapotoxin*). The fruit is known as the *soapberry*. The seeds yield a large quantity of fat of the consistence of butter. Other species of Sapindus have similar fruits containing like constituents. Among those employed are the fruits of *S. laurifolius*, Vahl, the pods of *S. emarginatus*, and the fruit-pulp of *S. detergens*, all of India.

LEVANT SOAPROOT. Formerly believed to be the root of *Gypsophila Struthium*, Linné, but now known to be derived from *G. Arrostii*, Gussone, *G. paniculata*, Linné (Flückiger, *Archiv der Pharm.*, 1890, p. 192). Asia Minor, north Africa, and south Europe (Sicily). Pale brown externally, white internally, corrugated longitudinally and transversely, and about 1 foot long and 2 inches in thickness. Its composition is similar to that of saponaria.

Megarrhiza californica, Man-root.—Root yielded J. P. Heamey (*Amer. Jour. Pharm.*, 1876, p. 451) a resinous body *megarrhizitin* and a bitter glucosid *megarrhizin*. Young (*ibid.*, 1883, p. 195) obtained another glucosid resembling *saponin* and possessing mydriatic qualities, which he called *megarrhin*. An alcohol-soluble and an ether-soluble resin were also found by Young. The root is cathartic.

Mackay Bean; the seed of *Entada scandens.*—Queensland. A substance believed to be saponin has been found in these seeds by John Moss. In its habitat the plant is considered very poisonous.

Randia dumetorum.—East Indies. Shrub; a fish poison, and to human beings an emet Fruit contains valerianic acid and saponin. A tincture is employed as an antispasmodic (Sawyer, *London Lancet*, 1891).

SARRACENIA.—PITCHER PLANT.

The root of *Sarracenia purpurea*, Linné.

Nat. Ord.—Sarraceniaceæ.

Common Names: *Pitcher plant, Side-saddle plant* or *flower, Fly trap, Huntsman's cup, Water cup.*

Botanical Source, Description, and History.—This plant is an indigenous perennial, of a very curious character. The leaves, or acidia, are 6 to 9 inches long, radical, short-globose, inflated or cup-form, contracted at the mouth, having a broad, arched, lateral wing from ½ to 1 inch in width, and extended on the outside of the mouth into a broad-cordate, erect lamina, or hood, covered above with reversed hairs. The scape is from 1 to 2 feet in height, terete, smooth, and supporting a single, large, purple, and nodding flower (W.).

Fig. 218.

Sarracenia purpurea.

This plant owes its strange appearance to a curious pitcher-shaped metamorphosis of the leaf, which resembles very much an old-fashioned side-saddle; 6 of these generally belong to each plant. The leaf, which springs from the root, is formed by a large, hollow tube, swelling out in the middle, curved and diminishing downward till it ends in a stem, contracted at the mouth, and furnished with a large, spreading, heart-shaped appendage at the top, which is hairy within, the hairs pointing downward, so as to cause everything which falls upon the leaf to be carried toward the petiole; a broad, wavy wing extends the whole length on the inside; these lie upon the ground with the mouth turned upward, so as to catch the water when it falls. They hold nearly a wineglassful, and are generally filled with water and aquatic insects, which undergo decomposition or a sort of *digestion*, and serve as a nutriment to the plant. The root is in the form of stems or fibers, 5 to 7 or 8 inches in length, of various diameters, not exceeding that of a quill, dented at unequal intervals, having a smooth fracture, and without rootlets or medullary sheath; it is readily reduced to a slightly aromatic powder and a fibrous residue, and communicates its bitter taste to water, alcohol, or ether. Oil is colored light-amber by it. The stem rises direct from the root; it is round, quite smooth, and bears an elegant, deeply reddish-purple terminal flower, having 2 flower-cups; the external consisting of 3 small leaves; the internal of 5, egg-shaped, obtuse leaves, shiny, and of a brownish-purple. The blossoms are 5, guitar-shaped, obtuse, repeatedly curved inward and outward, and finally inflected over the stigma, which is broad and spreading, divided at its margin into 5 bifid lobes, alternating with the petals, and supported on a short cylindrical style; this is surmounted by the stamens, which are numerous, having short threads, and large, 2-celled, oblong, yellow anthers attached to them on the under surface. In the yellow-flowered species of the southern states, the bottle is very long, resembling a trumpet, by which name it is often called.

The whole species are water plants, and are found only in wet meadows, wet, boggy places, marshes, mud lakes, etc., and grow from Labrador to Florida, flowering in June. There are several varieties, as the *S. heterophylla*, found in the swamps at Northampton, Mass., and the *S. rubra*, *S. flava* (trumpet-leaf), *S. variolaris*, *S. drummondii*, and *S. psyttacina*, which are common to the south, and all of which, probably, possess similar medicinal virtues. The attention of the medical world was first called to *Sarracenia purpurea*, by Drs. Herbert Miles and F. W. Morris, both of Halifax, N. S., in 1861 and 1862, both recommending its use in the treatment of smallpox. In this connection, see an interesting monograph on this plant, by Prof. Bentley (*Pharm. Jour. Trans.*, Vol. IV, 1862, pp. 294–302).

Chemical Composition.—The root is the part used; it has a bitter and astringent taste, and yields its properties to water. Björklund and Dragendorff (*Jahresb. der Pharm.*, 1864, p. 89) found the root to contain a volatile base (*sarracine*), a volatile acid (*acrylic acid*), starch (25.5 per cent), sugar, white resin (8.8 per cent), tannic acid, etc. The peculiar leaves of this plant showed about the same constituents as the root, only in different proportions. Hêtet (1879) claims to have observed in the root an alkaloid resembling veratrine, and E. Schmidt found a peculiar acid coloring matter (*sarracenic acid*), soluble in alcohol, little soluble in ether and benzin, and forming a yellow lake with alum (*N. Jahrbuch f. Pharm.*, 1872, p. 98).

Action, Medical Uses, and Dosage.—The therapeutical actions of sarracenia are not fully ascertained. It is supposed to be a stimulating tonic, diuretic, and laxative; in connection with Osmunda regalis and blue cohosh, it will form a valuable syrup for *chlorosis*, *uterine derangements*, *dyspepsia*, and other gastric difficulties. An infusion of the leaf has been found equally available with that of the root. The best mode of employing it is not well determined; though the powder may be given in doses of from 20 to 30 grains, 3 or 4 times a day; and the infusion or syrup, from 1 to 3 fluid ounces. Dr. Porcher, of South Carolina, instituted some experiments upon himself, using the recent root. He found it to possess bitterness and astringency, and to produce diuresis, gastric excitation, moderate catharsis, and, at the same time, to cause an increase and irregularity in the heart's action, and a feeling of congestion about the head. This was the result of 180 grains taken in 2 hours' time.

The root is useful in all cases where there is a sluggish, or torpid condition of the stomach, the intestines, the liver, the kidneys, or the uterus, producing *costiveness*, *dyspepsia*, *sick headache*, *amenorrhœa*, *dysmenorrhœa*, and the various functional derangements which are so commonly to be met with. The plant has been extolled as a prophylactic in *smallpox*, and also to modify it and shorten its duration when present. Although many physicians have made statements to this effect, yet all are not agreed. We do not think the plant possesses any such curative property as has been attributed to it in this disease, and believe those who have written in its favor, have allowed themselves to be mistaken. The plant, however, undoubtedly possesses valuable properties, which render it well worthy attention in this as well as in other diseases (J. King). Dr. Scudder suggests a strong tincture of the fresh root (℥viij to alcohol, 76 per cent, Oj) in doses of 1 to 20 drops.

SARSAPARILLA (U. S. P.)—SARSAPARILLA.

"The root of *Smilax officinalis*, Kunth; *Smilax medica*, Chamisso et Schlechtendal; *Smilax papyracea*, Duhamel; and of other, undetermined, species of *Smilax*"—(*U. S. P.*).

Nat. Ord.—Liliaceæ.

Common Names: (See next page.)

Illustration: (1 and 2) Bentley and Trimen, *Med. Plants*, 289, 290.

Botanical Source and History.—The Sarsaparillas are all climbing plants, having aculeate (prickly) stems; there are many species, but they do not all possess medicinal activity. Most of the drug-yielding species grow in the marshy forests of Mexico and the territory extending to the northern portion of Brazil. The botanical source of the sarsaparillas of commerce is not always exactly known; this, for example, is the case with Honduras sarsaparilla, which seems to be derived from several and partly undetermined species of Smilax, mostly from *Smilax officinalis*. The following species, however, are generally conceded to yield the drug in its various commercial forms.

Smilax officinalis has a twining, angular, prickly, and shrubby stem; the young shoots being unarmed. The leaves are ovate-oblong, acute, cordate, netted, 5 or 7-nerved, coriaceous, smooth, 1 foot long and 4 or 5 inches broad; the young ones are lanceolate, oblong, acuminate, and trinerved. The petioles are 1 inch long, smooth, bearing tendrils above the base. Flowers unknown. This plant grows in New Granada, on the banks of the Magdalena, was collected, in 1805, by Humboldt, and is called *Sarzaparilla* by the natives. Great quantities of it are sent to Carthagena, whence it is shipped to Jamaica, and, together with that coming from Central America (derived from *Smilax ornata*, Lemaire; see *Pharm. Jour. Trans.*, 1889, p. 889), constitutes *Jamaica sarsaparilla*.

Fig. 219.

Honduras sarsaparilla.

Smilax medica has an angular, zigzag, or flexuous stem, armed with straight aculei at the joints, and a few hooked ones in the intervals. The leaves are of the texture of paper, smooth, bright-green on each side, cordate, auriculate, shortly acuminate, and 5-nerved, with the viens of the under side prominent; they are variable in form, being ovate, somewhat panduriform, auriculate, and somewhat hastate, with the lobes of the base obtuse, sometimes obsolete, sometimes divaricating; their edges not straight, but as if irregularly crenate; the petioles and midrib are armed, when old, with straight, subulate prickles. The peduncles vary in length from 3 lines to 1 inch or more. The umbel is about 12-flowered, with the pedicels about 3 lines long. Schiede (1829) found this plant on the east slope of the Mexican Andes, where the root is gathered and then carried to Vera Cruz; it is supposed to furnish the *Vera Cruz* or *Mexican sarsaparilla* of commerce (L.).

Fig. 220.

Mexican sarsaparilla.

Smilax papyracea has a 4-cornered, or plane-angular, polished, prickly stem; leaves somewhat membranous, oval-oblong, obtuse at both ends, or usually pointletted at the apex, quite entire, unarmed, and 5-ribbed, with 3 more prominent ribs. Cirrhi are inserted beneath the middle of the petiole. This plant grows in the province of Rio Negro and neighboring places, and yields the *Brazilian* or *Para sarsaparilla*.

Smilax syphilitica, Kunth, has a round, smooth stem, furnished only at the knots with 2 to 4 short, thick, straight prickles. The leaves are a foot long, oblong-lanceolate, acuminate, shining, coriaceous, 3-nerved, and terminated by a long point (L.). Humboldt and Bonpland discovered this plant on the rivers Cassiquiare and Rio Negro.

Description.—The Mexican and South American sarsaparillas have numerous long, delicate roots proceeding from one caudex or rhizome; they are usually taken from the ground with the caudex attached, and are frequently packed in a peculiar manner for exportation (see commercial grades, next page). Those roots which have a deep orange-red tint are preferred, but more especially those whose taste is acrid. The stronger this is, the better is the quality of the root. Water, either cold or hot, and also diluted alcohol, extracts its medicinal virtues, which, however, are materially injured by too great or long-continued heat. Sarsaparilla should never be purchased unless, after having chewed it for a few minutes, it leaves a distinct, persistent pungency or acrimony in the mouth and fauces; without this effect it can not be relied upon as an efficient article.

The official sarsaparilla is thus described: "About 4 or 5 Mm. $\frac{1}{6}$ to $\frac{1}{5}$ inch thick, very long, cylindrical, longitudinally wrinkled, externally grayish-brown, or orange-brown; internally showing a whitish and mealy, or somewhat horny, cortical layer, surrounding a circular wood-zone, the latter enclosing a broad pith; nearly inodorous; taste mucilaginous, bitterish, and acrid. The thick, woody, knotty rhizome, if present, should be removed"—(*U. S. P.*). Commercially, the sarsaparillas are best distinguished as *mealy* and *non-mealy;* the latter are preferred for medicinal purposes.

Mealy Sarsaparillas.—Honduras Sarsaparilla is a kind much esteemed, and more commonly employed in this country. It is imported from Belize, and other parts of the Bay of Honduras, in parcels 2 or more feet in length; the roots are folded into a kind of hank, and held neatly and closely together by tying some of the roots transversely around those forming the parcel. These parcels, weighing from 2 to 20 pounds, are formed into large packages, weighing from 80 to 120 pounds, which are partially enveloped in hide or skin. The roots have a few rootlets attached, are bearded, of a grayish or reddish-brown color, approaching orange, and have a very mealy cortex.

Guatemala Sarsaparilla closely resembles the Honduras drug, being packed in a similar manner. Its orange color is, however, more decided, and its bark has a tendency to split and crack off, exposing the central ligneous column. It appeared in commerce about 1852—(*Pharmacographia*).

Brazilian Sarsaparilla (*Para*, *Lisbon* or *Rio Negro sarsaparilla*).—This variety is now less esteemed than formerly. "It is packed in a very distinctive manner, the roots being tightly compressed into a cylindrical bundle, 3 feet or more in length, and about 6 inches in diameter, firmly held together by the pliable stem of a bignoniaceous plant, closely wound round them, the ends being neatly shaved off"—(*Pharmacographia*). Its place of export is Para.

Caracas Sarsaparilla is also a mealy variety, resembling the preceding kind.

Non-Mealy Sarsaparillas.—Jamaica Sarsaparilla (*Bearded sarsaparilla*, *Red sarsaparilla*). "This drug consists of roots, 6 feet or more in length, bent repeatedly so as to form bundles of 18 inches long and 4 in diameter, which are secured by being twined round (but less trimly and closely than the Honduras sort) with a long root of the same drug. The rhizome is entirely absent, but the fibre or beard is preserved, and is reckoned a valuable portion of the drug. The roots are deeply furrowed, shrunken, and generally more slender than in the Honduras kind; the bark, when shaved off with a penknife, is seen to be brown, hard, and non-mealy throughout. Yet it is by no means uncommon to find roots which have a smooth bark rich in starch. In color, Jamaica sarsaparilla varies from a pale earthy-brown to a deeper ferruginous hue, the latter tint being the most esteemed"—(*Pharmacographia*). This drug (*Sarsæ radix*) is the official one of the *British Pharmacopœia*, and grows in the Isthmus of Panama, upon the mountains known as the Cordillera of Chiriqui, bordering on Costa Rica. Being exported through Jamaica, it has received the name of that place. Botanically, it is derived from *Smilax ornata*, Hooker filius.

Mexican Sarsaparilla (*Vera Cruz* or *Tampico sarsaparilla*).—Roots thin and shriveled, very fragile, pale dull-brown in color. Contains very little starch, but possesses considerable acridity. The plant grows in Papantla, Tuxpan, Nantla, etc., and is usually shipped at Vera Cruz and Tampico, being put up in large bales weighing from 150 to 200 pounds. The roots are not tied around the rhizome transversely, but merely envelop it longitudinally. The inside often contains earth and stone.

Guayaquil Sarsaparilla, from Ecuador via Guayaquil, is crudely packed in large bales, and is not generally made into separate hanks. "The rhizome (chump) and a portion of the stem are often present, the latter being round and not prickly. The root is dark, large, and coarse-looking, with a good deal of fibre. The bark is furrowed, rather thick, and not mealy in the slender portions of the root, which is near the rootstock, but as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting, when cut, a fawn-colored or pale-yellow interior"—(*Pharmacographia*).

Chemical Composition.—Besides volatile oil (Pareira, *Mat. Med.*), resin, starch, coloring matter, calcium oxalate, etc., sarsaparilla root contains several glucosids, to which its peculiar properties are due. According to Kobert (1892), these glucosids are: (1) *Parillin* of Palotta (1824), first obtained pure by Flückiger, previously also called *smilacin* (not Merck's), *salseparin*, and *parillic acid;* it is crystalline, nearly insoluble in cold water, soluble in 20 parts of boiling water, forming a bitter solution, which froths upon shaking; it is the least active of the glucosids. Flückiger (see Husemann and Hilger. *Pflanzenstoffe*, p. 408) obtained about 0.19 per cent. Boiling with diluted sulphuric acid produces sugar and *parigenin*, insoluble in water. (2) *Saponin* (*sarsaparill-saponin; smilacin* of Merck) is amorphous, more active than the preceding, soluble in water and alcohol. (3) *Sarsasaponin*, crystallizing in needles, readily soluble in water; the most poisonous of the three.

Action, Medical Uses, and Dosage.—Sarsaparilla is generally considered as an alterative, though stated by some to possess diuretic, diaphoretic, and emetic properties. Its mode of action, however, is not well understood, as it effects normal changes in the system without any appreciable change in the operation of the various organs. No medicine has, probably, ever passed through so many changes of popularity, having been at various times most highly lauded as an efficient alterative, and as often been pronounced inert. There is no doubt, however, that, when properly prepared, it exerts a favorable influence over the system. The diseases in which it has been more particularly recommended, are inveterate *syphilis, pseudo-syphilis, mercurio-syphilis*, and *struma* in all its forms. It has been used in several chronic diseases, as of the skin, as *herpes* (best associated with sodium sulphite), *rheumatic affections* (with potassium iodide), *passive general dropsy, gonorrhœal rheumatism*, and other depraved conditions of the system where an alterative is required. The decoction, made acid with nitric acid, is serviceable in *syphilitic sore throats*, and, acidulated with hydrochloric acid, is of some value in *chronic hepatic disorders*, with torpor. A drink is made in Angostura, which enjoys much reputation there as an alterative beverage. It is made of Rio Negro sarsaparilla, 1 pound; rasped guaiac wood, 6 ounces; aniseed and bruised liquorice root, of each, 2 ounces; mezereon root-bark, 1 ounce; molasses, 1 pound; and ½ dozen bruised cloves; pour upon these articles 2 gallons of boiling water, and shake the vessel 3 times a day. As soon as fermentation begins, it may be taken in doses of 4 fluid ounces, 2 or 3 times a day (C.—*Trans. Med. Bot. Soc.*, 1829). At the present day, sarsaparilla is but little used as above. Probably much of good that has been accomplished with sarsaparilla mixtures has been chiefly due to the active ingredients that have been so frequently associated with it. Dose of sarsaparilla, in powder, 30 grains, 3 or 4 times a day; of the infusion or syrup, 4 fluid ounces. Some believe sarsaparilla to contain an active cardiac-sedative principle.

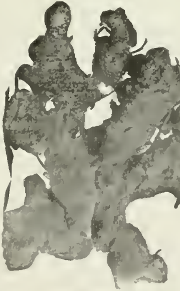
Related Species.—*Smilax sarsaparilla*, Linné, is "of doubtful origin, and so far as growing in the United States, it is not now recognized" (Walter H. Evans, *Lilly's Bulletin*, No. 16, Aug., 1891).

Smilax Tamnoides, Linné.—Indigenous. Tubers used like sarsaparilla.

BAMBOO BRIER, *Virginia sarsaparilla*.—Of this species Prof. King (*American Dispensatory*, 11th ed.) says: "There is a plant in the south extensively known as *Bamboo brier*, the root of which I have much used in practice, and with decidedly more successful results than from the use of any of the sarsaparillas of the shops, and I invite the attention of physicians to it, as a remedy in every respect superior to the usual commercial article, especially in primary and secondary *syphilitic diseases*."

This plant is derived from *Smilax lanceolata*, Linné, and, according to W. H. Evans (*loc. cit.*) has been confused with *Smilax Pseudo-China*, Linné. The stem is tall, often 30 to 40 feet, mostly unarmed; the branches are round, unarmed; leaves evergreen, paler beneath, rather thin, lanceolate to ovate-lanceolate, acute at each end, 3 to 5-ribbed, margin smooth, petiole short, most often without tendrils; the peduncles are short; flowers in May; the berries are 3-seeded, black when ripe; mature from August to September. This species grows in rich woods and swamps, where the entire rhizome frequently weighs 200 to 300 pounds when fresh. It grows from Virginia to Florida, and west to Arkansas and Texas (*Lilly's Bulletin*, No. 16, Aug., 1891). It was employed by the Indians as an antisyphilitic, and by the whites as a "blood purifier." *Rheumatism, scrofula*, and *cutaneous affections* are said to be cured by it. A decoction may be freely used. (See illustration, next page

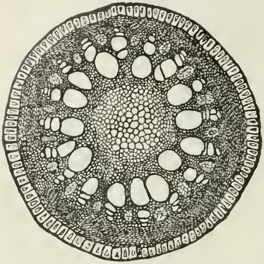
Fig. 221.



saparilla root

Smilax China, Linné, has a hard, large, knotty, uneven rhizome, brown or blackish externally, whitish within. Stem tapering, slightly prickly, growing 2 or 3 feet high without support, but acquiring a greater length if scrambling among bushes. Leaves thin, membranous, roundish, 5-nerved, acute or obtuse at each end, mucronate at the point; stipules distinct, obtuse. Umbels small, 10-flowered, greenish-yellow. Fruit red, about the size of a bird cherry (L.). This plant grows in eastern Asia (China and Japan), and furnishes the *China root* (*Rhizoma* [*radix*] *Chinæ*) of commerce. It has been used as a substitute for sarsaparilla, but is found not to be as active. It occurs in large, ligneous, knotty pieces, from 2 to 6 or more inches in length, and 1 to 2 inches in diameter; externally, it is grayish-brown; internally, a light-flesh, or yellowish-white color. It is inodorous, and has a slightly astringent taste (P.).

Fig. 222.



Bamboo brier root.

Smilax Aspera, Linné.—South Europe. Employed like sarsaparilla.

Smilax Pseudo-China, Linné, *False China root*, *China brier*, *American China root*, *China root of Mexico*.—Grows in New Jersey and west to southern Indiana and Missouri, south to Florida and the West Indies. The root is also used in Mexico, and regarded as diaphoretic and antisyphilitic. It is official in the *Mexican Pharmacopœia*, under the name Raiz de China de Mexico (*Smilax Pseudo-China*, Schlechtendal).

A False Jamaica Sarsaparilla, a species of *Philodendron*, is described by C. Hartwich (*Archiv der Pharm.*, 1894; also see *Pharm. Jour. Trans.*, Vol. VII, 1898, p. 583).

Carex Arenaria, Linné, *German sarsaparilla*, *Sand sedge*.—Europe. The long, creeping rhizome of this plant was at one time used like sarsaparilla for its effects in *syphilis*, *rheumatism*, *gout*, *lung* and *skin diseases*, its effects being exerted chiefly through the skin and kidneys. The decoction was employed.

Carex hirta and *Carex intermedia* were put to similar uses.

Arenaria rubra is a popular diuretic, in use among the Algerians, in *dropsy* and *affections of the urinary organs*.

Carnauba Root.—The long root of a wax-palm (*Corypha cerifera*) of Brazil. It resembles sarsaparilla in action, and contains an alkaloid, essential oil (both in small amounts), tannic acid, an acrid resin, and red coloring principle (Cleaver).

SASSAFRAS (U. S. P.)—SASSAFRAS.

The bark of the root and the pith of *Sassafras variifolium* (Salisbury), O. Kuntze (*Sassafras officinale*, Nees; *Laurus Sassafras*, Linné; *Laurus variifolium*, Salisbury).

Nat. Ord.—Laurineæ.

Illustration: Bentley and Trimen, *Med. Plants*, 220.

Botanical Source.—This is a small, indigenous tree, varying in height from 10 to 40 feet, with a trunk about 12 inches in diameter. The bark is rough and grayish; that of the twigs smooth and green. The leaves are alternate, petiolate, membranous, bright green, smooth above, finely downy beneath, very variable in form, some being obovate, others deeply 3-lobed, some lobed only on one side, all, however, tapering in a wedge-like manner into the petiole. The flowers which appear before the leaves, are small, greenish-yellow, in terminal and axillary, corymbose racemes, with linear bracts. Calyx 6-parted, membranous, and permanent at base. The male flowers have 9 stamens; the females 6; style simple. The fruit is an oval, succulent drupe, rather larger than a pea, bright-blue in color and borne upon red, clavate peduncles (L.).

Fig. 223.

Sassafras variifolium.

History and Description.—Sassafras is a well known tree common to the woods of North America, from Canada to Florida, and flowering in the latter part of April or early in May. The odor of the flowers is slightly fragrant, and they, together with the leaves and young branches, are used in decoction, in many parts of the country as a spring medicine to cleanse the blood. Sassafras was one of the chief remedies used by the American Indians, and the wood became known in Europe under the name *Lignum pavanum*, or *Lignum Floridum*, about the year 1582. (For a detailed account of the history of sassafras, see Dr. Frederick Hoffmann, in *Die Ætherischen Oele*, p. 514; J. U. Lloyd, *Amer. Druggist*, 1898, pp. 258 and 295; and Wm. Procter, Jr., *Amer. Jour. Pharm.*, 1866, pp. 481–492.) The root, bark, and the pith are the medicinal parts now in use, but the bark of the root is generally employed in this country; it is by far the most active part of the whole tree. Its virtues are due to a yellow essential oil, which may be obtained by distilling the wood with water (see *Oleum Sassafras*). Hot water, in infusion, or alcohol, takes up the active principles of the bark, but boiling dissipates them. The whole root of sassafras is official in the *British Pharmacopœia*, but only the root-bark and pith are official in this country.

I. SASSAFRAS (*U. S. P.*), *Sassafras*.—"The bark of the root of *Sassafras variifolium* (Salisbury), O. Kuntze (*Nat. Ord.*—Laurineæ)"—(*U. S. P.*). "In irregular fragments, deprived of the gray, corky layer; bright rust-brown, soft, fragile, with a short, corky fracture; the inner surface smooth; strongly fragrant; taste sweetish, aromatic, and somewhat astringent"—(*U. S. P.*). (See microscopical structure of the root-bark, described by Prof. E. S. Bastin, in *Amer. Jour. Pharm.*, 1895, p. 312; also see microscopical distinctions between root and stem bark in powdered form, by Katharine C. Burnett, *Pharm. Era*, Vol. XVII, 1897, p. 413.)

II. SASSAFRAS MEDULLA (*U. S. P.*), *Sassafras pith*.—"The pith of *Sassafras variifolium* (Salisbury), O. Kuntze (*Nat. Ord.*—Laurineæ)"—(*U. S. P.*). "In slender, cylindrical pieces, often curved or coiled, light, spongy, white, inodorous, and insipid. Macerated in water it forms a mucilaginous liquid, which is not precipitated on the addition of alcohol"—(*U. S. P.*). It is stated that pith collected before the 15th of October assumes a brown hue, probably on account of the presence of plant juices which would have disappeared after that date (*Amer. Jour. Pharm.*, 1856, p. 412).

Chemical Composition.—Dr. Reinsch (1845) obtained from the bark of the root essential oil, fatty matter, balsamic resin, wax, tannic acid, starch, and *sassafrid*, a principle, probably an oxidation product of tannic acid (*Amer. Jour. Pharm.*, Vol. XVIII, p. 159). (For the chemistry of the essential oil see *Oleum Sassafras;* also see Dr. Clemens Kleber, *Amer. Druggist*, Vol. XXXIII, 1898, p. 294.)

Action, Medical Uses, and Dosage.—Sassafras is a warm, aromatic stimulant, alterative, diaphoretic, and diuretic. It is generally used in combination with other alteratives, particularly podophyllum, whose flavor it improves, in *syphilitic affections*, *chronic rheumatism*, *scrofula*, and many *cutaneous eruptions*. Stubborn cases require also the aid of vapor, spirit or sulphur baths. The mucilage of the pith (2 drachms to 1 pint of water) is used as a local application in *acute ophthalmia*, and is a demulcent drink in *disorders of the chest*, *bowels*, *kidneys*, and *bladder*. The oil, in doses of from 5 to 10 drops on sugar, is used to afford relief in the distressing *pain attending menstrual obstructions*, and that following *parturition;* also used in *diseases of the kidneys and bladder*. I have also derived some benefit from its internal use in *gonorrhœa* and *obstinate gleet;* 5 to 10 drops on sugar, 3 times a day (J. King). Externally, as a rubefacient, in *painful swellings*, *sprains*, *bruises*, *rheumatism*, etc., and is said to check the progress of *gangrene*. An infusion of the bark (℥j to hot water Oj) administered internally and applied externally is reputed an excellent treatment for *rhus poisoning*.

Related Species.—*Umbellularia californica*, Nuttall. This is a large evergreen tree, which is found growing in the mountainous regions of California. It is known by various common names, of which the following have been recorded: *Mountain laurel*, *California laurel*, *California spice-tree*, *Sassafras laurel*, *Cajuput tree*, and *California olive*. There has been some considerable difficulty in determining its precise botanical position, and it has been variously described as *Umbellularia californica*, *Oreodaphne californica*, *Drimophyllum pauciflorum*, *Tetranthera californica*, and *Laurus regia*. The flowers appear in April, in lateral clusters, and are of a greenish-yellow color. The leaves are alternate, lanceolate, entire, and of a firm texture. They are borne on short leaf-stalks, and end in slender, acuminate points. The fresh or dry leaves are odorless, unless broken or bruised, when they exhale a pungent, aromatic odor, somewhat resembling cajuput oil. They are sharp and biting to the taste, and we find that both the odor and taste depend upon the presence of a volatile oil, which we obtained, in the proportion of 6 fluid drachms to 1 pound of green leaves, by distillation with water. This oil is the characteristic principle, and was previously examined by Mr. John P. Heaney, of California (*Amer. Jour. Pharm.*, 1875, p. 105; and *Med. and Surg. Jour.*, 1875), who obtained 4 per cent from the leaves. He states that the exhalation from the fresh leaves occasions headache; and this statement is supported by a communication received by us from Dr. L. Mann, although we perceived no ill effects when distilling the oil. The oil has a sharp, biting taste, an odor resembling cajuput and nutmegs, and is of a greenish-straw color. The oil is composed of a hydrocarbon, boiling at 175° C. (347° F.), and *oreodaphnol*, boiling at 210° C. (410° F.), and containing oxygen (Heamy, *loc. cit.*). The latter is probably allied to the *umbellol* of Stillman (*Amer. Jour. Pharm.*, 1880, p. 313). The seeds contain a crystalline fatty acid termed *umbellulic acid* ($C_{11}H_{22}O_2$) by Stillman and O'Neill, 1882.

Dr. L. Mann sent a specimen of this plant to Mr. Curtis G. Lloyd, who forwarded to him its botanical name, with description. Dr. Mann states that it is a valuable remedy in *nervous headache*, *cerebro-spinal meningitis*, *bilious colic*, and *atonic diarrhœa*. According to his experience, it certainly demands a careful investigation. Dose of the fluid extract of the leaf is from 5 minims to ½ fluid drachm, repeated 3 or 4 times a day, or as may be required.

SATUREJA.—SUMMER SAVORY.

The leaves of *Satureja hortensis*, Linné.

Nat. Ord.—Labiatæ.

Botanical Source.—Summer savory is an annual plant, with a branching and bushy stem, about 18 inches in height, woody at the base, and frequently changing to purple. The leaves are numerous, small, linear-oblong, entire, and acute at the end. The flowers are pink-colored, and borne on axillary, cymose peduncles. Calyx tubular, ribbed, and about as long as the corolla. Corolla bilabiate, with nearly equal divisions; the stamens are diverging and scarcely exserted (W.).

History and Chemical Composition.—This well-known plant is a native of the south of Europe, and is extensively cultivated in the gardens of this country and Europe for culinary purposes, flowering in July and August. The leaves are the parts employed. They have an aromatic odor and taste, analogous to those of thyme, and impart their properties to boiling water by infusion, but more freely to alcohol. Its virtues depend upon a volatile oil, which was found by Jahns (1882) to contain *carvacrol* (30 per cent) and the hydrocarbon, *cymol* (20 per cent), and an undetermined *terpene* (50 per cent).

Action, Medical Uses, and Dosage.—Summer savory is a stimulant, carminative, and emmenagogue. A warm infusion is beneficial in *colds*, *menstrual suppression*, and *flatulent colic;* the cold infusion is a gentle stimulating tonic during convalescence from *fevers*. The infusion may be used in doses of from 2 to 4 ounces, several times a day. The oil is sometimes used as a local application to carious teeth, for relieving *toothache;* and its tincture is a valuable carminative.

Related Species.—*Satureja montana*, Linné (*Micromeria montana*, Reichenbach). The *Winter savory*, with mucronate leaves, somewhat 1-sided peduncles, and acuminate and mucronate segments of the calyx, possesses similar properties. Haller examined this plant, in 1882, and obtained an orange-yellow essential oil, having an origanum-like odor. It contained *carvacrol* (about 35 to 40 per cent) traces of another phenol, and two hydrocarbons, probably terpenes.

Micromeria Douglassii, Bentham.—The *Yerba buena* of California, is a labiate plant of the tribe Satureineæ, closely allied to the common garden thyme (*Thymus vulgaris*). It is a native of California, and has a slender, creeping, perennial stem. The leaves are opposite, nearly round, and are borne on slender stalks. The flowers are small, purple, and in axillary clusters of from 1 to 3. This plant, it is stated, is not only a febrifuge, but possesses emmenagogue and anthelmintic properties. It is very probable that its virtues are simply those of a stimulating aromatic and tonic, and that its effects are due to these qualities. It may be employed in decoction, or in doses of from 15 to 90 minims of the fluid extract.

SCAMMONIUM (U. S. P.)—SCAMMONY.

"A resinous exudation from the living root of *Convolvulus Scammonia*, Linné"—(*U. S. P.*).

Nat. Ord.—Convolvulaceæ.

Illustration: Bentley and Trimen, *Med. Plants*, 187.

Botanical Source.—This plant has a perennial, fleshy, fusiform root, from 3 to 5 feet long, and from 3 to 5 inches in diameter, branched toward the lower end, with a grayish bark, and abounding in an acrid, milky juice. The stems are annual, numerous, slender, round, smooth, branching, twining, very slightly angular near the ends, and growing from 12 to 20 feet upon the soil, or on adjacent plants. The leaves are on long petioles, alternate, sagittate, oblong, acute, entire, quite smooth, truncate and angular at the base, with acute, spreading lobes, and of a bright-green color. The flowers are borne on axillary, solitary, 3-flowered peduncles, scarcely twice as long as the leaves. Sepals 5, rather lax, smooth, ovate, repand, obtuse, with a reflexed point, and covered at the edge. Corolla funnel-shaped, very much expanded, pale sulphur-yellow, thrice as long as the calyx, an inch or more in length; limb entire, and somewhat reflexed. Stamens 5, erect, converging, thrice as short as the corolla. Ovary 2-celled, 4-seeded, supporting a slender style as long as the stamens, with 2 linear-cylindrical, erect, oblong, parallel, distant, and white stigmas. Capsule 2-celled; seeds small and pyramid-shaped (L.).

History.—Scammony plant is a native of Turkey, Syria, Greece, Persia, etc., and somewhat resembles the Convolvulus panduratus. The official portion is the concrete juice of the root, the other parts of the plant yielding no milky juice whatever. It is collected in the month of June, the root being cut across, obliquely, near its crown, and shells fixed beneath, into which the milky juice gradually flows. This soon concretes under exposure to the air and evaporation, forming the gum-resin of commerce (scammony), of which but a few drachms are obtained from a single root. Evaporation being necessarily slow, partial fermentation sets in, producing porosity and a somewhat cheesy odor. It is seldom obtained in a pure state, being more or less adulterated with flour, ashes, meal, chalk, sand, tragacanth, colophony (resin), etc. It is imported directly from Smyrna, or from some of the Mediterranean ports. There were several varieties of scammony formerly known as the *Aleppo*, *Smyrna*, and *Montpellier*, of which the first-named was the best (*Virgin scammony*), but, owing to extensive adulteration of the drug, it is now more feasible to distinguish between *genuine* and *factitious scammony*, based on its resin contents. (For an interesting account of the production of scammony, near Smyrna, by Sidney H. Maltass, see *Amer. Jour. Pharm.*, 1854, pp. 139–146; also see D. Hanbury, on several commercial specimens of scammony, *ibid.*, 1854, p. 146; and Jos. Carson, *ibid.*, 1848, pp. 1–15.)

Description and Tests.—As required by the *U. S. P.*, scammonium is "in irregular, angular pieces or circular cakes, greenish-gray or blackish, internally porous, and breaking with an angular fracture, of a resinous lustre; odor peculiar, somewhat cheese-like; taste slightly acrid; powder gray or greenish-gray. When triturated with water, scammony yields a greenish emulsion; it does not effervesce on the addition of diluted hydrochloric acid, and the decoction, when cold, does not assume a blue color on the addition of iodine T.S. (absence of starch). Ether dissolves at least 75 per cent of it; and, when the ether has been evaporated, the residue, dissolved in hot solution of potassium hydrate, is not reprecipitated by diluted sulphuric acid"—(*U. S. P.*). The latter test excludes rosin, which, when mixed with scammony, is precipitated upon the addition of acid. This precipitate also turns dark-red immediately with concentrated sulphuric acid. Scammony resin is but slowly changed by this reagent to a light wine-colored red. Colophony, if present, may also be separated by means of oil of turpentine, in which scammony resin is nearly insoluble. Scammony, treated with ether, may yield to this solvent as much as 90 and 95 per cent of resin; gum and mineral and the other afore-mentioned insoluble adulterants remain undissolved. The resinous part of scammony is also soluble in alcohol (see *Resina Scammonii*).

The *British Pharmacopœia* (1898) directs for scammony that which is known in commerce as Virgin scammony. It is very brittle, easily reduced to powder, should afford only the slightest reactions with the tests for starch (allowing for scammony starch; see T. Greenish, *Amer. Jour. Pharm.*, 1875, p. 29), and should not yield more than 3 per cent of ash on incineration. "An alcoholic solution should not afford a blue color with test-solution of ferric chloride (absence of guaiacum resin)"—(*Br. Pharm.*). The whitish powder occasionally found on scammony is calcium carbonate, and effervesces with diluted hydrochloric acid. At Montpellier, in southern France, a factitious scammony (*Montpellier scammony*) has been manufactured, being prepared by evaporating the expressed juice of *Cynanchum monspeliacum*, Linné, a plant belonging to the natural order Asclepiadaceæ. According to Jessler (1865), the air-dried root of this plant contains 3.24 per cent of resin.

Chemical Composition.—Mr. Charles A. T. Doench (*Amer. Jour. Pharm*, 1882. p. 545) obtained from the root a yield of 5.4 per cent of scammony resin (also see his analysis of commercial specimens). Commercial scammony resin, as stated before, contains from 75 to 90 per cent and more of resin, soluble in ether and alcohol, very little soluble in water, and small quantities of gum, albuminous bodies, wax, extractive matters, traces of starch, etc. The active principle of scammony resin is the glucosid *scammonin* (Spirgatis), which is identical with *jalapin* of W. Mayer (*orizabin* of Maisch, 1887; and Th. Poleck, *Zeitschr. d. allgem. Oesterr. Apotheker Vereins*, 1892, p. 451). *Scammonin* is the anhydride of water-soluble *scammonic acid* (*jalapic acid*), and, by treatment with diluted acids, is decomposed into sugar and *scammonolic acid* (*jalapinolic acid* of Poleck). (For further details regarding these bodies, see *Orizaba root.*)

Action, Medical Uses, and Dosage.—Scammony is a powerful drastic cathartic, operating with harshness and griping. It was a favorite internal and external remedy with the Arabians. It does not appear to be poisonous even in large doses, but is seldom used alone, except in cases where a powerful impression on the bowels is desired; most commonly it is combined with other cathartics, whose action it augments, while its own virulence is diminished. Scammony is usually given in the form of an emulsion with sugar or sweet almonds. But when triturated with milk it is considered a superior preparation, as follows: Seven grains of pure scammony to be gradually triturated with 3 ounces of unskimmed milk, to which a few grains of ginger may be added, forms a safe purgative. Another form of using this gum-resin is that of biscuit. A paste is made of scammony, 1 drachm; Venice soap, 5 grains; sugar, 9 grains; biscuit, in powder, 1 ounce; and a few drops of water. Mix together, divide into 2 biscuits, and let them dry; 1 biscuit acts energetically. The dose of powdered scammony is from 3 to 12 grains; of the pure resin, half this quantity. Its use is always contraindicated by intestinal inflammation.

SCILLA (U. S. P.)—SQUILL.

"The bulb of *Urginea maritima* (Linné), Baker" (*Scilla maritima*, Linné, *Urginea Scilla*, Steinheil), "deprived of its dry, membranaceous outer scales, and cut into thin slices, the central portions being rejected"—(*U. S. P.*).

Nat. Ord.—Liliaceæ.

COMMON NAME: *Squills.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 281.

Botanical Source.—Squill is a perennial plant with a roundish-ovate bulb, very large, half above ground, with the integuments either pale-green or red, and giving off fibrous roots. The leaves proceed from the bulb, are broad-lanceolate, channeled, spreading, recurved, shining, deep-green, and make their appearance long after the flowers. The scape is 2 or 3 feet high, and terminated by a rather dense, long, ovate raceme. The flowers are about $\frac{3}{4}$ inch in diameter, spreading, pale, yellowish-green, with a green stain on the middle of each segment. Peduncles purplish; bracts linear, twisted, and deciduous. Filaments shorter than the segments of the perianth (L.—Wi.).

History and Description.—Squill is a native of almost every part of the Mediterranean coast, and is also met with in Portugal and France. It flowers in August and September. The only part used is the bulb. When recent it is pyriform, from 3 to 6 inches in its largest diameter, and consists of concentric scales, the outer ones of which are thin and membranous, while the inner ones are whitish, thick, fleshy, and full of juice; they weigh on an average from 1 to 4 pounds, though they have attained a weight of 10½ pounds. Two kinds of squill, both abounding in an acrid juice, and having a bitter taste, are met with in commerce, the *white* and the *red*, so called from the color of their scales. The white is preferred. The juice of the fresh bulb is very acrid and vesicating, but is rendered much milder by desiccation. According to Prof. Schroff (1865), scilla irritates the skin when rubbed into it, and this is due mainly to a mechanical effect, viz.: to the presence of hard crystals of oxalate of calcium, sharp pointed at each end. The crystals sometimes attain a length of 1 millimeter. When intended for medicinal use, squill bulbs ought not to be kept entire, but should be stripped of their outer scales, cut transversely into thin slices, and dried carefully at a temperature of about 37.7° C. (100° F.). When recent, these slices have a mucilaginous, disagreeably bitter, and somewhat acrid taste, with a feeble radish-like odor. As ordinarily met with, dried squill is in scales or slices of various sizes. They attract moisture from the air, and then become pliable and spoiled, on which account they, as well as their powder, should always be kept in well-closed vessels. The official drug is "in narrow segments, about 5 Cc. (2 inches) long, slightly translucent, yellowish-white or reddish, brittle and pulverizable when dry, tough and flexible after exposure to damp air; inodorous; taste mucilaginous, bitter, and acrid"—(*U. S. P.*). Squill yields its properties to water, spirit, or diluted acids; but the best solvents are proof-spirit or vinegar. Squill kills rats almost instantly; 2 drachms of powdered squill may be made into balls with ½ pound of strong-smelling cheese (or with fried lard), and spread where they visit.

Chemical Composition.—Squill contains mucilage, calcium oxalate (see above), dextrose, starch, albuminous bodies, volatile oil, mineral salts (leaving about 3 to 4 per cent of ash), a peculiar coloring matter in the red variety, producing dark-green with ferric chloride and an evanescent blue (Hartwich) with caustic alkali. The peculiar active principles of squill have been investigated by many chemists. E. Merck (1879), by an unpublished process, obtained amorphous, bitter *scillipicrin* soluble in water; amorphous, brown *scillitoxin* insoluble in water and ether, soluble in alcohol, a cardiac poison; and crystalline yellow *scillin*, not easily soluble in water, producing numbness, vomiting, etc. The bitter principle, *scillain*, was also isolated, in 1879, by E. Von Jarmerstedt, and more recently (1894) by Franz Kurtz. The latter obtained it by digesting the aqueous solution of an alcoholic extract of squill with lead oxide, removing lead from the solution by hydrogen sulphide, abstracting the bitter principle by animal charcoal and removing it from the charcoal with alcohol. *Scillain* so obtained is amorphous, readily soluble in water and alcohol, soluble with difficulty in ether; intensely bitter, neutral, and non-alkaloidal, containing no nitrogen. It is a glucosid, yielding upon hydrolysis *dextrose*, *butyric acid* and *iso-propyl-alcohol*. A glutinous carbohydrate ($C_6H_{10}O_5$) resembling dextrin, exists in squill in large quantity, and was called *sinistrin* by Schmiedeberg (1879), and *scillin* by Riche and Rémont (1880). It differs from dextrin in being lævo-rotatory, and upon hydrolysis yielding chiefly lævulose and other sugars. (For an excellent summary of the chemistry of squill, see F. X. Moerk, *Amer. Jour. Pharm.*, 1894, pp. 245–250.)

Action, Medical Uses, and Dosage.—Squill is irritant, emetic, cathartic, diuretic, and expectorant. In large doses it is a dangerous irritant poison, producing inflammation of the alimentary canal, and urinary organs, and proving fatal in the dose of only 24 grains of the powder. Some constitutions are so susceptible of its irritant action, that it can not be safely used in any dose, unless combined with opium. The usual effects of very large doses are violent vomiting and purging attended with severe abdominal pain. The urine may be bloody and is passed with difficulty; the skin becomes cold, and coma and convulsions supervene. The juice of fresh squill acts as a rubefacient, and if the skin be broken its diuretic effects may be exhibited. It is seldom used as an emetic or cathartic, on account of its uncertainty in producing these effects. In small doses it causes nausea and depression of the pulse, and never stimulates the circulation. It stimulates all of the secretory organs. Small doses of it relieve irritation of the mucous surfaces and check excessive secretions. Its expectorant action is greatly increased by the addition of opium, and its diuretic by the conjunction of digitalis, or some other vegetable or saline diuretic, as potassium acetate. It is used extensively in *dropsy* not due to organic changes. It acts better in general and passive than in local dropsies, and also in those of an asthenic character. *Dropsies of cardiac origin* are probably more often relieved by it. It may be used in all cases where no inflammation is present, and there is over-action of the kidneys. According to dose it may be made to restrain or to increase the amount of urine secreted. To check the renal flow, as in *diabetes*, the minute dose should be employed. While in the majority of cases the drug has been employed with digitalis in the cases showing enfeebled circulation, yet in small doses (1 to 10 drops of a strong tincture, bulb, ℥viii to alcohol, 76 per cent, Oj) it acts favorably where there is a "dry, harsh skin, parched tongue, fevered lips, and contraction of features" (Scudder). Squill long continued gives rise to gastric irritation and loss of appetite, and when these effects are the result of its internal use the tincture may be rubbed into the skin or applied to the abdomen by means of compresses saturated with it. In cardiac dropsy, when the heart's action is feeble and the pulse is weak and rapid, 2 grains of squill may be given in a fluid drachm of infusion of digitalis 3 times a day. As an expectorant it will be found useful in *chronic catarrh, humid asthma, pneumonia, phthisis, winter cough*, and other *chronic bronchial affections*. In chronic respiratory troubles, with but little febrile reaction and no inflammation, and scanty tenacious sputa, 1 part of syrup of squill may be added to 3 parts of syrup of wild cherry and a teaspoonful be administered 4 times a day. Troublesome vomiting or purging caused by squill is best corrected by opium. Where there is much inflammation or vascular excitement, it is contraindicated. Dose of the powder, as a diuretic and expectorant, from 1 to 3 grains; as an emetic, 6 to 12 grains; of the syrup, 1 or 2 fluid drachms; tincture, 1 to 20 drops. The pilular form is the best when squill is given in powder.

Specific Indications and Uses.—Chronic cough, with scanty, tenacious sputa; scanty, high-colored urine, with sense of pressure in the bladder; overactivity of the kidneys with inability to retain the urine; dropsy, with no fever or inflammation, and a general asthenic condition.

Related Species.—The following plants yield bulbs which may be used like squill, but on account of the cheapness of the latter, are not found in commerce (see *Pharmacographia* for fuller information).

Scilla indica, Baker (*Ledebouria hyacinthina*, Roth), India and Abyssinia; *Urginea indica*, Kunth (*Scilla Indica*, Roxburgh), India and east Africa; *Urginea altissima*, Baker (*Onithogalum altissimum*, Linné), south Africa, well represents squill; *Crinum Asiaticum*, var. *toxicarium*, Herbert (*Crinum toxicarium*, Roxburgh), India, Ceylon, and the Moluccas; *Drimia ciliaris*, Jacquin, *Itch bulb* of the Cape of Good Hope. The juice is a powerful local irritant.

Medeola virginica, Linné (*Gyromia virginica*, Nuttall) (*Nat. Ord.*—Liliaceæ).—This is the *Indian cucumber* found in shady situations and woods of the United States from the Mississippi River eastward. It bears greenish-yellow flowers in May and June. The rhizome is the part employed and resembles, both in taste and shape, our common cucumber. It is horizontal, from 1 to 1½ inches in length and ¼ inch in diameter, lower end pointed, has a white interior, and a brown-yellow exterior. It is beset with simple capillary rootlets. The rhizome contains starch. It is said to have been used as a food by the Indians (Pursh) and has been employed in *dropsical disorders*, it possessing both diuretic and hydragogue properties. It is now seldom used.

Gloriosa superba, Linné.—The tuberous root of this liliaceous climber contains, according to Warden, two resins and a bitter principle, *superbine*, which is very poisonous and closely allied, he believes, to the bitter principle of squill. Various statements are made regarding the toxic nature of the root and its reputed criminal uses. These reports, however, are not well established (Dymock).

SCOPARIUS (U. S. P.)—SCOPARIUS.

"The tops of *Cytisus Scoparius* (Linné), Link"—(*U. S. P.*) (*Genista scoparia*, Lamarck; *Spartium scoparium*, Linné; *Sarothamnus Scoparius*, Koch; *Sarothamnus vulgaris*, Wimmer).

Nat. Ord.—Leguminosea.

COMMON NAMES: *Broom, Irish broom, Broom tops.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 70.

Botanical Source.—This is a large, bushy shrub, growing from 4 to 9 feet in height, with numerous, long, straight, pentangular, dark-green, smooth, tough, very pliant branches. The leaves are deciduous, scattered, stalked, and ternate; the upper ones generally simple; leaflets uniform, obovate, obtuse, entire, and silky when young. The flowers are axillary, solitary, or in pairs, on simple stalks, longer than the leaves, papilionaceous, large and handsome, of a deep golden-yellow color. The fruit is a brown legume, flat, above an inch long, nearly smooth at the sides, fringed with hairs at each margin, and contains about 15 or 16 seeds. The swelling ovary soon splits the tube of the filaments (L.).

History and Description.—This plant is common to Europe and this country, and is frequently cultivated in gardens; it grows on dry and sandy soils, and flowers in May and June. The tops (*Scoparii Cacumina, Br. Pharm.; Herba Scoparii*) are the official parts. The seeds are also employed, and may be preserved for a longer time than the former. All parts of the plant have a peculiar, nauseously amarous taste, and, when rubbed, have a characteristic odor. They yield their virtues to water or alcohol. The young blossoms, when pickled, are said to be equal in quality to capers. The *U. S. P.* demands broom tops "in thin, flexible, branched twigs, pentangular, winged, dark-green, nearly smooth, tough, usually free from leaves; odor peculiar when bruised; taste disagreeably bitter" (*U.S.P.*). The seeds of *Spartium junceum*, Linné, of Europe, are possessed of emetic, purgative and diuretic properties.

Chemical Composition.—The flowers contain volatile oil, yellow fat, wax, sugar, gum, tannin, yellow coloring matter, mineral matter, etc. (Cadet de Gassicourt, 1824). Stenhouse, in 1851, isolated from broom tops the volatile, oily, narcotic, and bitter alkaloid, *sparteine* ($C_{15}H_{26}N_2$), and the yellow, crystallizable coloring matter, *scoparin*, which is diuretic and purgative. (For preparation and properties of sparteine, see *Sparteinæ Sulphas.*) *Scoparin* is obtained by evaporating an aqueous decoction of the plant to a smaller bulk, and allowing to stand for 24 hours. A jelly-like, crude scoparin is obtained, which is pressed out and purified by recrystallizing from hot water, then from hot alcohol. Hot alcohol converts it into a jelly-like insoluble, and a crystalline, soluble modification. It forms a pale-yellow, amorphous mass, or yellow crystals, quite soluble in hot water and hot alcohol, easily soluble in aqua ammoniæ, caustic alkalies, and alkali carbonates. When fused with caustic potash, *phloroglucin* and *protocatechuic acid* are formed (Hlasiwetz, 1866). Stenhouse gives the formula $C_{21}H_{22}O_{10}$, while Goldschmidt and von Hemmelmayr find $C_{20}H_{20}O_{10}$, or $C_{19}H_{16}O_8(OH)(OCH_3)$ (*Chem. Centralblatt*, Vol. II, 1893, p. 213; and *Amer. Jour. Pharm.*, 1894, p. 37).

Action, Medical Uses, and Dosage.—Broom is not without decided physiological effects—a staggering gait, impaired vision, and profuse vomiting and sweating have resulted from its use. The physiological effects of *scoparin* are not yet well studied, though it is regarded as diuretic and purgative. (For the action of *sparteine*, the cardiac principle, see *Sparteinæ Sulphas.*) In large doses, broom is emetic and cathartic; in small doses, diuretic. Used in all chronic forms of *dropsy;* said to never fail in increasing the flow of the urine; especially beneficial in *dropsy of the thorax*, combined with diseases of the lungs. *Scurvy* and *jaundice* have been successfully treated with it. Dose, of a strong decoction, prepared by boiling 1 ounce of the tops in a pint of water for 10 minutes, 4 fluid ounces every hour, until it produces some effect, using about 1 pint in 24 hours (dandelion and juniper berries may be made into a decoction with it); of the pulverized seed, from 10 to 15 grains, aided by the free use of diluents; of the tincture, 15 to 30 drops. The latter is inferior to the infusion.

Related Species.—*Ulex Europæus, Gorse, Whin, Furze.* A spiny plant, bearing bright-yellow flowers, and very common along the roadways and in waste places in Great Britain. A. W. Gerrard (1886) isolated from the seeds an alkaloid, *ulexine.* This alkaloid, according to the views of Kobert (1890), Moer (1891), and Partheil (1892), is identical with *cytisine* (see *Laburnum*, for description; also see *Amer. Jour. Pharm.*, 1893, p. 296). The action of ulexine is similar to that of cytisine and sparteine, giving to the heart vigorous and slower action. It induces greater arterial contraction, and proves diuretic. Its diuretic effects, however, are less pronounced than those of digitalis, which it most resembles. Cardiac paralysis is the result of toxic doses. A child was poisoned by milk from a cow which had eaten gorse. The remedy may be used in *dropsies of cardiac origin* (Kobert). Dose, of ulexine, $\frac{1}{20}$ to $\frac{1}{15}$ grain; of the nitrate, $\frac{1}{20}$ to $\frac{1}{12}$ grain, hypodermatically.

SCROPHULARIA.—CARPENTER'S SQUARE.

The leaves, tops, and roots of *Scrophularia nodosa*, Linné, var. *marilandica*, Gray (*Scrophularia nodosa*, var. *Americana*, Michaux).

Nat. Ord.—Scrophularineæ.

COMMON NAMES: *Figwort, Carpenter's square, Scrofula plant, Square stalk, Heal-all.*

ILLUSTRATION: Lloyd's *Drugs and Med. of N. A.*, Plate 37.

Botanical Source. *Scrophularia nodosa*, Linné, has a perennial, whitish, tuberous, and knotty root, with a leafy, erect, quadrangular, smooth stem, 2 to 4 feet in height, with paniculate, opposite branches above. The leaves are opposite, petiolate, ovate, ovate-oblong, or the upper lanceolate, acute, sharply and unequally serrated, rounded, acutish, or broadly cordate at base, veined, of a deep-green color, and 3 to 7 inches in length. The flowers are small, 3 or 4 lines long, ovoid, dark-purple, slightly drooping, on axillary and terminal, forked, angular, glandular peduncles in oblong, thyrsoid panicles. The calyx is in 5 segments, which are broadly ovate, obtuse, and slightly margined; the corolla of a dull-green color, with a livid-purple lip, and subglobose; the limb contracted, sublabiate, having a green scale or sterile filament, adnate to the upper side. Stamens didynamous; sterile anthers, broadly orbicular. Capsule ovate-oblong (L.—W.—G.). The variety *marilandica*, Gray, differs from the preceding chiefly in being taller (4 to 6 feet), and in having obtuse angles to the stems.

Fig. 224.

Scrophularia nodosa.

History and Description.—Figwort is a native of Europe, and found growing in different parts of the United States, in woods, hedges, damp copses, and banks, flowering from July to October. The American variety was formerly considered distinct from the European plant, and was named *Scrophularia marilandica*. Michaux, however, did not regard it as such, but placed it as a variety under the name *Scrophularia nodosa*, var. *Americana*, which name should have been retained. Gray, in his more recent works, gave it as the variety *marilandica*, under which it is now known. The plant is generally known to Eclectics as *Carpenter's square;* to other branches of the profession as *Figwort* and *Scrofula plant*. A variety lacking the cordate leaf-base, is more common in the southern localities of this country. It is the variety *lanceolata*, and the kind figured in *Drugs and Med. of N. A.* (see preceding page). Pursh named it *Scrophularia lanceolata*. The leaves and root are the medicinal parts, and yield their virtues to water or alcohol. The leaves have an offensive odor, and a bitter, unpleasant taste; the root is slightly acrid. Much of the odor and taste are lost by drying. The root is generally employed.

Chemical Composition.—J. U. Lloyd (*Drugs and Med. of N. A.*, Vol. II, p. 112) found the root to contain a small quantity of an alkaloid, fixed oil, and a brown, amorphous resin of a peppery taste, insoluble in water and benzol, soluble in alcohol and chloroform. The herb yielded abundant mucilage, but no alkaloid. F. Koch (*Archiv der Pharm.*, 1895) found the ether extract of the plant to contain *lecithin*, free cinnamic acid and butyric acid. The alcoholic extract contained *caffeotannic acid*, sugar (probably dextrose), and a resin, from which cinnamic acid may be isolated. According to van de Moer (1895), the aqueous and alcoholic extracts of the herb and the seeds are poisonous. From the alcoholic extract, an amorphous, yellow powder was obtained, resembling digitalis, medicinally.

Action, Medical Uses, and Dosage.—Figwort is alterative, diuretic, and anodyne; reputed highly beneficial in *hepatic diseases*, *scrofula*, *secondary syphilis*, *cutaneous diseases*, *dropsy*, and as a general deobstruent to the glandular system, when used in infusion or syrup. Prof. Goss valued it highly in conditions coming under the head of *struma*, when the fluids and solids are depraved, and ulceration readily follows contusions. Externally, in the form of fomentation, or ointment, it is valuable in *bruises*, *mammary inflammation*, *ringworm*, *piles*, *painful swelling*, *itch*, and *cutaneous eruptions of a vesicular character*. The root, in decoction, and drank freely, is said to restore the lochial discharge when suppressed, and to relieve the pains attending *difficult menstruation*. This plant possesses valuable and active medicinal properties. Its alterative properties are pronounced, though the remedy is very slow to produce its effects. Dose of the infusion or syrup, from 2 to 4 fluid ounces; fluid extract, 30 to 60 drops; strong tincture (℥viij to alcohol, 76 per cent, Oj), from 10 to 40 drops.

Specific Indications and Uses.—Struma; ulcerations about the eyes, ears, nose, or face; inclination to ulceration from abrasions or contusions; enlarged lymphatics, with perverted nutrition; full lips, pink and white countenance, with fullness or puffiness of the alæ nasi; epiphyseal thickenings and fullness of the joints (Goss, *Drugs and Med. of N. A.*, Vol. II, p. 115).

SCUTELLARIA (U. S. P.)—SCUTELLARIA.

"The herb of *Scutellaria lateriflora*, Linné"—(*U. S. P.*). The green herb is preferred in Eclectic pharmacy.

Nat. Ord.—Labiatæ.

Common Names: *Scullcap, Skullcap, Madweed.*

Illustration: Strong's *American Flora* (opposite page 100).

Botanical Source and History.—We introduce this plant, accompanied with illustrations, to overcome the confusion that has existed in commercial circles regarding the plant ordinarily sold as scullcap. The official species is the *Scutellaria lateriflora*, but the larger part of the drug sold upon the market under that name is derived from two other species of Scutellaria. The genus Scutellaria is well characterized by the calyx, which in all the species consists of 2 round lips closed in fruit, the upper lip of which has a helmet-shape appendage, giving to it the appearance of a mask or cap; hence the common name *scullcap*.

Fig. 225.

Scutellaria lateriflora.

Scutellaria lateriflora, Linné, the official scullcap, is the most widely-distributed of the species. It is common in every section of the United States, and is found growing in damp places on the banks of streams, and in similar situations. Inasmuch as this is the proper scullcap to use in medicine, and as it is often confounded with other species, we will give a close description of the plant (see Fig. 225). The stem is slender, herbaceous, 4-angled, much branched, and from 1 to 2 feet high; it is smooth, green when the plant grows in shady situations, but turns brown on exposure to the sun. The leaves are small, from 1 to 2 inches long, and about one-half as wide, ovate, rounded at the base, and acute at the apex. They are smooth, crenate, and are borne on opposite leafstalks, which are about 1 inch long. The flowers appear late in summer, and are borne in numerous, slender, simple, one-sided racemes, from the axils of the leaves; they are small, opposite, and have short pedicels, subtended at the base by small bracts. The calyx is about the length of the pedicel, and has the peculiar helmet-shape characteristic of the genus. When the fruit is mature, the calyx splits in the base, the upper lip falling away, the lower one remaining. The corolla is small, blue, about one-fourth of an inch long; it has a slender, exserted tube, and 2 subequal lips, the upper of which is arched, the lower, spreading. The stamens are 4, and included in the corolla. The fruit consists of 4 small nutlets.

Fig. 226.

Scutellaria versicolor.

Scutellaria versicolor, Nuttall, and *Scutellaria canescens*, Nuttall, are the species generally collected by herbalists, and substituted for Scutellaria lateriflora. We present an engraving of Scutellaria versicolor, and both this and S. canescens can readily be distinguished from official scullcap, by their being much more robust, having thicker stems, and growing from 2 to 4 feet high. The flowers are large in both, being 1 inch long; and instead of being borne in very slender, lateral racemes, as with S. lateriflora, they are borne in a single, large, terminal, branched raceme. The leaves are also much larger than those of S. lateriflora, being from 2 to 4 inches long, and nearly as broad. They are cordate at the base, and acute at the apex. The leaves of S. versicolor are thin, softly pubescent, and of a bright-green color; those of S. canescens are thick in texture, light-green, and often variegated with a purple line around the margin.

Scullcap is an indigenous herb, growing in damp places, meadows, ditches, and by the sides of ponds, flowering in July and August. Besides the names given above it is known by the names of *Blue scullcap*, *Side-flowering scullcap*, *Mad-dog weed*, and *Hoodwort*. The whole plant is official, though but the mature leaves and flowering tops should be employed. It should be gathered while in flower, dried in the shade, and kept in well-closed tin vessels. Alcohol or boiling water extracts its properties. It is officially described as "about 50 Cm. (20 inches) long, smooth; stem quadrangular, branched; leaves opposite, petiolate, about 5 Cm. (2 inches) long, ovate-lanceolate or ovate-oblong, serrate; flowers in axillary, one-sided racemes, with a pale-blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped; odor slight; taste bitterish"—(*U. S. P.*). The drug loses its properties largely when dried, and by age becomes inert; hence the many failures in therapy from the use of scutellaria.

Chemical Composition.—*Scutellaria lateriflora* contains volatile and fixed oil, tannin, gum, sugar, and a bitter principle (Cadet de Gassicourt, 1824). C. O. Myers and H. R. Gillespie (*Amer. Jour. Pharm.*, 1889, p. 555) obtained this bitter principle in the form of acicular crystals by treating an alcoholic extract of the drug with water and abstracting the principle from the aqueous solution with ether. The authors found it to be a glucosid; the presence of tannin in the drug could not be verified.

From the root of *Scutellaria lanceolaria*, Miquel (*Scutellaria baicalensis*, Georgi), growing in Japan. Takahashi (1889) isolated *scutellarin* ($C_{10}H_8O_3$), crystallizing in yellow tasteless needles, sparingly soluble in hot water, soluble in other simple solvents and in alkalis. It is not a glucosid, and seems to be physiologically inert.

Action, Medical Uses, and Dosage.—Scullcap is tonic, nervine, and antispasmodic. This is one of those valuable agents which a certain class of physicians consider inert; yet it has proved especially useful in *chorea*, *convulsions*, *tremors*, *intermittent fever*, *neuralgia*, and many *nervous affections*. In *delirium tremens*, an infusion drank freely will soon produce a calm sleep. In *intermittents* it may be beneficially combined with lycopus. Where teething has impaired the health of children, an infusion may be given with advantage. In all cases of *nervous excitability*, *restlessness*, or *wakefulness*, attending or following acute or chronic diseases, from physical or mental overwork, or from other causes, it may be drank freely with every expectation of beneficial results. The warm infusion has a tendency to keep the skin moist; the cold has a tonic influence, and either may be drank freely. When its soothing effects have ceased, it does not leave an excitable, irritable condition of the system, as is the case with some other nervines. Scullcap has been extolled as a remedy in *hydrophobia*, but this is still a matter of uncertainty. That it influences the cerebro-spinal centers, controlling nervous irritation there can be no doubt, and this fact is well illustrated by its control over *functional cardiac disorders*, due to purely nervous causes, with or without hysterical manifestations, and exhibiting intermittency of pulse. Specific scutellaria well represents the plant. Half an ounce of the recently dried leaves or herb, to ½ pint of boiling water, will make a very strong infusion. Dose of specific scutellaria, 1 to 30 drops; of scutellarin, 1 to 5 grains; fluid extract, 1 to 60 drops.

Specific Indications and Uses.—Nervousness, attending or following acute or chronic diseases, or from mental or physical exhaustion, teething, etc.; nervousness manifesting itself in muscular action; tremors, subsultus, etc.; hysteria, with inability to control the voluntary muscles; functional cardiac disorders of a purely nervous type, with intermittent pulse.

Related Species.—*Scutellaria pilosa*, Linné; *Scutellaria integrifolia*, Linné, and *Scutellaria hyssopifolia*, Linné, now regarded as a variety of the last-named species, are sometimes employed. They are decidedly bitter. They possess properties similar to scullcap.

Scutellaria galericulata, Linné.—Europe, Asia, and North America; *European scullcap.* Odor, alliaceous; taste, bitter. Applied to *old ulcerations*, and given internally in *intermittents*.

Brunella (or *Prunella*) *vulgaris*, Linné. *Self-heal*, or *Heal-all*, is bitter and astringent. It is a common herb in the woods and grassy situations of Asia, Europe, and North America. The flowers are borne in dense bracted spikes and are of a purplish-blue color. It was once used locally in *sore throat*, and internally in *diarrhœal* and *hemorrhagic affections*.

Derivative of Scutellaria. SCUTELLARIN (*Scutellarine*). The preparation, erroneously called scutellarine, is one of the concentrations and is to be classed therewith. It is of a light greenish-brown color, with a faint, tea-like odor, and a peculiar, herbaceous, somewhat gritty, resinous, tea-like taste. It is reputed a nervine and tonic, especially useful in cases of depression of the nervous and vital powers after long sickness, over-exercise, excessive study, or from long-continued and exhausting labors. One grain will, it is stated, frequently produce its quiet and soothing effect, controlling nervous agitation, and inducing a sensation of calmness and strength. It has been advantageously combined with oleoresin of cypripedium, resin of cimicifuga, and resin of caulophyllum, in various *female disorders*, both in the gravid or non-gravid state, accompanied with an excitable or irritable condition of the nervous system. It may be used wherever scullcap is indicated. Its dose is from 1 to 5 grains, 3 or 4 times a day, though an increased quantity will not produce any unpleasant effects (J. King).

SEDUM.—MOSSY STONECROP.

The plant of *Sedum acre*, Linné.

Nat. Ord.—Crassulaceæ.

COMMON NAMES: *Mossy stonecrop*, *Biting stonecrop*, *Small houseleek*.

Botanical Source and Description.—This is a low, moss-like, fleshy plant, native of Europe, but very common in cultivation, and sometimes naturalized in this country. It has a spreading, thick, green stem, from 1 to 3 inches high. The leaves are fleshy, small, sessile, erect, and numerous, almost entirely covering the stems. The flowers are bright-yellow, sessile, and arranged in 3-parted, terminal cymes. The sepals, petals, and carpels are in fives, in the central flowers of the cyme, and in fours in the others. The stamens are in number double the other parts of the flower. There are about half a dozen native species of Sedum, mostly found in dense patches, in rocky woods, throughout the United States. They all have white or light-purple flowers, which appear in June or July. *Sedum ternatum*, Michaux, is the most common species in Ohio and the neighboring states.

Chemical Composition.—Sedum acre was analyzed by Mylius (*Archiv der Pharm.*, 1872, pp. 97–110), who found it to contain wax, chlorophyll, acid resin, mucilage, sugar, an alkaloid, and other substances common to plants, but no starch. He describes the alkaloid as uncrystallizable, acrid and nauseous to the taste, not volatile, oxidizable in the air, soluble in ether, alcohol, chloroform, but little soluble in water. It unites with acids to form soluble salts. The hydrochlorate, in solution, is precipitated by excess of ammonia, or the hydrate, or carbonate of potassium. *Rutin* or *rutic acid* (see *Ruta*) is present in the ether extract; it produces dark-green with ferric chloride.

Action, Medical Uses, and Dosage.—Sedum acre has little or no odor, and its taste, at first herbaceous, is followed by a persistent acrid pungency. The leaves, pounded and applied to the surface of the body, will occasion a troublesome vesication. Taken internally, the plant, or its expressed juice, has an emeto-cathartic action, and was recommended in *scrofulous affections*, *malarial fevers*, and even in *epilepsy;* however, it is rarely employed at the present day, except, occasionally, as a local application to *glandular enlargements*, to *scrofulous ulcers*, and to some *chronic cutaneous maladies*—the fresh leaves only (bruised) being used—thus applied to *warts*, *corns*, or similar growths, it is said to ultimately effect their removal. It is said to relieve "the extreme sensitiveness associated with disorders of the reproductive function" (Scudder, *Spec. Med.*, p. 238). Internally, the expressed juice has been used in doses of from 1 to 2 fluid drachms, taken in beer or wine.

Related Species.—*Sempervivum tectorum*, Linné, *Common houseleek*. Houseleek has a fibrous root crowned with several rosaceous tufts of numerous, oblong, acute, keeled, fringed, extremely succulent leaves. The stem from the center of one of these tufts, is about a foot high, erect, round, downy, clothed with several, more narrow, sessile alternate leaves, and terminating in a sort of many-flowered cyme, with spiked branches. Flowers large, pale rose-colored, without scent. Segments of the calyx 12 or more, with a similar number of petals, stamens, and pistils. Offsets spreading (L.). This is a well-known perennial plant, a native of Europe, and is so succulent and hardy that it will grow on dry walls, and on the roofs of houses. It sends out runners with offsets, rarely flowering (W.). Its period of flowering is in August. It is much cultivated in some places. The fresh leaves are the parts used. They are thick, fleshy, mucilaginous, somewhat plano-convex, smooth, odorless, and of a mixed flavor, combining slight acidity with astringency. Their most important constituent, according to Vauquelin, is calcium malate. The fresh leaves are useful as a refrigerant, when bruised, and applied as a poultice, in *erysipelatous affections*, *burns*, *stings of insects*, and other *inflammatory conditions of the skin*. The leaf, sliced in two, and the inner surface applied to *warts* or *corns*, and changed twice a day, will, it is said, positively cure them. The juice, applied locally, has cured *ringworm*, *shingles*, and many other *cutaneous affections*. *Erysipelas* has been benefited by the free internal use of the leaves bruised in milk and water, in quantity sufficient merely to stain the liquid. The bruised leaves, applied as a poultice, have cured severe cases of *herpes circinata*. The leaves also possess an astringent property, which is beneficial in many cases. Minute doses of the tincture of sempervivum are said to "be indicated by a flushed surface and stinging pains, as from the sting of a bee or mosquito" (Scudder).

Sedum Telephium, Linné, is the common *Live-for-ever*, or *Garden opine*.

Sedum latifolium leaves are chewed and applied to *wounds* by the Cree Indians, who also used the leaves for tea.

Sedum dendriodeum, Mocino.—Mexican species used like *Sedum acre*.

SELINUM.—MARSH PARSLEY.

The root of *Selinum palustre*, Linné.

Nat. Ord.—Umbelliferæ.

COMMON NAMES: *Marsh parsley*, *Marsh smallage*.

Botanical Source.—Marsh parsley has a simple, tapering, perennial root, with many long fibers. Its stem is erect, 4 or 5 feet high, hollow, deeply furrowed, not hairy, branched and corymbose in the upper part, and bright-purple at the base. The leaves, about 5 or 6 on the stem, are alternate, remote, and ternate, with bipinnate divisions; the leaflets opposite, deeply pinnatifid, dark-green, smooth, their segments linear-lanceolate, never quite linear, acute, entire, or trifid; the petioles smooth, striated, dilated, and sheathing at the base, with a reddish membranous margin. The umbels are large, horizontal, of numerous, angular, general and partial rays. General bracts several, lanceolate, pointed, dependent, not half the length of the rays, with their margins membranous and partly colored; partial ones similar, but rather longer in proportion, and often confluent. Flowers white, numerous, and uniform, with involute petals. The fruit is very light straw-color, 4 lines long, shining, and obovate; the dorsal ridges very near each other, distinctly elevated, sharp, the lateral depressed and far within the broad, thin margin; the vittæ of the commissure subulate, straight, and about half the length of the fruit (L.).

History, Description, and Chemical Composition.—This plant is the *Cnidum palustre* of Sprengel, the *Peucedanum montanum* of Koch, and the *Conioselinum* of Fischer, also known as *Peucedanum palustre* of Moench. This plant grows in marshes and boggy meadows in the north and middle of Europe. The root is branched, fleshy, deep-brown externally, white and milky within, having a strong aromatic odor, and an acrid and piquant taste; the dried root is of a less deep-brown color, yielding a bright-yellow, grayish powder. The root abounds in a white, fetid, bitter juice, which hardens into a brown, acrid resin; it is the part employed. It imparts its properties to water or alcohol. According to Peschier, the root contains a volatile oil, a fatty oil, soluble in ether and alcohol, gummy matter, a yellow coloring principle, a nitrogenous principle, etc.

Action, Medical Uses, and Dosage.—Marsh smallage is emmenagogue, diuretic, and antispasmodic, but abandoned as an internal remedy on account of its caustic and dangerously poisonous properties. Ten or 20 grains, according to the patient's age, repeated every 5 hours, and, after a time, gradually augmented, have cured several cases of *epilepsy* in the course of from 3 to 6 months, but it must not be used where abdominal obstruction exists, or where there is an exalted sensibility of the genital apparatus. If it produces diarrhœa or colic, the doses must be lessened to twice, or even once, a day; sometimes it purges, nauseates, or causes gastralgia. In nervous and sanguine persons, especially those of irritable habits, it increases the violence of the disease. Two-grain doses, repeated twice daily, have proved almost immediately beneficial in the *dentition convulsions* of children. This agent generally exerts a favorable influence upon menstruation and its disorders. It has also been used with success in *pertussis*, *nervous affections*, etc. (J. King).

Related Species.—(See Levisticum, Heracleum, and Imperatoria.) *Selinum canadense*, Bentham and Hooker; *Marsh* or *Hemlock parsley*, *Selinum canadense*, or *Cnidium canadense* of Sprengel, and *Conioselinum canadense* of Fischer, which grows in swamps, wet woods, and around the mouths of large rivers from Canada to Carolina, and westward, is a species of the above plant, and deserves a trial in the diseases just mentioned. It is a plant 2 to 4 feet in height, somewhat resembling the Conium maculatum, and having an angular, flexuous, hollow stem. Leaves on large, inflated petioles, ternately divided; the divisions bipinnate, with linear-oblong, acute lobes. Umbels compound. Petals white, spreading. Involucre wanting, or 2 or 3-leaved. Styles slender, diverging. Fruit about 2 lines long, oblong, oval. Vittæ solitary in the dorsal interval, 2 or 3 in the lateral. It flowers in August and September (W.—G.). (See also page 1454.)

Æthusa Cynapium, Linné (*Nat. Ord.*—Umbelliferæ), *Fool's parsley*, *Dog parsley*, *Dog poison*, *Garden hemlock*, *Lesser hemlock*.—A European plant, having a strong resemblance to parsley, from which, however, it may be readily distinguished by its loathsome taste, and its nauseous odor when rubbed. The root is spindle-shaped, the flowers white, and the seeds globular and striated. A toxic, crystallizable alkaloid, *cynapine*, soluble in alcohol and in water, but not in ether, has been found in the herb (Ficinus, *Archiv der Pharm.*, 1828, p. 251). The seeds yield a volatile, oily base, somewhat like coniine, volatile oil, fatty oil, and several resins (Walz, *Neues Jahrbuch f. Pharm.*, Vol. XI, 1859, p. 355; and W. Bernhardt, *Archiv der Pharm.*, 1880, p. 117). The question as to the toxicity of this plant is still unsettled, several cases of poisoning having been reported from it, but Harley believes that *Conium maculatum*, which closely resembles this plant, has been mistaken for it. Æthusa is recommended for the gastro-intestinal troubles of infants, especially when artificially fed. The symptoms pointing to its use are practically those indicating ipecac. *Cholera infantum*, *summer diarrhœa*, and *convulsions*, attending intestinal disorders of children, have been treated with it. *Active delirium*, easily excited, and with tendency to rage, mental confusion, dizziness, simulating intoxication, and violent *headache*, with dizziness, are also said to be indications for the drug. A strong tincture of the flowering plant may be used, adding from 1 to 2 drops to 4 fluid ounces of water, and giving 1 teaspoonful every 2 or 3 hours.

SENECIO.—LIFE ROOT.

The root and herb of *Senecio aureus*, Linné.

Nat. Ord.—Compositæ.

Common Names: *Life root*, *Ragwort*, *False valerian*, *Golden senecio*, *Squaw weed*, *Female regulator*.

Botanical Source.—This plant has an erect, smoothish, striate stem, 1 or 2 feet high, floccose-woolly when young, simple or branched above, terminating in a kind of umbellate, simple or compound corymb. The radical leaves are simple and rounded, the larger mostly cordate, crenate-serrate, and long-petioled; the lower cauline leaves lyre-shaped; the upper ones few, slender, cut pinnatifid, dentate, sessile, or partly clasping, the terminal segments lanceolate. The peduncles are subumbellate and thick upward. Corymb is umbel-like. Rays from 8 to 12, 4 or 5 lines long, and spreading. Flowers golden-yellow. Scales linear, acute, and purplish at the apex (W.—G.).

History.—This is an indigenous, perennial plant, growing on the banks of creeks and on low, marshy grounds, throughout the northern and western parts of the Union, flowering in May and June. The root and herb are the medicinal parts, and the medicine is peculiar to Eclectic practitioners. It yields its properties to water or alcohol. It has not been analyzed, but appears to contain both an acrid and bitter principle, and tannin.

Action, Medical Uses, and Dosage.—Senecio is diuretic, pectoral, diaphoretic, tonic, and exerts a peculiar influence upon the reproductive organs, and particularly of the female, which has given to it, especially the *S. gracilis*, the name of *Female regulator*. This is one of our valuable remedies in the treatment of female diseases. It relieves irritation and strengthens functional activity. Ovarian or uterine atony, with impairment of function, increased mucous or mucopurulent secretions, or displacements of the womb and vaginal prolapse, are the chief guides to its use. It is very efficient in promoting the menstrual flow, and may be given alone, in infusion, or combined with equal parts of asarum and savine, in *amenorrhœa*, not connected with some structural lesion. It will also be found valuable in *dysmenorrhœa*, *sterility*, and *chlorosis*. In *menorrhagia*, combined with cinnamon and raspberry leaves, it has been found very serviceable, when administered during the intermenstrual period, as well as at the time of ovulation. Tenesmic and painful micturition of both sexes is often relieved by it. Senecio often cures *leucorrhœa* when associated with weakness of vaginal walls, allowing uterine displacements, and accompanied with vascular engorgement and pelvic weight. Senecio is of value in many genital disorders of the male, the indications being pelvic weight and full, tardy, or difficult urination and sensation of dragging in the testicles. Senecio aids digestion when tardy from congested or relaxed conditions of the gastric membranes. It is also useful in *capillary hemorrhage*, especially in *hematuria*, and in *albuminuria*, with bloody urine. *Pulmonary hemorrhage* has also been checked by it. It has proved an excellent diuretic in *gravel* and other urinary affections, either alone, or given in combination with other diuretics, and is said to be a specific in *strangury*. In *pulmonary* and *hepatic affections* it has proved advantageous, and, taken freely, the decoction has effected cures of *dysentery*. This remedy produces its effects slowly in chronic disorders. Dose of the decoction, 4 fluid ounces, 3 or 4 times a day; specific senecio, 1 to 30 drops.

Specific Indications and Uses.—Atony of the reproductive organs, with impairment of function; uterine enlargement, with uterine or cervical leucorrhœa; difficult tenesmic micturition; dragging sensations in the testicles; perineal weight and fullness.

Varieties of Senecio and Related Species.—There are several varieties of the above species, which possess similar medicinal virtues, as the *Senecio balsamitæ*, or *Balsam groundsel*, with the stem and peduncles villous at base; leaves few, small, distant, pubescent; radical ones oblong, spatulate, or lanceolate, sometimes cut-toothed, tapering into the petiole; cauline ones lyrate or pinnatifid; flowers subumbellate. This variety grows in pastures and on rocky hills (W.—G.).

Another, the *Senecio gracilis*, *Unkum*, or *Female regulator*, a slender state of the species, is found on rocky shores. Radical leaves orbicular, on long petioles, subcordate, crenate; cauline ones very few, remote, linear-oblong, dilated at the base, incisely dentate; peduncles very short, pilose, subumbelled; involucre smooth; rays few, very short.

The *Senecio obovatus*, a variety of the *S. aureus*, with the radical leaves obovate, crenate-serrate, petioled; cauline ones pinnatifid, toothed; flowers subumbelled, long-peduncled, bracted, with a cavity under the receptacle like some other of the genus; stem somewhat glabrous. Found in the meadows, etc. (W.). This plant, in infusion, has cured several cases of *amenorrhœa*. Several cases of abortion are stated to have followed its use, and it has been recommended as a substitute for ergot. It certainly deserves further investigation.

Senecio lanceolatus.—Found in shady cedar swamps in Vermont. It has all the leaves lanceolate-oblong, thin, sharply and unequally toothed, either wedge-shaped or somewhat cordate at the base, the upper cauline ones being pinnatifid-cut toward the base.

Among these varieties, the *Senecio gracilis* is considered the most efficient in uterine difficulties, and it is from this that the oleoresin, improperly called *senecin*, was at first prepared. The whole herb is used. The root grows just below the surface of the ground, and runs along horizontally. It is from ½ to 6 or 8 inches in length, and about 2 lines in diameter, reddish or purplish externally, white-purplish internally, with an aromatic taste, and having scattered fibers. When dried and mixed with the herb, it is found of various lengths, from ¼ to 1 or 2 inches, greenish-brown or yellowish-brown externally, with very fine longitudinal lines, a few fibers attached, short fracture, presenting under the microscope a shining, waxy surface, with a central pale-purple substance, surrounded by a greenish-yellow one, with a light-yellowish ring between the two. It is inodorous, and has a faintly bitter, herbaceous, peculiar, resinous taste, with a very slight degree of pungency. It yields its properties best to alcohol.

Senecio Doronicum, *Senecio Saracenicus*, *Senecio vulgaris*, and *Senecio Jacobæa*, are among the European species which have been employed in medicine, while, in Mexico, the *maturin* (*S. cerviariæfolius*) and *matrique* (*S. grayanus*) are said to furnish a dog-poison. Exalted temperature, pupillary dilatation, and convulsions are the reputed effects of these species, which, according to Henckel (*Amer. Jour. Pharm.*, 1891, p. 6), contain a glucosidal body, resembling digitalin in its action; resin, volatile oil, tannin, etc., are likewise present. Another Mexican dog-poison is *Yerba de la Puebla*, or *Senecio canicida*, and contains a poisonous organic acid, *senecic acid* (Rio de la Loxa, *Amer. Jour. Pharm.*, 1886, p. 170).

SENEGA (U. S. P.)—SENEGA.

"The root of *Polygala Senega*, Linné"—(*U. S. P.*).

Nat. Ord.—Polygaleæ.

COMMON NAMES: *Seneka root*, *Senega snakeroot*, *Seneca snakeroot*.

Botanical Source.—Senega is an indigenous plant, with a perennial, firm, hard, branching root, consisting of a moderately solid wood, and a thick bark; it sends up several annual stems, which are erect, simple, smooth, 8 to 14 inches high, and occasionally tinged with red. The leaves are alternate, nearly or quite sessile, lanceolate, with a sharpish point, smooth, paler underneath, 1 to 3 inches long, and about one-third as wide. The flowers are white, on short pedicels, in a close terminal spike, from 1 to 3 inches in length. Calyx of 5 sepals, the two largest, or wings, concave, roundish-ovate, white, slightly veined, and larger than the petals. Corolla of 3 petals, two lateral and obtuse, and a short-crested extremity; they are small and closed. Capsules small, obcordate, invested by the persistent calyx, compressed, 2-celled, and 2-valved. The seeds are 2 in number, oblong-ovate, acute at one end, slightly hairy, curved, blackish, with a longitudinal, bifid, white strophiola on the concave side. The spike opens slowly, so that the lower flowers are in fruit while the upper ones are in blossom (L.—W.).

Fig. 227.

Root of Polygala Senega.

History and Description.—Seneka, or Seneca snakeroot, as it is usually called, is found in various parts of the United States, in rocky woods, and on hillsides, flowering in July. Distinction is sometimes made in commerce between *Southern* and *Northern senega*. The latter is probably a botanical variety of the former. Southern senega comes from Kentucky, Virginia, Tennessee, North Carolina, Arkansas, Missouri, Ohio, Indiana, and Illinois, while Northern senega, since about 1871, was brought from Minnesota and Wisconsin (J. U. and C. G. Lloyd, *Amer. Jour. Pharm.*, 1881, p. 481; also see *Related Species*, next page, for *False Senega*). The dried root, which is the official part, is described by the *U. S. P.* as "about 10 Cm. (4 inches) long, with a very knotty crown, and spreading, tortuous branches, keeled when dry, fleshy and round after having been soaked in water; externally yellowish-gray or brownish-yellow; bark thick, whitish within, enclosing an irregular, porous, yellowish wood; odor slight, but unpleasant; taste sweetish, afterward acrid"—(*U. S. P.*). The knotty crown seems to be formed by the junction of several stems; the keel line extends the whole length of the root. The meditullium, or central portion, possesses but little or no medicinal properties, which reside chiefly in the thick, resinous bark. The recent root has a disagreeable, sickening odor, which diminishes very much by drying. Its taste is somewhat sweetish, succeeded by heat and pungency, irritating the mouth and fauces. It imparts its virtues to water or alcohol; alcohol of specific gravity 0.935 is its best solvent. Too high a temperature renders the acrid principle insoluble in water.

Chemical Composition.—The acrid principle of seneca root was discovered, in 1804, by Gehlen, and named *senegin* by Gmelin. It is the *polygalic acid* of Quevenne (1836). Bolley (1854) showed senegin to be identical with the glucosid *saponin* ($C_{32}H_{54}O_{18}$). W. Procter, Jr. (*Proc. Amer. Pharm. Assoc.*, 1859, p. 297), prepared polygalic acid (senegin) by exhausting the root with diluted alcohol, distilling off the solvent, and precipitating by ether-alcohol. The yield was about 5 per cent. J. Atlass (*Ueber Senegin*, Dissert., 1887) differentiated *polygalic acid*, of acid reaction, from neutral *senegin*, the former being precipitated by both neutral and basic lead acetate, senegin by basic lead acetate only. *Senegin* (*saponin*) is a white powder, acrid, excites sneezing, and is readily soluble in water; the solution is neutral, and froths upon shaking. It is insoluble in absolute cold alcohol, in ether, carbon disulphide, benzin, cold amyl alcohol, etc., very little soluble in chloroform. By boiling with diluted acids, senegin is decomposed into reducing sugar and *sapogenin*. Atlass obtained from the root 1.64 per cent of senegin. *Polygalic acid* closely resembles senegin in all its properties, except those mentioned. Joseph Kain (*Amer. Jour. Pharm.*, 1899, p. 86) found in senega another glucosid, lævo-rotatory, and soluble in absolute alcohol and ether. J. H. Schroeder (*ibid.*, 1896, p. 178) made a proximate analysis of the root, and noted the absence of tannin and starch, and the presence of volatile oil, fixed oil, resins, dextrose, saccharose (5.32 per cent), asparagine (0.62 per cent), ash (6.65 per cent). The volatile oil (0.10 per cent on an average) consists chiefly of methyl salicylate and valerianic ester (L. Reuter, *Archiv der Pharm.*, 1889, p. 313; see *ibid.*, pp. 452, 549.

and 927). Roots seemingly exhausted of the oil by distillation with water, produced additional quantities when slightly acidulated; the salicylic ether is also yielded by false senegas of commerce (E. Kremers and Martha M. James, *Pharm. Review*, 1898, p. 45).

Action, Medical Uses, and Dosage.—In large doses, senega is emetic and cathartic; in ordinary doses, it stimulates most of the secretions, acting especially as a sialagogue, expectorant, diuretic, diaphoretic, and emmenagogue. Its expectorant properties render it very useful in *chronic catarrh*, and protracted and *typhoid pneumonia*, *bronchorrhœa*, *chronic bronchitis*, with profuse secretion, *humoral asthma*, and in the commencing stages of *croup*. In active inflammation its use is contraindicated. In *relaxed sore throat*, it is recommended as a local stimulant; also as a diaphoretico-diuretic in *rheumatism*, and as an emmenagogue in *amenorrhœa*. It is not without effect upon *squamous skin diseases*, and its action in this direction should be studied. Dose of the powdered root, from 5 to 20 grains; of the infusion or syrup, from ½ to 2 fluid ounces. The extract prepared from an infusion of the root, obtained by percolation, and evaporated to the proper consistence by means of a water-bath, may be given in doses of from 1 to 4 grains; specific senega, 1 to 20 drops. Polygalic acid may be given for the same purposes as the root, in doses of from ¼ to ½ grain. It is best taken in hot, sweetened water.

Specific Indications and Uses.—Relaxation of the respiratory mucous membranes and of the skin; cough deep and hoarse, with excessive secretion, mucous rales, nausea, and sometimes vomiting; last stage of typhoid pneumonia, bronchorrhœa.

Related Species and Substitutes.—*Polygala rubella*, Willdenow, *Bitter polygala*, *Bitter milkwort*. This is the *Polygala polygama* of Walter. It is an indigenous herb, with a perennial, branched, and somewhat fusiform root. Stems simple, crowded, many from the same root, angular, smooth, and erect, from 6 to 12 feet high. This plant inhabits fields and pastures from Canada to Florida, being common to dry, sandy, or gravelly soils, and bearing handsome rose-purple flowers in July. The whole plant is used. It is inodorous, with a persistent and powerfully bitter taste, which is imparted to water or alcohol. It has not been analyzed, though its active constituent is probably similar to senegin. The *Polygala amara*, Linné (*Herba polygalæ*), and the *Polygala paucifolia*, or Fringed polygala, possess similar properties, and may be employed as substitutes. The root of the latter has a pleasant, spicy flavor, very similar to that of gaultheria. In doses of from 3 to 10 grains, bitter polygala is an excellent bitter tonic; from 10 to 30 grains act upon the bowels, and cause slight diaphoresis. An infusion has been found beneficial as a tonic in *debility of the digestive organs*. It may be used in all cases where a bitter tonic is indicated (Bigelow).

Polygala Nuttallii, Torrey and Gray, *Ground centaury*.—This plant, called *Nuttall's polygala*, the *Polygala Nuttallii* of Torrey and Gray, and the *Polygala fastigiata*, or *P. sanguinea* of Nuttall, is an annual plant, with erect, often branched-fastigiate stems, from 6 to 12 inches in height; sometimes 15 or more stems will grow from one root, and on the root will be observed something resembling a nearly developed flower. This plant grows in pine barrens and dry, sandy soils, from Massachusetts to New Jersey, and southward near the coast, flowering from July to October (G.). The whole plant is used. It yields its virtues to water or alcohol. The *P. Nuttallii* and the *P. fastigiata* are described by botanists as different species, but they closely resemble each other, and possess the same properties. Tonic, alterative, diuretic, and antifuruncular. It has been used as a domestic medicine on Long Island, N. Y., where it has the reputation of being almost infallible as a remedy in *fever* and *ague*. Two or 3 drachms of the plant made into a strong decoction will act as a purgative. It is much used, also, as an alterative in *boils*, *cutaneous eruptions*, and *especially in erysipelas*. I have found this plant decidedly efficient in *erysipelas* and *boils*, and would recommend it to the profession as a valuable remedial agent, whose powers are not yet fully understood (J. King).

The following species of Polygala have been employed: *Polygala scoparia*, Kunth, Mexico; *P. vulgaris*, Linné, Europe; *P. major*, Jacquin, southeastern Europe (*Radix polygalæ hungaricæ*); *P. venenosa*, Jacquin, Java (reputed toxic); *P. Serpentaria*, Ecklon and Zeyher, south Africa; and *P. butyracea*, Africa. The seeds of the latter yield a fat eaten by the native Africans. The *P. amara*, Linné, of Europe, yields a volatile solid oil, wax, tannin, pectin, and *polygalamarin*, a very bitter, crystalline principle, which causes water to foam when shaken with it (Reinsch, 1839).

Related to these are *Monnina polystachya*, Ruiz et Pavon (Peru). Used in metal polishing as a soap, and as a remedy for *diarrhœa*. The bark of the root yields *saponin*. *Soulamea amara*, Lamarck (Molucca Isles), an antiperiodic bitter.

Polygala sanguinea, Linné, *Caducous polygala*.—New Jersey to Florida. Possesses similar properties to senega, and may be used as a substitute.

Polygala Boykinii, Nuttall.—Growing in Georgia and southern Tennessee. Its root is smaller than that of senega, is without keel, and has a uniform bark and cylindrical, woody column. (See its microscopical and chemical examination, by G. Goebel, *Amer. Jour. Pharm.*, 1881, who found it to yield 3 per cent of senegin. Prof. Maisch, who received a specimen from Dr. Gunn, of Alabama, thought it to be the plant which yielded *False* or *White senega*, that had been on the market since about 1875, but decided, in 1889 (*Amer. Jour. Pharm.*, p. 449; and 1892, pp. 181 and 553), that this was derived from *Polygala alba*, Nuttall, which grows in Louisiana, Texas, New Mexico, Arizona, Arkansas, Kansas, Nebraska, and Dakota.

NORTHERN SENEGA.—According to J. U. and C. G. Lloyd (*Amer. Jour. Pharm.*, 1881, p. 481), this comes from Minnesota and Wisconsin, and is believed to be derived from a species intermediate between *Polygala Senega* and *P. latifolia*. It furnishes a larger root than the official drug. The crown is sometimes 2 or 3 inches broad, and the upper portion of the root nearly an inch in thickness. It is more fleshy, but less contorted than senega, and the branches do not so distinctly exhibit a keel.

Concerning a *Northern Senega*, collected in Minnesota, see Prof. L. E. Sayre (*Amer. Jour. Pharm.*, 1892, p. 113), and Prof. J. M. Maisch (*ibid.*, p. 182). Prof. Sayre reports it to contain 3.5 per cent of senegin and much methyl salicylate.

Admixtures.—Certain roots have been accidentally mixed with senega. Among these are ginseng, valerian, cypripedium, and the roots of *Cynanchum Vincetoxicum*, Persoon; *Ionidium Ipecacuanha*, Ventenat; and *Gillenia trifoliata*, Moench.

SENNA (U. S. P.)—SENNA.

"The leaflets of *Cassia acutifolia*, Delile (Alexandria Senna), and of *Cassia angustifolia*, Vahl (India Senna)"—(*U. S. P.*).

Nat. Ord.—Leguminosæ.

ILLUSTRATION: Bentley and Trimen *Med. Plants*, 89, 90, and 91.

Botanical Source and History.—There are several species of the cassia plant, which are supposed to furnish *Senna*, as the *C. acutifolia*, *C. obovata*, *C. angustifolia*, *C. lanceolata* of Forskal, and *C. æthiopica* of Guibourt, etc.

Cassia acutifolia, Delile (*C. lanceolata*, De Candolle; *C. senna*, Linné; *C. lenitiva*, Bischoff; *C. orientalis*, Persoon; *Senna acutifolia*, Batka).

A perennial shrub, growing from 2 to 10 feet high; stem erect and smooth. The leaves are alternate, narrow, and equally pinnated; leaflets in pairs, from 4 to 8 on each leaf, ovate, nearly sessile, smooth above, rather downy beneath, with the veins turning inward, forming a flexuose intramarginal line; petioles without glands; stipules softly spinescent, semihastate, spreading, and minute. The flowers are bright yellow, in erect, stalked, axillary and terminal racemes, and rather longer than the leaves; the pedicels are without bracts. Sepals linear, and obtuse. Stamens 10, the 5 lowest small and sterile, the next 2 large, curved, and perfect, the 3 uppermost minute and gland-like. The ovaries are linear, downy, and falcate, with a smooth recurved style. The fruit consists of legumes or pods, which are pendulous, oblong, flat, membranous, about 1 inch long, ½ inch broad, quite straight, tapering abruptly to the base, and rounded at the apex; the seeds are many, ash-colored, and cordate (L). It grows in Nubia and upper Egypt, Kordofan, Sennaar, and yields most of the commercial *Alexandria senna* consumed in this country.

Cassia angustifolia, Vahl (*C. elongata*, Lemaire; *C. acutifolia*, Nees; *C. lanceolata*, Wight et Arnott; *C. medicinalis*, Bischoff; *C. medica*, Forskal; *Senna angustifolia*, Batka; *S. officinalis*, Roxburgh).

Cassia angustifolia, although an annual, may with attention be kept alive beyond the year, and made to assume a suffruticose character. It differs from *C. acutifolia* in having its leaflets lanceolate instead of ovate, and the legumes longer and not so round. Its seeds are deep-brown. It grows in northern and central India, Arabia, and in the Somali country, and is being cultivated from African seeds in Tinnevelly, near the southernmost point of India. It furnishes the *India senna*.

Cassia obovata, Calladon (*C. Senna*, Forskal; *C. obtusata*, Hayne; *C. obtusa*, Wallich; *Senna obovata*, Batka). A perennial herbaceous plant, smaller than the preceding, being about 18 inches high, with an erect or procumbent, smooth stem, downy at the base. Leaves alternate, equally pinnate, smooth, with no gland upon the petiole; leaflets in 4 to 6 pairs, opposite, obovate, rounded, mucronate at the apex, unequal at the base, the uppermost gradually the largest; stipules narrowly triangular, rigid, acute, spreading, and persistent. The flowers are pale-yellow, on erect, rather lax, axillary, stalked racemes. The legumes are oblong, falcate, membranous, smooth, rounded at each end, with an elevated ridge upon the valves over each side, so as to have an equally interrupted ridge along the middle, toward which the veins of each suture are directed nearly at right angles;

the seeds, 6 to 8 in number, are cordate (L.). This species grows in the high, dry, uncultivated lands of Mysore, Egypt, Nubia, desert of Suez, central Africa, as far west as Senegambia, and is cultivated in many parts of southern Europe. It furnishes an inferior senna, known as the *Italian* or *Aleppo*, rarely to be found in the market. It is called in Egypt *Senna baladi* or *Wild senna*.

Cassia Sophera, Linné (*C. lanceolata*, Forskal), resembles the above, having, however, never more than 4 or 5 pairs of leaflets, oblong, and either acute or obtuse, not at all ovate or lanceolate, and perfectly free from downiness even when young; the petioles have constantly a small, round, brown gland a little above the base. The pods are erect, oblong, tapering to the base, obtuse, turgid, mucronate, and rather falcate, especially when young, at which time they are sparingly covered with coarse, scattered hairs. It grows in Arabia, and was considered by Forskal as the true *Mecca senna* (L.).

Description.—The two principal commercial varieties of senna used in this country are *Alexandrian* or *Egyptian* and the *Indian* or *Tinnevelly senna*.

ALEXANDRIA SENNA is collected from Senaar, Nubia, and upper Egypt, partly also from tropical Africa, near Timbuctoo, and forwarded to Alexandria and Cairo for the European markets. The leaves are gathered by cutting the branches in autumn, commencing in September, exposing them to the sun and atmosphere until they are quite dry, when the branches are removed by threshing, the leaves placed in sacks, and sent to the places of export. A preliminary crop is harvested in April. As received in this country, Alexandria senna is generally in bales and barrels, and is considered the finest and most valuable variety; the best and most esteemed is that which contains the least quantity of cynanchum leaves, senna leaf-stalks and pods, where the entire-lanceolate leaves are numerous, and where the odor and taste is strong and pure. It has a peculiar but not disagreeable odor, with an unpleasant, nauseous, mucilaginous, and sweetish taste, with hardly any perceptible bitterness, unless it be admixed with the leaves of the *Argel* (*Solenostemma Argel*, Hayne, or *Cynanchum oleæfolium*), which impart bitterness to the powder or infusion, and which is the most important impurity to remove. They may be recognized by having no visible lateral nerves on their under-surface; by being longer, thicker, and firmer than senna leaves, and by the greater regularity of their base.

When conforming to the *U. S. P.* standard "*Alexandria senna* consists of leaflets about 25 Mm. (1 inch) long and 10 Mm. (⅜ inch) broad, lanceolate, or lance-oval, subcoriaceous, brittle, rather pointed, unequally oblique at the base, entire, grayish-green, somewhat pubescent, of a peculiar odor, and a nauseous, bitter taste. It should be free from stalks, and from argel leaves (the leaves of *Solenostemma Argel*, Hayne; *Nat. Ord.*—Asclepiadeæ), which are frequently present; these leaves are thicker, 1-veined, wrinkled, glaucous, and even at the base"—(*U. S. P.*). The *German Pharmacopœia* allows the presence of argel leaves. *Garbled Alexandria senna* is a selected kind, free from stalks, and sometimes free from argel leaves.

INDIA SENNA is of two kinds, the *Bombay*, or *East Indian*, and the *Tinnevelly*. The first is usually imported from Bombay, though it comes from Mocha and other parts of the Red sea (*Mecca* or *Arabian senna* is frequently alluded to as *Bombay senna*); the Tinnevelly is the cultivated kind and is esteemed the best. The *Pharmacopœia* thus describes India senna: "India senna consists of leaflets from 3 to 5 Cm. (1½ to 2 inches) long, and 10 to 15 Mm. (⅜ to ⅝ inch) broad; lanceolate, acute, unequally oblique at the base, entire, thin, yellowish-green or dull green, nearly smooth; odor peculiar, somewhat tea-like; taste mucilaginous, bitter, and nauseous. It should be free from stalks, discolored leaves, and other admixtures"—(*U. S. P.*). Tinnevelly senna is the purest of all sennas, being free from stalks and foreign leaves. (For microscopical examination of Alexandria and India senna, see L. E. Sayre, *Amer. Jour. Pharm.*, 1896, p. 585, and 1897, p. 298, also R. H. Denniston, *Pharm. Review*, 1898, p. 105; and E. Latour, Senna and Its Adulterants, *Pharm. Jour. Trans.*, 1896, p. 481.)

TRIPOLI SENNA somewhat resembles the Alexandrian, but is considered much inferior to it; the leaves are more fragmentary, and the leaf-stalks more numerous. It very seldom contains any adulteration with the argel leaves. It is believed to be derived from *Cassia acutifolia*, while others regard it as the product of *C. æthiopica*, Guibourt, growing in Nubia, Fezzan, and probably in Ethiopia. The active principles of senna are taken up by cold or warm water, glycerin, alcohol, and proof-spirits; boiling destroys its virtues unless it be in vacuo. It should be powdered only as wanted, because the powder absorbs moisture, from which follows moldiness and destruction of its therapeutical virtue.

Chemical Composition.—Senna leaves contain mucilage (about 10 per cent), calcium oxalate and acetate (12 per cent), and other salts yielding 9 to 12 per cent of ash; a non-purgative bitter resin, soluble in alcohol and ether (Rau, *Amer. Jour. Pharm.*, 1866, p. 193), yellow coloring matter identified by Keussler (*Jahresb. der Pharm.*, 1878, p. 199) as *chrysophanic acid* and *emodin:* the sugar *catharto-mannit* (Kubly and Dragendorff, 1865), which is dextro-rotatory, non-reducing and non-fermentable, having the formula, $C_6H_7(OH)_5$ (*sennit* of A. Seidel, *Amer. Jour. Pharm.*, 1885, p. 557). The cathartic principle of senna leaves is a glucosid and was first obtained in a comparatively pure state by Kubly and Dragendorff (Wittstein's *Vierteljahrsschrift*, 1867, p. 96) and named by them *cathartic acid.* It is an amorphous, black, solid mass, almost insoluble in water and strong alcohol, insoluble in ether and chloroform, soluble in warm alcohol of 40 to 60 per cent, and readily soluble with dark-brown color in alkalies and alkali carbonates; from this solution it is precipitated in brown flakes by acids. Boiling with diluted mineral acids decomposes it into sugar and *cathartogenic acid.* It loses its purgative action by heat and prolonged exposure to air. It exists in the leaves in the form of soluble calcium and magnesium salts. Kubly and Dragendorff prepare cathartic acid by evaporating *in vacuo* an aqueous infusion of senna leaves to a thick syrup, adding an equal bulk of strong alcohol which precipitates inorganic salts and gum, evaporating and precipitating the filtrate with excess of strong alcohol. The precipitate is dissolved in water, and the cathartic acid liberated by the addition of hydrochloric acid. The precipitate is purified by washing with absolute alcohol and ether. Mr. O. C. Dilly (*Amer. Druggist*, 1893, p. 13) obtained by this method 0.9 per cent of cathartic acid from Alexandria, and 0.6 per cent from Tinnevelly senna. (For other methods see R. Stockman, *Amer. Jour. Pharm.*, 1885, p. 256; and A. Gentz, *ibid.*, 1893, p. 334.) A. Gentz obtained a yield of about 0.75 per cent (also see *Rheum* and *Frangula*). Senna pods are now sold in the London market, and are stated to be richer in the cathartic principle than the leaves, and to contain none of the griping resin of the latter (E. F. Salmon, *Amer. Jour. Pharm.*, 1889, p. 581). C. Symes (*ibid.*, 1890, p. 46) found 0.8 per cent of pure cathartic acid.

Action, Medical Uses, and Dosage.—Senna is a certain, manageable, and convenient cathartic, very useful in all forms of *febrile diseases* in which a laxative action is desired, particularly in the forming stage of *bilious and other fevers*, especially in children, and in other diseases where a severe impression on the bowels is not desired. Constipation does not follow its employment. It is also efficient in *flatulent* and *bilious colics.* Its influence is chiefly exerted on the small intestines, augmenting their mucous secretions, exciting increased peristaltic motion, and producing loose, yellowish-brown evacuations. A nursing infant may be purged by the milk of the mother who has taken senna, and so susceptible are some persons to its action, that its odor is said to induce a cathartic action. It does not act as a sedative, as is the case with some other cathartics, nor as a refrigerant; but has a slight stimulating influence, insufficient, however, to contraindicate its use in case of general excitement or reaction. Besides the nauseating taste of senna, it is apt to cause sickness at stomach, and very few persons can use it alone, without experiencing more or less griping pains and flatulence. The addition of cloves, ginger, cinnamon, or other aromatics, are excellent correctives of these unpleasant effects. A teaspoonful of cream of tartar to a teacupful of the decoction or infusion of senna, is a mild and pleasant cathartic, particularly suited for females, where it may be required soon after delivery. The addition of neutral laxative salts, as phosphate of sodium, Epsom, or Rochelle salts, is another mode, adopted by a certain class of practitioners, of preventing the tormina, and, at the same time, increasing the activity of the infusion of senna. These are, however, rarely used by Eclectics. Saccharine and aromatic substances are also combined for this purpose, as sugar, manna, aromatic seeds, electuary of senna, etc. The purgative effect of senna is much increased by the addition of the pure bitters; the decoction of guaiacum is said to answer a similar purpose. Senna is contraindicated in an inflammatory condition of the alimentary canal, or even irritation of those parts, general debility, hemorrhoids, prolapsus ani, etc. The dose, in powder, is from 30 to 50 grains; in tincture, from ½ to 2 fluid ounces; specific senna, 1 to 60 drops; electuary, 2 drachms; and of the infusion, which is the most usual mode of administration, from 2 to 4 fluid ounces. But, according to Mr. T. B. Groves, the tincture of senna is without action; the decoction is of less value than the infusion, and the infusion less than maceration; the solution by maceration alone purges without gripings, as by this method the larger portion of the cathartic principle is extracted, leaving behind the acrid constituents. Cathartic acid has the same action of senna, purging with griping in doses of 1½ to 3 grains. The seed-pods and leaf-stalks of senna are slower to act than senna, but are freer from griping and nauseating effects than the leaves.

Specific Indications and Uses.—Wind or bilious colics; a laxative for non-inflammatory conditions of the intestinal tract.

Related Species and Adulterants.—(See *Pharm. Jour. Trans.*, Vol. II, 1896, p. 481, for description of microscopical characters of true *Senna leaves; Coriaria myrtifolia*, Linné; *Solenostemma Argel*, Heyne; *Vaccinium Vitis-Idæa*, Linné; *Globularia Alypum*, Linné; *Tephrosia appolinea*, De Candolle; and *Cassia marilandica*, Linné.)

Cassia brevipes, De Candolle.—Central America. Apex blunt, with 3 veins running parallel the whole length of the leaf; otherwise they resemble India senna. Destitute of cathartic properties (E. M. Holmes, 1875).

Cassia pubescens, R. Brown.—Oval or ovate leaflets, about an inch long, obtuse and mucronate, soft pubescent on both surfaces, and with ciliated margin. Occasionally mixed with Arabian senna.

Solenostemma Argel, Hayne (*Cynanchum Argel*, Delile; *Cynanchum oleæfolium*, Nectoux).—This Asclepiad inhabits upper Egypt, and constitutes the chief adulterant of Alexandria senna, which, in shape, size, and color, the leaves resemble. They are, however, pubescent, more leathery, wrinkled, bitter to the taste, and have an even base, and indistinct, lateral veins. The flower-buds, blossoms, and pyriform fruit, containing pubescent seeds, are often present also.

Tephrosia appolinea De Candolle (*Galega apollinea*, Delile) (*Nat. Ord.*—Leguminosæ).—Southern Europe. An occasional admixture in senna. Base uneven, apex emarginate, and general shape obovate.

Colutea arborescens, Linné (*Nat. Ord.*—Leguminosæ), *Bladder senna*.—Southern and eastern Europe. The leaflets of this shrub, which bears yellow flowers and greenish, vesicular pods, containing numerous blackish-brown, roundish seeds, have been substituted for and occasionally used to adulterate senna. They are, however, much feebler in cathartic power. The thin, smooth leaflets (borne in pairs of 4 or 5) are oval, elliptic, or obovate, slightly emarginate, deep-green above, pale or grayish-green beneath, the lower surface being covered with an appressed pubescence. The odor is not pronounced, but the taste is bitter and nauseous.

Coriaria myrtifolia, Linné, has poisonous leaves (containing *coriamyrtin*). They are sometimes used as an adulterant of senna. Can be recognized by the tests for tannin (gelatin, mercuric chloride, tartar emetic, ferric chloride) (Charles Heisch, *Amer. Jour. Pharm.*, 1888, p. 459).

Globularia Alypum, Linné (*Nat. Ord.*—Globulariaceæ).—Southern Europe, in the region of the Mediterranean. This plant, as well as *Globularia vulgaris*, contains an amorphous, bitter glucosid, *globularin* (Walz), and a peculiar tannin. *Globularin* ($C_{15}H_{20}O_8$) is soluble in water, alcohol, chloroform, and ether. Mineral acids split it into glucose and *globularetin* (C_9H_6O) (Heckel and Schlagdenhauffen, 1883). *Globularetin*, when heated with alkalies, yields cinnamic acid, which is also a constituent of the leaves. The leaves are used as a substitute for senna, and are mildly purgative. They are ovate-oblong, entire, or nearly so, almost sessile, exhibit fine granules, and are bluish-green beneath.

Caseria esculenta.—India. Plant said to yield an acid closely analogous to cathartic acid. Praised in *hepatic torpor*.

Allamanda cathartica.—A Porto Rico shrub, the extract of the bark of which, in doses of from 1 to 2 grains, is reputed a fine hydragogue cathartic.

Related Preparation.—SPECIES LAXANTES (N. F.), *Laxative species, St. Germain tea* (*Ger. Pharm.*). "Senna, cut, 16 parts; elder flowers, 10 parts; fennel, bruised, 5 parts; anise, bruised, 5 parts; potassium bitartrate, in fine powder, 4 parts. Moisten the senna with a small quantity of water, then sprinkle over it, as uniformly as possible, the potassium bitartrate. When it has become dry, mix it lightly and uniformly with the other ingredients"—(*Nat. Form.*, 1st ed.).

SERENOA.—SAW PALMETTO.

The fruit of *Serenoa serrulata*, Bentham and Hooker (*Sabal serrulata*, R. & S.; *Chamærops serrulata*, Pursh).

Nat. Ord.—Palmæ.

Botanical Source.—This southern palm has a creeping and branching stem, attaining a length of from 6 to 10 feet. The leaves, which are from 2 to 4 feet high, have a circular, fan-shaped outline, are bright-green, and shorter than the slender, somewhat spiny-edged, plano-convex petiole. They have from 15 to 30 divisions, which are erect and slightly cleft at the apices, and are without the thready filaments in the sinuses. The plant bears a densely woolly spadix, shorter than the leaves. The petals are almost united, the style slender, and the fruit is an ovoid-oblong, sweetish drupe.

History and Description.—This well-known palm is plentiful along the Atlantic shores, from Florida to South Carolina, where it forms the "palmetto scrub" of the coast. Parts of the plant have been employed in various economic ways, such as the thatching of huts, making of mattresses, straw hats, and paper. The fruit, though sweet and edible, is not regarded as particularly palatable. It is the medicinal part. Animals show a partiality for it, and are said to become fat and sleek when feeding upon the berries. (For an extended description, see monograph on *Saw Palmetto*, by the late Dr. Edwin M. Hale, of Chicago.) The dried fruit is a 1-seeded, blackish-brown drupe, of an ovoid-oblong form, from ½ to 1 inch long, and about ¼ to ½ inch broad. The exterior has a few wrinkles, with rather large, smooth, flat areas. A single panicle may yield from 6 to 8 pounds of the berries.

Chemical Composition.—According to the researches of P. L. Sherman and C. H. Briggs (*Pharm. Archives*, June, 1899), the pulp of the fruit yields, by pressure, 1.5 per cent of an aromatic oil (*Saw palmetto oil*), of a characteristic fruity odor. Fresh saw palmetto berries mixed with water and distilled by us, yielded a pungent, greenish oil. A greenish oil separates from the fluid extract of the fresh berries. Both oils have the characteristic cheesy odor of the fresh berries. This reminds us of œnanthic ether. The nuts of the fruit amount to 17.5 per cent, and contain about 12 per cent of a fatty oil (*oil of nuts*), which is chemically different from that derived from the pulp. *Saw palmetto oil* is brownish-yellow to dark-red, of acid reaction, and slightly volatile with steam. It can be distilled in a vacuum almost entirely without decomposition. It is soluble in alcohol, ether, chloroform, and benzene, insoluble in water and acids, partly soluble in diluted aqueous potash. The oil consisted of about 63 per cent of free acids (*caproic acid*, $C_6H_{12}O_2$; very little *caprylic*, $C_8H_{16}O_2$; some *capric*, $C_{10}H_{20}O_2$; much *lauric*, $C_{12}H_{24}O_2$; and *palmitic acids*, $C_{16}H_{32}O_2$; and some *oleic acid*, $C_{18}H_{34}O_2$), and 37 per cent of ethyl- but no glyceryl-esters of these acids. The oil of the nuts is a thick liquid of a greenish color, only slightly soluble in alcohol, insoluble in water, soluble in benzene, chloroform, and ether. The specimen examined contained only 2.3 per cent of free acids, the rest were glycerides of *caprylic*, *capric*, *lauric*, *palmitic*, *stearic*, and *oleic acids*. The fruit contains large amounts of sugar, but neither a glucosid nor an alkaloid.

Action, Medical Uses, and Dosage.—Saw palmetto appears, from clinical reports, to be a nutritive tonic. It is also an expectorant, and controls irritation of mucous tissues. It has proved useful in *irritative cough*, *chronic bronchial coughs*, *whooping-cough*, *laryngitis*, acute and chronic, *acute catarrh*, *asthma*, *tubercular laryngitis*, and in the *cough of phthisis pulmonalis*. Upon the digestive organs it acts kindly, improving the appetite, digestion, and assimilation. However, its most pronounced effects appear to be those exerted upon the urino-genital tracts of both male and female, and upon all the organs concerned in reproduction. It is said to enlarge *wasted organs*, as the breasts, ovaries, and testicles, while the paradoxical claim is also made that it reduces *hypertrophy of the prostate*. Possibly this may be explained by claiming that it tends toward the production of a normal condition, reducing parts when unhealthily enlarged, and increasing them when atrophied. At any rate, it has been lauded as the "old man's friend," giving relief from the many annoyances commonly attributed to enlarged prostate. May its results not be due to its control over urethral irritation, and thereby reducing swollen conditions not in reality amounting to hypertrophy? Besides this, it increases the tonus of the bladder, allowing a better contraction and more perfect expulsion of the contents of that viscus. Thus it overcomes the tenesmic pain so dreaded by the sufferer. We would rather regard it a remedy for *prostatic irritation* and *relaxation of tissue* than for a hypertrophied prostate. It is said to relieve aching, dull, throbbing pain in the prostatic portion of the urethra, with mucoid or prostatic discharge. It relieves the irritation following a badly-treated *gonorrhœa. Orchitis, ovaritis, orchialgia, ovaralgia*, and *epidymitis* have been asserted cured with it. It is reputed to restore sexual activity after exhaustive excesses, and, even in the feeble woman, strengthens the sexual appetite. Long-continued use of it is said to slowly and surely cause the *mammæ to enlarge.* Its reputed power to reduce *uterine hypertrophy* is probably due to its power over relaxed tissues, the organ being not in reality hypertrophied, but large, flabby, and actively leucorrhœal. The remedy needs a more careful and extended study. The dose of the fluid extract is from 1 to 60 drops; of specific saw palmetto, 1 to 60 drops.

Specific Indications and Uses.—Relaxation of parts, with copious catarrhal discharges; lack of development, or wasting away of testicles, ovaries, or mammæ; prostatic irritation, with painful micturition, and dribbling of urine, particularly in the aged; tenderness of the glands, and other parts concerned in reproduction.

SERPENTARIA (U. S. P.)—SERPENTARIA.

The rhizome and roots of *Aristolochia Serpentaria*, Linné, and of *Aristolochia reticulata*, Nuttall"—(*U. S. P.*).

Nat. Ord.—Aristolochiaceæ.

Common Names: (1) *Virginia snakeroot*, (2) *Red River* or *Texas snakeroot.*

Illustration: Bentley and Trimen, *Med. Plants*, 246.

Botanical Source.—*Aristolochia Serpentaria*, also called Snakeroot and Snakeweed, is a perennial, herbaceous plant, with an extremely fibrous, knotty, brown root, sending up numerous stems. The stems rise singly or severally from the same root, are erect, simple or branched, jointed, flexuous, cylindrical, often with a reddish tinge, and most commonly under a foot high. The leaves are alternate, on short petioles, oblong, entire, acuminate, heart-shaped, at base 3-nerved, and more or less downy on the surface, having a slightly yellowish tint. The flowers grow close to the ground, curve downward, have a stiff, leathery texture, and a dull brownish-purple color. The peduncle, which supports them, has one or more bracts, and gradually enlarges into a furrowed obovate ovary. The calyx, like others in this singular genus, consists of a long, contorted tube, bent in the form of the letter S, swelling at its two extremities, having its throat surrounded by an elevated edge or brim, and its border expanded into a broad, irregular margin, forming an under and upper lip, which are closed in a triangular manner in the bud, and is dull-purplish or red. Corolla none. Anthers 12 in number, growing in pairs to the sides of the fleshy style, which is situated in the bottom of the calyx, and covered by a firm, spreading, convoluted stigma, which extends over the anthers. Capsule obovate, 6-angled, and 6-celled, with numerous small, flat seeds (B.—L.).

Fig. 228.

Aristolochia Serpentaria.

Aristolochia reticulata, or Red River snakeroot, has a very flexuous stem, oval, cordate, clasping, subsessile leaves, thickish, strongly reticulated, with the lobes decussating. The plant is not smooth, but hirsute. The flowers are small, radical, densely pubescent, and of a purplish hue.

Description.—Several species of Aristolochia have been confounded with the above, but as they are nearly identical in medicinal properties, the confusion is probably of but little consequence. These species are the *A. hirsuta*, Muhlenberg, growing in the southern states, and strongly resembling the above; the *A. hastata* of Nuttall, or *A. sagittaria* of Muhlenberg, growing in the south; as well as the *A. tomentosa*, a tall climbing species of Louisiana. *A. reticulata*, of southwestern growth, is now official.

Aristolochia Serpentaria is found in rich woods, hedges, and thickets, from Connecticut to Illinois, and southward to Louisiana, being more common near the Alleghanies, and flowering from April to July. In commerce, the dried root consists of a short, knotty, premorse rootstock, or head, with very numerous radicles, 3 inches or more in length, filiform, flexuous, interlaced, and brittle. The *U. S. P.* gives the following description: "The rhizome is about 25 Mm. (1 inch) long, thin, bent; on the upper side with approximate, short stem-bases; on the lower side with numerous, thin, branching roots, about 10 Cm. (4 inches) long; dull yellowish-brown, internally whitish; the wood-rays of the rhizome longest on the lower side; odor aromatic, camphoraceous; taste warm, bitterish, and camphoraceous. The roots of *Aristolochia reticulata* are coarser, longer, and less interlaced than those of *Aristolochia Serpentaria*"—(*U. S. P.*). Pinkroot and seneca are sometimes found mixed with the A. Serpentaria, as well as some other roots, especially golden seal (as much as 10 per cent, see Prof. Patch, in Merck's *Report*, 1896, p. 403), cypripedium, and ginseng roots. These adulterations may be detected by the difference in the appearance of the roots, and of the leaves and stems when present, as well as by the absence of the peculiar serpentaria flavor. The root of *Polemonium reptans* has also been substituted for serpentaria (*Amer. Jour. Pharm.*, 1887, p. 374). The active principles of the root are extracted by water, alcohol, or proof-spirit. The tincture is bright-green, and is rendered turbid by water.

Chemical Composition.—Mr. J. A. Ferguson (*Amer. Jour. Pharm.*, 1887, p. 481) found the rhizome and roots of *Aristolochia reticulata* to contain volatile oil (1 per cent), resin, soluble in petroleum ether (3.2 per cent), resin, soluble in ether (1.9 per cent), furthermore tannin, gum, starch (6.48 per cent), dextrin, sugar, malic acid, calcium oxalate, etc., and a crystallizable alkaloid, which he named *aristolochine*, perhaps the *aristolochin* of Chevallier and Feneulle. It is very bitter, soluble in water, alcohol, ether, chloroform, and benzol. The volatile oil of this species was investigated by Joseph C. Peacock, *ibid.*, 1891, pp. 257–264), who found it to contain a *terpene* ($C_{10}H_{16}$), boiling at 175° C. (314.6° F.), and 40 per cent of solid, camphor-like *borneol* ($C_{10}H_{18}O$), which exists in the oil, partly free, partly in the form of an ester. Spica (*Jahresb. der Pharm.*, 1887, p. 45) previously established the presence of borneol in the oil from *Aristolochia Serpentaria*, the lower fractions of which have a valerian-like odor.

Action, Medical Uses, and Dosage.—Virginia snakeroot, in small doses, promotes the appetite and gives tone to the organs of digestion, and is very useful, especially in the form of vinous tincture, in cases of enfeebled stomach following exhausting diseases. In full doses, it stimulates the system, producing increased arterial action, free diaphoresis, and frequently diuresis. In large doses, it causes an uneasy sensation at the stomach, with sickness, vomiting, and purging, headache, drowsiness, and disturbed sleep, and, in warm infusion, it produces diaphoresis, and is beneficial in *adynamic eruptive fevers*, where the eruption is tardy, or has receded. In the *typhoid stage of febrile diseases*, where strong stimulants, as brandy, etc., can not be borne, it will be found very available. In *periodic fevers*, it may be advantageously used with or without its combination with quinine. It is a good remedy when the renal function is suppressed by colds, and in other troubles resulting from the same cause, with a tendency to locate in the viscera. An infusion of it forms an excellent gargle in *putrid sore throat*, and in *atonic throat disorders*, with a tendency to destruction of tissues. *Dyspepsia* has been benefited by it in tonic doses, and *amenorrhœa* has been cured, especially when caused by cold. When its use is too long continued, it occasions sickness at stomach, emesis, gripings, and tenesmus. Long boiling impairs its virtues. A cold infusion is useful in convalescence from acute diseases. Atonic and torpid conditions are those in which serpentaria is valuable, while severe inflammations and high fevers contraindicate its use. Some cases of *colliquative sweating* are controlled by it; such cases are those requiring a cutaneous stimulant. Dose of the powder, as a tonic, 3 to 6 grains; as a stimulant, 20 to 30 grains; of the infusion, 1 or 2 fluid ounces; of the tincture, 1 or 2 fluid drachms; specific serpentaria, 1 to 30 drops.

Specific Indications and Uses.—A cutaneous stimulant, increasing secretion; sensation of dragging and weight in the loins, with scanty renal secretion, or urine containing triple phosphates; renal and other visceral disorders, the direct result of taking cold; fullness in the chest, with difficult respiration; malignant sore throat, with tendency to destruction of tissues; torpid and atonic conditions only.

Related Species.—A number of species of Aristolochia have been used in medicine. They all have similar properties, being stimulant, tonic, and emmenagogue. Of the European species there are the *A. longa*, *A. clematitis*, *A. pistolochia*, and *A. rotunda*. *Aristolochin* (*aristolochic acid*, Hesse) is the active principle of the seeds of *A. clematitis* and the roots of *A. rotunda* and

A. longa (J. Pohl, *Amer. Jour. Pharm.*, 1892, p. 82). It is a yellow crystalline acid, soluble in alcohol, ether, and chloroform, insoluble in petroleum ether, little soluble in warm water. Another plant having the common properties of this genus, is the *jarra* (*jarrhina*) or *milhomen* of Brazil—the *A. cymbifera* of Martius (see *Jahresb. der Pharm.*, 1887, p. 44). The *Yerba del India*, of Texas and Mexico (*A. fœtida*), is applied to *ulcers*. *A. argentina*, of the Argentine Republic, a diaphoretic and diuretic, and *A. indica*, of the East Indies, both contain alkaloids. In the former species, O. Hesse found the alkaloid *aristolochine*, *aristinic*, *aristidinic* and *aristolic acids* (*Amer. Jour. Pharm.*, 1896, p. 141; also see *Pharm. Jour. Trans.*, Vol. XXII, 1891, pp. 245 and 551).

SESAMUM.—BENNE.

The leaves and seed of *Sesamum indicum*, Linné.

Nat. Ord.—Pedaliaceæ.

Common Names: *Benne*, *Sesame leaves*, *Sesame seeds*.

Illustration: Bentley and Trimen, *Med. Plants*, 198.

Botanical Source.—Sesamum indicum is an annual plant, with an erect, pubescent, branching stem, 2 to 4 feet in height. The leaves are ovate-lanceolate, or oblong; the lower ones trilobed and sometimes ternate; the upper undivided, irregularly serrate and pointed. The flowers are of a pale-purple color, axillary, and borne on short glandular pedicels. The fruit is an oblong, mucronate, pubescent capsule, containing numerous small, oval, yellowish seeds (W.—Wi.).

History and Description.—There were formerly thought to be two species of this genus, the *S. indicum*, and the *S. orientale*, both of which were originally from India, and are now much cultivated in several parts of Africa, West Indies, and in the southern United States. That growing in the south is the S. indicum, and flowers in August. The latter species is now regarded as identical with the former. The parts used are the leaves and seeds. The seeds are rather small, sulphur-colored, sometimes very dark, and contain a large quantity of a sweetish, odorless oil, of a light-yellow color, mild to the taste, of specific gravity 0.9191, and which may be obtained by expression (see *Oleum Sesami*). It does not readily acquire rancidity, and forms an excellent substitute for olive oil. The negroes of the south make considerable use of the seeds as an article of diet. The leaves are ovate-oblong, narrowed at base, with margin irregularly toothed, or entire, the lower ones often having tridentate lobes or leaflets. They are smoothish, or pubescent, and strongly veined underneath. The fresh leaves contain a large amount of mucilage, which may be procured by macerating them in water and precipitating with alcohol.

Action, Medical Uses, and Dosage.—A fresh leaf or two added to ½ pint of water forms a pleasant, demulcent drink, very useful in *catarrhal affections*, *acute diarrhœa* and *dysentery*, *summer complaint of children*, and *affections of the bladder*, *kidneys*, and *urethra*. It may be drank freely. When the leaves are dried, their mucilage will be best extracted by water at 100° C. (212° F.). The mucilage forms an excellent soothing application in *ophthalmia*, *irritations*, *cutaneous affections*, etc.; but is inferior to slippery elm. The oil may be used topically in *eruptions* of a scaly or bran-like character, or, it may be given internally in the same manner as olive oil to produce a laxative effect. It is stated that the natives of India employ it as an abortive, and to promote the menstrual discharge. It is much used as a perfumed oil for the hair.

SEVUM (U. S. P.)—SUET.

"The internal fat of the abdomen of *Oris Aries*, Linné (*Class*, Mammalia: *Order*, Ruminantia), purified by melting and straining. Suet should be kept in well-closed vessels impervious to fat. It should not be used after it has become rancid"—(*U. S. P.*).

Common Names: *Suet*, *Mutton suet*, *Sheep tallow*.

Preparation, Description, and Chemical Composition.—Prepared suet (*Sevum præparatum*, *Br. Pharm.*), mutton suet or sheep tallow, is the adipose matter of the domestic sheep, *Oris Aries*. For medicinal purposes the kidney fat is melted at a gentle temperature and then strained, in order to separate the membranous portions. It may be rendered still purer by heating it in water at 100° C.

(212° F.). By a special process, the fatty substance in the state in which it is removed from the animal is heated with a small quantity of sulphuric acid of specific gravity 1.3 to 1.45. The acid dissolves the membrane and other impurities present, acquiring a dark color and thick syrupy consistence, while the fat separates in a state of purity.

Prepared suet is somewhat similar in its properties to lard, but is harder and more compact. To meet the demands of the *Pharmacopœia* it should be "a white, solid fat, nearly inodorous, and having a bland taste when fresh, but becoming rancid on prolonged exposure to the air. Insoluble in water or cold alcohol; soluble in 44 parts of boiling alcohol, in about 60 parts of ether, and slowly in 2 parts of benzin. From its solution in the latter, kept in a stoppered flask, it slowly separates in a crystalline form on standing. An alcoholic solution of suet is neutral or has only a slightly acid reaction with litmus paper moistened with alcohol. Suet melts between 45° and 50° C. (113° and 122° F.), and congeals between 37° and 40° C. (98.6° and 104° F.)"—(*U. S. P.*). Suet consists chiefly of stearin and palmitin (70 per cent) and olein (30 per cent), with a trace of *hircin*, which is a liquid oil, probably a mixture of the glycerides of capric and caprylic acids (also see *Adeps*).

Action and Medical Uses.—Suet is nutritive and emollient, but not so easy of digestion as the fat of the pig or ox; yet it may be made into a broth, with or without aromatics, and used in *diarrhœa*, *dysentery*, and *general debility*. It is sometimes used as a dressing to *blisters*, and may be applied to most of the purposes for which lard is used, on account of its superior hardness, and higher melting point. For forming an ointment, it will be found preferable to lard, especially when it is to be applied to several forms of *cutaneous disease*. The addition of benzoic acid, sulphite of sodium, or sweet gum, will prevent its tendency to become rancid and disagreeably odorous.

SILPHIUM.—INDIAN CUP-PLANT.

The root of *Silphium perfoliatum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Cup-plant*, *Indian cup-plant*, *Ragged cup*.

Botanical Source.—This plant has a perennial, horizontal, pitted rhizome, beset with radicles, and a large, smooth, square, herbaceous stem, 4 to 7 feet high, and often branched above. The leaves are opposite, connate-perfoliate, ovate, coarsely toothed, abruptly narrowed into winged petioles at the base, the upper pairs forming a cup-shaped disk with their connate bases; they are from 8 to 14 inches long, by 4 to 7 wide. The flowers are terminal, with 15 or 25 oblong, lanceolate, yellow rays, and a large, dark-colored disk. Heads in a trichotomous cyme, the central one on a long peduncle; the scales ovate, obtuse, and squarrose; the achenia broadly ovate, winged, and emarginate (W.—G.).

History, Description, and Chemical Composition.—This plant is common to the western states, and is found growing in rich bottom or interval lands, bearing numerous yellow flowers in August. The root is the medicinal part. It is large, long, and crooked, and imparts its properties to water or alcohol. It has a persistent, acrid taste. There are several species of *Silphium*, which yield, by incision and exudation, a fine, fragrant, and bitterish gum-like frankincense, of white or amber color, and which is chewed by the Indians to sweeten the breath.

Action, Medical Uses, and Dosage.—Cup-plant is tonic, diaphoretic, and alterative. A strong infusion of the root, made by long steeping, or an extract, is said to be one of the best remedies for the removal of *ague-cake* or *enlarged spleen*. It is also useful in *intermittent* and *remittent fevers*, *internal bruises*, *debility*, *ulcers*, *liver affections*, and as a general alterative restorative. The gum is said to be stimulant and antispasmodic. The dose of the powdered root is 20 grains; tincture (fresh root, ℥viij to alcohol, 76 per cent, Oj), 1 to 20 drops, in water.

Related Species.—*Silphium laciniatum*, Linné (*Silphium gummiferum*), *Compass-plant*, *Polar-plant*, *Compass-weed*, *Rosin-weed*. Western and southwestern United States. This plant, which grows from 5 to 10 feet high, exudes from the stem and leaves transparent or translucent tears of an oleoresin resembling gum mastich, and possessing a pleasant, terebinthinate taste and odor. It consists of volatile oil (20 per cent), acid resin (37 per cent), sugar, wax, and inorganic salts (L. J. Morris, *Amer. Jour. Pharm.*, 1881, pp. 487–491). From the fact that the lower leaves of this plant point directly north and south, when growing in open prairie lands, it has received the name "compass-weed." Rosin-weed is said to be emetic in decoction. It has effected cures in *intermittent fever*, and is beneficial in dry, obstinate *coughs*, *asthmatic affections*, and *pulmonary catarrhal diseases*. Said to cure *heaves* in horses. The resin secreted by this plant is possessed of diuretic properties, increasing the flow of urine, to which it imparts a strong aromatic odor. The root has been used to some extent in *vesical catarrh*, *gonorrhœa*, and *gleet*. It is a remedy for *asthma*, with spasmodic, dry cough, with sense of constriction and dryness in the throat; not useful if there be congestion or profuse secretion. It has been employed as an expectorant in *cough* and other pulmonary difficulties. It has been prepared by cutting it in small pieces, covering each layer with loaf-sugar, and the whole with brandy. After standing for several days, express, strain, and bottle for use. A strong tincture of the fresh plant (℥viii to alcohol, 76 per cent, Oj) may be given in doses of from 1 to 10 drops.

Fig. 229.

Silphium laciniatum.

Silphium terebinthinaceum, Linné, *Prairie burdock*.—Also yields a resinous exudate.

SINAPIS ALBA (U. S. P.)—WHITE MUSTARD.

"The seed of *Brassica alba* (Linné), Hooker filius et Thompson"—(*U. S. P.*) (*Sinapis alba*, Linné; *Leucosinapis alba*, Spach).

Nat. Ord.—Cruciferæ.

Illustration: Bentley and Trimen, *Med. Plants*, 23.

SINAPIS NIGRA (U. S. P.)—BLACK MUSTARD.

"The seed of *Brassica nigra* (Linné), Koch"—(*U. S. P.*) (*Sinapis nigra*, Linné; *Brassica sinapoides*, Roth).

Nat. Ord.—Cruciferæ.

Illustration: Bentley and Trimen, *Med. Plants*, 22.

Botanical Source.—*Sinapis alba* is an annual plant, with a thinly hirsute stem, 2 to 5 feet high. The leaves are smoothish, lyrately pinnate, irregularly dentate, rugged, and pale-green; the lower lobes oblong and deeper; the terminal larger. Flowers large, pale-yellow; petals ovate, with straight claws; sepals linear, green, equal at base, and spreading. The siliques or pods are spreading, hispid, torose at the place of the seeds, nerved, shorter than the compressed, ensiform beak, about 4-seeded. The seeds are globose, large, and pale (W.—L.).

Sinapis nigra is also an annual plant, with a round, smooth, striate, branching stem, 3 to 6 feet high. The lower leaves are large, lyrate, rough, variously lobed, and dentate; the upper linear-lanceolate, smooth, entire, and pendulous; all petiolate. Flowers small, sulphur-yellow; calyx spreading; petals obovate. Pods very numerous, nearly an inch long, bluntly quadrangular, nearly even and smooth, appressed close to the rachis of the raceme, tipped by a small, short, 4-sided style, but wholly destitute of the ensiform beak of the above species. The seeds are numerous, small, globose, blackish-brown, and veined (L.—W.).

Fig. 230.

Brassica nigra.

Description.—These plants are indigenous to Europe, and have been introduced into this country, where they are cultivated for use, and are found growing in old fields and waste places, flowering in June and July. The *U. S. P.* describes *White mustard-seed* as "about 2 Mm. ($\frac{1}{12}$ inch) in diameter, almost globular, with a circular hilum; testa yellowish, finely pitted, hard; embryo oily, with a curved radical, and 2 cotyledons, one folded over the other; free from starch; inodorous; taste pungent and acrid"—(*U. S. P.*). *Black* *mustard-seed* is "about 1 Mm. ($\frac{1}{25}$ inch) in diameter, almost globular, with a circular hilum; testa blackish-brown or grayish brown, finely pitted, hard; embryo oily, with a curved radical, and 2 cotyledons, one folded over the other; free from starch; inodorous when dry, but when triturated with water, of a pungent, penetrating, irritating odor; taste pungent and acrid"—(*U. S. P.*). Both kinds of mustard-seeds are employed in medicine, in the form of flour, and the white seed is likewise used entire. Table mustard is prepared from the white seed, but the finest quality is prepared with the purest flour of both the white and black, in nearly equal quantities. Wheat flour is sometimes added to diminish the pungency, and turmeric has been added to improve the color. The medicinal flour of mustard should be made with the black and white seeds only, without any adulteration.

Chemical Composition.—Both white and black mustard-seeds contain *mucilage* (19 per cent in black mustard-seed), non-drying *fatty oil* (an average of 25 per cent; Hassall [*Pharm. Jour. Trans.*, Vol. IV, 1874, p. 670] found 35.7 per cent); it is light to brown-yellow, and consists of the glycerides of stearic and oleic acids, *erucic* (or *brassic*) *acid* ($C_{22}H_{42}O_2$), which is the principal acid, *behenic* ($C_{22}H_{44}O_2$) and *sinapolic* ($C_{20}H_{38}O_4$) *acids*. In both kinds of seeds much nitrogenous matter is present (26 to 31 per cent; see methods of analysis of black and white mustard by C. H. Piesse and L. Stansell, *Pharm. Jour. Trans.*, Vol. XI, 1880, p. 416). The nitrogenous ferment, *myrosin*, likewise occurs in both kinds of seeds. It is soluble in water, insoluble in alcohol. Starch is absent in ripe mustard-seed, and the ash varies from 4 to 5 per cent. The most important constituents of mustard are the glucosids *sinigrin*, in black, and *sinalbin*, in white mustard-seed, both of complicated, yet analogous, composition.

SINIGRIN (*potassium myronate*, $C_{10}H_{16}NS_2KO_9$, or $C_3H_5N{:}C{:}[S.C_6H_{11}O_5][O.SO_2OK]$, Gadamer) and *myrosin* were first isolated by Bussy (1839), and their behavior further studied by Will and Körner (1863). Dr. J. Gadamer (*Archiv der Pharm.*, 1897, pp. 44–114) obtained a yield of 1.3 per cent. It crystallizes in brilliant-white needles, is soluble in water, yielding a neutral solution of bitter taste. It is very little soluble in cold alcohol, insoluble in ether. In contact with myrosin in aqueous solution, at a temperature not above 70° C. (158° F.), it is readily decomposed into *allyl-mustard oil* (*allyl-isothiocyanide*, or volatile oil of mustard, which see), dextrose, and acid potassium sulphate, according to the equation: $C_{10}H_{16}NS_2KO_9+H_2O=C_3H_5NCS+C_6H_{12}O_6+KHSO_4$. At and above the temperature named, the activity of the myrosin is destroyed.

SINALBIN ($C_{30}H_{42}N_2S_2O_{15}$, Gadamer, 1897), so named and investigated by Will and Laubenheimer (1870), may be obtained from white mustard-seed in the quantity of 2.5 per cent (Gadamer). It crystallizes in nearly colorless prisms, is readily soluble in boiling water, little soluble in alcohol, insoluble in ether. In contact with myrosin and water, sinalbin undergoes decomposition analogous to that of sinigrin—namely, into non-volatile, pungent *sinalbin-mustard-oil* (*para-oxybenzyl-* [or *acrinyl-*] *isothiocyanide*, $C_6H_6[OH].CH_2.NCS$), *dextrose*, and *acid sinapine sulphate*, according to the equation: $C_{30}H_{42}N_2S_2O_{15}+H_2O=C_7H_7O.NCS+C_6H_{12}O_6+C_{16}H_{24}NO_5.HSO_4$.

The basis *sinapine* ($C_{16}H_{25}NO_5$, Gadamer) was ascertained by von Babo and Hirschbrunn (1852) to be the ester of *choline* ($C_5H_{15}NO_2$) and *sinapic acid* ($C_{11}H_{12}O_5$) (see researches regarding the latter, *Archiv der Pharm.*, 1897, pp. 102–114). According to Gadamer, the basis *sinapine* also occurs in black mustard-seed in the form of an acid sulphate, but no sinalbin occurs in the latter kind of seed. Neither does sinigrin occur in white mustard-seed. *Sinapine sulphocyanide* (*rhodanide*) ($C_{16}H_{24}NO_5.SCN$, characterized by the blood-red coloration of rhodanides with ferric chloride) does not occur as such in white mustard-seed, as was believed by von Babo and Hirschbrunn (also see *Oleum Sinapis Volatile*).

The efficiency of commercial mustard-seeds and "mustard farina" depends on the amount of volatile oil that is formed when in prolonged contact (5 to 6 hours, perhaps less) with myrosin and water. This amount is determined by distilling the mixture and determining the volatile oil, in the form of *thiosinamine* (see *Oleum Sinapis Volatile*). Piesse and Stansell thus obtained from commercial black mustard-seed 0.473 per cent, from black farina 1.38 to 1.5 per cent of oil, the higher value in the latter case being due to a concentration of the mustard substance by loss of water. (For further details regarding the analysis of white and black mustard-seeds, see Piesse and Stansell, *loc. cit.*, and A. R. Leeds and E. Everhart, *Amer. Jour. Pharm.*, 1882, p. 404; also see J. U. Lloyd's tests for starch in powdered mustard, *ibid.*, 1898, p. 433.)

Action, Medical Uses, and Dosage.—Mustard is an irritant, stimulant, rubefacient, vesicant, and diuretic. It is used in small quantities, internally, as a condiment and mild but efficient excitant of the organs of digestion. In drachm doses, it acts as an emetic, and will thus be found serviceable in cases of *gastric torpidity*, *poisoning by narcotics*, to stimulate the stomach, and to aid other emetics in fulfilling their indications. In large doses, the volatile oil is poisonous, causing inflammation of the stomach and bowels, and impairing the normal character of the fluids of the system by its absorption. Externally, it quickly excites redness of the skin, and, if too long applied, inflammation, ulceration, and even sloughing; but if removed in time, the redness is succeeded only by induration of the cuticle, and occasionally desquamation. The stinging pain which remains after the removal of the mustard, may be mitigated by sponging the part with cold water, or dropping ether on it. Sinapisms are beneficially applied over the abdomen and spine, in *gastric and enteric inflammations*, and over the epigastrium, in *vomiting* from irritability of the stomach; also to the spine, wrists, and ankles, to arouse the system in *apoplectic and comatose conditions*, and in *typhus fever;* to the feet and legs, for pains in the head during *fevers* and other diseases, and in determinations to the head; and to various parts for removing pain, mitigating *local inflammations*, or arousing from stupor. In the treatment of *cholera*, mustard is an excellent rubefacient application, likewise in *dyspepsia* and *obstinate constipation*. Applied to the breasts, it will often relieve *suppression of the menses*, as well as *menorrhagia;* to be applied intermittingly. Ellingwood advises a cold sitz-bath, strong with mustard, to restore *arrested menses*. A mustard-bath, at about 28.3° C. (85° F.), imparts a sense of coldness, and even distinct chills may be felt in the limbs, abdomen, and back. This continues until the person is removed from the bath, when stinging, glowing, and burning of the surface indicate that reaction is established. Mustard should be cautiously employed upon young children, as it has, in several recorded instances, induced suppression of the urine or strangury. The volatile oil of mustard is a powerful rubefacient and vesicatory; and, in the dose of 2 drops, several times a day, in some mucilaginous vehicle, it is a good diuretic, useful in *dropsy*, and has been serviceable in *colic*. The usual dose, however, of volatile oil of mustard is from $\frac{1}{12}$ to $\frac{1}{4}$ drop. A liniment, composed of 1 part of the oil, dissolved in 16 parts of alcohol, or in 10 parts of olive or almond oil, is a good substitute for a sinapism, though less manageable. White mustard-seed, taken entire, was formerly used as a favorite tonic in *dyspepsia*, and as a laxative, the seed passing unchanged, and probably acting by mechanical irritation. Dose of mustard, as an emetic, 1, 2, or 3 drachms, with 6 or 8 ounces of warm water (see *Charta Sinapis* and *Cataplasma Sinapis*). A prolonged application of a mustard cataplasm causes blistering, with even ulceration and gangrene. A mustard plaster is prepared from equal parts of wheaten or rye flour and lukewarm or cold water, spread upon fabric, and applied with a thin tissue, as of gauze, intervening between the plaster and skin. Its effects should be closely watched, especially in delicate individuals and the old and young. It often gives relief in *pleurisy* and the early stage of other *painful chest affections*. *Acute cardiac pain*, whether or not due to *angina pectoris*, is often promptly relieved by a mustard plaster. The same is very efficient when applied to the nape of the neck for the relief of *headache*, with fullness of the cerebral vessels, or when due to congestion. The application of mustard poultices to the spine—one to the cervical portion one day, one to the dorsal region the next day, and one to the lumbar the third day, repeating the procedure from day to day, has been advised in the treatment of *spinal irritation*. Care should be exercised that the skin be not blistered, rubefacient effect only being desired (Ellingwood). *Acute cerebro-spinal meningitis* has been aborted by wrapping the patient in a blanket wrung out of hot mustard-water (*ibid.*), while to reestablish the eruption after recession in the *exanthemata*, a hot mustard-bath is frequently all that will be required.

Specific Indications and Uses.—A counter-irritant and revulsive in local painful affections and internal congestions; a convenient emetic for narcotic poisoning.

Related Species.—*Brassica juncea*, Hooker filius (*Sinapis juncea*, Linné). Grown in place of the *Brassica nigra* in India, central Africa, and Russia. In the latter place it furnishes a fine, yellow flour, known as *sarepta* or *Russian mustard*. The fixed oil is there used like olive oil. The seeds closely resemble, and have the same constituents as those of black mustard *Pharmacographia*; also see *Amer. Jour. Pharm.*, 1875, p. 260).

Brassica campestris, Linné.—Several varieties of this species are cultivated, chief among which are *Brassica Napus* and *Brassica Rapa*. The roots furnish the vegetable *turnip*, and the seeds the oils known as *colza oil* and *rape-seed oil*. These oils are subacrid and brown, or greenyellow, before refining, but yellow and bland after purification. H. Ritthausen found a considerable quantity of potassium myronate (*sinigrin*) in yellow and brown turnip-seeds (*Brassica Rapa*) from India and east Prussia, yielding oil of mustard, while seeds from *B. Napus*, grown in Russia and in Prussia, were free from it.

Brassica sinapistrum, Boissier (*Sinapis arvensis*, Linné), *Charlock*.—Europe and the United States. A weed having deep-brown, smoothish seeds, not so pungent, and smaller than those of *Brassica nigra*.

Brassica sinensis.—The *petsai* of the Chinese. The oil is purgative, and has been employed in *cutaneous affections*. It is also used for illuminating purposes (see *Amer. Jour. Pharm.*, 1885, p. 306).

Brassica oleracea, Linné, var. *capitata*, *Cabbage*.—The leaves of cabbage are highly praised as a topical remedy for indolent and fetid *ulcers*.

Raphanus sativus, Linné, *Garden radish*, cultivated.—This yields a small quantity of a volatile oil, heavier than water, and containing sulphur. It has the taste but not the odor of the garden radish. Moreigne (1896) obtained from *Raphanus niger* only 0.0025 per cent of volatile oil, from which solid *raphanol* ($C_{29}H_{58}O_4$) separated (Gildemeister and Hoffmann, *Die Ætherischen Oele*, 1899, p. 544).

Raphanus raphanistrum, Linné, *Wild radish*, *Jointed charlock*.—Also yields oil of mustard.

Other Agents Acting Upon the Skin.—Under this head we include methods and agents used for their effects upon the skin and upon the blood supply of the visceral and other parts. These methods, very popular at one time, are not often resorted to at the present day. However, advantageous effects may occasionally be derived from them, and especially from the spirit vapor-bath.

Spirit Vapor-bath, *Hot-air bath*.—"A spirit vapor-bath exerts a most powerful, yet beneficial influence upon the whole system, aiding very materially our endeavors to remove disease. This highly valuable mode of producing activity of the cutaneous vessels has long been practiced in many sections of the country as a domestic remedial agent, and was first introduced to the notice of the medical profession by myself, about twenty-five years ago, since which it is in much use among physicians. The advantages to be derived from this method of producing perspiration are very great, and it is not followed with any of those injurious consequences which often attend the internal administration of a sudorific. It is to be given as follows: The patient is undressed, ready for getting into bed, having removed the shirt and underclothing worn through the day, and put on a nightshirt or other clothing to be worn only while sweating, and during the night, if the bath is taken at bedtime. He is then seated on a high windsor, or wooden-bottomed chair, or, instead thereof, a bench or board may be placed on a common open-bottomed chair, care being taken that the bottom is so covered that the flame will not burn him. After seating himself, a large blanket or coverlet is thrown around him from behind, covering the back part of his head and body, as well as the chair, and another must be passed around him in front, which last is to be pinned at the neck, loosely, so that he can raise it and cover his face, or remove it down from his face, from time to time, as occasion requires, during the operation of the bath. The blankets must reach down to the floor, and cover each other at the sides, so as to retain the vapor and prevent it from passing off.

"This having been done, a saucer or tin vessel, into which is put 1 or 2 tablespoonfuls of whiskey, brandy, spirits, alcohol, or any liquor that will burn, is then placed upon the floor, directly under the center of the bottom of the chair, raising a part of the blanket from behind to place it there; then light a piece of paper, apply the flame to the liquor, and as soon as it kindles, let down the part of the blanket which has been raised, and allow the liquor to burn till it is consumed, watching it from time to time to see that the blankets are not burned. As soon as consumed, put more liquor into the saucer, about as much as before, and again set it on fire, being very careful to pour no liquor into the saucer while the flame exists, as there would be danger of burning the patient, blankets, and perhaps the house. Continue this until the patient sweats or perspires freely, which in a majority of cases will be in 5 or 10 minutes.

"If, during the operation, the patient feels faint or thirsty, cold water must be sprinkled or dashed in his face, or he may drink 1 or 2 swallows of it; and in some cases, the head may be bathed with cold water.

"As soon as free perspiration is produced, wrap the blankets around him, place him in bed, and cover him up warm, giving him about 1 pint of either good tea, ginger, or some herb tea to drink, as warm as he can take it. After 2 or 3 hours, remove the covering, piece by piece, at intervals of 20 or 25 minutes between each, that he may gradually cease perspiring.

"There is no danger of taking cold after this hot-air bath, if the patient uses ordinary precaution; and if his disease will allow, he can attend to his business on the next day the same as usual. In fact, the whole is a very easy, safe, agreeable, and beneficial operation, much more so than a mere reading of the above explanation would lead one to suppose. Chairs have been manufactured expressly for this purpose.

"This bath is much employed by many physicians, and is highly beneficial in *colds*, *pleurisy*, and all *febrile* and *inflammatory attacks*, *diarrhœa*, *dysentery*, *sluggishness of cutaneous vessels*, and in all *chronic disease* where there is an abnormal condition of the skin. In acute diseases, it may be repeated once a day, if required; in chronic diseases, once or twice a week, or once in a fortnight, according to indications.

"Where it can be done, it is always preferable to bathe the patient with an alkaline wash, both before and after this vapor-bath" (J. King).

HÆMOSPASIS.—*Cupping, Hæmospastic medication, Dry cupping.* "This is a powerful revulsive treatment. Anything which draws the blood to a part may be said to act hæmospastically. Dry cupping does so; it not only draws the blood from the internal parts to the surface, but likewise attracts morbid action, and thus affords relief. Common ½ pint tumblers will answer for adults very well, in place of ordinary cupping glasses. A piece of paper or cotton, rolled up and fired, and dropped into the tumbler, and allowed to burn a minute or two, fits the tumbler for application to the spot. One, two, or more may be applied, and repeated so often as may be desirable; they should remain until ready to fall off. Rubber cups are now to be had which are easily applied by first compressing the bulb to create a vacuum, then applying the cup to the affected part, and finally relaxing the pressure on the bulb. *Intermittent fever* has been asserted to have been invariably cured by M. Condret, by applying 8 to 10 middle-sized cupping-glasses, on each side of the spinal column, from the neck downward, and allowing them to remain for about 30 or 40 minutes. To be applied at the commencement of the cold stage. One to 4 applications effect the cure. Also useful in cases of difficult respiration from *congestion of the lungs* or *mucous membrane of the bronchii*, etc." (J. King).

HÆMOSTASIS "is a term applied to the retention of venous blood in the extremities by ligature. Tie a handkerchief, or any suitable cord, around the upper part of the arms, and the thighs, and then, by means of a piece of wood, twist or turn the cord sufficiently tight to check the circulation of the venous blood, but not the arterial, which may be known by the action of the pulse. In a short time the legs and arms will be much distended, and an amount of blood removed from the trunk and retained in the limbs, which the most heroic practitioner dare not remove by the lancet. If the subject faint, promptly loosen or remove the ligatures; if he be plethoric and of firm, vigorous constitution, he must be reduced by cathartics, diuretics, sudorifics, and be under the influence of gentle nauseants, at the time of the operation. This has been found very useful in *uterine hemorrhage, hemoptysis,* and other *hemorrhages, inflammations of the brain, lungs, bowels,* etc., *congestions, puerperal convulsions,* and wherever it is deemed advisable to lessen the amount of blood in the head and trunk, without injuring the system" (J. King).

FIRING.—*Firing, Button coutery.* "Obtain a thick iron-wire shank, abont 2 inches long, and inserted into a small wooden handle; on its extremity, which must be slightly curved, affix a disk or button of iron, exactly ¼ inch thick, and ½ inch in diameter. The whole instrument to be only 6 inches in length. The face of the disk for application must be flat.

Mode of Application.—"Light a small spirit-lamp and hold the button over the flame, keeping the forefinger of the hand holding the instrument, at the distance of about ½ inch from the bottom. As soon as the finger feels uncomfortably hot, the instrument is ready for use, and the time required for heating it to this degree, will be about ½ minute. It is to be applied as quickly as possible to the parts, the skin being tipped successively, at intervals of ½ inch, over the affected part, as lightly and rapidly as possible, always taking care to bring the flat surface of the disk fairly in contact with the skin. In this way the process of firing a whole limb, or the loins, making about 100 applications, does not occupy a minute, and the one heating by the lamp suffices. To ascertain whether the heat be sufficient, look sidewise at the spots as you touch them, and each spot will be observed to become of a glistening white, much whiter than the surrounding skin. In from 5 to 30 minutes the skin becomes bright red, and a glow of heat is felt over the part. The iron must never be made red hot—it is very little hotter than boiling water—should never make an eschar, and rarely raise a blister. On the next day after its application a number of circular red marks will be seen on the skin, the cuticle not even being raised, and the surface ready, if necessary, for a fresh application. There is no discharge whatever, and in most cases the patient is unconscious of what has been done. It is vastly superior to a blister in many cases; even the most delicate female will not object to its frequent repetition when required.

"A powerful counter-irritant. Recommended by Dr. Corrigan in *paralysis, local muscular rheumatism, sciatica, lumbago, neuralgic pains,* etc., and wherever a counter-irritant is required. Also applied each side of the spinal column, in *intermittents, epilepsy, mania,* and other diseases" (J. King). This procedure is now seldom practiced.

MOXA.—Moxa is a term derived from the Portuguese language and applying to a variety of cylinders of combustible vegetable materials which burn without fusing, and were formerly used for revulsive effects in deep-seated inflammations, etc. Species of *Artemisia* furnish *Chinese moxa,* while the mature pith of the sunflower, *Helianthus annuus,* which contains a large proportion of potassium nitrate, has also been used. Moxas are also prepared by saturating paper, hemp, cotton, etc., impregnated with a weak nitre solution, and by means of adhesive material forming them into cylinders, which should be about 1 inch long by ¼ to ⅓ inch thick. The custom of using the moxa is a very ancient one. The cylinder is grasped by a forceps or other holder and the end is applied to the skin. Protecting the surrounding tissues by a damp cloth, alum-paper, or other means, the other end of the cylinder is ignited, and combustion supported by blowing the breath upon it, or by means of a bellows. Any degree of inflammation, even to destruction of the skin, may be produced by regulating the time of application. Deep cauterization may be prevented by applying ammonia water immediately after the use of the moxa. It should be applied only where the hard tissues have a good muscular covering. The application is said to be at first agreeable, but finally becomes quite painful. It has been used for deep-seated *inflammations* and *nervous*, *vascular*, or *other forms of local irritation*. The galvanic cautery, which can be better used upon the deeper structures, even to the osseous tissues, has largely superseded the moxa.

SISYMBRIUM.—HEDGE MUSTARD.

The seeds and herb of *Sisymbrium officinale*, Scopoli (*Erysimum officinale*, Linne). *Nat. Ord.*—Cruciferæ.

COMMON NAME: *Hedge mustard.*

Botanical Origin.—This is an annual, herbaceous plant, with a round, more or less hairy, branching stem, from 1 to 3 feet high. The leaves are runcinate; the lower ones 3 to 8 inches long by 1 to 3 wide, the lower segments placed at right angles to the midvein, or pointing backward, and the terminal segment largest; the upper ones in 3 lanceolate segments placed at right angles. The flowers are small, yellow, and terminate the slender, virgate raceme, which becomes 1 or 2 feet long. Siliques or pods subulate, erect, sessile, and closely appressed to the rachis. Seeds in a single row in each cell, ovoid, and marginless (W.—G.).

History and Chemical Composition.—This is an unsightly weed, inhabiting the United States and Europe, growing in waste places, and flowering from May to September. Its taste is herb-like, faintly resembling that of mustard. The seeds, leaves, and flowering tops are used; the former possess the greatest pungency and yield oil of mustard (Pless). Water extracts its active properties by infusion.

Action, Medical Uses, and Dosage.—Hedge mustard is reputed expectorant, and has been used with advantage in *hoarseness, old coughs, asthma*, and *ulcerated throat;* likewise said to exert some influence as a diuretic in *urinary obstructions.* The powdered seeds may be used internally in the dose of from 5 to 30 grains, or an infusion may be given every 2 or 3 hours in tablespoonful doses. The juice rubbed up with sugar or honey is also used.

Related Species.—*Sisymbrium sophia*, or *Flax weed*, with bipinnately-divided leaves, the lobes oblong-linear, incised; pedicels four times the length of the calyx; petals smaller than the sepals; is a very intensely pungent plant. Its seeds have been recommended in *gravel*, and to remove *worms;* and a fomentation of the leaves as an application to *obstinate ulcers.*

Sisymbrium muralis (*Diloplaxis muralis*) has been employed by the French alone or in a syrup, with potassium iodide, as a remedy for *blood dyscrasia*, especially in *scorbutic and scrofulous affections.*

Sisymbrium Alliaria, Scopoli (*Erysimum Alliaria*, Linné; *Alliaria officinalis*, Andrew), or *Hedge garlic*, contains a bitter body and volatile oil, consisting of oil of mustard (90 per cent) and oil of garlic (10 per cent); it imparts to the plant an alliaceous odor (Pless, 1846).

SODA (U. S. P.)—SODA.

FORMULA: NaOH. MOLECULAR WEIGHT: 39.96.

SYNONYMS: *Sodium hydrate, Sodium hydroxide, Caustic soda, Soda caustica, Natrium hydricum, Natrum causticum, Sodæ hydras, Hydrate of soda.*

"Soda should be kept in well-stoppered bottles made of hard glass"—(*U. S. P.*).

Preparation.—Caustic soda may be prepared by the interaction of sodium carbonate with milk of lime (compare *Potassa*). The process of the *British Pharmacopœia* (1885) is to rapidly evaporate solution of soda (see *Liquor Sodæ*) in a silver or clean iron vessel until there remains an oily fluid, which solidifies on cooling. In recent years, caustic soda is prepared on a large scale by the electrolytic decomposition of brine, resulting in chlorine gas and metallic sodium, which, as soon as formed, decomposes water with formation of solution of caustic soda (see *Pharm. Jour. Trans.*, Vol. XXV, 1894–95; and *Amer. Jour. Pharm.*, 1896, p. 114). The *British Pharmacopœia* (1898, appendix) recognizes three grades of sodium hydroxide: (1) The caustic soda of commerce, containing as impurities alumina, carbonates, chlorides, phosphates, silicates, and sulphates. (2) Purified sodium hydroxide, obtained by dissolving caustic soda in ethylic alcohol, filtering, and evaporating to dryness in a silver dish. The product is free from phosphates and sulphates, and contains but traces of carbonate, but is not quite free from alumina. (3) A solution of pure sodium hydroxide, free from alumina, is prepared either by the action of metallic sodium on water, or by the interaction of pure barium hydroxide and sodium sulphate, as follows: $Ba(OH)_2+Na_2SO_4 = BaSO_4+2NaOH$.

Description.—Soda, as demanded by the *U. S. P.*, occurs in "dry, white, translucent pencils, or fused masses, showing a crystalline fracture, odorless, and having an acrid and caustic taste. Great caution is necessary in tasting and handling it, as it rapidly destroys organic tissues. Exposed to the air, it rapidly deliquesces, absorbs carbon dioxide, and becomes covered with a dry coating of carbonate. Soluble in 1.7 parts of water at 15° C. (59° F.), and in 0.8 part of boiling water; very soluble in alcohol. When heated to about 525° C. (977° F.), soda melts to a clear, oily liquid, and at a bright-red heat it is slowly volatilized unchanged. When introduced into a non-luminous flame, it imparts to it an intense, yellow color. A solution of soda, even when greatly diluted gives a strongly alkaline reaction with litmus paper"—(*U. S. P.*).

Tests.—"The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of organic matter), and, after being acidulated with acetic acid, separate portions of it should yield no precipitate on the addition of platinic chloride T.S., or sodium cobaltic nitrite T.S., or excess of tartaric acid T.S. (limit of potassium). If 1 Gm. of soda be dissolved in 10 Cc. of water and the solution slightly supersaturated with acetic acid, 10 Cc. of the solution should not be colored or rendered turbid by the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, copper, lead, etc.), nor by the subsequent addition of ammonia water in slight excess (absence of iron, aluminum, etc.). The remainder of the acidulated solution should not be rendered turbid by ammonium oxalate T.S. (absence of calcium). If a solution of 1.2 Gm. of soda in 10 Cc. of water be slightly supersaturated with nitric acid, then 0.5 Cc. of decinormal silver nitrate V.S. added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of silver nitrate V.S. (limit of chloride). If to a solution of 2.5 Gm. of soda in 10 Cc. of water, strongly supersaturated with hydrochloric acid, 0.1 Cc. of barium chloride T.S. be added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride T.S. (limit of sulphate). If 0.7 Gm. of soda be dissolved in 1.5 Cc. of water, and the solution added to 10 Cc. of alcohol, not more than a slight, white precipitate should occur within 10 minutes (limit of silicate, etc.). After boiling this alcoholic solution with 5 Cc. of calcium hydrate T.S., and filtering, not the slightest effervescence should take place on adding the filtrate to an excess of diluted hydrochloric acid (limit of carbonate). If 0.2 Gm. of soda be dissolved in 2 Cc. of water and carefully mixed with 5 Cc. of pure sulphuric acid and 3 drops of indigo T.S., the blue color should not be entirely discharged (limit of nitrate)"—(*U. S. P.*). From 2 to 3 per cent of sodium nitrate has been added to caustic soda by manufacturers, in order to obtain a product of pure whiteness (*Amer. Jour. Pharm.*, 1887, p. 78, from *Pharm. Centralhalle*, 1888). "To neutralize 0.4 Gm. of soda should require not less than 9 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 10 per cent of pure sodium hydrate), phenolphtalein being used as indicator"—(*U.S.P.*). (Also compare *Potassa.*)

Action, Medical Uses, and Dosage.—Soda is largely employed in pharmacy in the production of various sodium salts. As a medicine, it is but little used, though it might be employed in place of caustic potash as an escharotic, on account of its lesser deliquescent properties. Its poisonous and chemical actions resemble those of potassium hydroxide, and the antidotes are the same for both. Internally, the carbonate and bicarbonate of sodium are generally preferred to soda, which, however, may be given in solution (*Liquor Sodæ, U. S. P.*) in doses of 10 to 30 drops, largely diluted with water, or 5 to 15 grains of the salt may be given, dissolved in a large quantity of water.

Sodium and Its Compounds.—SODIUM, *Natrium*. Symbol: Na. Atomic Weight: 23. Sodium occurs abundantly in nature, combined with chlorine, in the form of rock-salt, and dissolved in sea water, salt lakes, etc. It occurs in the ashes of plants growing near the sea, and is prepared by exposing to a white heat a mixture of sodium carbonate, coal, and chalk (compare *Potassium*). A considerably lower heat is required when reducing sodium by Castner's process (*Amer. Jour. Pharm.*, 1886, p. 541), which consists in heating the fused sodium hydroxide or carbonate with metallic carbides, or with carbon intimately mixed, in definite proportions, with finely divided metals. With iron carbide, the reaction takes place as follows: $6NaOH+2FeC_2=3Na_2+Fe_2+2CO+2CO_2+3H_2$. Metallic sodium was obtained by Sir Humphry Davy, in 1807, by the electrolytic decomposition of sodium chloride. Sodium is a soft and malleable metal, exhibiting a silver-white lustre on freshly-cut surfaces. Its specific gravity is 0.97, it melts at 95.6° C. (204° F.), and volatilizes at a red heat. It retains its softness and malleability at 0° C. (32° F.). Exposed to the air, it oxidizes readily, but less so than potassium. Large pieces may be kept in well-closed vessels without changing, except being oxidized on the surface. Smaller pieces are best kept under petroleum or petrolatum. When particles of sodium are thrown on water, they rapidly move about on its surface, and decompose the water with formation of sodium hydroxide (see *Soda*) and hydrogen gas. Unless the water is warm, or thickened with gum, the heat evolved is not high enough to ignite the gas (compare *Potassium*). Sodium and its salts impart to the non-luminous flame of the Bunsen burner a bright-yellow color, which is not visible through blue cobalt glass. With oxygen, sodium forms two oxides—the *monoxide* (Na_2O), which combines with water to form the strong alkali, *sodium hydroxide*, as follows: $Na_2O+H_2O=2NaOH$; and the *dioxide* or *peroxide* (Na_2O_2), a yellowish powder soluble in water with evolution of much heat and liberation of oxygen, of which it yields 20 per cent. Although prepared as early as 1815, by Gay Lussac, it is only in recent years that this substance came into use as a powerful bleaching agent. It is obtained by burning metallic sodium in dry air or oxygen, or by strongly heating sodium oxide in a current of air. Sodium combines with mercury, forming an *amalgam*, which is used in the process of extracting gold from auriferous rocks. Sodium also forms a liquid alloy with metallic potassium. The various medicinal sodium salts will be described each under its appropriate head.

SODII ACETAS (U. S. P.)—SODIUM ACETATE

FORMULA: $NaC_2H_3O_2+3H_2O$. MOLECULAR WEIGHT: 135.74.

SYNONYMS: *Acetate of soda, Sodæ acetas, Acetas sodicus, Acetas natricus, Terra foliata, Tartari crystallisata.*

"Sodium acetate should be kept in well-stoppered bottles"—(*U. S. P.*).

Preparation.—Acetate of sodium, formerly called *Crystallized foliated earth of tartar* (J. F. Meyer, 1767), was first obtained by Duhamel in 1736, and may be prepared in several ways, either by dissolving sodium carbonate in distilled pyroligneous (acetic) acid, or by double decomposition between calcium acetate (see *Acidum Aceticum*) and sodium sulphate (Glauber's salt), and recrystallizing the product, or by the interaction of lead acetate and sodium carbonate. (For details see this *Dispensatory*, preceding edition.)

Description.—As described by the *U. S. P.*, sodium acetate consists of "colorless, transparent, monoclinic prisms, or a granular, crystalline powder, odorless, and having a cooling, saline taste. Efflorescent in warm, dry air. Soluble, at 15° C. (59° F.), in 1.4 parts of water, and in 30 parts of alcohol; in 0.5 part of boiling water, and in 2 parts of boiling alcohol. When heated to 60° C. (140° F.), the salt begins to liquefy. At 123° C. (253.4° F.), it becomes dry and anhydrous; at 315° C. (599° F.), it is decomposed, with evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intense, yellow color, gives an alkaline reaction with litmus paper, and effervesces with acids"—(*U. S. P.*). (On an explosive mixture of sodium acetate and potassium nitrate, see *Amer. Jour. Pharm.*, 1873, p. 128.)

Tests.—"The aqueous solution (1 in 20) of the salt colors litmus paper or T.S. blue, but does not redden phenolphtalein T.S. unless carbonate be present"—(*U. S. P.*). C. E. Smith (*Digest of Criticisms on the U. S. P.*, Part II, 1898) and Fr. Collischonn (*Chemiker Zeitung*, 1892, p. 1921, and *Amer. Jour. Pharm.*, 1893, p. 69) observe that the salt, even when crystallized from solution slightly acidulated with acetic acid, distinctly reddens phenolphtalein. "If 5 Cc. of the aqueous solution (1 in 20) be heated with 1 Cc. of sulphuric acid and 0.5 Cc. of alcohol, acetic ether will be formed, recognizable by its odor"—(*U. S. P.*). The reaction takes place as follows: $2NaC_2H_3O_2+2C_2H_5OH+H_2SO_4=2CH_3.COOC_2H_5+Na_2SO_4+2H_2O$. When sodium acetate is treated with sulphuric acid only, acetic acid is evolved. With the above aqueous solution (1 in 20) of the salt, the *U. S. P.* further directs: "On the addition of a few drops of ferric chloride T.S., the solution assumes a deep red color, and, when boiled, yields a brown precipitate"—
